**BACKGROUNDS:** The most important diagnostic criteria for Schnitzler syndrome include chronic urticaria, the presence of monoclonal IgM immunoglobulin, marked inflammation (leukocytosis, elevated CRP and erythrocyte sedimentation rate), subfebrile temperatures or fevers and bone and joint pains. It is a rare idiopathic disease that may lead to potentially life-threatening complications such as development of secondary amyloidosis or transformation into malignant lymphoproliferation. Schnitzler syndrome should be included in differential diagnostics of chronic urticaria and fevers of unknown origin. The diagnostic algorithm is based on clinical presentation and serum and urine electrophoreses to detect monoclonal components. Blockade of interleukin-1 (IL-1), key cytokine in the pathogenesis of the disease, dominates current therapeutic protocols. Anakinra (Kineret), recombinant human IL-1 receptor antagonist, is the most widely used treatment option. According to literature, disease remission was obtained in all treated patients. Therefore, anakinra represents a significant diagnostic possibility to differentiate Schnitzler syndrome from e.g. monoclonal gammopathy of unknown significance (MGUS) associated with urticaria of different aetiology. Biological therapy with rilonacept (Arcalyst) and canakinumab (Ilaris)

represents a new treatment alternative for patients, allowing prolonged dosing intervals of 1 and 8 weeks, respectively (compared to 24 hours with anakinra). The review article also presents findings of various imaging methods (conventional radiography, computed tomography, traditional bone scintigraphy) and photographs of patients with Schnitzler syndrome before and after anakinra therapy.

**DESIGN:** The aim of the review is to draw attention to the existence of this rare autoinflammatory and potentially premalignant condition, present a simple diagnostic algorithm and provide an overview of therapeutic options for the patients.

**CONCLUSIONS:** Malign potential of Schnitzler syndrome, possible development into systemic amyloidosis and the fact that patients are frequently referred to oncology clinics for differential diagnostics of monoclonal gammopathy, are the main reasons why clinical oncologists should be aware of Schnitzler syndrome.

Recurrent aphthous ulcers--a Toll-like receptor-mediated disease?

Hietanen J(1), Häyrynen-Immonen R, Al-Samadi A, Trokovic N, Koskenpato K, Konttinen YT.

Author information:

(1)Department of Oral Pathology, Institute of Dentistry, University of Helsinki, Helsinki, Finland.

**BACKGROUND:** Recurrent aphthous ulcer (RAU) is characterized by acute and painful inflammatory ulcerations, which heal spontaneously but tend to recur. Many pathogens have been proposed as causative agents, but none has been consistently proven. According to our hypothesis, RAU is an autoinflammatory disorder triggered by pathogen-associated molecular patterns (PAMPs) shared by different pathogenic and commensal microbes.

**METHODS:** PAMP-reactive Toll-like receptors (TLRs) were mapped in oral epithelium in healthy controls compared to RAU.

RESULTS: In controls, the superficial epithelium formed a TLR(-), a PAMP non-reactive physical barrier zone, but all TLRs were found deeper in the epithelium, usually restricted to suprabasal and basal cell layers. In RAU, the epithelial TLR polarity was lost: TLRs 1, 2, 5, 7, and 8 were found throughout the epithelium, but also TLRs 4, 6, and 10 extended higher up than normally, whereas TLR-3 was almost lost in RAU. In RAU lesions, connective tissue stroma was heavily infiltrated by TLR(+) inflammatory cells.

CONCLUSIONS: Normal TLR architecture prevents inflammatory responses against normal microbes but still contains a deep TLR(+) , PAMP-reactive dormant defense zone. In RAU, the TLR(+), PAMP-reactive zone extends to surface or subsurface exposed to microbial PAMPs. TLR reactivity is further enhanced by recruitment of inflammatory leukocytes forming a new deep line of defense. The organization of the TLR system in healthy mucosa and its changes in RAU are compatible with active pathogenic involvement of TLRs, which together with the typical clinical picture and course suggest that RAU is a TLR-mediated disease.

**OBJECTIVES:** To analyze available evidence on vaccinations in paediatric patients with rheumatic and autoinflammatory diseases. This evidence formed the basis of the recently constructed European League against Rheumatism (EULAR) recommendations for vaccination of these patients.

**METHODS:** A systematic literature review in the MEDLINE and EMBASE databases was conducted using various terms for vaccinations, paediatric rheumatic and autoinflammatory diseases and immunosuppressive drugs. Only papers on paediatric patients (<18 years of age) were selected. A panel of 13 experts in the field graded methodological quality and extracted data using predefined criteria.

**RESULTS:** 27 papers were available. No studies were found on autoinflammatory diseases. 14 studies considered live-attenuated vaccines. Evidence so far supports the safety and immunogenicity of non-live composite vaccines, although studies were underpowered to accurately assess safety. Live-attenuated vaccines did not cause disease flares or severe adverse events, not even in patients on methotrexate and low dose glucocorticosteroids. Seven patients on anti-TNFalpha therapy were described receiving the live-attenuated measles, mumps, rubella (n=5) or varicella (n=2) booster without severe adverse events.

**CONCLUSIONS:** Data on safety and efficacy of vaccinations in paediatric patients with rheumatic diseases is reassuring, but too limited to draw definite conclusions. More research is needed on the safety and efficacy of especially live-attenuated vaccines in patients with rheumatic and autoinflammatory diseases using high dose immunosuppressive drugs.

Basic science for the clinician 51: the inflammasome.

Sigal LH(1).

Author information:

(1)Division of Rheumatology, Department of Medicine, University of Medicine and Dentistry of New Jersey-Robert Wood Johnson Medical School, New Brunswick, NJ 08903-001, USA. lensigal@gmail.com

The innate immune system is packaged in a number of discrete, but intercommunicating, systems. The inflammasome is a multimolecular complex that detects intracellular foreign molecules of a variety of sorts and promptly promotes the secretion of IL-1 $\beta$  and IL-18. When all goes well, defense of the organism in the early period of infection is enhanced by this system; when certain elements of the inflammasomal systems go awry, inflammatory diseases of a variety of sorts result. A family of multimolecular detection systems are activated at times of infection and tissue damage; it is the dysfunction of this innate immune defense system that intrigues rheumatologists, as this is the cause of a series of newly described autoinflammatory diseases.

Deregulated inflammasome signaling in disease.

Lamkanfi M(1), Vande Walle L, Kanneganti TD.

Author information:

(1)Department of Biochemistry, Ghent University, Ghent, Belgium.

Inflammasomes are multi-protein complexes that sense microbial molecules and endogenous danger signals in intracellular compartments. Inflammasome assembly results in caspase-1 activation, which in turn drives maturation and secretion of the pro-inflammatory cytokines interleukin 1 $\beta$  (IL-1 $\beta$ ) and IL-18, and induces pyroptosis to eliminate the infectious agent. The importance of inflammasomes in regulating immune responses was recognized with the discovery of polymorphisms in genes encoding inflammasome components and their linkage to aberrant production

of IL-1 $\beta$  and IL-18 in autoimmune and hereditary periodic fevers syndromes. We review the current knowledge on the role of inflammasomes in regulating innate and adaptive immune responses with an emphasis on the role of these immune complexes in autoinflammatory disorders and autoimmune diseases such as colitis, type I diabetes, multiple sclerosis and vitiligo.

The inflammasome: an integrated view.

Gross O(1), Thomas CJ, Guarda G, Tschopp J.

Author information:

(1)Department of Biochemistry, University of Lausanne, Epalinges, Switzerland.

An inflammasome is a multiprotein complex that serves as a platform for caspase-1 activation and caspase-1-dependent proteolytic maturation and secretion of interleukin-1 $\beta$  (IL-1 $\beta$ ). Though a number of inflammasomes have been described, the NLRP3 inflammasome is the most extensively studied but also the most elusive. It is unique in that it responds to numerous physically and chemically diverse stimuli. The potent proinflammatory and pyrogenic activities of IL-1 $\beta$  necessitate that inflammasome activity is tightly controlled. To this end, a priming step is first required to induce the expression of both NLRP3 and proIL-1 $\beta$ . This event renders the cell competent for NLRP3 inflammasome activation and IL-1 $\beta$  secretion, and it is highly regulated by negative feedback loops. Despite the wide array of NLRP3 activators, the actual triggering of NLRP3 is controlled by integration a comparatively small number of signals that are common to nearly all activators. Minimally, these include potassium efflux, elevated levels of reactive oxygen species (ROS), and, for certain activators, lysosomal destabilization. Further investigation of how these and potentially other as yet uncharacterized signals are integrated by the NLRP3 inflammasome and the relevance of these biochemical events in vivo should provide new insight into the mechanisms of host defense and

autoinflammatory conditions.

Recognition of nucleic acids by pattern-recognition receptors and its relevance in autoimmunity.

Kawasaki T(1), Kawai T, Akira S.

Author information:

(1)Laboratory of Host Defense, WPI Immunology Frontier Research Center, Department of Host Defense, Research Institute for Microbial Diseases, Osaka University, Osaka, Japan.

Host cells trigger signals for innate immune responses upon recognition of conserved structures in microbial pathogens. Nucleic acids, which are critical components for inheriting genetic information in all species including pathogens, are key structures sensed by the innate immune system. The corresponding receptors for foreign nucleic acids include members of Toll-like receptors, RIG-I-like receptors, and intracellular DNA sensors. While nucleic acid recognition by these receptors is required for host defense against the pathogen, there is a potential risk to the host of self-nucleic acids recognition, thus precipitating autoimmune and autoinflammatory diseases. In this review, we discuss the roles of nucleic acid-sensing receptors in guarding against pathogen invasion, discriminating between self and non-self, and contributing to autoimmunity and autoinflammatory diseases.

Proteasomes are multisubunit proteases that play a critical role in maintaining cellular function through the selective degradation of ubiquitinated proteins. When 3 additional  $\beta$  subunits, expression of which is induced by IFN- $\gamma$ , are substituted for their constitutively expressed counterparts, the structure is converted to an immunoproteasome. However, the underlying roles of immunoproteasomes in human diseases are poorly understood. Using exome analysis, we found a homozygous missense mutation (G197V) in immunoproteasome subunit,  $\beta$  type 8 (PSMB8), which encodes one of the  $\beta$  subunits induced by IFN- $\gamma$  in patients from 2 consanguineous families. Patients bearing this mutation suffered from autoinflammatory responses that included recurrent fever and nodular erythema together with lipodystrophy. This mutation increased assembly intermediates of immunoproteasomes, resulting in decreased proteasome function and ubiquitin-coupled protein accumulation in the patient's tissues. In the patient's skin and B cells, IL-6 was highly expressed, and there was reduced expression of PSMB8. Downregulation of PSMB8 inhibited the differentiation of murine and human adipocytes in vitro, and injection of siRNA against Psmb8 in mouse skin reduced adipocyte tissue volume. These findings identify PSMB8 as an essential component and regulator not only of inflammation, but also of adipocyte differentiation, and indicate that immunoproteasomes have pleiotropic functions in maintaining the homeostasis of a variety of cell types.

To evaluate the circulating levels of adipokines (leptin and adiponectin) and ghrelin in patients with familial Mediterranean fever (FMF) and also to assess the relationships between these molecules and disease-related parameters. Forty-eight FMF patients in attack-free period (31 men, [M], 17 women, [F], mean age  $35.8 \pm 8.6$  years, and a mean body mass index [BMI] of  $24.7 \pm 3.1$ ) and 40 age-, sex-, and BMI-matched healthy controls (24 M, 16 F, mean age  $35.5 \pm 8.5$  years, and a mean BMI of  $24.5 \pm 2.8$ ) were included in the study. Patients and controls with a history of any other chronic diseases and obese or underweight subjects were excluded. High-sensitive C-reactive protein (hs-CRP), leptin, adiponectin, and total ghrelin concentrations were studied. Age, sex, BMI, waist circumference, and smoking status were similar between FMF patients and controls ( $P > 0.05$ ). Adipose tissue-derived molecules including leptin, and adiponectin were lower than healthy controls but only adiponectin levels reached the statistical significance ( $16.7 \pm 8.9$  ng/ml vs.  $27.7 \pm 15.9$  ng/ml,  $P < 0.001$ ) and leptin concentrations just missed significance ( $25.2 \pm 16.2$  ng/ml vs.  $34.9 \pm 27.2$  ng/ml,  $P = 0.051$ ). Ghrelin concentrations were not different between the groups. Adiponectin levels were significantly and negatively correlated with hs-CRP ( $P < 0.05$ ,  $r = -0.24$ ). The results of this study suggest that low-grade chronic inflammation during attack-free period in FMF patients may suppress adiponectin production or low levels of adiponectin might contribute to subclinical inflammation in these patients.

Tumor necrosis factor receptor-associated periodic fever syndrome in a 58-year-old man: caution not to discount TRAPS as a diagnosis in older patients.

Sinožić D(1), Toplak N, Milotić I.

Author information:

(1)Department of Angiology, Endocrinology and Rheumatology, General Hospital Celje, Celje, Slovenia. dean.sinozic@guest.arnes.si

Tumor necrosis factor receptor-associated periodic fever syndrome (TRAPS) is a rare systemic autoinflammatory disorder characterized by recurrent episodes of fever and localized inflammation of different organs. The disease is dominantly inherited, with an onset usually in early childhood. We describe a case of a 58-year-old patient with TRAPS caused by the low-penetrance R92Q mutation in TNFRSF1A gene. The patient responded well to anti-tumor necrosis factor  $\alpha$  therapy. Although periodic fever syndromes, including TRAPS, mainly begin in early childhood, it is important to consider periodic fever syndrome also in patient presenting at an age older than the average reported case for TRAPS.

Antiviral TRIMs: friend or foe in autoimmune and autoinflammatory disease?

Jefferies C(1), Wynne C, Higgs R.

Author information:

(1)Molecular and Cellular Therapeutics, Royal College of Surgeons in Ireland, 123 St. Stephen's Green, Dublin 2, Ireland. cjefferies@rcsi.ie

The concept that viral sensing systems, via their ability to drive pro-inflammatory cytokine and interferon production, contribute to the development of autoimmune and autoinflammatory disease is supported by a wide range of clinical and experimental observations. Recently, the tripartite

motif-containing proteins (TRIMs) have emerged as having key roles in antiviral immunity - either as viral restriction factors or as regulators of pathways downstream of viral RNA and DNA sensors, and the inflammasome. Given their involvement in these pathways, we propose that TRIM proteins contribute to the development and pathology of autoimmune and autoinflammatory conditions, thus making them potential novel targets for therapeutic manipulation.

Clinical review#: Lipodystrophies: genetic and acquired body fat disorders.

Garg A(1).

Author information:

(1)Division of Nutrition and Metabolic Diseases, Department of Internal Medicine, Center for Human Nutrition, University of Texas Southwestern Medical Center at Dallas, Dallas, Texas 75390-8537, USA. abhimanyu.garg@utsouthwestern.edu

**CONTEXT:** Lipodystrophies are heterogeneous, genetic or acquired disorders characterized by selective loss of body fat and predisposition to insulin resistance. The extent of fat loss determines the severity of associated metabolic complications such as diabetes mellitus, hypertriglyceridemia, and hepatic steatosis.

**EVIDENCE ACQUISITION AND SYNTHESIS:** Both original and review articles were found via PubMed search reporting on clinical features and management of various types of lipodystrophies and were integrated with the author's knowledge of the field.

**CONCLUSION:** The autosomal recessive congenital generalized lipodystrophy and autosomal dominant familial partial lipodystrophy (FPL) are the two most common types of genetic lipodystrophies. Mutations in AGPAT2, BSCL2, CAV1, and PTRF have been reported in congenital generalized lipodystrophy and in LMNA, PPARG, AKT2, and PLIN1 in FPL. CIDEA is the disease gene for autosomal recessive, FPL and LMNA and ZMPSTE24 for autosomal recessive, mandibuloacral dysplasia-associated lipodystrophy. Recently, an autosomal recessive autoinflammatory lipodystrophy syndrome was reported to be due to PSMB8 mutation. Molecular genetic bases of

many rare forms of genetic lipodystrophies remain to be elucidated. The most prevalent subtype of acquired lipodystrophy currently occurs with prolonged duration of protease inhibitor-containing, highly-active antiretroviral therapy in HIV-infected patients. The acquired generalized and partial lipodystrophies are mainly autoimmune in origin and display complement abnormalities. Localized lipodystrophies occur due to drug or vaccine injections, pressure, panniculitis, and other unknown reasons. The current management includes cosmetic surgery and early identification and treatment of metabolic and other complications with diet, exercise, hypoglycemic drugs, and lipid-lowering agents.

B cells are resistant to immunomodulation by 'IVIg-educated' dendritic cells.

Maddur MS(1), Hegde P, Sharma M, Kaveri SV, Bayry J.

Author information:

(1)Institut National de la Santé et de la Recherche Médicale, Unité 872, 15 rue de l'Ecole de Médecine, Paris, France.

Intravenous immunoglobulin (IVIg) can exert beneficial effects in autoimmune and inflammatory diseases via several mutually non-exclusive mechanisms. While, IVIg can directly modulate the functions of both innate and adaptive immune cells such as dendritic cells (DC), macrophages, B and T cells, several reports have also highlighted that the regulation of immune responses by IVIg can be indirect. In view of these results, we aimed at exploring whether indirect regulation of immune cells by 'IVIg-educated' innate cells is a universal phenomenon. We addressed this question by deciphering the modulation of B cell functions by 'IVIg-educated' DC. Our results indicate that human B cells are resistant to immunomodulation by 'IVIg-educated' DC. However, IVIg at therapeutic concentrations can directly inhibit B cell activation and proliferation. These results thus suggest that, indirect modulation of immune cells by IVIg is not a universal phenomenon.

Staged correction of an equinovarus deformity due to pyoderma gangrenosum using a Taylor spatial frame and tibiotalar calcaneal fusion with an intramedullary device.

Bellamy JL(1), Holland CA, Hsiao M, Hsu JR; STReC (Skeletal Trauma Research Consortium).

Author information:

(1)Brooke Army Medical Center, Fort Sam Houston, San Antonio, TX, USA, jaime.bellamy@amedd.army.mil.

Pyoderma gangrenosum is a rare autoinflammatory syndrome manifested by skin lesions eventually creating ulcers. Surgical management can lead to scarring and contracture at the site of the lesion due to the pathergy phenomenon. A 43-year-old woman presented with a 5-year history of severe equinovarus deformity due to chronic pyoderma gangrenosum on her posteromedial ankle. She underwent a staged fusion. A gradual "closed" correction was performed in a Taylor spatial frame for 8 weeks in order to obviate the need for a surgical release in the area of the ulcer. She was ambulatory and full weight-bearing within 4 weeks of her frame removal. She maintained her correction with an accommodative foot orthosis until she had an uneventful tibiotalar calcaneal fusion with an intramedullary device. This case represents the success of using a Taylor spatial frame for staged fusion involving soft-tissue correction of severe, rigid equinovarus deformity due to pyoderma gangrenosum.

Comment in

Endocrinology. 2011 Nov;152(11):4005-6.

Clinical evidence that the blockade of IL-1 $\beta$  in type-2 diabetic patients improves glycemia is indicative of an autoinflammatory mechanism that may trigger adiposity-driven pancreatic damage. IL-1 $\beta$  is a key contributor to the obesity-induced inflammation and subsequent insulin resistance, pancreatic  $\beta$ -cell dysfunction, and the onset of type 2 diabetes. Our previous studies demonstrated that the ceramides activate the Nod-like receptor family, pyrin domain containing 3 (Nlrp3) inflammasome to cause the generation of mature IL-1 $\beta$  and ablation of the Nlrp3 inflammasome in diet-induced obesity improves insulin signaling. However, it remains unclear whether the posttranslational processing of active IL-1 $\beta$  in pancreas is regulated by the NLRP3 inflammasome or whether the alternate mechanisms play a dominant role in chronic obesity-induced pancreatic  $\beta$ -cell exhaustion. Here we show that loss of ASC, a critical adaptor required for the assembly of the NLRP3 and absent in melanoma 2 inflammasome substantially improves the insulin action. Surprisingly, despite lower insulin resistance in the chronically obese NLRP3 and ASC knockout mice, the insulin levels were substantially higher when the inflammasome pathway was eliminated. The obesity-induced increase in maturation of pancreatic IL-1 $\beta$  and pancreatic islet fibrosis was dependent on the NLRP3 inflammasome activation. Furthermore, elimination of NLRP3 inflammasome protected the pancreatic  $\beta$ -cells from cell death caused by long-term high-fat feeding during obesity with significant increase in the size of the islets of Langerhans. Collectively, this study provides direct in vivo evidence that activation of the NLRP3 inflammasome in diet-induced obesity is a critical trigger in causing pancreatic damage and is an

important mechanism of progression toward type 2 diabetes.

2932. Ann Rheum Dis. 2011 Dec;70(12):2155-8. doi: 10.1136/ard.2011.149922. Epub 2011 Aug 21.

On-demand anakinra treatment is effective in mevalonate kinase deficiency.

Bodar EJ(1), Kuijk LM, Drenth JP, van der Meer JW, Simon A, Frenkel J.

Author information:

(1)Department of General Internal Medicine, Radboud University Nijmegen Medical Centre, The Netherlands.

**BACKGROUND:** Mevalonate kinase deficiency (MKD) is a hereditary autoinflammatory syndrome marked by recurrent attacks of fever and inflammation. Severe enzyme deficiency results in mevalonic aciduria (MA) and milder deficiency in hyperimmunoglobulin D syndrome (HIDS). Treatment remains a challenge.

**OBJECTIVE:** To observe the effect of the recombinant interleukin-1 receptor antagonist anakinra in patients with MKD.

**METHODS:** A prospective observational study was undertaken. Two patients with MA started continuous treatment with anakinra (1-2 mg/kg/day) and nine patients with HIDS chose between continuous treatment and on-demand treatment (starting at first symptoms of attack, 100 mg/day or 1 mg/kg/day for 5-7 days).

**RESULTS:** Anakinra induced partial remission in one patient with MA but there was no response in the other patient with MA. In one patient with HIDS continuous treatment induced complete remission for 7 months but was stopped because of side effects. Eight patients with HIDS preferred on-demand treatment from the start. This induced a clinical response ( $\geq 50\%$  reduction in duration) in 8 of 12 treated attacks without a change in attack frequency. Anakinra prevented fever attacks due to vaccination without inhibiting antibody induction. No major side effects were seen.

**CONCLUSIONS:** On-demand treatment with anakinra in HIDS decreases the duration and severity of fever attacks. Because of the burden of daily injections and relatively long asymptomatic intervals of HIDS, all patients with HIDS preferred

on-demand treatment.

Nakajo-Nishimura syndrome (NNS) is a disorder that segregates in an autosomal  
recessive fashion. Symptoms include periodic fever, skin rash, partial

lipomuscular atrophy, and joint contracture. Here, we report a mutation in the human proteasome subunit beta type 8 gene (PSMB8) that encodes the immunoproteasome subunit  $\beta 5i$  in patients with NNS. This G201V mutation disrupts the  $\beta$ -sheet structure, protrudes from the loop that interfaces with the  $\beta 4$  subunit, and is in close proximity to the catalytic threonine residue. The  $\beta 5i$  mutant is not efficiently incorporated during immunoproteasome biogenesis, resulting in reduced proteasome activity and accumulation of ubiquitinated and oxidized proteins within cells expressing immunoproteasomes. As a result, the level of interleukin (IL)-6 and IFN- $\gamma$  inducible protein (IP)-10 in patient sera is markedly increased. Nuclear phosphorylated p38 and the secretion of IL-6 are increased in patient cells both in vitro and in vivo, which may account for the inflammatory response and periodic fever observed in these patients. These results show that a mutation within a proteasome subunit is the direct cause of a human disease and suggest that decreased proteasome activity can cause inflammation.

Assessment of cardiac functions using tissue Doppler imaging in children with familial Mediterranean fever.

Ozdemir O(1), Agras PI, Aydin Y, Abaci A, Hizli S, Akkus HI, Fidan C.

Author information:

(1)Department of Paediatric Cardiology, Kecioren Training and Research Hospital, Ankara, Turkey. pedkard@gmail.com

**OBJECTIVE:** Familial Mediterranean fever may carry a potential for cardiovascular disorders because of sustained inflammation during its course; however, there has been a limited number of studies investigating the cardiac functions in children. The aim of this study was to assess both ventricular diastolic functions using conventional echocardiography and tissue Doppler imaging in children with familial Mediterranean fever.

**PATIENTS AND METHODS:** The study population included 25 patients with familial Mediterranean fever - mean age was 11.8 plus or minus 5.30 years - and 23 healthy patients as controls - mean age was 9.88 plus or minus 3.69 years. Both ventricular functions were measured using echocardiography comprising standard M-mode and conventional Doppler and tissue Doppler imaging during an attack-free period.

**RESULTS:** The conventional echocardiographic parameters with myocardial performance index were in normal ranges and similar in patients with familial Mediterranean fever and controls, with a p-value more than 0.05. However, right ventricular diastolic dysfunction was observed in patients with familial Mediterranean fever documented by tissue Doppler imaging, with a p-value less than 0.05 for E't and A't wave ratio.

**CONCLUSION:** Using tissue Doppler imaging, we have demonstrated that although left ventricular functions were comparable in the patients and healthy children, right ventricular diastolic function indices were impaired in patients with familial Mediterranean fever during childhood. Impaired right ventricular diastolic function may be an early manifestation of cardiac involvement in children with familial Mediterranean fever.

Renal and suprarenal insufficiency secondary to familial Mediterranean fever associated with amyloidosis: a case report.

Toros AB(1), Erdenen F, Sari ND, Gokcay S.

Author information:

(1)Department of Gastroenterology, Istanbul Education and Research Hospital, Samatya, Fatih, Istanbul, Turkey. aburaktoros@yahoo.com.

**INTRODUCTION:** Familial Mediterranean fever is an autosomal recessive disease that predominantly affects people of the Mediterranean coast. One of the most frequent complications of the disease is amyloidosis. This clinical entity is known as secondary (also called AA) amyloidosis.

**CASE PRESENTATION:** In this report, we describe the case of a 33-year-old Turkish

man with familial Mediterranean fever and chronic renal insufficiency. He was admitted to our clinic with symptoms of suprarenal insufficiency. The patient died three months later as a result of cardiac arrest.

**CONCLUSION:** Our aim is to make a contribution to the literature by reporting a case of combined insufficiency due to the accumulation of renal and adrenal amyloid in a patient with familial Mediterranean fever, which has very rarely been described in the literature. We hope that adrenal insufficiency, which becomes fatal if not diagnosed and treated rapidly, will come to mind as easily as chronic renal failure in clinical practice.

The multidrug resistance gene-1 (MDR1, adenosine triphosphate-binding cassette transporter: ABCB1, P-glycoprotein) encodes membrane proteins that play a crucial role in protecting cells from xenobiotics, chemicals, and drugs. The TT genotype of 3435 codon in exon 26 of MDR1 gene causes overexpression of gene activity and effluxes many chemically diverse compounds across the plasma membrane. We studied the association between C3435T polymorphisms (single nucleotide polymorphism) of MDR1 gene and colchicine-resistant familial Mediterranean fever (FMF) patients. Total genomic DNA samples from 52 FMF patients of colchicine unresponsiveness were used for FMF (MEFV) and MDR1 genes profile analyses. Target genes were genotyped by multiplex PCR-based reverse-hybridization Strip Assay method. The preliminary current results showed increased T allele frequency (0.596) in colchicine unresponsiveness of FMF patients. The distributions of the CC, CT, and

TT genotypes in colchicine nonresponder FMF patients were 17%, 46%, and 37%, respectively. Our results indicate that C3435T polymorphism in exon 26 of MDR1 gene is associated with colchicine resistance in nonresponder FMF patients during the common therapy protocol.

"Mutation negative" familial cold autoinflammatory syndrome (FCAS) in an 8-year-old boy: clinical course and functional studies.

Hedrich CM(1), Bruck N, Paul D, Hahn G, Gahr M, Rösen-Wolff A.

Author information:

(1)Christian Hedrich, Children's Hospital Dresden, Pediatric Rheumatology and Immunology, University Medical Center Carl Gustav Carus, Technical University Dresden, Fetscherstr. 74, 01307 Dresden, Germany.  
christian.hedrich@uniklinikum-dresden.de

Cryopyrinopathies are a subgroup of autoinflammatory syndromes. Most cases have mutations in the CIAS1/NLRP3 gene, encoding the cryopyrin/NLRP3 protein. Cryopyrin, together with other proteins, is involved in the assembly of the cryopyrin/NLRP3 inflammasome. Mutations in CIAS1/NLRP3 result in increased IL-1 $\beta$  cleavage from biologically inactive pro-IL-1 $\beta$ . This results in systemic inflammation and three associated disorders of different severity, forming a clinical continuum with overlapping features. The mildest form, familial cold autoinflammatory syndrome (FCAS), is characterized by remitting fevers, urticaria-like rash, polyarthralgia/arthritis, and usually caused by cold exposure. More severe forms are Muckle-Wells syndrome (MWS) and CINCA/NOMID. We report an 8-year-old boy with FCAS, who presented with overlapping features with MWS. He showed good response to seasonal anakinra treatment. Mutation analysis in CIAS1/NLRP3, PYCARD, and CASP1 was performed. Serum cytokine profiles, and cytokine expression from resting monocytes, and in response to mild hypothermia, and LPS stimulation were determined. Mutations in CIAS1/NLRP3, PYCARD, and CASP1 were not found. In response to mild hypothermia, an enhanced IL-1 $\beta$  expression by

patient monocytes resulted in increased IL-6 and TNF- $\alpha$  secretion, as compared to control cells. The addition of the IL-1 $\beta$  receptor antagonist (anakinra) reversed these effects. In response to LPS stimulation, patient monocytes produced high level of IL-1 $\beta$ , IL-6 and TNF- $\alpha$ . This was markedly less pronounced in control monocytes. FCAS results in cold-induced cytokine dysregulation and systemic inflammation. Symptoms can be treated, using IL-1 $\beta$  antagonists. Further research is warranted, particularly in order to investigate pathophysiological mechanisms in "mutation negative" individuals.

Idiopathic recurrent pericarditis (IRP) impairs quality of life. Although its precise etiology is not certain, it is believed to be immunologically mediated. Its optimal treatments are unknown. Initial therapy is with non-steroidal anti-inflammatory drugs and colchicine. Steroids, which are often used, however may promote recurrences. European guidelines advocate azathioprine or cyclophosphamide in refractory cases despite limited evidence. We report two adults with IRP successfully treated with the interleukin-1 antagonist, anakinra. We combine this experience with the first systematic literature review of immunosuppression in IRP. A total of 8 papers were included in the review, which alongside our patients described 18 cases. The best treatments comprised anakinra and intravenous immunoglobulin, with respective remission rates of 100% and 67%. Cyclophosphamide and azathioprine were less efficacious. The unprovoked

inflammatory episodes in our patients alongside their prompt response to anakinra indicate that in some instances IRP may represent an autoinflammatory condition. We suggest that in IRP refractory to initial treatment, anakinra should be considered as a potential therapy. Clinical trials are required to confirm its benefits in IRP.

**BACKGROUND:** MEFV mutations and decreased expression level of the gene are related to FMF pathology. DNA methylation at CpG islands is a well-known mechanism for transcriptional silencing. MEFV has a CpG island, spanning a part of the first intron and the whole of the second exon of the gene covering 998 bp region. Here, we tested the hypothesis that the MEFV transcript level in FMF patients correlates with its methylation level, and methylation, by allowing transcription silencing, has a role in FMF ethiopathogenesis.

**METHODS:** The study group was composed of pediatric FMF patients (N = 51) and age-gender matched healthy controls (N = 21). The relative expression level of MEFV was assessed via quantitative real-time PCR (qRT-PCR) and bisulfite sequencing (BS) was performed to analyse the methylation level quantitatively.

**RESULTS:** MEFV expression in FMF patients were decreased compared to healthy controls (P = 0.031). Methylation level of exon 2 of MEFV was found to be slightly higher in FMF patients compared to healthy controls (76% versus 74%) (P = 0.049). The expression level of the MEFV was negatively correlated with the methylation level of the CpG island in both FMF and healthy controls groups (cor

= -0.29, P = 0.041) but more so in the FMF only group (cor = -0.36, P = 0.035).

CONCLUSIONS: In this study, the relation between reduced MEFV expression level and FMF was confirmed. Observed slight increase in methylation in FMF patients, and correlation of methylation with expression might be indicative of its role in FMF, however a larger dataset is needed to confirm our preliminary findings.

Biologics in atopic dermatitis.

Taïeb A(1), Seneschal J, Mossalayi MD.

Author information:

(1)Department of Dermatology and Pediatric Dermatology, Inserm U 1035, University Bordeaux Segalen, France. alain.taieb@chu-bordeaux.fr

Atopic dermatitis (AD) accounts for a significant share of chronic inflammatory skin disorders. There is a niche for the development of biologics to treat recalcitrant autoinflammatory stage AD seen mostly in adults. The heterogeneity of patient response to various existing biotherapies points to involvement of various immune responses and suggests that therapies must preferably target early development of allergen-specific B- and T-cell clones. In addition to immune targets, tissue factors that help restore the normal epidermal environment constitute interesting therapeutic tools. Several approaches are needed to find the appropriate targets in a field where so many have been investigated without definitive proof of concept for human systemic therapy. The keys to success are probably (1) to influence the inflammatory skin pattern towards less pruritogenic effects, requiring us to better understand pruritogenic inflammation and (2) to limit the amplification loop of disease by attacking abnormal regulatory mechanisms which perpetuate skin autoinflammation.

Comment in

Oral Dis. 2012 Jul;18(5):521; author reply 520.

Recurrent aphthous stomatitis (RAS) is the most common idiopathic intraoral ulcerative disease in the USA. Aphthae typically occur in apparently healthy individuals, although an association with certain systemic diseases has been reported. Despite the unclear etiopathogenesis, new drug trials are continuously conducted in an attempt to reduce pain and dysfunction. We investigated four controversial topics: (1) Is complex aphthosis a mild form of Behçet's disease (BD)? (2) Is periodic fever, aphthous stomatitis, pharyngitis, and adenitis (PFAPA) syndrome a distinct medical entity? (3) Is RAS associated with other systemic diseases [e.g., celiac disease (CD) and B12 deficiency]? (4) Are there any new RAS treatments? Results from extensive literature searches, including a systematic review of RAS trials, suggested the following: (1) Complex aphthosis is not a mild form of BD in North America or Western Europe; (2) Diagnostic criteria for PFAPA have low specificity and the characteristics of the oral ulcers warrant further studies; (3) Oral ulcers may be associated with CD; however, these ulcers may not be RAS; RAS is rarely associated with B12 deficiency; nevertheless, B12 treatment may be beneficial, via mechanisms that warrant further study; (4) Thirty-three controlled trials published in the past 6 years reported some effectiveness, although potential for bias was high.

Current concepts of hyperinflammation in chronic granulomatous disease.

Rieber N(1), Hector A, Kuijpers T, Roos D, Hartl D.

Author information:

(1)Children's Hospital, University of Tübingen, 72076 Tübingen, Germany.

Chronic granulomatous disease (CGD) is the most common inherited disorder of phagocytic functions, caused by genetic defects in the leukocyte nicotinamide dinucleotide phosphate (NADPH) oxidase. Consequently, CGD phagocytes are impaired in destroying phagocytosed microorganisms, rendering the patients susceptible to bacterial and fungal infections. Besides this immunodeficiency, CGD patients suffer from various autoinflammatory symptoms, such as granuloma formation in the skin or urinary tract and Crohn-like colitis. Owing to improved antimicrobial treatment strategies, the majority of CGD patients reaches adulthood, yet the autoinflammatory manifestations become more prominent by lack of causative treatment options. The underlying pathomechanisms driving hyperinflammatory reactions in CGD are poorly understood, but recent studies implicate reduced neutrophil apoptosis and efferocytosis, dysbalanced innate immune receptors, altered T-cell surface redox levels, induction of Th17 cells, the enzyme indolamine-2,3-dioxygenase (IDO), impaired Nrf2 activity, and inflammasome activation. Here we discuss immunological mechanisms of hyperinflammation and their potential therapeutic implications in CGD.

The diagnosis and outcomes of persistent diarrhea in infants aged 0-24 months--a Turkish cohort study.

Eğritaş O(1), Sari S, Dalgıç B, Poyraz A, Ensarı A.

Author information:

(1)Department of Pediatric Gastroenterology, Gazi University School of Medicine, Ankara, Turkey. odulmd2003@yahoo.com

**BACKGROUND/AIMS:** Infantile persistent diarrhea series are not well documented in the literature. Evaluating the literature, the aim of this study was to document persistent diarrhea cases followed in our center and to constitute a practical diagnostic algorithm for the pediatrician by means of surveying methods.

**METHODS:** Diarrheas lasting more than 14 days were accepted as persistent diarrhea. Forty-one persistent diarrhea cases aged 0-24 months were investigated in this study. The cases were evaluated for the presence of mucus and/or leukocytes in stool and were thus divided into two major groups as colitis or enteropathies. For the differential diagnosis of the persistent colitis group, stool cultures, dietary restrictions, complete blood count, acute phase reactants, pathergy test, gene analysis for familial Mediterranean fever and Behçet's disease, colonoscopy, and biopsies were performed. In the persistent enteropathy group, differential diagnosis was made with the following tests: serum and stool electrolytes, arterial blood gases, serum albumin, total protein, lipid profile, stool alpha-1 antitrypsin level, stool pH, presence of stool fat and reducing substance, endoscopy, and biopsies.

**RESULTS:** The 27 persistent enteropathy cases included 7 celiac disease, 5 intestinal lymphangiectasia, 2 microvillus inclusion disease, 2 abetalipoproteinemia, and 11 cow's milk allergy. The 13 cases of the infantile colitis group included 1 Behçet's disease, 1 colitis ulcerosa and 11 cow's milk allergy. Two cases presenting as pancreatic insufficiency were diagnosed as cystic fibrosis. One case was diagnosed as cystic fibrosis plus cow's milk allergy.

**CONCLUSIONS:** Reviewing the literature, these cases represent the largest non-infectious infantile group of persistent diarrheas. A practical diagnostic algorithm for persistent diarrheas has been constituted.

2945. Curr Opin Pharmacol. 2011 Aug;11(4):423-8. doi: 10.1016/j.coph.2011.07.002. Epub 2011 Jul 29.

NLRs in immune privileged sites.

Rosenzweig HL(1), Planck SR, Rosenbaum JT.

Author information:

(1)Casey Eye Institute, Oregon Health & Science University, Portland, OR, USA.  
rosenzwh@ohsu.edu

Innate immune receptors such as the nucleotide-binding domain, leucine-rich repeat-containing (NBD-LRR) receptors, referred to as NLRs, are known to serve as a critical component of host defense. However, their participation in inflammatory responses within immune privileged sites such as the brain and eye is less understood. The potential importance of NLRs in regulation of inflammation within these particular sites is further underscored by their association with autoinflammatory disorders, wherein localized inflammation can occur within the brain or eye as neuroinflammation or uveitis, respectively. Many NLRs are expressed within the brain and eye and in this review, we discuss their roles in the inflammation of the central nervous system (CNS) and uveitis.

**OBJECTIVE:** Although the genetic etiology of familial Mediterranean fever (FMF) is known, limited information is available regarding the regulation of inflammation during attack-free periods. The aim of this study was to determine the alterations in serum copper (Cu), zinc (Zn) and selenium (Se) levels that may be associated with inflammation during attack-free periods in FMF patients.

**MATERIALS AND METHODS:** This study included 33 patients with FMF and 30 healthy volunteers. Erythrocyte sedimentation rate (ESR), the serum C-reactive protein (CRP) level and serum levels of Cu, Zn and Se in FMF patients and healthy volunteers were assessed by the atomic absorption spectrophotometry method.

**RESULTS:** ESR and serum CRP levels and serum Cu and Zn levels were similar between patients with FMF during an attack-free period and healthy controls ( $p>0.05$ ). Serum Se levels in the patient group were significantly higher than in the control group ( $p<0.05$ ).

**CONCLUSION:** Our study shows that levels of trace elements in serum are variable in patients with FMF during attack-free periods. Serum Se concentrations may at least in part contribute to the subclinical inflammation in FMF patients during attack-free periods. However, further studies are necessary to confirm this result.

**Publisher:** Ailesel Akdeniz ateşi (FMF) hastalığının genetik etiyolojisi bilinmesine rağmen, ataksız dönemdeki inflamasyonun düzenlenişi hakkındaki bilgiler sınırlıdır. Bu çalışmanın amacı, FMF hastalığının ataksız döneminde inflamasyonla ilişkili olabilecek serum bakır (Cu), çinko (Zn) ve selenyum (Se) seviyelerindeki değişimleri değerlendirmektir. Bu çalışma 33 FMF hastası ve 30 sağlıklı gönüllüyle düzenlendi. FMF hastalarındaki eritrosit sedimentasyon hızı (ESH), serum C reaktif protein (CRP), Cu, Zn ve Se düzeyleri atomik absorbsiyon spektrofotometri metoduyla değerlendirildi. ESH, serum CRP, Cu ve Zn seviyeleri ataksız periyottaki FMF hastaları ve sağlıklı kontroller arasında benzer düzeydeydi ( $p>0.05$ ). Hasta grubunda serum Se düzeyleri kontrol grubundan anlamlı derecede daha yüksekti ( $p<0.05$ ). Bizim çalışmamız ataksız dönemdeki FMF hastalarında serumdaki eser element seviyelerinin değişken olabildiğini göstermektedir. Serum Se konsantrasyonları FMF hastalarında en azından ataksız dönemdeki subklinik inflamasyona katkıda bulunabilir. Bu sonuçları değerlendirmek

için yeni çalışmalara ihtiyaç bulunmaktadır.

Systemic autoinflammatory diseases encompass different rare clinical entities characterized by recurrent acute inflammatory episodes secondary to a dysregulated inflammatory process. Since their first clinical descriptions, the Mendelian hereditary nature of some of them became evident, with their genetic and molecular basis being recently elucidated. There are disease-causing mutations in genes encoding for different proteins involved in the innate immune response and inflammation. Herein, we will introduce the reader to an updated review of the main clinical, physiopathological and therapeutic features of the different hereditary systemic autoinflammatory diseases.

Inflammasome activation in obesity-related inflammatory diseases and autoimmunity.

Lukens JR(1), Dixit VD, Kanneganti TD.

Author information:

(1)Department of Immunology, St. Jude Children's Research Hospital, Memphis, Tennessee 38105, USA.

The inflammasome is a highly regulated protein complex that triggers caspase-1 activation and subsequent secretion of IL-1 $\beta$  and IL-18. Recognition of microbial components and danger signals by NOD-like receptor (NLR) family members in the cytosol promotes inflammasome activation and downstream inflammatory cytokine production. Pathogen recognition by NLRs and downstream release of inflammasome-derived cytokines are important in host defense against numerous infections. Recent studies have also identified a unique role for inflammasome regulation in the induction and pathogenesis of multiple autoimmune and inflammatory disorders. We now know that obesity-related factors and endogenous markers of cellular stress can lead to unchecked activation of the inflammasome and provoke inflammation and subsequent destruction of vital organs. This review will highlight recent findings that link inflammasome signaling to the progression of autoinflammatory and autoimmune diseases. We will focus on the contribution of inflammasome activation to the pathogenesis of autoinflammatory and autoimmune diseases that are of major significance to human health including type 2 diabetes, atherosclerosis, multiple sclerosis, and type 1 diabetes.

The first reported case of compound heterozygous IL1RN mutations causing deficiency of the interleukin-1 receptor antagonist.

Stenerson M(1), Dufendach K, Aksentijevich I, Brady J, Austin J, Reed AM.

Author information:

(1)Mayo Clinic, Rochester, Minnesota 55905, USA.

Interleukin-1 receptor antagonist (IL-1Ra) deficiency is a rare autoinflammatory disease involving neonatal onset of pustulosis, periostitis, and sterile osteomyelitis. We report the case of a 2-week-old male who presented with a swollen, erythematous left index finger and elevated serum markers of inflammation. He later developed cyclical fevers, diffuse pustular skin lesions, and thrombus formation. After not responding to broad-spectrum antimicrobial therapy and achieving only moderate success with systemic steroid therapy, he was ultimately treated with recombinant IL-1Ra, anakinra, and experienced significant clinical improvement. Sequencing of his IL1RN gene revealed that the patient was compound heterozygous for a known mutation (E77X) associated with IL-1Ra deficiency and a novel mutation in exon 2 of the gene (c.140delC; p.T47TfsX4). His case highlights IL-1Ra deficiency as an autoinflammatory disease that is distinct from neonatal-onset multisystem inflammatory disease but that also responds well to anakinra. Our patient is the first reported compound heterozygote for E77X and the novel mutation in exon 2 of the gene, the latter of which adds to what will surely be a growing database of pathologic mutations in IL1RN.

Mutations in the PSTPIP1 gene and aberrant splicing variants in patients with pyoderma gangrenosum.

Nesterovitch AB(1), Hoffman MD, Simon M, Petukhov PA, Tharp MD, Glant TT.

Author information:

(1)Department of Dermatology, Rush University Medical Center (RUMC), Chicago, IL, USA.

**BACKGROUND:** Pyoderma gangrenosum (PG) is a rare, noninfectious form of skin ulceration, typically accompanied by neutrophilic infiltration. Several familial cases have been reported, suggesting the involvement of genetic factors in the

aetiology of PG. Two mutations (A230T and E250Q) in the PSTPIP1 gene, encoding proline-serine-threonine phosphatase-interacting protein (PSTPIP)1 have been identified in patients with PAPA (pyogenic sterile arthritis with PG and acne) syndrome, a rare autoinflammatory disorder with autosomal dominant inheritance. AIM: The aim of this study was to sequence PSTPIP1 complementary cDNA and genomic DNA for mutations, and to identify genetic polymorphisms in the promoter region of PSTPIP1 in patients with PG.

METHODS: The genomic region and cDNA of the PSTPIP1 gene were sequenced from peripheral blood leucocytes of 14 patients with PG and 20 healthy controls.

RESULTS: One patient (PG1) had aberrant splicing variants of the PSTPIP1 transcript with deletions of exons 9, 11 and 12 and of exons 9-12 together, and all other patients with PG carried deletions of exon 11 and of 11-12. We also identified a novel mutation (G258A) in patient PG3, and novel polymorphisms [(CCTG)(6) and (CCTG)(8) tandem repeats] in the promoter region of the PSTPIP1 gene.

CONCLUSION: All combinations of aberrant splicing variants had frame shifts and premature stop codons leading to truncated proteins and loss of function of PSTPIP1. The (CCTG)(n) tandem repeats in the promoter region of PSTPIP1 had no association with PG. The mutations G258A and R52Q are predicted by the improved prediction algorithm to have a possibly damaging effect on PSTPIP1 function.

[MEFV gene mutation spectrum in familial Mediterranean fever (FMF) : a single center study in the Aegean region of Turkey].

[Article in German]

Coker I(1), Colak A, Yolcu I, Türkön H, Nalbantoglu SM.

Author information:

(1)Ministry of Health, Department of Clinical Biochemistry, Tepecik Research Hospital, Gaziler Cad., Yenisehir, 35120, Izmir, Turkey.

**OBJECTIVES:** Familial Mediterranean fever (FMF), an autosomal recessive autoinflammatory disorder, is characterized by recurrent, self-limiting fever and serositis which is frequently seen in Mediterranean populations. In this study, we retrospectively evaluated the MEFV gene mutation distribution of 883 citizens of the Aegean region with preliminary diagnosis of FMF who were referred to the Tepecik Research and Education Hospital's Tissue Typing and Molecular Diagnostic Laboratory (Izmir, Turkey) between 2006 and 2009.

**METHODS:** The FMF Strip Assay® (ViennaLab Diagnostics, Vienna, Austria) was used to determine the 12 most common MEFV gene mutations in patients prediagnosed with FMF.

**FINDINGS:** Allelic frequencies of the major mutations in the mutation positive groups, including M694V, E148Q, M680I(G>C), and V726A, accounted for 48.4, 16.5, 13.5, and 9.7%, respectively.

**CONCLUSION:** The M694V mutation was found to be the most common mutation among FMF patients in the Aegean region, which is in accordance with mutation studies reported from other regions of the country and different ethnic populations. An English full-text version of this article is available at SpringerLink as supplemental.

Deficiency of interleukin-1-receptor antagonist syndrome: a rare auto-inflammatory condition that mimics multiple classic radiographic findings.

Thacker PG(1), Binkovitz LA, Thomas KB.

Author information:

(1)Department of Radiology, Mayo Clinic, 200 First St. SW, Rochester, MN 55905, USA. thacker.paul@mayo.edu

Deficiency of interleukin-1-receptor antagonist (DIRA) syndrome is a newly identified inflammatory disease of the skeleton and appendicular soft tissues presenting in early infancy that has yet to be reported in the radiology

literature. The radiological manifestations of DIRA syndrome include multifocal osteitis of the ribs and long bones, heterotopic ossification and periarticular soft-tissue swelling. Thus, the pediatric radiologist should be made aware of this novel disease because its radiographic findings can mimic multiple other disease entities. With knowledge of the unique clinical presentation of DIRA syndrome and its multiple radiographic manifestations, the pediatric radiologist may be the first to suggest the correct diagnosis.

Prevalence of connective tissue diseases in egyptian patients presenting with Fever of unknown origin.

Abdelbaky MS(1), Mansour HE, Ibrahim SI, Hassan IA.

Author information:

(1)Internal Medicine and Rheumatology.

**OBJECTIVE:** To estimate the prevalence of connective tissue diseases in patients presenting with fever of unknown origin (FUO).

**PATIENTS AND METHODS:** In this study thirty patients diagnosed as FUO (Group 1), in 2008, were included in an observational study and diagnostic workup.

Additionally, retrospective analysis of seventy patients' files (Group 2), for patients who presented with prolonged unexplained pyrexia to the same hospital in the previous two years, was performed. Patients were subjected to: full clinical assessment including full history taking, thorough clinical examination, laboratory investigations including the basic investigations for patients with prolonged fever, complete blood count, erythrocytes sedimentation rate, urine analysis and culture, blood culture, sputum culture and plain chest X ray. Further diagnostic work up and/or procedures were requested according to the potential diagnostic clues (PDC) present in every patient.

**RESULTS:** Out of 100 FUO patients, 50% were found to have infectious diseases, 24% were found to have connective tissue diseases, 8% miscellaneous causes and 7% neoplastic diseases ( $P < 0.05$ ). In 11 patients no definite cause for FUO could be

identified. Connective tissue patients were: eight systemic lupus patients (33.3%), five patients with familial mediterranean fever (20.8%), four patients with rheumatoid arthritis (16.6%), three patients (12.5%) with Still's disease and Rheumatic fever and one patient with Behçet syndrome/Crohn's disease (4.3%), ( $P < 0.05$ ).

**CONCLUSIONS:** Despite the advanced technology, FUO remains a challenging medical problem. Infections were the most common cause of FUO in Egypt, confirming the trends found in other parts of the world. There was an increased prevalence of connective tissue patients presented with prolonged unexplained fever. A keen clinical eye, meticulous history taking and repeated physical examination remained the most important diagnostic tools in FUO patients.

Clinical care of children with sterile bone inflammation.

Twilt M(1), Laxer RM.

Author information:

(1)Division of Rheumatology, The Hospital for Sick Children, University of Toronto, Toronto, Ontario, Canada. marinka.twilt@sickkids.ca

**PURPOSE OF REVIEW:** To review the current literature of sterile bone inflammation in childhood and to evaluate the evidence for clinical care including diagnostic methods and treatment.

**RECENT FINDINGS:** Chronic noninfectious osteomyelitis includes several different entities marked by sterile bone inflammation associated with histologic evidence of a predominant neutrophil infiltration in the absence of autoantibodies and autoreactive T cells, some of which are associated with a genetic mutation. Whole body MRI is helpful in detecting asymptomatic lesions. Initial treatment with NSAIDs is usually sufficient to control symptoms as the bone heals. However, if the lesions persist and do not respond to first-line treatment, or involve the spine or hip, treatment with bisphosphonate will usually lead to a resolution of symptoms. Rarely, treatment with anti-TNF agents is required.

**SUMMARY:** This review summarizes recent information on diagnosis, treatment and prognosis of disorders involving sterile bone inflammation in childhood. It also addresses the evolving differential diagnosis for autoinflammatory disorders that include sterile bone inflammation and presents a treatment algorithm for management.

Suppressor of cytokine signaling 1-deficient (SOCS1(-/-)) mice, which are lymphopenic, die <3 wk after birth of a T cell-mediated autoimmune inflammatory disease characterized by leukocyte infiltration and destruction of vital organs. Notably, Foxp3(+) regulatory T cells (Tregs) have been shown to be particularly potent in inhibiting inflammation-associated autoimmune diseases. We observed that SOCS1(-/-) mice were deficient in peripheral Tregs despite enhanced thymic development. The adoptive transfer of SOCS1-sufficient Tregs, CD4(+) T lymphocytes, or administration of SOCS1 kinase inhibitory region (KIR), a peptide that partially restores SOCS1 function, mediated a statistically significant but short-term survival of SOCS1(-/-) mice. However, the adoptive transfer of SOCS1-sufficient CD4(+) T lymphocytes, combined with the administration of SOCS1-KIR, resulted in a significant increase in the survival of SOCS1(-/-) mice both short and long term, where 100% death occurred by day 18 in the absence of treatment. Moreover, the CD4(+)/SOCS1-KIR combined therapy resulted in decreased leukocytic organ infiltration, reduction of serum IFN- $\gamma$ , and enhanced peripheral accumulation of Foxp3(+) Tregs in treated mice. These data show that

CD4(+)/SOCS1-KIR combined treatment can synergistically promote the long-term survival of perinatal lethal SOCS1(-/-) mice. In addition, these results strongly suggest that SOCS1 contributes to the stability of the Foxp3(+) Treg peripheral population under conditions of strong proinflammatory environments.

[The laboratory approach in the diagnosis of systemic autoinflammatory diseases].

[Article in Italian]

Cantarini L(1), Rigante D, Brizi MG, Sebastiani GD, Lucherini OM, Galeazzi M, Frediani B.

Author information:

(1)Centro di Ricerca Interdipartimentale per le Malattie Autoimmuni Sistemiche ed Autoinfiammatorie, Policlinico Le Scotte, U.O.C. Reumatologia, Università degli Studi di Siena, Viale Bracci 1, Siena, Italy. cantariniluca@hotmail.com

Systemic autoinflammatory diseases are a group of inherited disorders of the innate immunity characterized by the recurrence of febrile attacks lasting from few hours to few weeks and multi-district inflammation of different severity involving skin, serosal membranes, joints, gastrointestinal tube and central nervous system. The vast majority of these conditions is caused by mutations in genes involved in the control of inflammation and apoptosis mechanisms. The group includes familial Mediterranean fever, mevalonate kinase deficiency syndrome, tumor necrosis factor receptor-associated periodic syndrome, cryopyrin-associated periodic syndromes, hereditary pyogenic and granulomatous disorders. Their diagnostic identification derives from the combination of clinical and biohumoral data, though can be sometimes confirmed by genotype analysis.

A role of IL-1R1 signaling in the differentiation of Th17 cells and the development of autoimmune diseases.

Sha Y(1), Markovic-Plese S.

Author information:

(1)Department of Neurology; University of North Carolina at Chapel Hill; Chapel Hill, NC USA.

IL-1 cytokine family plays a key role in the innate immune response against pathogen- and danger-associated molecular patterns. More recently, IL-1 receptor type 1 (IL-1R1) signaling has been identified as a critical step in the differentiation and commitment of Th17 cells, which mediate the development of autoimmune diseases. Given its significance in the induction of the adoptive immune response, this complex signaling pathway is tightly regulated. Upon binding of IL-1 to IL-1R1, IL-1R accessory protein (AcP) is recruited to form a high affinity IL-1R1-IL-1RAcP heterodimeric receptor, which initiates the downstream signaling cascade. Multiple negative regulators of this pathway, including inhibitory membrane-bound IL-1RII, secreted soluble (s)IL-1RI, sIL-1RII and sIL-1RAcP, the regulatory IL-1R1 antagonist (IL-1R1a) and the IL-1R1-signaling-induced single Ig-IL-1R-related (SIGIRR), provide a negative feedback control of this pathway, and suppress excessive IL-1 signaling and Th17 cell differentiation. IL-1R1 signaling induces human Th17 cell differentiation, leading to the expression of IL-1R-associated protein kinase (IRAK)4 and retinoic acid-related orphan nuclear hormone receptor (ROR), Th17 cell lineage transcription factors, which together with signal transducer and activator of the transcription (STAT)3, activate this cell lineage's specific cytokine expression profile, including IL-17A, IL-17F, IL-21 and IL-22. Given the role of IL-1 signaling and Th17 cells in the development of the autoinflammatory and autoimmune diseases, therapeutic strategies inhibiting IL-1R1 signaling are discussed as a novel approach for the treatment of autoimmune diseases and particularly multiple sclerosis (MS).

The regulation of MEFV expression and its role in health and familial Mediterranean fever.

Grandemange S(1), Aksentijevich I, Jeru I, Gul A, Touitou I.

Author information:

(1)Unité Médicale des Maladies Auto-Inflammatoires, CHRU de Montpellier, INSERM U844, UM1, Hopital Arnaud de Villeneuve, Montpellier, France.

Familial Mediterranean fever (FMF) is a hereditary recurrent fever associated with mutations in the gene MEFV encoding pyrin. It is expressed mainly in neutrophils and macrophages, and modulates the production of the potent pro-inflammatory cytokine interleukin-1 $\beta$  through regulation of nuclear factor- $\kappa$ B and caspase-1. The MEFV gene expression depends on multiple levels of regulation. Sequence variants located in the promoter and at the 3'-untranslated region of the gene modulate this expression. Two studies demonstrated decreased mRNA levels in FMF patients compared with healthy subjects, whereas two others found no significant differences. The diverse experimental settings may have resulted in variable quantification of the 15 splice variants that have been identified recently. Some of these isoforms are regulated by nonsense-mediated decay in both cell- and transcript-specific manner, and may be differentially translated in THP1 cells. In addition, pyrin may be cleaved by caspase 1. The full-length pyrin was less abundant than the cleaved fragment in mononuclear cells from FMF patients than in controls, whereas the opposite was observed in granulocytes. Altogether, the regulation of MEFV expression is more complex than anticipated in both physiological and pathological conditions. Its deregulation is likely to alter the inflammasome function and subsequently result in uncontrolled inflammation as seen in FMF.

Adult-onset Still's disease and chronic recurrent multifocal osteomyelitis: a hitherto undescribed manifestation of autoinflammation.

Rech J(1), Manger B, Lang B, Schett G, Wilhelm M, Birkmann J.

Author information:

(1)Department of Medicine 3, University Erlangen-Nuremberg, Krankenhausstr. 12, 91054, Erlangen, Germany. juergen.rech@uk-erlangen.de

Still's disease and chronic recurrent multifocal osteomyelitis (CRMO) are febrile rheumatic diseases of unknown etiology, which predominantly affect children but can also have their initial manifestation in adults. Both can present as intermittent, relapsing episodes and are considered potential candidates within the expanding spectrum of autoinflammatory disorders, although no genetic abnormalities have been described for either of them. Here, we describe a man with an initial manifestation of abacterial multifocal osteitis at the age of 41. During a relapsing-remitting course of his illness, he increasingly developed symptoms of adult-onset Still's disease (AOSD), and the diagnosis was established according to the Yamaguchi criteria. When treated with anakinra, not only the acute symptoms disappeared promptly, but also the osteitis went into complete remission. This is to our knowledge the first description of a simultaneous occurrence of these two manifestations of autoinflammation in adulthood.

The NLRP3 inflammasome in health and disease: the good, the bad and the ugly.

Menu P(1), Vince JE.

Author information:

(1)Department of Biochemistry, University of Lausanne, Epalinges, Switzerland. philippe.menu@unil.ch

While interleukin (IL)-1 $\beta$  plays an important role in combating the invading pathogen as part of the innate immune response, its dysregulation is responsible for a number of autoinflammatory disorders. Large IL-1 $\beta$  activating platforms, known as inflammasomes, can assemble in response to the detection of endogenous host and pathogen-associated danger molecules. Formation of these protein complexes results in the autocatalysis and activation of caspase-1, which processes precursor IL-1 $\beta$  into its secreted biologically active form. Inflammasome and IL-1 $\beta$  activity is required to efficiently control viral, bacterial and fungal pathogen infections. Conversely, excess IL-1 $\beta$  activity contributes to human disease, and its inhibition has proved therapeutically beneficial in the treatment of a spectrum of serious, yet relatively rare, heritable inflammasomopathies. Recently, inflammasome function has been implicated in more common human conditions, such as gout, type II diabetes and cancer. This raises the possibility that anti-IL-1 therapeutics may have broader applications than anticipated previously, and may be utilized across diverse disease states that are linked insidiously through unwanted or heightened inflammasome activity.

Hyper-IgD syndrome or mevalonate kinase deficiency.

Stoffels M(1), Simon A.

Author information:

(1)Department of General Internal Medicine, Radboud University Nijmegen Medical Centre, Nijmegen, The Netherlands.

PURPOSE OF REVIEW: The hyper-IgD and periodic fever syndrome (HIDS) is one of the classical monogenetic hereditary autoinflammatory disorders, and together with the more severe mevalonic aciduria it is also known as 'mevalonate kinase

deficiency' (MKD). In this study, we will give an overview of the primary research on mevalonate kinase deficiency published in the past 2 years.

RECENT FINDINGS: Besides an inventory of a number of recent case reports, literature review shows there are several interesting developments in the basic field of research. First, a group of articles was recently published on chemically instead of genetically induced MKD mouse and cell models, investigating the effects of several isoprenoid pathway intermediates. Second, another study confirms a role for small GTPases and their isoprenylation in the inflammatory response in mevalonate kinase deficiency. Lastly, there are now, finally, modest new indications about the role of IgD.

SUMMARY: Both pathophysiological studies and clinical observations in the last 2 years have supported the central role of IL-1 in HIDS. There are some intriguing results and hypotheses about the link between isoprenoid metabolism and the IL-1 pathway through geranylgeranylation that deserve to be further examined.

Author information:

(1)Division of Cardiology, Cardiovascular Department, S Leopoldo Mandic Hospital, Merate;

Three cases of recurrent pleuropericarditis were observed within the same family - in two sisters and their niece, who were 18, 35 and 18 years of age, respectively. One patient was treated with pericardiectomy, and the other two were treated with colchicine. Mutations associated with autoinflammatory diseases (tumour necrosis factor receptor-associated periodic syndrome and familial Mediterranean fever) were absent; the condition was found to be sex linked.

Pyoderma gangrenosum, acne, and suppurative hidradenitis (PASH)--a new autoinflammatory syndrome distinct from PAPA syndrome.

Braun-Falco M(1), Kovnerystyy O, Lohse P, Ruzicka T.

Author information:

(1)Department of Dermatology and Allergy, Ludwig-Maximilian-University, Munich, Germany. braun-falco@med.uni-muenchen.de

**BACKGROUND:** PAPA syndrome is a recently identified hereditary autoinflammatory syndrome clinically characterized by pyogenic arthritis, severe acne, and pyoderma gangrenosum. It is caused by mutations in the PSTPIP1 gene and may be closely linked to the aseptic abscesses syndrome, which has been shown to be associated with CCTG repeat amplification in the promoter region of PSTPIP1.

**OBJECTIVE:** We describe two unrelated patients with a clinical presentation quite similar to, yet distinct from, PAPA syndrome.

**RESULTS:** Both patients had pyoderma gangrenosum and acute or remittent acne conglobata, but, in contrast to PAPA syndrome, lacked any episodes of pyogenic arthritis. Instead, they had suppurative hidradenitis. Mutations in PSTPIP1 exons 1 to 15 were excluded. In the promoter region, an increased repetition of the CCTG microsatellite motif was present on one allele in both patients. Alterations of the most commonly affected exons of the MEFV, NLRP3, and TNFRSF1A genes also were not detectable. One patient was treated with the interleukin (IL)-1 receptor antagonist anakinra and responded well, although without complete remission. This implies that IL-1 $\beta$  may be of pathogenetic importance.

**LIMITATIONS:** Small number of patients, no gene mutation identified, and unclear efficacy of therapy are limitations.

**CONCLUSIONS:** The clinical triad of pyoderma gangrenosum, acne, and suppurative hidradenitis represents a new disease entity within the spectrum of autoinflammatory syndromes, similar to PAPA and aseptic abscesses syndrome. For this disease, we propose the acronym "PASH" syndrome. PASH syndrome may respond to IL-1 $\beta$  blockade.

**BACKGROUND:** Pathogens have represented an important selective force during the adaptation of modern human populations to changing social and other environmental conditions. The evolution of the immune system has therefore been influenced by these pressures. Genomic scans have revealed that immune system is one of the functions enriched with genes under adaptive selection.

**RESULTS:** Here, we describe how the innate immune system has responded to these challenges, through the analysis of resequencing data for 132 innate immunity genes in two human populations. Results are interpreted in the context of the functional and interaction networks defined by these genes. Nucleotide diversity is lower in the adaptors and modulators functional classes, and is negatively correlated with the centrality of the proteins within the interaction network. We also produced a list of candidate genes under positive or balancing selection in each population detected by neutrality tests and showed that some functional classes are preferential targets for selection.

**CONCLUSIONS:** We found evidence that the role of each gene in the network conditions the capacity to evolve or their evolvability: genes at the core of the network are more constrained, while adaptation mostly occurred at particular positions at the network edges. Interestingly, the functional classes containing most of the genes with signatures of balancing selection are involved in autoinflammatory and autoimmune diseases, suggesting a counterbalance between the beneficial and deleterious effects of the immune response.

**AIMS/HYPOTHESIS:** The adult non-obese Goto-Kakizaki (GK) rat model of type 2 diabetes, particularly females, carries in addition to hyperglycaemia a genetic predisposition towards dyslipidaemia, including hypercholesterolaemia. As cholesterol-induced atherosclerosis may be programmed in utero, we looked for signs of perinatal lipid alterations and islet microangiopathy. We hypothesise that such alterations contribute towards defective pancreas/islet vascularisation that might, in turn, lead to decreased beta cell mass. Accordingly, we also evaluated islet inflammation and endothelial activation in both prediabetic and diabetic animals.

**METHODS:** Blood, liver and pancreas were collected from embryonic day (E)21 fetuses, 7-day-old prediabetic neonates and 2.5-month-old diabetic GK rats and Wistar controls for analysis/quantification of: (1) systemic variables, particularly lipids; (2) cholesterol-linked hepatic enzyme mRNA expression and/or activity; (3) pancreas (fetuses) or collagenase-isolated islet (neonates/adults) gene expression using Oligo GEArray microarrays targeted at rat endothelium, cardiovascular disease biomarkers and angiogenesis, and/or RT-PCR; and (4) pancreas endothelial immunochemistry: nestin (fetuses) or von Willebrand factor (neonates).

**RESULTS:** Systemic and hepatic cholesterol anomalies already exist in GK fetuses and neonates. Hyperglycaemic GK fetuses exhibit a similar percentage decrease in total pancreas and islet vascularisation and beta cell mass. Normoglycaemic GK neonates show systemic inflammation, signs of islet pre-microangiopathy, disturbed angiogenesis, collapsed vascularisation and altered pancreas development. Concomitantly, GK neonates exhibit elevated defence mechanisms.

**CONCLUSIONS/INTERPRETATION:** These data suggest an autoinflammatory disease, triggered by in utero programming of cholesterol-induced islet microangiopathy interacting with chronic hyperglycaemia in GK rats. During the perinatal period, GK rats show also a marked deficient islet vascularisation in conjunction with decreased beta cell mass.

Bone mineral density in familial Mediterranean fever.

Berkdemir Siverekli N(1), Sahin O, Senel S, Hayta E, Kaptanoglu E, Elden H.

Author information:

(1)Faculty of Medicine, Department of Rheumatology, Cumhuriyet University, 58141 Sivas, Turkey.

The aim of this study was to evaluate the bone mineral density (BMD) in familial Mediterranean fever (FMF) and to search the effects of genetic factors, family history of FMF and types of clinical attacks on BMD. Forty-four attack-free patients with FMF and 36 healthy voluntary subjects were included in the study. BMD measurements of lumbar spine and left proximal femur were performed by dual energy X-ray absorptiometry (DEXA). There was no statistically significant difference between patient and control groups regarding median values of lumbar BMD ( $P = 0.06$ ), lumbar T ( $P = 0.08$ ) and Z ( $P = 0.12$ ) scores, femoral neck BMD ( $P = 0.13$ ), femoral T ( $P = 0.22$ ) and Z ( $P = 0.16$ ) scores and total femur BMD ( $P = 0.14$ ), T ( $P = 0.19$ ) and Z ( $P = 0.27$ ) scores. Patients with negative FMF family history had significantly lower femoral neck BMD ( $P = 0.018$ ), femoral neck T ( $P = 0.009$ ) and Z ( $P = 0.01$ ) scores and total femur BMD ( $P = 0.033$ ) than patients with positive FMF family history. There was no significant difference among the groups regarding mutation characteristic and types of attacks in lumbar BMD, T and Z scores, femoral neck BMD, T and Z scores and total femur BMD, T and Z scores ( $P > 0.05$ ). We found that the bone loss of patients with FMF is not different from that of the controls. The increased bone loss in the patients with negative family history for FMF should be further investigated with larger patient groups taking into consideration of the risk factors related to family history for osteoporosis.

The periodic fever syndromes are disorders of innate immunity. They may be inherited or acquired and present as recurrent attacks of apparently spontaneous self-limiting inflammation without evidence of autoantibodies or infection. Over the past decade-and-a-half there has been significant progress in their understanding and treatment.

Resistin and visfatin: are they valuable enough to be the differential diagnosis in familial Mediterranean fever with acute appendicitis?

Kisacik B(1), Erol MF, Yilmaz G, Yilmaz FM, Maras Y, Kalyoncu U, Karadag O, Kiraz S, Ertenli I, Calguneri M.

Author information:

(1)Department of Internal Medicine Division of Rheumatology, Gaziantep University Faculty of Medicine, Gaziantep, Turkey. Bunyamin\_k@hotmail.com

Familial Mediterranean fever (FMF) is an autosomal recessive disease which predominantly affects certain ethnic groups mainly Sephardic Jews, Turks, Arabs, and Armenians. Differential diagnosis of an attack of FMF with appendicitis could be difficult in patients presenting with acute abdomen. Circulating levels of resistin and visfatin have been shown to increase in several inflammatory conditions. In this study we aimed to investigate the role of resistin and visfatin in diseases activity by monitoring these adipokines' levels in patients with FMF (attacks and attack-free period) and acute appendicitis. The study involves four groups: group 1-31 FMF patients at attack (M/F, 14/17), group 2-27 FMF patients at attack-free period (M/F, 9/18), group 3-29 acute appendicitis patients (M/F, 16/13), and group 4-20 healthy controls (M/F, 10/10). Erythrocyte sedimentation rate, C-reactive protein, white blood cell count, fibrinogen, resistin, visfatin, interleukin-1 $\beta$ , interleukin-6, interleukin-10, TNF- $\alpha$ , and IFN- $\gamma$  were evaluated concurrently. Resistin level could be a useful test in diagnosis of FMF patients in attacks period but not in acute appendicitis as differential diagnosis. Measuring visfatin levels would not give additional information neither for attacks and attack-free period nor FMF attack and appendicitis.

The emerging role of interleukin-1 $\beta$  in autoinflammatory diseases.

Lane T(1), Lachmann HJ.

Author information:

(1)National Amyloidosis Centre, Division of Medicine, UCL Medical School, Royal Free Campus, Rowland Hill Street, London, England NW3 2PF, UK. t.lane@ucl.ac.uk

The autoinflammatory syndromes are a group of multisystem disorders characterized by recurrent episodes of fever and systemic inflammation affecting the eyes, joints, skin, and serosal surfaces in the absence of an immune reaction. Recent

advances have revealed the importance of interleukin-1 $\beta$ , not only in the pathogenesis of many of these rare inherited diseases, but also in acquired diseases. The development and availability of anti-interleukin-1 $\beta$  therapeutics have introduced the possibility of proof-of-concept studies, which are likely to further widen this field.

Genetics of monogenic autoinflammatory diseases: past successes, future challenges.

Aksentijevich I(1), Kastner DL.

Author information:

(1)Inflammatory Disease Section, National Human Genome Research Institute, Building 10/Room 10C101B, 10 Center Drive, MSC 1849, Bethesda, MD 20892-1849, USA. aksentii@exchange.nih.gov

The term autoinflammation was initially coined to distinguish disorders characterized by recurrent episodes of inflammation in the absence of high-titer autoantibodies and antigen-specific T cells from the more common autoimmune diseases. Although this concept originally applied to monogenic hereditary recurrent fevers, it has expanded over time to include polygenic (complex) autoinflammatory diseases. Understanding of the pathogenesis of autoinflammatory diseases has grown rapidly in the past decade owing to advances in genome research and technology. Genome-wide linkage analysis, positional cloning, homozygosity mapping and candidate gene screening have led to the identification of mutations in 12 genes that are associated with monogenic diseases. Genome-wide association studies have begun to elucidate the molecular basis of complex autoinflammatory diseases. The discovery of disease-causing genetic variants has defined autoinflammation as disorder within the innate immune system, implicating IL-1 as a master cytokine, and has led to a breakthrough in therapy, with IL-1 inhibitors producing rapid and sustained amelioration of symptoms. Despite major advances, however, a substantial number of patients have no mutations in the known autoinflammatory genes. The challenge now is to find the undiscovered

genes, considering that most cases are sporadic or occur within small families. New approaches and tools such as next-generation sequencing are discussed.

Novel protagonists in autoinflammatory arthritis of familial Mediterranean fever.

Al-Salam S(1), Conca W.

Author information:

(1)Department of Pathology, Faculty of Medicine & Health Sciences, United Arab Emirates University, Al Ain, United Arab Emirates.

To clarify mechanisms responsible for the self-limiting and nonerosive features of autoinflammatory joint disease in familial Mediterranean fever (FMF), we performed a study on synovial tissue obtained surgically from an acutely inflamed hip joint from a boy feared to have septic arthritis but later found to be homozygous for mutation M694I in pyrin/marenostrin. We defined by immunohistology the infiltrating cells and examined the in situ expression of plausible protagonists in synovitis of FMF: myeloperoxidase, lysozyme, galectin 1, galectin 3, p65 (RelA)/nuclear factor  $\kappa$ B, inducible nitric-oxide synthase, cyclooxygenase 2, and cleaved caspase 3. Neutrophils deficient in myeloperoxidase and lysozyme, macrophages, and mast cells outnumbered T and B lymphocytes as well as plasma cells. Among cells of adaptive immunity, B lymphocytes were predominant. Galectin 1 was detected in numerous cells of the innate immune system throughout the synovial tissue, whereas expression of galectin 3 was less abundant and scattered. p65 (RelA)/nuclear factor  $\kappa$ B and inducible nitric-oxide synthase were both upregulated in most of the infiltrating cells. Cyclooxygenase 2 expression was low, and cleaved caspase 3 was undetectable. We conclude that the exquisitely inflammatory yet nondestructive character of FMF arthritis could correlate with the presence of nonpathogenic neutrophils lacking effector molecules and the widespread expression of anti-inflammatory galectin 1 in regulatory cells of the innate immune system. Intrinsic apoptosis seemed irrelevant for confining synovial autoinflammation, but regulation through pyroptosis or the adaptive

immune system remains possible.

Disease causing mutations in the TNF and TNFR superfamilies: Focus on molecular mechanisms driving disease.

Lobito AA(1), Gabriel TL, Medema JP, Kimberley FC.

Author information:

(1)Protein Sciences, Catalyst Biosciences, 260 Littlefield Avenue, South San Francisco, CA 94080, USA.

The tumor necrosis factor (TNF) and TNF receptor (TNFR) superfamilies comprise multidomain proteins with diverse roles in cell activation, proliferation and cell death. These proteins play pivotal roles in the initiation, maintenance and termination of immune responses and have vital roles outside the immune system. The discovery and analysis of diseases associated with mutations in these families has revealed crucial mechanistic details of their normal functions. This review focuses on mutations causing four different diseases, which represent distinct pathological mechanisms that can exist within these superfamilies: autoimmune lymphoproliferative syndrome (ALPS; FAS mutations), common variable immunodeficiency (CVID; TACI mutations), tumor necrosis factor receptor associated periodic syndrome (TRAPS; TNFR1 mutations) and hypohidrotic ectodermal dysplasia (HED; EDA1/EDAR mutations). In particular, we highlight how mutations have revealed information about normal receptor-ligand function and how such studies might direct new therapeutic approaches.

Pitfalls in familial mediterranean fever: acute intestinal strangulation/obstruction due to primary adhesions.

d'Annunzio E(1), Chafai N, Tired E.

Author information:

(1)Service de chirurgie générale et digestive, hôpital Saint-Antoine, 184, rue du Faubourg-Saint-Antoine, 75012 Paris, France.

Familial Mediterranean Fever (FMF) presents in 90% of patients with painful attacks of peritoneal inflammation, which may mimic an acute surgical abdomen. These episodes characteristically resolve spontaneously within 72 hours. However, recurrent episodes of primary peritonitis may lead to the development of primary intraperitoneal adhesions, even in the absence of previous abdominal surgery. When an atypical bout of pain fails to resolve spontaneously and rapidly, the surgeon must consider the diagnosis of intestinal obstruction due to an adhesive band with the associated risk of strangulation with bowel necrosis. In this case report, we describe this rare but classical presentation of FMF for which any delay in diagnosis or treatment may result in severe morbidity.

Familial mediterranean Fever and hypercoagulability.

Tayer-Shifman OE(1), Ben-Chetrit E.

Author information:

(1)Rheumatology Unit, Division of Medicine, Hadassah-Hebrew University Medical Center. Jerusalem, Israel.

Familial Mediterranean fever (FMF) is an autosomal recessive hereditary disease which is characterized by recurrent attacks of fever and peritonitis, pleuritis, arthritis, or erysipelas-like skin disease. As such, FMF is a prototype of autoinflammatory diseases where genetic changes lead to acute inflammatory episodes. Systemic inflammation - in general - may increase procoagulant factors, and decrease natural anticoagulants and fibrinolytic activity. Therefore, it is anticipated to see more thrombotic events among FMF patients compared with healthy subjects. However, reviewing the current available literature and based upon our personal experience, thrombotic events related purely to FMF are very rare. Possible explanation for this discrepancy is that along with the procoagulant activity during FMF acute attacks, anticoagulant and fibrinolytic changes are also taking place. Colchicine which is the treatment of choice in FMF may also play a role in reducing inflammation thereby decreasing hypercoagulability.

Psoriatic juvenile idiopathic arthritis: a tale of two subgroups.

Stoll ML(1), Punaro M.

Author information:

(1)Department of Pediatrics, University of Texas Southwestern Medical Center, Department of Rheumatology, Texas Scottish Rite Hospital for Children, Dallas, Texas 75219, USA.

**PURPOSE OF REVIEW:** The International League of Associations for Rheumatology criteria parse out juvenile idiopathic arthritis (JIA) into seven groups, with the aim of creating homogeneous subgroups suitable for clinical and research evaluation. However, prior studies have shown that psoriatic JIA (psJIA) may be a heterogeneous entity.

**RECENT FINDINGS:** PsJIA is composed of two subgroups, differentiated by age at onset. Older children with psJIA have features of spondyloarthritis, including

relative male preponderance, increased risk of axial involvement, and enthesitis. Extrapolating from studies on adults with psoriatic arthritis, the mechanism of older-onset PsJIA appears to involve autoinflammatory dysregulation centered at the synovial-entheseal complex; there may also be a role for gut inflammation in a subset of patients. In contrast, patients with early-onset PsJIA bear similarities to early-onset oligoarticular and polyarticular JIA patients, including female preponderance, antinuclear antibody (ANA) positivity, and certain human leukocyte antigen types, suggesting a possible role for traditional autoimmune mechanisms. Both groups, however, share a high frequency of dactylitis.

**SUMMARY:** This review demonstrates that PsJIA is a heterogeneous entity, with different clinical, genetic, and possibly pathophysiological features. Future studies are needed to explore the mechanisms of arthritis in both subgroups, particularly in the early-onset children.

**OBJECTIVE:** The goal of this study was to describe the spectrum of clinical signs of mevalonate kinase deficiency (MKD).

**METHODS:** This was a retrospective French and Belgian study of patients identified on the basis of MKD gene mutations.

**RESULTS:** Fifty patients from 38 different families were identified, including 1

asymptomatic patient. Symptoms began during the first 6 months of life in 30 patients (60%) and before the age of 5 years in 46 patients (92%). Symptoms consisted of febrile diarrhea and/or rash in 23 of 35 patients (66%). Febrile attacks were mostly associated with lymphadenopathy (71%), diarrhea (69%), joint pain (67%), skin lesions (67%), abdominal pain (63%), and splenomegaly (63%). In addition to febrile attacks, 27 patients presented with inflammatory bowel disease, erosive polyarthritis, Sjögren syndrome, and other chronic neurologic, renal, pulmonary, endocrine, cutaneous, hematologic, or ocular symptoms. Recurrent and/or severe infections were observed in 13 patients, hypogammaglobulinemia in 3 patients, and renal angiomyolipoma in 3 patients. Twenty-nine genomic mutations were identified; the p.Val377Ile mutation was the most frequently found (29 of 38 families). Three patients died of causes related to MKD. The disease remained highly active in 17 of the 31 surviving symptomatic patients followed up for >5 years, whereas disease activity decreased over time in the other 14 patients. Interleukin 1 antagonists were the most effective biological agents tested, leading to complete or partial remission in 9 of 11 patients.

CONCLUSION: MKD is not only an autoinflammatory syndrome but also a multisystemic inflammatory disorder, a possible immunodeficiency disorder, and a condition that predisposes patients to the development of renal angiomyolipoma.

High incidence of NLRP3 somatic mosaicism in patients with chronic infantile neurologic, cutaneous, articular syndrome: results of an International Multicenter Collaborative Study.

Tanaka N(1), Izawa K, Saito MK, Sakuma M, Oshima K, Ohara O, Nishikomori R, Morimoto T, Kambe N, Goldbach-Mansky R, Aksentijevich I, de Saint Basile G, Neven B, van Gijn M, Frenkel J, Aróstegui JI, Yagüe J, Merino R, Ibañez M, Pontillo A, Takada H, Imagawa T, Kawai T, Yasumi T, Nakahata T, Heike T.

Author information:

(1)Kyoto University Graduate School of Medicine, Kyoto, Japan.

**OBJECTIVE:** Chronic infantile neurologic, cutaneous, articular (CINCA) syndrome, also known as neonatal-onset multisystem inflammatory disease (NOMID), is a dominantly inherited systemic autoinflammatory disease. Although heterozygous germline gain-of-function NLRP3 mutations are a known cause of this disease, conventional genetic analyses fail to detect disease-causing mutations in ~40% of patients. Since somatic NLRP3 mosaicism has been detected in several mutation-negative NOMID/CINCA syndrome patients, we undertook this study to determine the precise contribution of somatic NLRP3 mosaicism to the etiology of NOMID/CINCA syndrome.

**METHODS:** An international case-control study was performed to detect somatic NLRP3 mosaicism in NOMID/CINCA syndrome patients who had shown no mutation during conventional sequencing. Subcloning and sequencing of NLRP3 was performed in these mutation-negative NOMID/CINCA syndrome patients and their healthy relatives. Clinical features were analyzed to identify potential genotype-phenotype associations.

**RESULTS:** Somatic NLRP3 mosaicism was identified in 18 of the 26 patients (69.2%). Estimates of the level of mosaicism ranged from 4.2% to 35.8% (mean  $\pm$  SD 12.1  $\pm$  7.9%). Mosaicism was not detected in any of the 19 healthy relatives (18 of 26 patients versus 0 of 19 relatives;  $P < 0.0001$ ). In vitro functional assays indicated that the detected somatic NLRP3 mutations had disease-causing functional effects. No differences in NLRP3 mosaicism were detected between

different cell lineages. Among nondescript clinical features, a lower incidence of mental retardation was noted in patients with somatic mosaicism. Genotype-matched comparison confirmed that patients with somatic NLRP3 mosaicism presented with milder neurologic symptoms.

CONCLUSION: Somatic NLRP3 mutations were identified in 69.2% of patients with mutation-negative NOMID/CINCA syndrome. This indicates that somatic NLRP3 mosaicism is a major cause of NOMID/CINCA syndrome.

nurullah.akkoc@gmail.com

Familial Mediterranean fever (FMF) is characterized by recurrent, self-limited episodes of polyserositis, with articular involvement also being a common manifestation. The pattern and joint predilection of arthritis show many similarities to those of spondyloarthritis. Moreover, case series suggest an increased prevalence of ankylosing spondylitis or spondyloarthritis among FMF patients. FMF is caused by mutations in the MEFV gene encoding pyrin, which is believed to be involved in regulation of interleukin-1 $\beta$  activation. Recent studies conducted in populations with a high background carrier rate of MEFV variants have reported an increased frequency of M694V among AS patients with no personal or family history of FMF. These findings are of interest, as both candidate gene and genome-wide association studies suggest that the interleukin-1 cytokine pathway may be implicated in the pathogenesis of ankylosing spondylitis. Therefore, association of M694V with ankylosing spondylitis can be recognized as

a geographic region-specific risk factor affecting a common inflammatory pathway in the disease pathogenesis.

[The role of interleukin-1 and interleukin-1-receptor antagonist in development of familial mediterranean fever and other autoinflammatory diseases].

[Article in Russian]

Dzhidoian Z(1).

Author information:

(1)Department of Therapy №2, Yerevan State Medical University after M. Heratsi, Armenia.

Autoinflammatory diseases constitute a group of genetic disorders whose main clinical features are recurrent episodes of inflammatory lesions that can affect the skin, joints, bones, eyes, gastrointestinal tract and nervous system, in

association with signs of systemic inflammation. Example of these disorders is familial Mediterranean fever (FMF). FMF is an autosomal recessive disease characterized by recurrent episodes of fever and inflammation affecting serosal surfaces, joints and skin. The gene of FMF is expressed in granulocytes, monocytes, dendritic cells and serosal and sinovial fibroblasts, which result in formation of pyrin. A large percentage of FMF-associated pyrin mutations reside in C-terminal B30.2 domain. Pyrin normally suppresses IL-1 $\beta$ , but when mutated in case of FMF, it does not. Inhibition of the interaction between pyrin and caspase-1 leads to an increase in caspase-1 activity and subsequent increase in IL-1 $\beta$  secretion. The interleukin-1-receptor antagonist binds to the interleukin-1 receptor, thereby blocking access of interleukin-1 to the receptor. The outcome of an inflammatory process is likely to be affected by the relative amounts of interleukin-1 and interleukin-1-receptor antagonist.

Juvenile idiopathic arthritis.

Prakken B(1), Albani S, Martini A.

Author information:

(1)Centre for Molecular and Cellular Intervention, Department of Paediatrics, University Medical Centre Utrecht, Netherlands.

Juvenile idiopathic arthritis is a heterogeneous group of diseases characterised by arthritis of unknown origin with onset before age of 16 years. Pivotal studies in the past 5 years have led to substantial progress in various areas, ranging from disease classification to new treatments. Gene expression profiling studies have identified different immune mechanisms in distinct subtypes of the disease, and can help to redefine disease classification criteria. Moreover, immunological studies have shown that systemic juvenile idiopathic arthritis is an acquired autoinflammatory disease, and have led to successful studies of both interleukin-1 and interleukin-6 blockade. In other forms of the disease, synovial inflammation is the consequence of a disturbed balance between proinflammatory effector cells (such as T-helper-17 cells), and anti-inflammatory regulatory

cells (such as FOXP3-positive regulatory T cells). Moreover, specific soluble biomarkers (S100 proteins) can guide individual treatment. Altogether these new developments in genetics, immunology, and imaging are instrumental to better define, classify, and treat patients with juvenile idiopathic arthritis.

Chronic Proliferative Dermatitis in Mice: NF $\kappa$ B Activation Autoinflammatory Disease.

Liang Y(1).

Author information:

(1)Department of Dermatology, Yale University School of Medicine, 15 York Street, New Haven, CT 06510, USA.

Autoinflammatory diseases are a heterogeneous group of congenital diseases characterized by the presence of recurrent inflammation, in the absence of

infectious agents, detectable autoantibodies or antigen-specific autoreactive T-cells. SHARPIN deficient mice presents multiorgan chronic inflammation without known autoantibodies or autoreactive T-cells, designated Sharpin(cpdm). Histological studies demonstrated epidermal hyperproliferation, Th-2 inflammation, and keratinocyte apoptosis in this mutant. The mutant mice have decreased behavioral mobility, slower growth, and loss of body weight. Epidermal thickness and mitotic epidermal cells increase along with disease development. K5/K14 expression is distributed through all layers of epidermis, along with K6 expression in interfollicular epidermis, suggesting epidermal hyperproliferation. K1/K10 is only detectable in outer layers of spinosum epidermis, reflecting accelerated keratinocyte migration. Alpha smooth muscle actin is overexpressed in skin blood vessels, which may release the elevated white blood cells to dermis. CD3(+)CD45(+) cells and granulocytes, especially eosinophils and mast cells, aggregate in the mutant skin. TUNEL assay, together with Annexin-V/propidium iodide FACS analysis, confirmed the increase of apoptotic keratinocytes in skin. These data validate and provide new lines of evidence of the proliferation-inflammation-apoptosis triad in Sharpin(cpdm) mice, an NFκB activation autoinflammatory disease.

**PURPOSE OF REVIEW:** The advent of molecular techniques has resulted in the ability to tailor medications to specific protein targets. This review will emphasize several biological therapies, specifically directed toward cytokine receptors and

inhibitors, and their role in the treatment of atopic and autoinflammatory diseases.

RECENT FINDINGS: Translational research and the identification of the molecular pathophysiology of diseases have led to more targeted treatment approaches. The biologic modulators encompassing monoclonal antibodies as cytokine inhibitors, receptor blocking antibodies, and new fusion receptors are now being applied to diseases beyond their original application.

SUMMARY: The expanded use of biological therapies has experienced success in the treatment of numerous disorders, especially in subsets of patients with disease that has been refractory to conventional therapies.

Immunoglobulin light chain levels can be used to determine disease stage in children with juvenile idiopathic arthritis.

Kutulculer N(1), Karaca NE, Azarsiz E, Aksu G, Gulez N.

Author information:

(1)Faculty of Medicine, Ege University, Department of Pediatrics, Izmir, Turkey.  
necil.kutukculer@ege.edu.tr

OBJECTIVE: Patients with some inflammatory diseases have been shown to have increased levels of immunoglobulin light chains. In this study, we measured the concentrations of immunoglobulin kappa and lambda light chains in sera of patients with juvenile idiopathic arthritis (JIA) (study group), familial mediterranean fever (FMF) (disease control group) and in healthy children. Our aim was to compare immunoglobulin light chain levels with other well-known markers of inflammation, such as the erythrocyte sedimentation rate (ESR) and the acute phase reactants (APRs), serum amyloid A (SAA) and C-reactive protein (CRP), to find out if immunoglobulin light chain determinations have any discriminating value in the follow-up of these patients.

RESULTS: ESR, CRP, SAA, kappa and lambda chain levels and lambda/IgG ratio showed a statistically significant difference between active and remission stages in JIA

patients. Kappa correlated very well with SAA and ESR in both stages. On the other hand, lambda correlated with SAA and ESR only in the remission period. There was no significant difference in kappa and lambda chain levels between active and remission stages in FMF patients. In addition, kappa and lambda chain concentrations showed no correlation with other markers of inflammation and immunoglobulin levels neither in entire FMF group nor in different subgroups with respect to clinical status. Immunoglobulin light chains kappa and lambda as well as levels of three markers of inflammation were found to be significantly higher in JIA patients who were in the active stage of disease when compared to data of healthy children

CONCLUSION: Ig light chains especially kappa chain concentrations are helpful to determine disease stage in JIA patients but with our current data, they do not exhibit superiority to any of the classical tests for inflammation.

[Autoinflammatory diseases as cause of wound healing defects].

[Article in German]

Löhrer R(1), Eming R, Wolfrum N, Krieg T, Eming SA.

Author information:

(1)Klinik und Poliklinik für Dermatologie und Venerologie, Universität zu Köln, Kerpenerstr. 62, 50937, Köln, Deutschland.

Ulcerations of the skin and mucosal membranes are a common feature of autoinflammatory diseases. They can give raise to chronic wound healing defects and should be considered in the differential diagnosis of chronic skin ulcers. The increased activation of the innate immune system in the absence of an apparent provocation for inflammation is a hallmark of autoinflammatory diseases. Mutations and alterations of signaling pathways regulating the innate immune response to physical trauma/tissue damage result into an unrestrained activation of the inflammasome, which leads to increased activation of Interleukin-1. Uncontrolled recruitment and activation of myeloid effector cells within the

wound site lead to the release of potent proteases that cause the degradation of structural components of the skin. The majority of these diseases respond well to immunosuppressive and immunomodulatory treatment regimes. Therapeutic resistance converts the acute inflammatory response into a chronic and non-resolving inflammatory process that leads to tissue degeneration. In this article we will focus on the review of those autoinflammatory diseases that often display ulcerative cutaneous and aphthous lesions including pyoderma gangrenosum, Behçet disease, PAPA syndrome and hyperimmunoglobulinemia D with periodic fever syndrome (HIDS). Furthermore, the article will be complemented by an overview of those inflammatory diseases that are associated with non-ulcerative cutaneous manifestations.

Pathogenesis of systemic juvenile idiopathic arthritis: some answers, more questions.

Mellins ED(1), Macaubas C, Grom AA.

Author information:

(1)Department of Pediatrics, Stanford University, 300 Pasteur Drive, Stanford, CA 94305, USA. mellins@stanford.edu

Systemic juvenile idiopathic arthritis (sJIA) has long been recognized as unique among childhood arthritides, because of its distinctive clinical and epidemiological features, including an association with macrophage activation syndrome. Here, we summarize research into sJIA pathogenesis. The triggers of disease are unknown, although infections are suspects. Once initiated, sJIA seems to be driven by innate proinflammatory cytokines. Endogenous Toll-like receptor ligands, including S100 proteins, probably synergize with cytokines to perpetuate inflammation. These and other findings support the hypothesis that sJIA is an autoinflammatory condition. Indeed, IL-1 is implicated as a pivotal cytokine, but the source of excess IL-1 activity remains obscure and the role of IL-1 in chronic arthritis is less clear. Another hypothesis is that a form of hemophagocytic lymphohistiocytosis underlies sJIA, with varying degrees of its

expression across the spectrum of disease. Alternatively, sJIA with MAS might be a genetically distinct subtype. Yet another hypothesis proposes that inadequate downregulation of immune activation is central to sJIA, supporting evidence for which includes 'alternative activation' of monocyte and macrophages and possible deficiencies in IL-10 and T regulatory cells. Some altered immune phenotypes persist during clinically inactive disease, which suggests that this stage might represent compensated inflammation. Despite much progress being made, many questions remain, providing fertile ground for future research.

**OBJECTIVE:** Behçet's disease (BD) is an inflammatory disorder of unknown cause with higher prevalence along the ancient Silk Road. BD shares epidemiological and clinical features with familial Mediterranean fever (FMF). Moreover, association of BD and certain MEFV gene mutations has been described in recent decades. We studied the role of MEFV mutations in Iranian Azeri Turkish patients with BD.

**METHODS:** Fifty-three BD patients who met the International Study Group criteria for BD were analysed for five common MEFV mutations (M694V, V726A, M680I, M694I, and E148Q) using amplification refractory mutation system and polymerase chain reaction (PCR) restriction-digestion testing methods. A cohort of 200 healthy Azeri Turkish individuals who had been previously genotyped regarding the five common MEFV mutations served as the control group.

**RESULTS:** Eighteen patients were found to carry a single MEFV mutation and one additional patient was compound heterozygote. There was a statistically significant difference between the patient group and ethnically matched healthy individuals regarding M694V and M680I mutations ( $p = 0.01$  and  $p = 0.04$ , respectively). Both BD groups (carriers and non-carriers of MEFV mutations) were similar in their clinical symptoms.

**CONCLUSION:** Definite MEFV mutations seem to be a susceptibility factor for BD in our cohort of Iranian Azeri Turkish patients.

A Case of Henoch-Schönlein Purpura with P369S Mutation in MEFV Gene.

Ertan P(1), Tekin G, Sahin GE, Kasirga E, Taneli F, Kandioğlu AR, Sözeri B.

Author information:

(1)Department of Pediatrics, Celal Bayar University, School of Medicine, Manisa, Turkey.

**BACKGROUND:** Henoch-Schönlein purpura (HSP) is the most common vasculitis of childhood. HSP can affect multiple organs presenting with a characteristic rash

in most of the patients. Familial Mediterranean Fever (FMF) is an inherited inflammatory disease common in mediterranean populations. HSP is the most common vasculitis seen in children with FMF.

CASE PRESENTATION: A 16 year old boy was referred with history of abdominal pain lasting for 20 days. He was hospitalized and had appendectomy. Due to the persistence of his abdominal pain after surgery he was admitted to our hospital. His physical examination showed palpable purpuric rashes symmetrically distributed on lower extremities. Abdominal examination revealed periumbilical tenderness. Laboratory tests showed elevated erythrocyte sedimentation rate, Creactive protein and fibrinogen. Urinalysis revealed microscopic hematuria and severe proteinuria. The fecal occult blood testing was positive. Based on these clinic findings, the patient was diagnosed as HSP with renal, gastrointestinal tract and skin involvement. We performed DNA analysis in our patient because he had diagnosis of vasculitis with severe symptoms and found that he was carrying heterozygote P369S mutation.

CONCLUSION: Our case is noteworthy as it indicates that it may be important not to overlook presence of FMF mutations in patients with a diagnosis of severe vasculitis.

Comment on

Immunity. 2011 May 27;34(5):755-68.

Familial Mediterranean fever is caused by mutations of the PYRIN protein. Chae et al. (2011) provide evidence for a ASC protein-dependent pathway of caspase-1

activation in which gain-of-function PYRIN mutations lead to IL-1 $\beta$  cytokine overproduction and inflammatory disease.

Regulation of the antimicrobial response by NLR proteins.

Elinav E(1), Strowig T, Henao-Mejia J, Flavell RA.

Author information:

(1)Department of Immunobiology, Yale University School of Medicine, New Haven, CT 06520, USA.

Nucleotide-binding, oligomerization domain (NOD)-like receptor (NLR) proteins are a family of innate immune receptors that play a pivotal role in microbial sensing, leading to the initiation of antimicrobial immune responses.

Dysregulation of the function of multiple NLR family members has been linked, both in mice and humans, to a propensity for infection and autoinflammatory disease. Despite our increased understanding of NLR function and interactions, many aspects related to mechanisms of sensing, downstream signaling, and in vivo functions remain elusive. In this review, we focus on key members of the NLR family, describing their activation by diverse microbes, downstream effector functions, and interactions with each other and with other innate sensor protein families. Also discussed is the role of microbial sensing by NLR receptors leading to activation of the adaptive immune arm that collaborates in the antimicrobial defense.

Author information:

(1)Molecular Biology Genetics and Biotechnology Graduate Program, Institute of Science and Technology, Istanbul Technical University, Istanbul, Turkey.

A defect in MEFV gene expression regulation has been implicated in familial Mediterranean fever (FMF) etiopathophysiology. Here we show significantly higher expression level in second exon lacking MEFV transcript in FMF patients compared with healthy controls ( $P=0.026$ ). Our results also point out a possible role of exon 2 deleted MEFV transcript in FMF pathogenesis.

Canakinumab is a fully human monoclonal antibody targeted at IL-1 $\beta$  which has shown to be effective in the control the symptoms of patients affected by CAPS and other autoinflammatory diseases. Its effect is rapid and sustained. In clinical trials conducted up until now, the most common adverse effects reported with the use of this drug have been different types of infections, migraines and vertigo.

[Pathophysiological mechanisms underlying cryopyrin-associated periodic syndromes: genetic and molecular basis and the inflammasome].

[Article in Spanish]

Aróstegui JI(1).

Author information:

(1)Unidad de Enfermedades Autoinflamatorias, Servicio de Inmunología, Hospital Clínic de Barcelona, Barcelona, España. jiaroste@clinic.ub.es

NLRP3 gene (formerly known as CIAS1) encodes for cryopyrin (Nalp3) protein, which belongs to the Nod-like family of innate immune receptors. Cryopyrin recruits different adaptor and effectors proteins into a cytosolic macromolecular complex termed Nalp3-inflammasome, which senses both several pathogen-associated and damage-associated molecular patterns as well as inorganic particles (asbestos, silica), and triggers innate immune and inflammatory responses. Gain-of-function NLRP3 mutations are the common molecular basis of cryopyrin-associated periodic syndromes (CAPS), which encompasses three clinical entities along a spectrum of disease severity (familial cold autoinflammatory syndrome, Muckle-Wells syndrome and CINCA-NOMID syndrome). This hypermorphic cryopyrin provokes an increased, unregulated secretion of different inflammatory cytokines (IL-1 $\beta$ , IL-18, IL-33) in patients with CAPS, and in vivo administration of IL-1 blocking agents results in excellent therapeutic responses in these patients.

[Syndrome of Muckle-Wells and autoinflammatory familial syndrome induced by cold].

[Article in Spanish]

Calvo Penadés I(1), López Montesinos B, Marco Puche A.

Author information:

(1)Unidad de Reumatología Pediátrica, Hospital Universitario La Fe, Valencia, España. calvo\_inm@gva.es

Familial cold autoinflammatory syndrome (FCAS) and Muckle-Wells syndrome (MWS) belong to the cryopyrin-associated periodic syndromes (CAPS) with CIAS1 gene mutations as a common molecular basis. Patients with FCAS have the least severe clinical phenotype but are characterized by the development of symptoms induced by a generalized exposure to cold appearing during the first months of childhood. It is important to make differential diagnosis between FCAS and acquired cold urticaria (ACU) and familial atypical cold urticaria (FACU). Muckle-Wells syndrome is characterized by recurrent fever and urticarial rash, progressive sensorineural deafness and the development of secondary amyloidosis, but it is not considered the most severe disease of this group. Sensorineural deafness and amyloidosis are the two major complications of MWS and determine poor prognosis of the disease.

[Syndrome CINCA/NOMID].

[Article in Spanish]

Modesto C(1).

Author information:

(1)Médico Adjunto, Unidad de Reumatología Pediátrica, Hospital Vall d'Hebron, Barcelona, España. cmodesto@vhebron.net

CINCA/NOMID syndrome was first reported in 1981, identified as a new disease in 1987 and the main cause discovered in 2001, when mutations in the CIAS1 gene modifying the structure of the protein cryopirin were found in those patients (although other factors seem to play a role). Together with the major symptoms that characterized the syndrome, neurological, cutaneous and articular manifestations, others have been added which seem to be quite constant among CINCA/NOMID diagnosed patients: pre and perinatal symptoms, morfological changes, outbreaks of fever and biological abnormalities which reveal a persistent inflammatory background. The radiological studies have been able to identify the physis as the origin of the osteoarticular malformations seen in this syndrome. Diferential diagnosis includes diseases with similar onset at the neonatal period or infancy: systemic onset juvenile idiopathic athritis, periodic fever associated with mevalonate kinase deficiency, deficiency of IL-1 receptor antagonist (DIRA) and Muckle-Wells syndrome.

[Autoinflammatory syndromes].

[Article in Spanish]

Antón J(1).

Author information:

(1)Unidad de Reumatología Pediátrica, Hospital Sant Joan de Déu, Universidad de Barcelona, Barcelona, España. janton@hsjdbcn.org

Autoinflammatory syndromes are characterised by recurrent or persistent inflammation with no increase in the antibody titers or antigen-specific T lymphocytes, and absence of infection. Initially, they included the hereditary periodic fever syndromes, a group of innate immune system monogenic diseases characterised by recurrent febrile episodes, with different characteristics, duration and interval, accompanied by other symptoms. Secondary amyloidosis is a complication in this group. The advances in the last few years has led to the identification of susceptible genes, new proteins, and characterising mechanisms and pathogenic routes that have led to an improvement in the diagnosis and establishing more effective treatments. Among these routes, are the changes in the inflammasome components, a group of cytoplasmic proteins that regulate the production of several inflammatory response mediators. The initial group of monogenic autoinflammatory diseases have increased in the last few years, due to including several polygenic hereditary diseases.

Comment in

Immunity. 2011 May 27;34(5):695-7.

Missense mutations in the C-terminal B30.2 domain of pyrin cause familial Mediterranean fever (FMF), the most common Mendelian autoinflammatory disease. However, it remains controversial as to whether FMF is due to the loss of an inhibitor of inflammation or to the activity of a proinflammatory molecule. We generated both pyrin-deficient mice and "knockin" mice harboring mutant human B30.2 domains. Homozygous knockin, but not pyrin-deficient, mice exhibited spontaneous bone marrow-dependent inflammation similar to but more severe than human FMF. Caspase-1 was constitutively activated in knockin macrophages and active IL-1 $\beta$  was secreted when stimulated with lipopolysaccharide alone, which is also observed in FMF patients. The inflammatory phenotype of knockin mice was completely ablated by crossing with IL-1 receptor-deficient or adaptor molecule ASC-deficient mice, but not NLRP3-deficient mice. Thus, our data provide evidence for an ASC-dependent NLRP3-independent inflammasome in which gain-of-function pyrin mutations cause autoinflammatory disease.

Intussusception is the most common cause of intestinal obstruction in early childhood. The cause of most intussusceptions is unknown but it can complicate the course of Henoch-Schonlein purpura (HSP) as a result of the vasculitic process. Familial Mediterranean fever (FMF), a common disease in Israel, is also associated with HSP. In a few patients, particularly in children, HSP has been reported to precede the diagnosis of FMF. We describe two patients with an unusual clinical course of severe abdominal pain as a result of intussusception. The correlation between intussusception, HSP and FMF are discussed.

Expanding the panel of MEFV mutations for routine testing of patients with a clinical diagnosis of familial Mediterranean fever.

Kilim Y(1), Magal N, Shohat M.

Author information:

(1)Recanati Genetic Institute, Rabin Medical Center (Beilinson Campus), Petah Tikva, Israel.

**BACKGROUND:** Since the identification of the MEFV gene 198 mutations have been identified, not all of which are pathologic. The screening methods used in Israel to test patients suspected of having FMF include a kit that tests for the five main mutations (M694V, V726A, M680Ic/g, M694I, E148Q), and the sequencing of MEFV

exon 10 in combination with restriction analysis for detecting additional mutations

**OBJECTIVES:** To determine the contribution of testing for five additional mutations - A744S, K695R, M680Ic/t, R761H and P369S - to the molecular diagnosis of patients clinically suspected of having FMF.

**METHODS:** A total of 1637 patients were tested for FMF mutations by sequencing exon 10 and performing restriction analysis for mutations E148Q and P369S.

**RESULTS:** Nearly half the patients (812, 49.6%) did not have any detectable mutations, 581 (35.5%) had one mutation, 241 (14.7%) had two mutations, of whom 122 were homozygous and 119 compound heterozygous, and 3 had three mutations. Testing for the additional five mutations enabled us to identify 46 patients who would have been missed by the molecular diagnosis kit and 22 patients in whom only one mutation would have been found. Altogether, 4.3% of the patients would not have been diagnosed correctly had only the kit that tests for the five main mutations been used.

**CONCLUSIONS:** This study suggests that testing for the additional five mutations as well as the five main mutations in patients with a clinical presentation of FMF adds significantly to the molecular diagnosis of FMF in the Israeli population.

kivitys@gmail.com

**BACKGROUND:** Amyloidosis of familial Mediterranean fever (FMF) may lead to end-stage renal failure, culminating in kidney transplantation. Since amyloidosis is prompted by high serum amyloid A (SAA) levels, increased SAA is expected to persist after transplantation. However, no data are available to confirm such an

assumption.

**OBJECTIVES:** To determine SAA levels in kidney-transplanted FMF-amyloidosis patients and evaluate risk factors for the expected high SAA levels in this patient group.

**METHODS:** SAA, C-reactive protein (CRP) and erythrocyte sedimentation rate (ESR) values were obtained from 16 kidney-transplanted FMF-amyloidosis patients, 18 FMF patients without amyloidosis and 20 kidney-transplanted patients with non-inflammatory underlying disease. Demographic, clinical and genetic risk factors evaluation was based on data extracted from files, interviews and examination of the patients.

**RESULTS:** SAA level in FMF patients who underwent kidney transplantation due to amyloidosis was elevated with a mean of  $21.1 \pm 11.8$  mg/L (normal  $\leq 10$  mg/L). It was comparable to that of transplanted patients with non-inflammatory disorders, but tended to be higher than in FMF patients without amyloidosis ( $7.38 \pm 6.36$ ,  $P = 0.08$ ). Possible risk factors for the elevated SAA levels in kidney transplant patients that were excluded were ethnic origin, MEFV mutations, gender, age and disease duration.

**CONCLUSIONS:** Kidney-transplanted patients with FMF-amyloidosis and with other non-FMF causes displayed mildly elevated SAA levels, possibly resulting from exposure to foreign tissue rather than from various FMF-related factors.

Comment in

Isr Med Assoc J. 2011 Nov;13(11):714; author reply 714.

**BACKGROUND:** Familial Mediterranean fever (FMF) is a recessively inherited disease

with a variety of clinical presentations. The disease is associated with mutations in the FMF gene (MEFV), which encodes for the pyrin protein. The role of the E148Q pyrin mutation in the FMF phenotype remains inconclusive, and some authors even view it as a disease-insignificant polymorphism. The calculated change imposed by this mutation on pyrin structure may help to understand the role of this mutation.

**OBJECTIVES:** To calculate the relative electrochemical effect of the E148Q mutation on the structure of pyrin protein.

**METHODS:** The electronic properties of the wild-type pyrin molecule and its common mutated forms were computed for the full-length molecule and its segments, encoded by exons 2 and 10, using the HyperChem 7.5 program with one of the molecular mechanical methods (MM+). The change in the structure of the molecule, expressed as a change in energy gain, conferred by the mutations was determined.

**RESULTS:** The E148Q mutation caused deviation from the wildtype pyrin segment encoded by exon 2 by 1.15% and from the whole pyrin molecule by 0.75%, which was comparable to the R202Q mutation and less than the M694V mutation which caused a deviation from the wild-type structure of the whole pyrin molecule by 1.5%.

**CONCLUSIONS:** A quantum chemistry-based model suggests that the structural effect of the E148Q mutation is indeed low but not zero.

Uveitis in Blau syndrome from a de novo mutation of the NOD2/CARD15 gene.

Raiji VR(1), Miller MM, Jung LK.

Author information:

(1)Children's National Medical Center, Department of Ophthalmology, George Washington University, Washington, DC, USA. veena.raiji@gmail.com

Blau syndrome (MIM 186580) is a rare autoinflammatory, familial granulomatous condition that occurs secondary to a single amino acid mutation of the NOD2/CARD15 gene on chromosome 16p12-q21. We report the case of a 2.5-year-old girl who presented for ophthalmic examination in the setting of rash and synovitis. Initially, small, evanescent, ovoid corneal subepithelial opacities unique to Blau syndrome were observed. She later developed a fulminant panuveitis that responded to immunomodulatory therapy. Subsequent genetic testing confirmed the diagnosis of Blau syndrome. Despite immunosuppression, at almost 7 years of age, she continues to have persistent panuveitis with vision of 20/20.

Helminth parasites and the modulation of joint inflammation.

Matisz CE(1), McDougall JJ, Sharkey KA, McKay DM.

Author information:

(1)Gastrointestinal Research Group, Department of Physiology and Pharmacology, The Calvin, Phoebe and Joan Snyder Institute of Infection Immunity and Inflammation, 1877 HSC University of Calgary, 3330 Hospital Drive NW, Calgary, AB, Canada T2N 4N1.

There is an urgent need to develop better therapeutics for autoimmune and autoinflammatory diseases, of which musculoskeletal disorders such as rheumatoid arthritis are particularly prevalent and debilitating. Helminth parasites are accomplished masters at modifying their hosts' immune activity, and so attention has focused on rodent-helminth model systems to uncover the workings of the mammalian immune response to metazoan parasites, with the hope of revealing molecules and/or mechanisms that can be translated into better treatments for human autoimmune and idiopathic disorders. Substantial proof-of-principal data supporting the concept that infection with helminth parasites can reduce the severity of concomitant disease has been amassed from models of mucosal inflammation. Indeed, infection with helminth parasites has been tried as a therapy in inflammatory bowel disease, and there are case reports relating to other conditions (e.g., autism); however, the impact of infection with parasitic helminths on musculoskeletal diseases has not been extensively studied. Here, we present the view that such a strategy should be applied to the amelioration of joint inflammation and review the literature that supports this contention.

Behçet's disease (BD) and familial Mediterranean fever (FMF), which are two separate diseases sharing some clinical features, may also coexist in the same patient. Further investigations are needed to understand whether this coexistence is due to either chance or geographical distribution patterns of these diseases or to common etiopathogenetic characteristics. Spondylarthritis as part of the clinical picture in these two diseases has been questioned and probably it is not a prominent characteristic of any of them. We report a 35-year-old Tunisian man who had an association of BD, FMF and Human Leukocyte Antigen (HLA) B27 positive ankylosing spondylitis. Although that spondylarthritis is an infrequent joint involvement of FMF and BD, it must be looked for in case of association of these diseases.

University, School of Medicine, 38039 Kayseri, Turkey. sozgocmen@hotmail.com

Familial Mediterranean fever (FMF) is an autoinflammatory disease characterized by recurrent fever, peritonitis/pleuritis, or arthritis attacks. Patients may have FMF-associated mutations of pyrin. The role of biologics such as anti-tumor necrosis factor (TNF) agents (infliximab, etanercept, adalimumab, golimumab) and anakinra, canakinumab, or rilonacept in the treatment of FMF needs to be clarified. Herein we present reports of three patients (all were positive for HLA B27) with typical spondylitis associated with FMF who were successfully managed with anti-TNF agents, along with a literature review. The patients were a 37-year-old man with concomitant Crohn's disease and amyloidosis who was treated with infliximab (INF, 5 mg/kg for 3 years) and switched to adalimumab (ADA), and two female patients (a 24-year-old and a 31-year-old) with FMF who developed severe spondylitis and who were also treated with ADA. Anti-TNF agents can control FMF attacks quite effectively and they reveal a promising role in the treatment of FMF-associated amyloidosis and spondylitis.

TNFRSF1A [corrected] R92Q mutation, autoinflammatory symptoms and multiple sclerosis in a cohort from Argentina.

Kauffman MA(1), Gonzalez-Morón D, Garcea O, Villa AM.

Author information:

(1)Neurogenetics Clinic, Neurology Division, Hospital JM Ramos Mejia, School of Medicine, University of Buenos Aires, Neuroimmunology Unit, 609-1221, Urquiza, Buenos Aires, Argentina. marcelokauffman@marcelokauffman.info

Systemic autoinflammatory diseases are genetic disorders characterized by seemingly unprovoked inflammation, without major involvement of the adaptive immune system. Among them it is recognized the TNF receptor associated periodic syndrome (TRAPS) caused by mutations in the TNFRSF1A gene and characterized by symptoms such as recurrent high fevers, rash, abdominal pain, arthralgia and myalgia. Recent studies have recognized the potential role of TNFRSF1A mutations

in Multiple Sclerosis (MS). Our aim was to investigate the role of TNFRSF1A R92Q gene mutation in a cohort of 90 Argentinean MS patients, where we determined the frequency of the TNFRSF1A R92Q mutation. We also compared autoinflammatory symptoms, MS clinical characteristics and treatment response and tolerability in R92Q carriers and non-carriers. Also, we used a case-control study design to obtain the genotypes of 78 healthy controls and assess the role of this mutation as a risk factor for MS. We found that five patients (5.5%) carried the R92Q mutation, four reported autoinflammatory symptoms previous to MS onset. We found no differences in MS clinical features, treatment response and tolerability between carriers and non-carriers. R92Q mutation was more frequent in MS patients as compared to controls. This increases the risk to develop MS in about 4.5 times. The TNFRSF1A R92Q mutation is a common finding in Argentinean MS patients. This genetic variant might be a risk factor for MS.

The inflammasomes in kidney disease.

Anders HJ(1), Muruve DA.

Author information:

(1)Department of Medicine, University of Calgary, Calgary, AB, T2N 4N1 Canada.  
hjanders@med.uni-muenchen.de

Renal inflammation is a universal response to infectious and noninfectious triggers. Sensors of the innate immune system, such as Toll-like receptors or RIG-like receptors, provide danger recognition platforms on renal cells that integrate and translate the diverse triggers of renal inflammation by inducing cell activation and the secretion of proinflammatory cytokines and chemokines. As a new entry, the inflammasome-forming NLR genes integrate various danger signals into caspase-1-activating platforms that regulate the processing and secretion of pro-IL-1 $\beta$  and pro-IL-18 into the mature and active cytokines. Accumulating data now document a role for the NLRP3 inflammasome and IL-1 $\beta$ /IL-18 in many diseases, including atherosclerosis, diabetes, amyloidosis, malaria, crystal-related

diseases, and other autoinflammatory disorders, identifying this innate immune pathway as an attractive therapeutic target. Here we review the current knowledge regarding inflammasome signaling and outline existing evidence on the expression and functional role of the inflammasome-caspase-1-IL-1 $\beta$ /IL-18 axis in kidney disease. We further provide a perspective on the potential roles of the inflammasomes in the pathogenesis of acute and chronic kidney diseases.

Patients with the autoinflammatory disease Tumour Necrosis Factor receptor-associated periodic syndrome (TRAPS) who suffer from demyelinating disease have been described, and one of the milder TRAPS mutations (R92Q in the TNFRSF1A gene) has been suggested as a risk factor for multiple sclerosis (MS). In a study population of 967 MS patients and 1022 controls, we replicate association [ $P=5\times 10^{-4}$ , 3% in patients versus 1% in controls, OR=2.26 (95% CI 1.41-3.61)], which appears independent of an established common risk variant in the same gene. No other non-synonymous variants in the same allele frequency range influencing risk of MS were observed.

Enhanced exon 2 skipping caused by c.910G>A variant and alternative splicing of MEFV genes in two independent cases of familial Mediterranean fever.

Tone Y(1), Toma T, Toga A, Sakakibara Y, Wada T, Yabe M, Kusafuka H, Yachie A.

Author information:

(1)Department of Pediatrics, School of Medicine, Institute of Medical, Pharmaceutical and Health Sciences, Kanazawa University, 13-1 Takaramachi, Kanazawa 920-8641, Japan.

Most reported cases of familial Mediterranean fever (FMF) involve missense mutations of MEFV concentrated within exon 10. We experienced two independent pedigrees of a unique variant in the MEFV gene that might cause excessive exon 2 skipping due to enhanced alternative splicing. In this study, we tried to elucidate the molecular mechanism of the MEFV variant as a cause of the FMF phenotype. Peripheral blood was obtained from volunteers and two patients with homozygous c.910G>A variant of the MEFV gene. MEFV messenger RNA (mRNA) expression patterns in mononuclear cells and granulocytes were compared using forward and reverse primers from exons 1 and 3, respectively. Expression profiles of pyrin were examined by transfecting wild-type and variant MEFV genes into HEK293T cells. Expression of normal-sized mRNA was extremely reduced in these patients, whereas that of aberrant short mRNA, deleting exon 2 ( $\Delta$ ex2), was significantly increased. Immunohistochemical and immunoblotting analyses revealed a truncated immunoreactive pyrin protein in cells transfected with  $\Delta$ ex2 cDNA. The MEFV gene c.910G>A variant results in accelerated aberrant splicing with abnormal protein size, presumably leading to anomalous pyrin function. This is the first report to show that an MEFV variant other than missense mutation is responsible for the FMF phenotype.

Melatonin and its day and night rhythm of alterations in familial mediterranean Fever: a brief research letter.

Musabak U(1), Kilciler G, Uygun A, Kantarcioglu M, Polat Z, Sagkan RI, Bagci S.

Author information:

(1)Department of Immunology, Gulhane Military Medical Academy and School of Medicine, 06018 Etlik, Ankara, Turkey.

**OBJECTIVE:** The pineal hormone melatonin plays a crucial role in immunomodulation, mainly by effecting T cells. The aims of the present study were to compare the melatonin levels in patients with Familial Mediterranean Fever (FMF) and healthy controls and to find out if it associates with interferon(IFN) $\gamma$  and interleukin(IL)-10.

**MATERIALS AND METHODOLOGY:** Twenty five patients with FMF and 16 healthy donors were enrolled into the study. Melatonin, IFN  $\gamma$  and IL-10 measurements were assayed by using enzyme immunoassay (EIA) method.

**RESULTS:** Serum melatonin levels at 03.30 am in both patients during attack-free phase and healthy controls were significantly higher than those levels of corresponding groups measured at 10.00 am. The melatonin levels at 03.30 and 10.00 am in patients during attack-free phase were higher than those levels measured in healthy controls at the same time points. IFN $\gamma$  and IL-10 did not show any day and night rhythm in both patients and healthy controls. In addition, there was no association among day and night levels of melatonin, IFN $\gamma$  and IL-10.

**CONCLUSIONS:** We conclude that melatonin may play a role in FMF pathogenesis.

However, its modulatory effect on immune response most likely does not depend on T cells. Further comprehensive studies should be performed in order to reveal the role of melatonin in the pathogenesis of this disease.

Coexistence of vasculitides with familial Mediterranean fever.

Aksu K(1), Keser G.

Author information:

(1)Department of Internal Medicine, Division of Rheumatology, Ege University School of Medicine, 80. Sk. No: 27/3, 35040, Izmir, Bornova, Turkey.

kenan.aksu@ege.edu.tr

Familial Mediterranean fever (FMF) is the most common autoinflammatory disease characterized by recurrent self-limited attacks of fever accompanied with peritonitis, pleuritis, or arthritis. FMF may coexist with various systemic inflammatory diseases including vasculitides, spondyloarthritis, multiple sclerosis, and inflammatory bowel disease. Among these coexistences, this review concentrates on vasculitic disorders, with the aim of increasing the awareness of FMF-vasculitis association. This association does not merely show a coincidentally increased frequency of vasculitic disorders in FMF; rather, it seems that FMF patients might be at increased risk of developing vasculitis. Indeed, as also suggested by some authors, vasculitis might be an essential feature of FMF. Among the vasculitic disorders reported to be associated with FMF, Henoch-Schönlein purpura, and classical polyarteritis nodosa come the first, possibly followed up by protracted febrile myalgia. There is also an ongoing debate whether Behçet's disease (BD) more frequently seen in FMF than expected by chance alone. In this review, the associations of various vasculitic disorders with FMF and the possible pathogenic mechanisms underlying these associations, as well as the frequencies and clinical significances of FMF-related MEFV mutations in various vasculitides including BD, are discussed in the context of the

available data.

Nanocavity effect on photophysical properties of colchicine: a proof by circular dichroism study and picosecond time-resolved analysis in various reverse micellar assemblies.

Ghatak C(1), Rao VG, Pramanik R, Sarkar S, Sarkar N.

Author information:

(1)Department of Chemistry, Indian Institute of Technology, Kharagpur, WB, India.

In August 2009, colchicine won Food and Drug Administration (FDA) approval in the United States as a stand-alone drug for the treatment of acute flares of gout and familial Mediterranean fever. Recently, it is now the center of attraction in medicinal research. In this present paper, we have employed two other analogues of colchicine for exploring the photophysical properties inside nanocavity environment in details. Here we have a series of interesting results that have interesting similarity with the colchinoid-tubulin interaction. To monitor fluorescence properties of colchinoids, we have used absorption, emission, and time-resolved spectroscopy and to monitor structural properties we have measured circular dichroism. Steady-state anisotropy and dynamic light scattering results give an idea about the microenvironment sensed by the colchinoids molecules. A sharp increment for colchicine, very small increment for isocolchicine and no increment for colcemid in fluorescence and different circular dichroism (CD) spectra of all of these colchinoids upon embedment inside nanocavity of reverse micelle made a supposition that all these changes of fluorescence properties and CD results of colchinoids is not solely due to viscosity effect but also the constraint, that is, very narrow space to spread over, given by the nanocavity of reverse micelle. Moreover, we have noticed that the B ring of the colchinoids also have a pronounced effect on the interaction nature as well as on conformational change of these compounds after entrapment.

joerg.schedel@kliniken-nordoberpfalz.ag

Hereditary periodic (fever) syndromes, also called autoinflammatory syndromes, are characterized by relapsing fever and additional manifestations such as skin rashes, mucosal manifestations, or joint symptoms. Some of these disorders present with organ involvement and serological signs of inflammation without fever. There is a strong serological inflammatory response with an elevation of serum amyloid A (SAA), resulting in an increased risk of secondary amyloidosis. There are monogenic disorders (familial mediterranean fever (FMF), hyper-IgD-syndrome (HIDS), cryopyrin-associated periodic syndromes (CAPS), "pyogenic arthritis, acne, pyoderma gangrenosum" (PAPA), and "pediatric granulomatous arthritis (PGA) where mutations in genes have been described, which in part by influencing the function of the inflammasome, in part by other means, lead to the induction of the production of IL-1 $\beta$ . In "early-onset of enterocolitis (IBD)", a functional IL-10 receptor is lacking. Therapeutically, above all, the IL-1 receptor antagonist anakinra is used. In case of TRAPS and PGA, TNF-antagonists (etanercept) may also be used; in FMF colchicine is first choice. As additional possible autoinflammatory syndromes, PFAPA syndrome (periodic fever with aphthous stomatitis, pharyngitis and adenitis), Schnitzler syndrome, Still's disease of adult and pediatric onset, Behçet disease, gout, chronic recurrent multifocal osteomyelitis (CRMO) and Crohn's disease also are mentioned.

Normal autonomic nervous system responses in uncomplicated familial Mediterranean fever: a comparative case-control study.

Nussinovitch U(1), Livneh A, Kaminer K, Langevitz P, Feld O, Nussinovitch M, Volovitz B, Lidar M, Nussinovitch N.

Author information:

(1)The Heller Institute of Medical Research, and Department of Medicine F, Sheba Medical Center, Tel Hashomer, Israel, 52621. enussi@yahoo.com

There is a paucity of knowledge regarding the autonomic nervous system function in patients with familial Mediterranean fever (FMF). Therefore, our aim was to evaluate autonomic responses in patients with FMF using complementary tests. The study groups included 33 patients with uncomplicated FMF and 39 control subjects. Autonomic function was evaluated by measuring responses to metronomic breathing, the Valsalva maneuver, and the Ewing maneuver. Autonomic parameters were computed from electrocardiograms with designated computer software. There were no statistically significant differences in any of the measured parameters of autonomic function between the patient and control group. The measured autonomic parameters of both groups were similar to those previously reported in healthy individuals. In conclusion, patients with FMF who did not develop amyloidosis due to continuous colchicine treatment appeared to have normal autonomic function, as reflected by the normal response to physiological autonomic stimuli.

**OBJECTIVE:** To analyze the prevalence of diagnosed and suspected autoinflammatory diseases in Eastern and Central European (ECE) countries, with a particular interest on the diagnostic facilities in these countries.

**METHODS:** Two different strategies were used to collect data on patients with periodic fever syndromes from ECE countries- the Eurofever survey and collection of data with the structured questionnaire.

**RESULTS:** Data from 35 centers in 14 ECE countries were collected. All together there were 11 patients reported with genetically confirmed familial Mediterranean fever (FMF), 14 with mevalonate-kinase deficiency (MKD), 11 with tumor necrosis factor receptor associated periodic syndrome (TRAPS) and 4 with chronic infantile neurological cutaneous and articular syndrome (CINCA). Significantly higher numbers were reported for suspected cases which were not genetically tested. All together there were 49 suspected FMF patients reported, 24 MKD, 16 TRAPS, 7 CINCA and 2 suspected Muckle-Wells syndrome (MWS) patients.

**CONCLUSIONS:** The number of genetically confirmed patients with periodic fever syndromes in ECE countries is very low. In order to identify more patients in the future, it is important to organize educational programs for increasing the knowledge on these diseases and to establish a network for genetic testing of periodic fever syndromes in ECE countries.

Identification and functional consequences of a recurrent NLRP12 missense

mutation in periodic fever syndromes.

**OBJECTIVE:** To gain insight into the molecular bases of genetically unexplained periodic fever syndromes (PFS) by screening NLRP12, a gene in which only a nonsense and a splice site mutation have so far been identified, and to assess the functional consequences of the identified missense variation.

**METHODS:** NLRP12 was screened for mutations by direct sequencing. Functional assays were performed in HEK 293T cells stably expressing the proapoptotic protein ASC and procaspase 1, in order to determine the effects of normal and mutated NLRP12 proteins on speck formation, caspase 1 signaling, and NF- $\kappa$ B activation.

**RESULTS:** A heterozygous NLRP12 missense mutation involving a CpG site (c.1054C>T; p.Arg352Cys) was identified in exon 3, which encodes the nucleotide-binding site (NBS) of the protein, in 2 patients from different countries and carrying different NLRP12 haplotypes. The mutation, which does not alter the inhibitory effect of NLRP12 on NF- $\kappa$ B activation, increases speck formation and activates caspase 1 signaling. To define this new class of PFS, we propose the term NLRP12-associated disorders (NLRP12AD).

**CONCLUSION:** Given the rarity of known NLRP12-associated disorders, the identification of this NLRP12 molecular defect contributes to the delineation of the clinical spectrum associated with mutations in this gene and highlights the importance of screening NLRP12 in patients presenting with unexplained PFS. This study also demonstrates, by means of functional assays, the deleterious effect of this recurrent missense mutation; the gain of function for speck formation and caspase 1 signaling associated with this NBS mutation is consistent with the inflammatory phenotype of PFS.

goldbacr@mail.nih.gov

Neonatal-onset multisystem inflammatory disease (NOMID)/chronic infantile neurologic, cutaneous, and arthritis (CINCA) syndrome is the most severe clinical phenotype in the spectrum of cryopyrin- (NLRP3/NALP3) associated periodic syndromes (CAPS). The study of patients with NOMID/CINCA has been instrumental in characterizing the extent of organ-specific inflammatory manifestations and damage that can occur with chronic interleukin (IL)-1 $\beta$  overproduction. Mutations in CIAS1/NLRP3 lead to constitutive activation of the "NLRP3 inflammasome," an intracellular platform that processes and secretes increased amounts of IL-1 $\beta$ . The pivotal role of IL-1 $\beta$  in NOMID/CINCA has been demonstrated in several clinical studies using IL-1--blocking agents that lead to rapid resolution of the inflammatory disease manifestations. NOMID/CINCA is a monogenic autoinflammatory syndrome; and the discovery of the role of IL-1 in NOMID has led to the exploration in the role of IL-1 in other disorders including gout and Type II diabetes. The inflammation in NOMID/CINCA is continuous with intermittent flares, and organ manifestations encompass the central nervous system, eye, inner ear, and bones. This review discusses updates on the pathogenesis of NOMID/CAPS, emerging long term-outcome data regarding IL-1--blocking agents that have influenced our considerations for optimal treatment, and a monitoring approach tailored to the patient's disease severity and organ manifestations.

PFAPA syndrome in siblings. Is there a genetic background?

Antón-Martín P(1), Ortiz Movilla R, Guillén Martín S, Allende LM, Cuesta Rubio MT, López González MF, Ramos Amador JT.

Author information:

(1)Department of Pediatrics, Division of Infectious Diseases, Hospital Universitario de Getafe, Madrid, Spain. pilarantonmartin@hotmail.com

"PFAPA syndrome" is an autoinflammatory entity composed of periodic fever, aphthous stomatitis, pharyngitis, and cervical adenitis. There have been many reports of children with the disease, but only occasionally have been described in siblings, and no specific genetic mutation has been determined yet. Corticosteroids are the mainstay in the treatment of the acute attacks. The role of surgery in long-term follow-up (tonsillectomy with or without adenoidectomy) is controversial. We report two brothers affected with the syndrome, in whom corticosteroids as the only treatment led to an improvement. A genetic work-up was performed, making very unlikely other possible syndromes of recurrent fever. CONCLUSION: PFAPA syndrome is the most common recurrent periodic fever disorder described in childhood. Its genetic background has not been elucidated yet. Our contribution with two siblings affected with PFAPA syndrome further support the genetic basis for the entity.

Pericarditis: pathophysiology, diagnosis, and management.

Imazio M(1).

Author information:

(1)Cardiology Department Maria Vittoria Hospital, Via Cibrario 72, 10141, Torino, Italy, massimo\_imazio@yahoo.it.

Pericarditis, the most common disease of the pericardium, may be isolated or a manifestation of a systemic disease. The etiology of pericarditis is varied and includes infectious (especially viral and tuberculosis) and noninfectious causes (autoimmune and autoinflammatory diseases, pericardial injury syndromes, and cancer [especially lung cancer, breast cancer, and lymphomas]). Most cases remain idiopathic with a conventional diagnostic evaluation. A targeted etiologic search should be directed to the most common cause on the basis of the patient's clinical background, epidemiologic issues, specific presentations, and high-risk features associated with specific etiologies or complications (fever higher than 38°C, subacute onset, large pericardial effusion, cardiac tamponade, lack of response to NSAIDs). The management of pericardial diseases is largely empiric because of the relative lack of randomized trials. NSAIDs are the mainstay of empiric anti-inflammatory therapy, with the possible addition of colchicine to prevent recurrences.

A clinical perspective of IL-1 $\beta$  as the gatekeeper of inflammation.

Dinarello CA(1).

Author information:

(1)Department of Medicine, University of Colorado, Aurora, CO 80045, USA.  
cdinarello@mac.com

An expanding spectrum of acute and chronic non-infectious inflammatory diseases is uniquely responsive to IL-1 $\beta$  neutralization. IL-1 $\beta$ -mediated diseases are often called "auto-inflammatory" and the dominant finding is the release of the active form of IL-1 $\beta$  driven by endogenous molecules acting on the monocyte/macrophage. IL-1 $\beta$  activity is tightly controlled and requires the conversion of the primary transcript, the inactive IL-1 $\beta$  precursor, to the active cytokine by limited proteolysis. Limited proteolysis can take place extracellularly by serine proteases, released in particular by infiltrating neutrophils or intracellularly by the cysteine protease caspase-1. Therefore, blocking IL-1 $\beta$  resolves inflammation regardless of how the cytokine is released from the cell or how the precursor is cleaved. Endogenous stimulants such as oxidized fatty acids and lipoproteins, high glucose concentrations, uric acid crystals, activated complement, contents of necrotic cells, and cytokines, particularly IL-1 itself, induce the synthesis of the inactive IL-1 $\beta$  precursor, which awaits processing to the active form. Although bursts of IL-1 $\beta$  precipitate acute attacks of systemic or local inflammation, IL-1 $\beta$  also contributes to several chronic diseases. For example, ischemic injury, such as myocardial infarction or stroke, causes acute and extensive damage, and slowly progressive inflammatory processes take place in atherosclerosis, type 2 diabetes, osteoarthritis and smoldering myeloma. Evidence for the involvement of IL-1 $\beta$  and the clinical results of reducing IL-1 $\beta$  activity in this broad spectrum of inflammatory diseases are the focus of this review.

Recurrence of secondary glomerular disease after renal transplantation.

Ponticelli C(1), Moroni G, Glassock RJ.

Author information:

(1)Division of Nephrology, Scientific Institute Humanitas, Rozzano, Milano, Italy.

The risk of a posttransplant recurrence of secondary glomerulonephritis (GN) is quite variable. Histologic recurrence is frequent in lupus nephritis, but the lesions are rarely severe and usually do not impair the long-term graft outcome. Patients with Henoch-Schonlein nephritis have graft survival similar to that of other renal diseases, although recurrent Henoch-Schonlein nephritis with extensive crescents has a poor prognosis. Amyloid light-chain amyloidosis recurs frequently in renal allografts but it rarely causes graft failure. Amyloidosis secondary to chronic inflammation may also recur, but this is extremely rare in patients with Behcet's disease or in those with familial Mediterranean fever, when the latter are treated with colchicine. Double organ transplantation (liver/kidney; heart/kidney), chemotherapy, and autologous stem cell transplantation may be considered in particular cases of amyloidosis, such as hereditary amyloidosis or multiple myeloma. There is little experience with renal transplantation in light-chain deposition disease, fibrillary/immunotactoid GN, or mixed cryoglobulinemic nephritis but successful cases have been reported. Diabetic nephropathy often recurs but usually only after many years. Recurrence in patients with small vessel vasculitis is unpredictable but can cause graft failure. However, in spite of recurrence, patient and graft survival rates are similar in patients with small vessel vasculitis compared with those with other renal diseases. Many secondary forms of GN no longer represent a potential contraindication to renal transplantation. The main issues in transplantation of

patients with secondary GN are the infectious, cardiovascular, or hepatic complications associated with the original disease or its treatment.

Cryopyrin-associated periodic syndromes: otolaryngologic and audiologic manifestations.

Ahmadi N(1), Brewer CC, Zalewski C, King KA, Butman JA, Plass N, Henderson C, Goldbach-Mansky R, Kim HJ.

Author information:

(1)Georgetown University Hospital, Washington, DC, USA.

**OBJECTIVE:** Cryopyrin-associated periodic syndromes (CAPS) represent a spectrum of CIAS1 gene-mediated autoinflammatory diseases characterized by recurrent systemic inflammation. The clinical spectrum of CAPS varies from mild to severe and includes the syndromes historically described as familial cold autoinflammatory syndrome (FCAS), Muckle-Wells syndrome (MWS), and neonatal-onset multisystem inflammatory disease (NOMID). This article presents the largest cohort of patients with CAPS. The objective is to describe the pathogenesis, otolaryngologic, and audiologic manifestations of CAPS.

**STUDY DESIGN:** Prospective (2003-2009).

**SETTING:** National Institutes of Health.

**SUBJECTS AND METHODS:** Fifty-seven patients with a diagnosis of CAPS were identified (31 NOMID, 11 NOMID/MWS, 9 MWS, and 6 FCAS). Comprehensive data regarding clinical manifestations, audiologic phenotype, and fluid attenuation inversion recovery MRI (FLAIR-MRI) of the brain and inner ear were obtained.

**RESULTS:** Complete audiologic data obtained on 70% of ears revealed conductive hearing loss in 4 (11%) NOMID ears and mixed hearing loss in 5 (13%) NOMID and 2 (14%) NOMID/MWS ears. Sensorineural hearing loss (SNHL), worse in higher frequencies, was the most common type of hearing loss and was present in 23 (61%)

NOMID, 10 (71%) NOMID/MWS, and 4 (33%) MWS ears. All of the patients with FCAS had normal hearing except 2, who had SNHL from 4 to 8 kHz. On FLAIR-MRI sequence, cochlear enhancement was noted in 26 of 29 (90%) NOMID, 6 of 11 (55%) NOMID/MWS, 3 of 9 (33%) MWS, and 1 of 6 (17%) FCAS patients and was significantly associated with the presence of hearing loss. Maxillary sinus hypoplasia and mucosal thickening were found in 39% and 86% of the cohort, respectively.

CONCLUSION: CIAS1 pathway-mediated CAPS is associated with unregulated autoinflammation mediated by interleukin-1 in the cochlea and hearing loss. Timely diagnosis is crucial to initiate early treatment with interleukin-1 receptor antagonists.

P-wave dispersion in systemic AA amyloidosis of familial Mediterranean fever.

Nussinovitch U(1), Livneh A, Nussinovitch M, Volovitz B, Ben-Zvi I, Lidar M, Nussinovitch N.

Author information:

(1)The Heller Institute of Medical Research and Department of Medicine F, Sheba Medical Center, Tel Hashomer, Israel. enussi@yahoo.com

Familial Mediterranean fever (FMF) is a hereditary disease characterized by attacks of fever and polyserositis. Recent studies differ as to whether FMF is associated with an abnormally high P-wave duration and P-wave dispersion, markers for supraventricular arrhythmogenicity. The aim of our study was to further evaluate atrial dispersion in FMF patients with amyloidosis. The study groups consisted of 16 patients with FMF and amyloidosis, and 16 age- and sex-matched control subjects. All participants underwent 12-lead electrocardiography under strict standards. P-wave length and P-wave dispersion in each individual patient were computed from a randomly selected beat and an averaged beat constructed from 7 to 12 beats, included in a 10-s electrocardiogram. No statistically significant differences were found between the groups for minimal, maximal, and average P-wave duration and P-wave dispersion, calculated either from a random beat or averaged beats. In conclusion, although a small difference cannot be excluded because of the small study groups, FMF patients with amyloidosis appear to have atrial conduction parameters similar to those of healthy controls, and therefore apparently do not have an increased electrocardiographic risk for developing supraventricular arrhythmias.

mssr.cabral@gmail.com

Familial Mediterranean Fever (FMF) is an hereditary autosomal recessive disease characterized by recurrent attacks of fever, arthritis and serositis: peritonitis, pleurisy and/or pericarditis. Its main complication is systemic AA amyloidosis. The authors present a case of a 8-years-old female child with african ancestry, who was admitted three times since 5 years-old with abdominal pain, fever and high acute phase reactants. At the first admission appendectomy was made and at the third hospital admission the clinical picture was accompanied by myalgia, purpuric lesions and non nephrotic proteinuria. A renal biopsy was performed and was compatible with Henoch-Schönlein nephritis. Serum Amyloid A protein had high levels - 92 mg/L (> 6.8) and a diagnosis of Familial Mediterranean Fever was confirmed by genetic test (homozygote for M694V in MEFV gene). She started colchicine and is doing well, without any further complaints. FMF must be considered in the differential diagnosis of recurrent attacks of fever and abdominal pain in children, even with an atypical presentation (p.e. Protracted Febrile Myalgia Syndrome). Genetic study allows the confirmation of the diagnosis and has prognostic implications.

Role of interleukin-1 $\beta$  in NLRP12-associated autoinflammatory disorders and resistance to anti-interleukin-1 therapy.

Jéru I(1), Hentgen V, Normand S, Duquesnoy P, Cochet E, Delwail A, Grateau G, Marlin S, Amselem S, Lecron JC.

Author information:

(1)Université Pierre et Marie Curie-Paris 6, UMR S933, Paris, France.

**OBJECTIVE:** A new class of autoinflammatory syndromes called NLRP12-associated disorders (NLRP12AD) has been associated with mutations in NLRP12. Conflicting data on the putative role of NLRP12 in interleukin-1 $\beta$  (IL-1 $\beta$ ) signaling have been found in in vitro analyses. This prospective study was undertaken to assess the secretion of IL-1 $\beta$  and 3 IL-1 $\beta$ -induced cytokines (IL-1 receptor antagonist [IL-1Ra], IL-6, and tumor necrosis factor  $\alpha$  [TNF $\alpha$ ]) in patients' peripheral blood mononuclear cells (PBMCs) cultured ex vivo and to evaluate the patients' response to IL-1Ra (anakinra), a major drug used in the treatment of autoinflammatory disorders.

**METHODS:** Patients' disease manifestations and cytokine measurements were recorded before anakinra treatment was started, during 14 months of therapy, and after discontinuation of anakinra treatment.

**RESULTS:** Spontaneous secretion of IL-1 $\beta$  by patients' PBMCs was found to be dramatically increased (80-175 fold) compared to healthy controls. Consistent with these findings, anakinra initially led to a marked clinical improvement and to a rapid near-normalization of IL-1 $\beta$  secretion. However, a progressive clinical relapse occurred secondarily, associated with an increase in TNF $\alpha$  secretion, persistent elevated levels of IL-1Ra and IL-6, and a reactivation of IL-1 $\beta$  secretion. Anakinra was discontinued after 14 months of therapy.

**CONCLUSION:** Our findings provide in vivo evidence of the crucial role of IL-1 $\beta$  in the pathophysiology of NLRP12AD. This is the first time anakinra has been used to treat this disorder. This study provides new insights into the mechanisms underlying resistance to anti-IL-1 therapy observed in a few patients with autoinflammatory syndromes. Our data also point to the potential of ex vivo cytokine measurements as predictors of response to treatment.

Caspase-1-processed cytokines IL-1 $\beta$  and IL-18 promote IL-17 production by  $\gamma\delta$  and CD4 T cells that mediate autoimmunity.

Lalor SJ(1), Dungan LS, Sutton CE, Basdeo SA, Fletcher JM, Mills KH.

Author information:

(1)School of Biochemistry and Immunology, Trinity College, Dublin 2, Ireland.

IL-1 $\beta$  plays a critical role in promoting IL-17 production by  $\gamma\delta$  and CD4 T cells. However, IL-1-targeted drugs, although effective against autoinflammatory diseases, are less effective against autoimmune diseases. Conversely, gain-of-function mutations in the NLRP3 inflammasome complex are associated with enhanced IL-1 $\beta$  and IL-18 production and Th17 responses. In this study, we examined the role of caspase-1-processed cytokines in IL-17 production and in induction of experimental autoimmune encephalomyelitis (EAE). Killed *Mycobacterium tuberculosis*, the immunostimulatory component in CFA used for inducing EAE, stimulated IL-1 $\beta$  and IL-18 production by dendritic cells through activation of the inflammasome complex and caspase-1. Dendritic cells stimulated with *M. tuberculosis* and myelin oligodendrocyte glycoprotein promoted IL-17 production by T cells and induced EAE following transfer to naive mice, and this was suppressed by a caspase-1 inhibitor and reversed by administration of IL-1 $\beta$  or IL-18. Direct injection of the caspase-1 inhibitor suppressed IL-17 production by CD4 T cells and  $\gamma\delta$  T cells in vivo and attenuated the clinical signs of EAE.  $\gamma\delta$  T cells expressed high levels of IL-18R and the combination of IL-18 and IL-23, as with IL-1 $\beta$  and IL-23, stimulated IL-17 production by  $\gamma\delta$  T cells, but also from CD4 T cells, in the absence of TCR engagement. Our findings demonstrate that caspase-1-processed cytokines IL-1 $\beta$  and IL-18 not only promote autoimmunity by stimulating innate IL-17 production by T cells but also reveal redundancy in the functions of IL-1 $\beta$  and IL-18, suggesting that caspase-1 or the inflammasome may be an important drug target for autoimmune diseases.

Economic impact of juvenile idiopathic arthritis and familial Mediterranean fever.

Yucel IK(1), Seyahi E, Kasapcopur O, Arisoy N.

Author information:

(1)Department of Pediatric Rheumatology, Cerrahpasa Medical School, Istanbul University, Istanbul, Turkey.

The aim of the study was to determine the economical impact of juvenile idiopathic arthritis (JIA) and familial Mediterranean fever (FMF) in Turkey. A total of 100 patients (69 F/31 M) with JIA and 100 with FMF (68 F/32 M) who were consecutively seen in the outpatient clinic of the pediatric rheumatology department at Cerrahpasa Medical School between August 2008 and January 2009 were studied. Cost data were collected through a questionnaire filled out by the parents. The mean age (JIA:  $11 \pm 5$  years; FMF:  $12 \pm 4$  years) and mean disease duration (JIA:  $5 \pm 3$  years; FMF:  $4 \pm 3$  years) of the patients were similar. JIA patients were assigned to 5 subtypes (polyarticular:  $n = 45$ , oligoarticular:  $n = 30$ , systemic onset:  $n = 13$ , psoriatic:  $n = 6$ , and enthesopathy-related JIA:  $n = 6$ ). Forty-nine percent of the patients with JIA were treated with anti-TNF drugs and 61% with DMARDs. All patients with FMF were using colchicine. The total annual cost of JIA ( $\text{€}3,994 \pm 4,101$ ) was considerably higher than that of FMF ( $\text{€}162 \pm 77$ ) ( $P < 0.001$ ). Medication fee was the major determinant of total costs in both diseases constituting 85% in JIA and 39% in FMF. Among the subtypes of JIA, total annual costs were the highest among patients with polyarticular type ( $\text{€}6,045 \pm 4,078$ ). Medications especially anti-TNF drugs were the major contributor among all determinants of costs in JIA. The low costs of health care system and prominent changes in the health care policies for the last 5 years in Turkey might have played role in our findings.

QT dispersion in amyloidosis due to familial Mediterranean fever.

Nussinovitch U(1), Nussinovitch N, Nussinovitch M, Volovitz B, Feld O, Ben-Zvi I, Livneh A.

Author information:

(1)The Heller Institute of Medical Research, and Department of Medicine F, Sheba Medical Center, Tel Hashomer Israel and Sackler Faculty of Medicine, Tel Aviv University, Tel Aviv, Israel. enussi@yahoo.com

Cardiac amyloid deposition in FMF may cause increased QT dispersion (QTd), a marker for cardiac arrhythmias. The aim of this study was to further evaluate repolarization dispersion in familial Mediterranean fever (FMF) with amyloidosis. Findings on 12-lead electrocardiography were compared between 18 patients with FMF-amyloidosis and 18 age- and sex-matched control subjects. Repolarization and dispersion parameters were computed with designated computer software, and results of the 5 beats were subsequently averaged. There were no statistically significant differences between the groups as to average corrected QT interval length, average QTd interval, average QT corrected dispersion, or QT dispersion ratio. JT dispersion and JT corrected dispersion were also similar in both groups. In conclusion, patients with FMF-amyloidosis seem to have QT and JT dispersion parameters similar to those of healthy subjects. Future research and longer follow-ups should be conducted in order to evaluate the prognostic importance of repolarization dispersion parameters in amyloidosis of FMF.

OBJECTIVE: Tumor necrosis factor (TNF) receptor-associated periodic syndrome (TRAPS) is an autosomal-dominant multisystemic autoinflammatory condition. Patients display different mutations of the TNF receptor superfamily 1A gene

(TNFRSF1A), coding for a nearly ubiquitous TNF receptor (TNFR1). No TNFRSF1A mutation has been identified in a proportion of patients with TRAPS-like phenotype.

**METHODS:** We investigated mechanisms downregulating the TNF-induced inflammatory response such as (1) receptor shedding, producing a secreted form acting as a TNF inhibitor; (2) receptor internalization with subsequent induction of apoptosis; and (3) negative regulation of nuclear factor- $\kappa$ B (NF- $\kappa$ B) transcription. We analyzed the sequence of genes known to play a pivotal role in these pathways, in 5 patients with TRAPS symptoms and showing shedding and/or apoptosis defects, but without mutations of the TNFRSF1A gene.

**RESULTS:** Sequence analysis of 3 genes involved in TNFR1 shedding (ERAP1, NUCB2, RBMX) and 3 genes involved in negative regulation of NF- $\kappa$ B signaling (TNFAIP3, CARP-2) or NF- $\kappa$ B transcription (ZFP36) revealed only a few unreported variants, apparently neutral.

**CONCLUSION:** Our study rules out any involvement in the pathogenesis of TRAPS of some of the genes known to regulate TNFR1 shedding and TNF-induced NF- $\kappa$ B signaling and transcription. Gene(s) responsible for TRAPS-like syndrome remain to be investigated among currently unidentified genes likely involved in these pathways, or by applying the genome-wide function-free sequencing approach.

t.herlin@dadlnet.dk

Autoinflammatory diseases are characterized by attacks of apparently unprovoked inflammation without significant levels of autoantibodies or antigen-specific T-cells. Within the past decade, a number of different genetic causes of fever

syndromes have been identified: familial Mediterranean fever (FMF), hyper IgD syndrome, cryopyrin-associated periodic syndromes and tumour necrosis factor receptor-associated periodic syndrome. The recent awareness and recognition of pathogenic mechanism of these diseases have led to new possibilities for medical treatment with targeted biological agents.

Chronic recurrent multifocal osteomyelitis.

Wipff J(1), Adamsbaum C, Kahan A, Job-Deslandre C.

Author information:

(1)Service de rhumatologie A, Université Paris Descartes, AP-HP, hôpital Cochin, Paris, France. julien.wipff@cch.aphp.fr

Chronic recurrent multifocal osteomyelitis (CRMO), also known as chronic nonbacterial osteomyelitis, is an orphan disease that manifests as recurrent flares of inflammatory bone pain with or without a fever. The pain is related to one or more foci of nonbacterial osteomyelitis. To distinguish unifocal CRMO from a tumor or an infection, a bone biopsy is required in nearly all patients and a trial of antibiotic therapy in many. CRMO is now considered the pediatric equivalent of SAPHO syndrome, and recent data suggest that CRMO should be classified among the autoinflammatory diseases. The treatment of CRMO is not standardized. Although no randomized placebo-controlled trials are available, there is general agreement that nonsteroidal antiinflammatory drugs constitute the best first-line treatment and that bisphosphonates and biotherapies such as TNF $\alpha$  antagonists are effective in the most severe forms. Although CRMO is considered a benign disease, recent data suggest an up to 50% rate of residual impairments despite optimal management.

Familial Mediterranean fever (FMF) is an autoinflammatory disease characterized by recurrent episodes of fever and serosal or synovial inflammation. We examined the utility of CD64 (FcγRI) expression in polymorphonuclear neutrophils (PMNs) as clinical and biological parameters in patients with FMF. We studied 12 Japanese FMF patients (mean age;  $22.8 \pm 15.5$  years, male/female: 2/10), along with rheumatoid arthritis patients (RA,  $n = 38$  male/female: 6/32, mean age;  $52.2 \pm 15.3$  years), systemic lupus erythematosus (SLE,  $n = 15$  male/female: 0/15, mean age;  $38.5 \pm 15.9$  years) and 12 healthy subjects (male/female: 3/9, mean age;  $37.9 \pm 17.2$  years). CD64 expression on PMNs was determined using flow cytometry. The quantitative expression of CD64 in patients with FMF ( $2439.6 \pm 2215.8$  molecules per PMN) was significantly higher than in healthy subjects ( $547.8 \pm 229.5$ ,  $P = 0.003$ ) or in patients with RA ( $606.5 \pm 228.2$ ,  $P < 0.0001$ ) and SLE ( $681.3 \pm 281.1$ ,  $P = 0.004$ ). The increased CD64 expression on PMNs isolated from untreated FMF patients was down-regulated by colchicine treatment. NACHT-LRR-PYD-containing protein 3 (NLRP3) activation using MurNAc-L-Ala-D-isoGln (MDP) resulted in increased CD64 expression on PMNs from healthy subjects. Our results suggest that quantitative measurement of CD64 expression on PMNs can be a valuable tool to discriminate between FMF and autoimmune diseases.

Vascular comorbidities in familial Mediterranean fever.

Ozçakar ZB(1), Yalçinkaya F.

Author information:

(1)Division of Pediatric Nephrology, School of Medicine, Ankara University, Çınar Sitesi 5. Blok No: 62, Ümitköy, 06530, Ankara, Turkey.

Familial Mediterranean fever (FMF) is a common hereditary autoinflammatory disorder characterized by recurrent febrile attacks and polyserositis. The MEditerranean FeVer (MEFV) gene missense mutations altering the structure and function of pyrin protein play a significant role in the pathophysiology of the disease. Mutated pyrin is associated with the loss of delicate control of the inflammatory pathways, which results in a prolonged or augmented inflammation that predisposes these patients and carriers of the MEFV mutation to a pro-inflammatory state. This increased inflammation might lead to susceptibility to vascular comorbidities in FMF patients and even in carriers. In this review, we aim to discuss the vascular comorbidities seen in FMF patients. For this purpose, a thorough search was done in Web sites such as Pubmed, Web of Science, Scopus and Google Scholar, and the most relevant articles and case reports were evaluated. It seems that various vasculitides and the emerging problem of atherosclerosis have increasingly been recognized in these patients and, on the other hand, cardiac amyloidosis appears as a rare but devastating complication of FMF. Future studies will shed light on the unknown aspects of the emerging vascular problems in patients with FMF.

Spontaneous insertion of a b2 element in the ptpn6 gene drives a systemic autoinflammatory disease in mice resembling neutrophilic dermatosis in humans.

Nesterovitch AB(1), Szanto S, Gonda A, Bardos T, Kis-Toth K, Adarichev VA, Olasz K, Ghassemi-Najad S, Hoffman MD, Tharp MD, Mikecz K, Glant TT.

Author information:

We found a spontaneous autosomal mutation in a mouse leading to neutrophil infiltration with ulceration in the upper dermis of homozygous offspring. These animals had increased neutrophil numbers, associated with normal lymphocyte count, in peripheral blood and bone marrow, suggesting a myeloproliferative disorder; however, granulocyte precursor proliferation in bone marrow was actually reduced (because circulating neutrophils were less susceptible to apoptosis). Neutrophil infiltration of the skin and other organs and high serum levels of immunoglobulins and autoantibodies, cytokines, and acute-phase proteins were additional abnormalities, all of which could be reduced by high-dose corticosteroid treatment or neutrophil depletion by antibodies. Use of genome-wide screening localized the mutation within an 0.4-Mbp region on mouse chromosome 6. We identified insertion of a B2 element in exon 6 of the Ptpn6 gene (protein tyrosine phosphatase, non-receptor type 6; also known as Shp-1). This insertion involves amino acid substitutions that significantly reduced the enzyme activity in mice homozygous for the mutation. Disease onset was delayed, and the clinical phenotype was milder than the phenotypes of other Ptpn6-mutants described in motheaten (me, mev) mice; we designated this new genotype as Ptpn6(meB2/meB2) and the phenotype as meB2. This new phenotype encompasses an autoinflammatory disease showing similarities to many aspects of the so-called neutrophilic dermatoses, a heterogeneous group of skin diseases with unknown etiology in humans.

Successful treatment with anti-tumor necrosis factor (anti-TNF)-alpha of proteinuria in a patient with familial mediterranean fever (FMF) resistant to colchicine: anti-TNF drugs and FMF.

Erten S, Erten SF, Altunoglu A.

Familial mediterranean fever (FMF) is an autoinflammatory disease characterized by recurrent attacks of fever, peritonitis, pleuritis, and genetically by autosomal recessive inheritance. The major renal involvement in FMF is the occurrence of amyloidosis that can be prevented by a daily regimen of colchicine. About 5-10% of cases with familial mediterranean fever may be resistant to colchicine. In literature, there is a controversy about the treatment of FMF patients resistant to colchicine. We describe a case with FMF, proteinuria, and bilateral sacroiliitis, which responded to anti-TNF (tumor necrosis factor)-alpha therapy with infliximab and etanercept.

The shortage of geranylgeranyl-pyrophosphate (GGPP) was associated to an increased IL-1 $\beta$  release in the autoinflammatory syndrome mevalonate kinase deficiency (MKD), a rare inherited disease that has no specific therapy.

Farnesyltransferase inhibitors (FTIs) act at the end of mevalonate pathway. Two FTIs, tipifarnib (Tip) and lonafarnib (Lon), were therefore evaluated as possible therapeutical choices for the treatment of MKD. FTIs could lead to a redirection of the limited available number of mevalonate intermediates preferentially to GGPP synthesis, eventually preventing the uncontrolled inflammatory response. The effect of Tip and Lon on intracellular cholesterol level (ICL) and on proinflammatory cytokines secretion was evaluated in a cellular model of MKD, chemically obtained treating RAW 264.7 cells with lovastatin (Lova) and alendronate (Ald). The combination of FTIs with the isoprenoid geraniol (GOH) was also tested both in this model and in monocytes isolated from MKD patients. Tip and Lon proved to revert the ICL lowering and to significantly reduce the lipopolysaccharide-induced cytokines secretion in Ald-Lova -RAW 264.7 cells. This anti-inflammatory effect was amplified combining the use of GOH with FTIs. The effect of GOH and Tip was successfully replicated in MKD patients' monocytes. Tip and Lon showed a dramatic anti-inflammatory effect in monocytes where mevalonate pathway was chemically or genetically impaired.

Inflammasome activation: from inflammatory disease to infection.

Dunne A(1).

Author information:

(1)School of Biochemistry and Immunology, and School of Medicine, Trinity College Dublin, Dublin 2, Ireland. aidunne@tcd.ie

The recognition of pathogen-derived molecules by the innate immune system is mediated by a number of receptors, including members of the TLR (Toll-like receptor), RLH [RIG (retinoic acid-inducible gene)-like helicase] and the NLR (NOD-like receptor) families. NLRs in particular are also involved in the recognition of host-derived 'danger'-associated molecules which are produced under conditions of cellular stress or injury. Activation of these receptors leads to the assembly of high-molecular-mass complexes called inflammasomes which in turn leads to the generation of active caspase 1 and to the production of

mature IL-1 $\beta$  (interleukin 1 $\beta$ ). The discovery that NLRP3 (NLR-related protein 3) can recognize host-derived particulate matter such as uric acid and cholesterol crystals has led to this inflammasome being implicated in a number of inflammatory diseases, including gout, atherosclerosis and Type 2 diabetes. In addition, aberrant NLRP3 activation has also been observed in a number of heritable disorders now referred to as cryopyrinopathies. On the other hand, a number of studies have reported that recognition of both viral and bacterial products by NLRs is required for effective pathogen clearance. The present review discusses both aspects of NLR activation and will highlight the role of additional inflammasome complexes in sensing infection.

Neuroendocrine immune system in familial Mediterranean fever.

Topaloğlu R(1), Bilginer Y, Alikışifoğlu A, Ozaltın F, Beşbaş N, Ozen S, Bakkaloğlu A.

Author information:

(1)Unit of Pediatric Nephrology and Rheumatology, Department of Pediatrics, Hacettepe University Faculty of Medicine, Ankara, Turkey.

Familial Mediterranean fever (FMF) is an autoinflammatory disorder and is characterized by self-limited attacks of inflammation. Although mutations in the gene coding for pyrin are responsible for the inflammation seen in attacks, the question of whether the failure to mount an appropriate cortisol response to inflammation has any additive effects allowed us to plan this study. The aim was to determine the interactions between the neuroendocrine and immune system in patients with FMF and investigate the role of the neuroendocrine system in the acute inflammation process. Demographic characteristics, disease activity, mutation analysis, and duration of the disease were defined in 15 FMF patients (7 female, 8 male; mean age  $\pm$  SD: 9.1  $\pm$  4.2 years). The diagnosis was based on Tel-Hashomer criteria. Ten healthy volunteers and 21 active juvenile idiopathic arthritis (JIA) patients formed the control groups. Furthermore, 10 of these 15 patients with FMF were also studied during the attack-free period. Erythrocyte

sedimentation rate (ESR) C-reactive protein (CRP), fibrinogen, adrenocorticotrophic hormone (ACTH), cortisol, insulin-like growth factor-1 (IGF)-1, IGF binding protein (BP)-3, urinary cortisol levels, interleukin (IL)-1beta, IL-6, and tumor necrosis factor (TNF)-a were evaluated in FMF patients with attack and during the attack-free period. Although the median levels of ACTH (12.7 pg/ml) and cortisol (12 ug/dl) at 08:00 a.m. were lower in FMF patients during attack than in the attack-free period, these differences did not reach statistical significance. On the other hand, the median levels of ACTH were significantly lower during attack than in the healthy control group ( $p < 0.05$ ). Median levels of IGF-1 (118.5 ng/ml) were significantly lower during FMF attack than in the attack-free period ( $p < 0.05$ ). There was a negative correlation between IGF-1 and CRP ( $r = -0.47$ ). The median level of IL-6 was 18.1 pg/dl during FMF attack and was significantly higher than in the attack-free period and in the healthy control group ( $p < 0.05$ ). There was a negative correlation between cortisol level at 08:00 am and IL-6 ( $r = -0.45$ ). When we compared JIA with FMF patients during attack, inappropriately low secretion of adrenal cortisol and ACTH and low urine cortisol levels were more pronounced in JIA than FMF. Although it is more prominent in chronic inflammation, the neuroendocrine immune system seems to be impaired in relation to acute inflammation in FMF.

Perinatal onset mevalonate kinase deficiency.

Steiner LA(1), Ehrenkranz RA, Peterec SM, Steiner RD, Reyes-Múgica M, Gallagher PG.

Author information:

(1)Department of Pediatrics, Yale University School of Medicine, New Haven, CT, USA.

Defects in mevalonate kinase, a critical rate-limiting enzyme in cholesterol and isoprene metabolism, have been associated with 2 clinical phenotypes: mevalonic

aciduria, which presents in infancy or early childhood with growth failure, dysmorphic features, and neurologic disease; and hyperimmunoglobulinemia D and periodic fever syndrome, which usually presents outside the neonatal period as an autoinflammatory periodic fever syndrome. This report describes a kindred with 2 siblings affected by severe mevalonate kinase deficiency (mevalonic aciduria) with perinatal onset. Dysmorphic and central nervous system abnormalities, anemia, and cholestasis were prominent features in 1 sibling. Both cases were fatal, 1 in the immediate neonatal period and 1 in utero. The small number of cases of mevalonate kinase deficiency presenting in the perinatal period have typically been severely affected, with signs and symptoms of a severe multisystem disorder. Predominant features of perinatal onset mevalonate kinase deficiency include intrauterine growth restriction, cerebral ventriculomegaly, dysmorphic features, skeletal abnormalities, dyserythropoietic anemia with extramedullary erythropoiesis, thrombocytopenia, cholestatic liver disease, persistent diarrhea, renal failure, recurrent sepsis-like episodes, and failure to thrive. Clinical findings may mimic severe intrauterine viral infection, a chromosomal abnormality, or an acute sepsis syndrome, potentially contributing to delays in diagnosis of this rare condition. Perinatal onset mevalonate kinase deficiency is associated with a very poor prognosis, with death in utero or in early infancy. Detailed autopsy findings in mevalonate kinase deficiency have rarely been reported.

Author information:

(1)Centre for Diabetes, Barts and The London School of Medicine and Dentistry, Queen Mary University of London, Whitechapel, London E1 2AT, UK.

Tumor necrosis factor receptor-associated periodic syndrome (TRAPS) is an autosomal dominant autoinflammatory condition caused by mutations in the TNFRSF1A gene which encodes the tumor necrosis factor (TNF) receptor, TNFR1. We investigated the effect of three high penetrance and three low penetrance TNFRSF1A mutations upon NF- $\kappa$ B transcription factor family subunit activity, and the resulting impact upon secretion of 25 different cytokines. Whilst certain mutations resulted in elevated NF- $\kappa$ B p65 subunit activity, others instead resulted in elevated c-Rel subunit activity. Interestingly, high p65 activity was associated with elevated IL-8 secretion, whereas high c-Rel activity increased IL-1 $\beta$  and IL-12 secretion. In conclusion, while all six TNFRSF1A mutations showed enhanced NF- $\kappa$ B activity, different mutations stimulated distinct NF- $\kappa$ B family subunit activities, and this in turn resulted in the generation of unique cytokine secretory profiles.

Coexistence of Takayasu's arteritis with familial Mediterranean fever.

Zihni FY(1), Kalfa M, Ocakçı PT, Tarhan F, Parildar M, Keser G, Aksu K.

Author information:

(1)Division of Rheumatology, Department of Internal Medicine, Ege University School of Medicine, 80. Sk. No: 27/3, 35040, Bornova, Izmir, Turkey.

Familial Mediterranean fever (FMF) is the most common autoinflammatory disease characterized by recurrent self-limited attacks of fever, accompanied with peritonitis, pleuritis or arthritis. It is well known that FMF may coexist with vasculitic pathologies, especially with those involving small and medium vessels. Among the vasculitic pathologies reported to be associated with FMF, Henoch-Schönlein purpura and polyarteritis nodosa come the first, possibly followed up by protracted febrile myalgia. However, coexistence of FMF with any

large vessel vasculitis has not been reported to date. Here, we present a case with FMF who later developed Takayasu arteritis, with a severe disease course, being resistant to corticosteroids and conventional immunosuppressive agents, and requiring infliximab treatment.

Comprehensive analysis of a large-scale screen for MEFV gene mutations: do they truly provide a "heterozygote advantage" in Turkey?

Berdeli A(1), Mir S, Nalbantoglu S, Kutukculer N, Sozeri B, Kabasakal Y, Cam S, Solak M.

Author information:

(1)Molecular Medicine Laboratory, Children's Hospital, School of Medicine, Ege University, Bornova, Izmir, Turkey. afigberdeli@yahoo.com

Familial Mediterranean fever (FMF) is a hereditary autoinflammatory disorder characterized by episodes of inflammation in the absence of high-titer autoantibodies or antigen-specific T cells. The Mediterranean fever (MEFV) gene located on chromosome 16p13.3, which encodes the 781-amino-acid protein pyrin, is the causative gene for this monogenic Mendelian disease. This study presents the molecular analysis of an MEFV gene mutation screen of 5518 Turkish individuals with clinical diagnoses of FMF. Patients were genetically diagnosed using the FMF StripAssay and DNA sequencing analysis. Contrary to the results achieved by the FMF StripAssay, DNA sequencing analysis identified large-scale coding and noncoding novel sequence variants, together with a significant group (76%) of individuals who were receiving colchicine and had a single heterozygous mutation, despite the recessive inheritance of FMF. In conclusion, sequence analysis, unlike other routine laboratory techniques, may enable screening for a broad range of nucleotide variations and may prevent less common, population-restricted, novel sequence variants from being overlooked.

An approach to the hospitalized patient with urticaria and fever.

Micheletti R(1), Rosenbach M.

Author information:

(1)Departments of Dermatology and Internal Medicine, University of Pennsylvania, Philadelphia, PA 19104, USA.

Urticaria is a common skin disorder with a long differential diagnosis. Most cases are readily treated symptomatically and have no systemic implications. However, a number of diseases and syndromes, including vasculitides, immunologic disorders, infectious diseases, hematologic diseases, and autoinflammatory syndromes, can present with urticaria and systemic symptoms, which may lead to hospitalization of the patient. These urticarial syndromes are important to recognize as they often have significant health implications. A comprehensive history and physical exam is important in distinguishing cases of simple urticaria from these syndromes. The presence of atypical wheals, systemic symptoms such as fever or arthralgia, and a lack of response to antihistamine therapy are important diagnostic clues that should prompt further workup.

Alteration in the gene encoding protein tyrosine phosphatase nonreceptor type 6 (PTPN6/SHP1) may contribute to neutrophilic dermatoses.

Nesterovitch AB(1), Gyorfy Z, Hoffman MD, Moore EC, Elbuluk N, Trynieszewska B, Rauch TA, Simon M, Kang S, Fisher GJ, Mikecz K, Tharp MD, Glant TT.

Author information:

(1)Department of Dermatology, Rush University Medical Center, Chicago, IL 60612, USA.

We have found a B2 repeat insertion in the gene encoding protein tyrosine phosphatase nonreceptor type 6 (PTPN6) in a mouse that developed a skin disorder with clinical and histopathological features resembling those seen in human neutrophilic dermatoses. Neutrophilic dermatoses are a group of complex heterogeneous autoinflammatory diseases that all demonstrate excessive neutrophil infiltration of the skin. Therefore, we tested the cDNA and genomic DNA sequences of PTPN6 from patients with Sweet's syndrome (SW) and pyoderma gangrenosum and found numerous novel splice variants in different combinations. Isoforms resulting from deletions of exons 2, 5, 11, and 15 and retention of intron 1 or 5 were the most common in a patients with a familial case of SW, who had a neonatal onset of an inflammatory disorder with skin lesions and a biopsy specimen consistent with SW. These isoforms were associated with a heterozygous E441G mutation and a heterozygous 1.7-kbp deletion in the promoter region of the PTPN6 gene. Although full-length PTPN6 was detected in all other patients with either pyoderma gangrenosum or SW, it was always associated with splice variants: a partial deletion of exon 4 with the complete deletion of exon 5, alterations that were not detected in healthy controls. The defect in transcriptional regulation of the hematopoietic PTPN6 appears to be involved in the pathogenesis of certain subsets of the heterogeneous group of neutrophilic dermatoses.

A 20-year-old Turkish male presented with fever, abdominal pain, and systemic lethargy. His clinical history revealed symptoms to be self-limiting but reoccurring over the past six months. Blood and urine specimens collected indicated renal amyloidosis. A kidney CT image indicated kidney inflammation. He was diagnosed with Familial Mediterranean Fever with the development of secondary amyloidosis and treated with colchicine.

Recent insights into the pathogenesis of type AA amyloidosis.

van der Hilst JC(1).

Author information:

(1)Department of Internal Medicine and Infectious Diseases, University Medical Centre Utrecht, Utrecht, the Netherlands. j.c.h.vanderhilst@umcutrecht.nl

The amyloidoses are a group of life-threatening diseases in which fibrils made of misfolded proteins are deposited in organs and tissues. The fibrils are stable, insoluble aggregates of precursor proteins that have adopted an antiparallel beta-sheet structure. In type AA, or reactive, amyloidosis, the precursor protein of the fibrils is serum amyloid A (SAA). SAA is a 104-amino-acid protein that is produced in the liver in response to proinflammatory cytokines. Although the protein that is produced by the liver contains 104 amino acids, only the N-terminal 66-76 amino acids are found in amyloid fibrils. Furthermore, SAA has been shown to have an alpha-helical structure primarily. Thus, for SAA to be incorporated into an amyloid fibril, two processes have to occur: C-terminal cleavage and conversion into a beta-sheet. Only a minority of patients with elevated SAA levels develop amyloidosis. Factors that contribute to the risk of amyloidosis include the duration and degree of SAA elevation, polymorphisms in SAA, and the type of autoinflammatory syndrome. In the Hyper-IgD syndrome, amyloidosis is less prevalent than in the other autoinflammatory diseases. In

vitro work has shown that the isoprenoid pathway influences amyloidogenesis by farnesylated proteins. Although many proteins contain domains that have a potential for self-aggregation, amyloidosis is only a very rare event. Heat shock proteins (HSPs) are chaperones that assist other proteins to attain, maintain, and regain a functional conformation. In this review, recent insights into the pathogenesis of amyloidosis are discussed, in addition to a new hypothesis for a role of HSPs in the pathogenesis of type AA.

Accurate and simple measurement of the pro-inflammatory cytokine IL-1 $\beta$  using a whole blood stimulation assay.

Yang B(1), Pham TH, Goldbach-Mansky R, Gadina M.

Author information:

(1)Translational Immunology Section, Office of Science and Technology, National Institute of Arthritis and Musculoskeletal and Skin Diseases.

Inflammatory processes resulting from the secretion of soluble mediators by immune cells, lead to various manifestations in skin, joints and other tissues as well as altered cytokine homeostasis. The innate immune system plays a crucial role in recognizing pathogens and other endogenous danger stimuli. One of the major cytokines released by innate immune cells is Interleukin (IL)-1. Therefore, we utilize a whole blood stimulation assay in order to measure the secretion of inflammatory cytokines and specifically of the pro-inflammatory cytokine IL-1 $\beta$ (1, 2, 3). Patients with genetic dysfunctions of the innate immune system causing autoinflammatory syndromes show an exaggerated release of mature IL-1 $\beta$  upon stimulation with LPS alone. In order to evaluate the innate immune component of patients who present with inflammatory-associated pathologies, we use a specific immunoassay to detect cellular immune responses to pathogen-associated molecular patterns (PAMPs), such as the gram-negative bacterial endotoxin, lipopolysaccharide (LPS). These PAMPs are recognized by pathogen recognition receptors (PRRs), which are found on the cells of the innate immune system (4, 5,

6, 7). A primary signal, LPS, in conjunction with a secondary signal, ATP, is necessary for the activation of the inflammasome, a multiprotein complex that processes pro-IL-1 $\beta$  to its mature, bioactive form (4, 5, 6, 8, 9, 10). The whole blood assay requires minimal sample manipulation to assess cytokine production when compared to other methods that require labor intensive isolation and culturing of specific cell populations. This method differs from other whole blood stimulation assays; rather than diluting samples with a ratio of RPMI media, we perform a white blood cell count directly from diluted whole blood and therefore, stimulate a known number of white blood cells in culture (2). The results of this particular whole blood assay demonstrate a novel technique useful in elucidating patient cohorts presenting with autoinflammatory pathophysiologies.

mttahara@qg7.so-net.ne.jp

A Japanese girl with neonatal-onset chronic hepatitis and systemic inflammation was diagnosed with hyper-immunoglobulinemia D and periodic fever syndrome (HIDS). However, she lacked the typical HIDS features until the age of 32 months. She had compound heterozygous MVK mutations, H380R and A262P, the latter of which was novel. These findings suggest that HIDS patients could lack typical episodes of recurrent fever at the onset and that HIDS should be considered as a possible cause of neonatal-onset chronic hepatitis.

[Signal receptors of congenital immunity: a new molecular target for diagnostics and treatment of inflammatory diseases].

[Article in Russian]

Kozlov IG.

The discovery of signal receptors of congenital immunity (signal PRR) not only provided a novel view of basic aspects of pathogenesis of chronic inflammatory diseases but also created a basis for the development of additional diagnostic criteria for these pathologies and new pharmaceuticals for their treatment. Reduced expression and function of PRR due to mutations/polymorphisms or epigenetic disturbances of regulation can be regarded as immunodeficient conditions manifest as severe infectious inflammatory diseases. In contrast, excessive expression and activation of PRR as a rule leads to chronic autoinflammatory, autoimmune, and atopic diseases involving adaptive immunity and aggression against own tissues and cells. Assessment of certain mutations in PRR genes, their expression and activation provides a powerful tool for in-depth diagnostics of inflammatory diseases. Simultaneously, new lines of immunostimulating and anti-inflammatory therapy are developed based on the knowledge of molecular physiology of PRR with the use of synthetic agonists and antagonists of signal PRR.

[Inflammasomes and related diseases].

[Article in Japanese]

Saito MK(1).

Author information:

(1)Center for iPS Cell Research and Application, Kyoto University, Kyoto, Japan.

Although inflammation is important for host defense, excessive inflammation sometimes causes serious consequences. IL-1 $\beta$  is one of major proinflammatory cytokines. Dysregulation of IL-1 $\beta$  promotes development of several diseases. Mature IL-1 $\beta$  is produced by cleavage of its proform by a protein complex named inflammasome. Inflammasome consists of NOD-LRRs containing family (NLR proteins), an adaptor protein, and a cysteine protease caspase-1. Several NLRs can be assembled into inflammasome in response to various stimulatory signals. Genetic disorder of inflammasome-IL-1 system cause autoinflammatory diseases such as cryopyrin-associated autoinflammatory disease, familial Mediterranean fever, deficiency of IL-1 receptor antagonist, and PAPA syndrome. This article reviews recent advances in the study of inflammasome and related diseases.

kuemmerle.deschner@uni-tuebingen.de

**OBJECTIVE:** Muckle-Wells syndrome (MWS) is an inherited autoinflammatory disease caused by mutations in the NLRP3 gene that result in excessive interleukin-1 (IL-1) release. It is characterized by severe fevers, rashes, arthralgia, and conjunctivitis, leading to sensorineural deafness and amyloidosis. The recombinant IL-1 receptor antagonist anakinra blocks the biologic activity of IL-1. The aim of this study was to determine the short- and long-term efficacy and safety of anakinra therapy in children and adults with severe MWS.

**METHODS:** A single-center observational study was performed. Standardized assessments included clinical features, the Disease Activity Score (DAS) for MWS, classic and novel markers of inflammation, and patient-derived measures of health status. The primary outcome was a score of <10 on the DAS for MWS at 2 weeks and at the last followup visit. Measures of MWS disease activity were investigated using descriptive statistics and paired comparative analysis.

**RESULTS:** A total of 12 patients with severe MWS (5 children and 7 adults) received anakinra for a median of 11 months (range 5-14 months). The median followup was 11 months (range 5-14 months). Disease activity was significantly lower in all patients at 2 weeks ( $P = 0.0005$ ). Organ manifestations of MWS improved, as did all patient-derived measures of health status, markers of inflammation, and hearing loss in 2 of the patients. Levels of the novel neutrophil activation biomarker S100A12 followed clinical disease activity. Treatment was well tolerated, and no serious adverse events were observed.

**CONCLUSION:** Anakinra was found to be a safe and effective treatment of severe MWS, leading to a significant improvement in disease activity at 2 weeks as well as long-term. Anakinra therapy should therefore be considered in children and adults with severe MWS disease requiring IL-1 blockade.

Clinical presentation and pathogenesis of cold-induced autoinflammatory disease in a family with recurrence of an NLRP12 mutation.

Borghini S(1), Tassi S, Chiesa S, Caroli F, Carta S, Caorsi R, Fiore M, Delfino L, Lasigliè D, Ferraris C, Traggiai E, Di Duca M, Santamaria G, D'Ossualdo A, Tosca M, Martini A, Ceccherini I, Rubartelli A, Gattorno M.

Author information:

(1)Istituto G. Gaslini and University of Genoa, Genoa, Italy.

**OBJECTIVE:** NLRP12 mutations have been described in patients affected with peculiar autoinflammatory symptoms. This study was undertaken to characterize NLRP12 mutations in patients with autoinflammatory syndromes, particularly a novel missense mutation, p.D294E, affecting a protein sequence crucial for ATP binding, which was identified in a Caucasian family with familial cold-induced autoinflammatory syndrome in some family members.

**METHODS:** Fifty patients were tested for NLRP12 mutations. A Caucasian family with the p.D294E missense mutation of NLRP12 in some family members was clinically characterized. In vitro analysis of the effects of the mutation on NF- $\kappa$ B activity was performed in HEK 293 cells after cotransfection of the cells with a luciferase NF- $\kappa$ B-responsive element and mutant or wild-type (WT) NLRP12 expression plasmids. NF- $\kappa$ B activity was also evaluated 24 hours after stimulation with tumor necrosis factor  $\alpha$  in monocytes from individual family members carrying the mutation. Furthermore, secretion of interleukin-1 $\beta$  (IL-1 $\beta$ ), production of reactive oxygen species (ROS), and activation of antioxidant systems in patient and healthy donor monocytes, under resting conditions and after stimulation with pathogen-associated molecular patterns (PAMPs), were also assessed.

**RESULTS:** In the family assessed, the p.D294E mutation segregated in association with a particular sensitivity to cold exposure (especially arthralgias and myalgia), but not always with an inflammatory phenotype (e.g., urticarial rash or fever). In vitro, the mutant protein maintained the same inhibitory activity as that shown by WT NLRP12. Consistently, NLRP12-mutated monocytes showed neither increased levels of p65-induced NF- $\kappa$ B activity nor higher secretion of IL-1 $\beta$ . However, the kinetics of PAMP-induced IL-1 $\beta$  secretion were significantly accelerated, and high production of ROS and up-regulation of antioxidant systems were demonstrated.

**CONCLUSION:** Even with a variable range of associated manifestations, the extreme

sensitivity to cold represents the main clinical hallmark in an individual carrying the p.D294E mutation of the NLRP12 gene. Although regulation of NF- $\kappa$ B activity is not affected in patients, redox alterations and accelerated secretion of IL-1 $\beta$  are associated with this mild autoinflammatory phenotype.

Renal amyloidosis in children.

Bilginer Y(1), Akpolat T, Ozen S.

Author information:

(1)Hacettepe University Faculty of Medicine, Pediatric Nephrology and Rheumatology Unit, Ankara, Turkey.

Renal amyloidosis is a detrimental disease caused by the deposition of amyloid fibrils. A child with renal amyloidosis may present with proteinuria or nephrotic syndrome. Chronic renal failure may follow. Amyloid fibrils may deposit in other organs as well. The diagnosis is through the typical appearance on histopathology. Although chronic infections and chronic inflammatory diseases used to be the causes of secondary amyloidosis in children, the most frequent cause is now autoinflammatory diseases. Among this group of diseases, the most frequent one throughout the world is familial Mediterranean fever (FMF). FMF is typically characterized by attacks of clinical inflammation in the form of fever and serositis and high acute-phase reactants. Persisting inflammation in inadequately treated disease is associated with the development of secondary amyloidosis. The main treatment is colchicine. A number of other monogenic autoinflammatory diseases have also been identified. Among them cryopyrin-associated periodic syndrome (CAPS) is outstanding with its clinical features and the predilection to develop secondary amyloidosis in untreated cases. The treatment of secondary amyloidosis mainly depends on the treatment of

the disease. However, a number of new treatments for amyloid per se are in the pipeline.

Familial Mediterranean fever: an association with non-alcoholic fatty liver disease.

Rimar D(1), Rosner I, Rozenbaum M, Zuckerman E.

Author information:

(1)Liver Unit, Carmel Medical Center, Haifa 34363, Israel.

The purpose of this study is to characterize the chronic liver disease (CLD) that may be associated with familial Mediterranean fever (FMF). Twenty-seven patients (mean age,  $48 \pm 18$  years; F/M, 16:11) with FMF who were referred for assessment of CLD were studied. Data regarding FMF and CLD were obtained from patient medical files. Liver biopsy was performed in 21 of 27 patients and deferred in six (cirrhotic coagulopathy in five and one who improved after colchicine dose reduction). Patients with FMF and non-alcoholic fatty liver disease (NAFLD) were compared to matched controls from a cohort of 150 patients with NAFLD per liver biopsy but without FMF. The mean Tel Hashomer severity score was  $1.7 \pm 0.9$ . The mean daily dose of colchicine was  $1.4 \pm 0.4$  mg over a mean duration of  $21 \text{ years} \pm 10$ . Seven of ten patients who underwent mutation analysis for FMF were homozygous for M694V. In 15 patients, there was evidence of NAFLD: five with "simple" steatosis, three with non-alcoholic steatohepatitis (NASH), and seven with NASH-cirrhosis. An additional five patients had "cryptogenic" cirrhosis, which in most patients represents the end result of unrecognized NASH, and one had normal liver tissue. Comparing FMF patients with NAFLD to matched controls with NAFLD did not reveal excess of metabolic syndrome in FMF patients. Of our FMF patients, 74% had evidence of NAFLD, 75% of which with severe manifestation. The extremely high proportion of NAFLD in our cohort of FMF patients without overt metabolic syndrome may indicate an unappreciated novel association between

FMF and NAFLD.

The Eurofever Project: towards better care for autoinflammatory diseases.

Ozen S(1), Frenkel J, Ruperto N, Gattorno M; Eurofever Project.

Author information:

(1)Department of Pediatrics, Faculty of Medicine, Hacettepe University, Ankara, Turkey. sezaozen@hacettepe.edu.tr

Autoinflammatory diseases are a group of diseases characterized by inflammatory attacks. The monogenic forms of these diseases are also classified as the hereditary periodic fever syndromes. All are characterized by attacks of fever along with certain clinical features and high acute phase reactants. Most of these monogenic diseases are associated with hereditary disorders of the interleukin-1 pathway. The most common autoinflammatory disease is familial Mediterranean fever. The other rather common monogenic diseases are the tumor necrosis factor receptor-associated periodic syndrome, hyperimmunoglobulinemia D with periodic fever syndrome, and cryopyrin-associated periodic fever syndromes (CAPS). However, a number of multifactorial diseases such as Behçet disease are now also categorized under the topic of autoinflammatory diseases. The main features and management of these diseases will be reviewed. Finally, we introduce the "Eurofever" project, aimed to increase awareness and education for the aforementioned diseases. We conclude that the pediatrician should be aware of the features and management of autoinflammatory diseases since all present with fever-the most common symptom of pediatric practice.

Explosion of autoimmune diseases and the mosaic of old and novel factors.

Agmon-Levin N(1), Lian Z, Shoenfeld Y.

Author information:

(1)The Zabłudowicz Center for Autoimmune Diseases and Department of Medicine B, Sheba Medical Center, Tel-Hashomer, Israel.

In recent decades, an enormous effort has been made to elucidate the pathogenesis of autoimmune and autoinflammatory diseases. Autoimmunity is a multifactorial process in which genetic, immunological, environmental and hormonal factors play in concert, together representing what was termed years ago the 'mosaic of autoimmunity'. To date, more than 80 systemic and organ-specific autoimmune diseases have been defined, and their cumulative burden is substantial, both medically and financially. Furthermore, the burden of autoimmune and autoinflammatory diseases is rising, making these diseases a ubiquitous global phenomenon that is predicted to further increase in the coming decades. In this issue of the journal, additional aspects of autoimmunity are detailed. Immune dysregulation and loss of self-tolerance are the cornerstones of autoimmunity.

Familial Mediterranean fever--a review.

Shohat M(1), Halpern GJ.

Author information:

(1)From the 1Raphael Recanati Genetic Institute, Rabin Medical Center, Felsenstein Medical Research Center, Petah Tikva, Israel.

Familial Mediterranean fever is inherited in an autosomal recessive manner. There are two phenotypes: types 1 and 2. Familial Mediterranean fever type 1 is

characterized by recurrent short episodes of inflammation and serositis, including fever, peritonitis, synovitis, pleuritis, and, rarely, pericarditis. The symptoms and severity vary among affected individuals, sometimes even among members of the same family. Amyloidosis, which can lead to renal failure, is the most severe complication. Familial Mediterranean fever type 2 is characterized by amyloidosis as the first clinical manifestation of familial Mediterranean fever in an otherwise asymptomatic individual. Routine treatment of end-stage renal disease, including renal transplantation, is advised. Lifelong treatment with colchicine is required for homozygotes for the p.Met694Val mutation or compound heterozygotes for p.Met694Val and another disease-causing allele; this prevents the inflammatory attacks and the deposition of amyloid. Individuals who do not have the p.Met694Val mutation and who are only mildly affected should be either treated with colchicine or monitored every 6 months for the presence of proteinuria. Molecular genetic testing of the MEFV gene, the only gene currently known to be associated with familial Mediterranean fever, can be offered to family members, especially when the p.Met694Val allele is present, because renal amyloidosis can be prevented by colchicine.

The function and regulation of immunoglobulin D.

Chen K(1), Cerutti A.

Author information:

(1)Immunology Institute, Department of Medicine, Mount Sinai School of Medicine, One Gustave, L. Levy Place, New York, NY 10029, USA.

Recent discoveries of IgD in ancient vertebrates suggest that IgD has been preserved in evolution from fish to human for important immunological functions. A non-canonical form of class switching from IgM to IgD occurs in the human upper respiratory mucosa to generate IgD-secreting B cells that bind respiratory bacteria and their products. In addition to enhancing mucosal immunity, IgD class-switched B cells enter the circulation to 'arm' basophils and other innate

immune cells with secreted IgD. Although the nature of the IgD receptor remains elusive, cross-linking of IgD on basophils stimulates release of immunoactivating, proinflammatory and antimicrobial mediators. This pathway is dysregulated in autoinflammatory disorders such as hyper-IgD syndrome, indicating that IgD orchestrates an ancestral surveillance system at the interface between immunity and inflammation.

**BACKGROUND** Familial Mediterranean fever (FMF) is an autosomal recessive disorder characterized by sporadic, paroxysmal attacks of fever and serosal inflammation. Although the disease usually begins before the age of 20 years, we aimed to evaluate the demography, clinical features and treatment outcome of familial Mediterranean fever in Iranian adult patients above 20 years old. **METHODS** In this cross-sectional study, adult patients (first attack at the age of >20 years) with a diagnosis of FMF who referred to the gastroenterology and rheumatology Clinics of Ardebil University of Medical Science (situated in north west of Iran) over the period of 2004-2009 were enrolled. FMF diagnosis was based on clinical criteria. **RESULTS** Forty four FMF patients (30 male and 14 female) with the mean [ $\pm$  Standard Deviation (SD)] age of first attack of  $29 \pm 7.8$  years were enrolled. Abdominal pain (95.5%) and fever (91%) were the most common clinical findings. All of the patients had satisfactorily responded to therapy. Response was complete in 76.7% and partial in 23.3% of the patients. There was no clinical or laboratory evidence of amyloidosis at the time of diagnosis or during follow-up. **CONCLUSION** Our findings demonstrated that adult-onset FMF in Iran has different characteristics (more common in males, lesser prevalence of arthritis and erysipelas-like erythema, less delay in diagnosis) and treatment outcome (favorable response even to low-dose colchicine) in comparison with the previous data on early onset patients.

Monogenic autoinflammatory syndromes at a dermatological level.

Rigante D(1), Cantarini L.

Author information:

(1)Department of Pediatric Sciences, Università Cattolica Sacro Cuore, Largo A. Gemelli, 8, 00168, Rome, Italy. drigante@gmail.com

Autoinflammatory syndromes include an expanding list of diseases characterized by

unprovoked recurrent attacks of systemic inflammation with lack of autoantibodies or autoreactive T-cells. This group of conditions encompasses monogenic diseases with Mendelian inheritance which are caused by specific mutations of different genes regulating the innate immunity: familial Mediterranean fever, mevalonate kinase deficiency syndrome, tumor necrosis factor receptor-associated periodic syndrome, cryopyrin-associated periodic syndromes, pyogenic disorders and deficiency of interleukin-1 receptor antagonist: all these diseases can present with dermatological manifestations, which often represent the prominent clinical features or, in some cases, the presenting sign. The purpose of this review is to increase the recognition among clinicians and mostly dermatologists of the monogenic autoinflammatory syndromes, highlighting the cutaneous signs of these conditions, in consideration of the possibility to prevent irreversible damages when their diagnosis and treatment are precociously established.

Autoinflammation: translating mechanism to therapy.

Doherty TA(1), Brydges SD, Hoffman HM.

Author information:

(1)Division of Allergy, Immunology, and Rheumatology, University of California at San Diego, School of Medicine, 9500 Gilman Dr., La Jolla, CA 92093-0635, USA.

Autoinflammatory syndromes are a clinically heterogeneous collection of diseases characterized by dysregulation of the innate immune system. The hereditary recurrent fever disorders were the first to be defined as autoinflammatory. Several of the responsible genes are now known to encode proteins forming multimeric complexes called inflammasomes, which are intracellular "danger sensors" that respond to a variety of different signals by activating caspase-1, responsible for cleavage and subsequent release of bioactive IL-1 $\beta$ . This discovery of the causative link between autoinflammation and IL-1 $\beta$  maturation has led to a significantly improved understanding of the mechanisms of innate immunity, as well as life-altering treatments for patients. Targeting IL-1 $\beta$  for the treatment of autoinflammatory syndromes is an excellent example of the power

of translational research. Given the central role of inflammation in many complex multigenic diseases, these treatments may benefit larger numbers of patients in the future. Here, we review current treatment strategies of autoinflammatory diseases with a focus on IL-1 antagonism.

Familial Mediterranean fever presenting with pulmonary embolism.

Ruiz XD(1), Gadea CM.

Author information:

(1)University of Connecticut Heath Center, Department of Medicine. 230 Farmington Avenue, Farmington, CT 06030-1235, USA. xruiz@resident.uchc.edu

Familial Mediterranean fever (FMF) is the autoinflammatory disease and hereditary periodic fever syndrome that most commonly affects people of Eastern Mediterranean origin. It is characterized by recurrent self-limited attacks of fever and serositis, with an increase in acute-phase reactant markers, and is transmitted in an autosomal recessive pattern. Inflammation shifts the hemostatic mechanisms favoring thrombosis. There are few reports of an increased risk of hypercoagulability in patients with FMF in the absence of amyloidosis and nephrotic syndrome. In this case report, we describe a 43-year-old Turkish patient who presented with right-sided pleuritic chest pain and pulmonary embolism. The patient described having prior similar attacks of serositis, but had never been diagnosed with FMF. Further workup revealed an increase in acute phase reactants, negative hypercoagulability studies and heterozygosity for the M694V mutation in the pyrin (MEFV) gene. We identified untreated FMF and chronic inflammation as his only risk factor for pulmonary embolism. With this case report, we support recent studies that have demonstrated that inflammation may lead to prothrombotic states in patients with FMF.

Expression of Toll-like receptors and their signaling pathways in rheumatoid synovitis.

Tamaki Y(1), Takakubo Y, Hirayama T, Konttinen YT, Goodman SB, Yamakawa M, Takagi M.

Author information:

(1)Department of Orthopaedic Surgery, Yamagata University School of Medicine, 2-2-2 Iida Nishi, Yamagata, Japan. [ytamaki@med.id.yamagata-u.ac.jp](mailto:ytamaki@med.id.yamagata-u.ac.jp)

**OBJECTIVE:** Toll-like receptors (TLR) recognizing endogenous and exogenous danger signals could play a role in rheumatoid arthritis (RA). Our aim was to describe the presence, localization, and extent of expression of TLR and their adapters.

**METHODS:** TLR 1, 2, 3, 4, 5, 6, and 9 receptors, and myeloid differentiation primary response protein 88, Toll/interleukin receptor (TIR) domain-containing adapter protein MyD88 adapter-like, and TIR domain-containing adapter-inducing interferon/TIR-containing adapter molecule-1 adapters were analyzed in RA (n = 10) and osteoarthritis (OA; n = 5) samples using real-time polymerase chain reaction (PCR). Their colocalization with cellular markers CD68, CD15, CD3, CD4, CD8, CD20, dendritic cell lysosomal-associated membrane protein (DC-LAMP), CD123, and 5B5 was analyzed in double immunofluorescence staining.

**RESULTS:** In RA,  $\beta$ -actin standardized messenger RNA of TLR 2, 3, and 9 ( $p < 0.001$ ) were particularly high. TLR 5 and 6 were also elevated ( $p < 0.05$ ), but TLR 1 and 4 and adapters did not differ between RA and OA. In double-staining, TLR and adapters were strongly labeled in myeloid and plasmacytoid dendritic cells (DC), moderately in CD68+ type A lining cells/macrophages, and weakly to moderately in 5B5+ type B lining cells/fibroblasts. CD3+/CD4+ and CD3+/CD8+ T cells and CD20+ B cells in perivenular areas and in lymphoid follicles were moderately TLR- and weakly adapter-positive. In OA, TLR and adapters were weakly immunolabeled in vascular, lining, and inflammatory cells.

**CONCLUSION:** RA synovium showed abundant expression of TLR. RA synovitis tissue seems to be responsive to TLR ligands. DC, type A cells/macrophages, and type B cells/fibroblasts are, in that order from highest to lowest, equipped with TLR, suggesting a hierarchical responsiveness. In RA, danger-associated molecular patterns to TLR interactions may particularly drive DC to autoinflammatory and

autoimmune cascades/synovitis.

The pathogenesis of oligoarticular/polyarticular vs systemic juvenile idiopathic arthritis.

Lin YT(1), Wang CT, Gershwin ME, Chiang BL.

Author information:

(1)Department of Pediatrics, National Taiwan University Hospital and National Taiwan University College of Medicine, Taipei, Taiwan.

Juvenile idiopathic arthritis (JIA) has had a long and difficult problem with classification. It is clearly a heterogeneous and multi-factorial autoimmune disease but all too often the distinctions among subtypes were unclear. In fact, there is now increasing evidence of a distinct pathogenesis of oligo/polyarticular JIA compared to systemic JIA. Oligo/polyarticular JIA is an antigen-driven lymphocyte-mediated autoimmune disease with abnormality in the adaptive immune system. Cartilage-derived auto-antigens activate autoreactive T cells including Th1 and Th17 cells with production of pro-inflammatory cytokines IFN- $\gamma$  and IL-17. On the other hand, the inhibition of regulatory T (Treg) cells including natural Foxp3(+) Treg and self-heat shock protein-induced Treg cells with decreased anti-inflammatory cytokine IL-10 results in the loss of immune tolerance. Imbalance between autoreactive Th1/Th17 and Treg cells leads to the failure of T cell tolerance to self-antigens, which contributes to the synovial inflammation of oligo/polyarticular JIA. By contrast, systemic JIA is an autoinflammatory disease with abnormality in the innate immune system. A loss of control of the alternative secretory pathway leading to aberrant activation of phagocytes including monocytes, macrophages and neutrophils seems to be involved in the release of pro-inflammatory cytokines IL-1, IL-6, IL-18 and pro-inflammatory S100-proteins, which contribute to the multisystem inflammation of systemic JIA. Markedly distinct pathogenesis of oligo/polyarticular JIA and systemic JIA implies that they might need different treatment strategies.

Diagnosis and management of familial Mediterranean fever: integrating medical genetics in a dedicated interdisciplinary clinic.

Zadeh N(1), Getzug T, Grody WW.

Author information:

(1)Department of Pathology and Laboratory Medicine, UCLA Medical Center, Los Angeles, California 90049, USA. nzadeh@gmail.com

Familial Mediterranean fever is an autosomal recessive genetic disorder characterized by recurrent febrile polyserositis, especially prevalent in individuals of Mediterranean descent. Familial Mediterranean fever can have nonspecific manifestations that mimic many common acquired disorders such as infections, acute appendicitis, cholecystitis, and arthritis, which can delay diagnosis for many years and subject patients to extensive evaluations and even unnecessary surgery. Untreated familial Mediterranean fever can result in serious complications such as end-stage renal disease and malabsorption secondary to amyloid deposition in the kidneys and digestive tract, male and female infertility, and growth retardation in children. These significant sequelae, along with the episodic acute attacks, are readily preventable by treatment with oral colchicine and underscore the necessity of early detection and treatment from a medical, psychosocial, and economic standpoint. We describe our comprehensive approach to the accurate diagnosis and effective management of this disorder by means of a dedicated familial Mediterranean fever clinic that incorporates medical genetics on equal footing with general medicine. In addition to providing the clinician with the presenting features of familial Mediterranean fever, methods of diagnosis including molecular testing, and current management based on our extensive experience with hundreds of affected individuals, we also advance this approach as a model for the incorporation of medical genetics practice into the more traditional domains of general medicine.

Colchicine inhibits cationic dye uptake induced by ATP in P2X2 and P2X7 receptor-expressing cells: implications for its therapeutic action.

Marques-da-Silva C(1), Chaves MM, Castro NG, Coutinho-Silva R, Guimaraes MZ.

Author information:

(1)Instituto de Biofísica Carlos Chagas Filho, Universidade Federal do Rio de Janeiro, Rio de Janeiro, RJ, Brazil.

**BACKGROUND AND PURPOSE:** The two longest C-termini of the purinergic P2X receptors occur in the P2X2 and P2X7 receptors and are thought to interact with multiple cytoplasmic proteins, among which are members of the cytoskeleton, including microtubules. In this work we asked whether disrupting the microtubule cytoskeleton might affect the functions of these receptors.

**EXPERIMENTAL APPROACH:** Functions of heterologously expressed P2X2 and P2X7 receptors were evaluated with electrophysiology and dye uptake following ATP application. Permeabilization and secretion of pro-inflammatory agents were quantified from fresh or cultured peritoneal mouse macrophages, treated in vitro or in vivo with colchicine.

**KEY RESULTS:** Disrupting the microtubule network with colchicine did not affect currents generated by ATP in P2X2 and P2X7 receptor-expressing cells but inhibited uptake of the dye Yo-Pro-1 in *Xenopus* oocytes and HEK293 cells expressing these channels. Peritoneal mouse macrophages showed less ATP-induced permeabilization to ethidium bromide in the presence of colchicine, and less reactive oxygen species (ROS) formation, nitric oxide (NO) and interleukin (IL)-1 $\beta$  release. Colchicine treatment did not affect ATP-evoked currents in macrophages. Finally, in vivo assays with mice inoculated with lipopolysaccharide and ATP showed diminished ROS, IL-1 $\beta$ , interferon- $\gamma$  and NO production after colchicine treatment.

**CONCLUSIONS AND IMPLICATIONS:** Colchicine has known anti-inflammatory actions and is used to treat several conditions involving innate immunity, including gout and familial Mediterranean fever. Here we propose a new mechanism of action -

inhibition of pore formation induced by activation of P2X receptors - which could explain some of the anti-inflammatory effects of colchicine.

(1)Department of Medicine, University of Colorado, Aurora, CO 80045, USA.

cdinarello@mac.com

More than any other cytokine family, the IL-1 family of ligands and receptors is primarily associated with acute and chronic inflammation. The cytosolic segment of each IL-1 receptor family member contains the Toll-IL-1-receptor domain. This domain is also present in each Toll-like receptor, the receptors that respond to microbial products and viruses. Since Toll-IL-1-receptor domains are functional for both receptor families, responses to the IL-1 family are fundamental to innate immunity. Of the 11 members of the IL-1 family, IL-1 $\beta$  has emerged as a therapeutic target for an expanding number of systemic and local inflammatory conditions called autoinflammatory diseases. For these, neutralization of IL-1 $\beta$  results in a rapid and sustained reduction in disease severity. Treatment for autoimmune diseases often includes immunosuppressive drugs whereas neutralization of IL-1 $\beta$  is mostly anti-inflammatory. Although some autoinflammatory diseases are due to gain-of-function mutations for caspase-1 activity, common diseases such as gout, type 2 diabetes, heart failure, recurrent pericarditis, rheumatoid arthritis, and smoldering myeloma also are responsive to IL-1 $\beta$  neutralization. This review summarizes acute and chronic inflammatory diseases that are treated by reducing IL-1 $\beta$  activity and proposes that disease severity is affected by the

anti-inflammatory members of the IL-1 family of ligands and receptors.

Comment in

Eur J Neurol. 2011 Aug;18(8):e96; author reply e97.

**BACKGROUND AND PURPOSE:** To describe and characterize the association between familial Mediterranean fever (FMF) and multiple sclerosis (MS).

**METHODS:** The patient registry of The National Center for FMF was screened for the coexistence of FMF and MS. Tel-Hashomer criteria were used for the diagnosis of FMF, and FMF severity was evaluated, using the simplified FMF severity scale. McDonald criteria were used for the diagnosis of MS, and neurologic disability was measured using the expanded disability status scale (EDSS).

**RESULTS:** We identified nine patients, affected with both FMF and MS. The onset of the FMF averaged 15.6 (3-37) years. Most patients suffered from abdominal and joint attacks, and 50% of the patients sustained a moderate to severe FMF. The onset of the MS was at an average age of 31.6 (17-50) years. Neurologic manifestations varied individually, without a dominant deficit, and the course was in a relapsing-remitting pattern in most. The median EDSS was in general of low score (3.0), apart from the patients who were homozygous for the M694V mutation, in whom the MS was more severe. Based on our case series, the frequency of MS in our FMF population is 0.075%, twice higher the expected rate in the general population (P=0.0057).

CONCLUSIONS: Multiple sclerosis is more common in FMF than in the general Israeli population. Homozygosity for the M694V MEFV mutation may aggravate the phenotype of MS and predispose FMF patients to develop MS.

Familial Mediterranean fever (FMF) is a hereditary inflammatory disorder transmitted as an autosomal recessive trait. It predominantly affects people living in, or originating from, areas around the Mediterranean and was difficult to diagnose until mutations in the MEFV gene were identified. This study aims to analyse the five most common MEFV mutations in Egyptian patients diagnosed clinically as FME Thirty-eight unrelated patients were tested for the presence of

the MEFV gene mutations V726A, M694V, M694I, M680I and E148Q, using polymerase chain reaction-restriction fragment length polymorphism (PCR-RFLP) and the amplification refractory mutation system (ARMS). Twenty-three patients (60.5%) had one or more mutations, whereas no mutation was found in the remaining 15 patients (39.5%). The most common mutation was M694I (42.5%), followed by V726A (22.5%), M680I (17.5%) and E148Q (17.5%). The M694V mutation was not detected. The profile of MEFV gene mutations in this study suggests that the origin of FMF in Egypt is heterogeneous, a finding in concordance with that for other Arab populations; however, some differences were observed as M694V, the most common mutation reported in Arabs, was not detected in this study.

Recently, a new set of criteria was established for the diagnosis of familial Mediterranean fever (FMF) in childhood. The aim of this study is to validate the new criteria set among heterozygous patients with clinical features of FMF. The study group consisted of FMF patients, who had a mutation at a single allele, who were followed in four pediatric nephrology-rheumatology centers in Turkey. Patients were evaluated by the new criteria set and also by the Tel Hashomer criteria. According to the new criteria, the diagnosis of FMF was established by the presence of two or more of five criteria (fever, abdominal pain, chest pain, arthritis, family history of FMF). The study group consisted of 110 FMF (54 male, 56 female) patients. Majority of the patients had heterozygous pM694V mutation (65%). The sensitivity of the new criteria set and that of the Tel Hashomer criteria in our study group were found to be 93% and 100%, respectively. In conclusion, this study designates that sensitivity of the new criteria set is also high in patients who had a mutation at a single allele.

Setting up TRAPS.

Pettersson T(1), Kantonen J, Matikainen S, Repo H.

Author information:

(1)Department of Medicine, University of Helsinki and Helsinki University Central Hospital, Haartmaninkatu 4, Helsinki, Finland. tom.pettersson@hus.fi

Tumour necrosis factor (TNF) receptor-associated periodic syndrome (TRAPS) is a dominantly inherited autoinflammatory disease caused by heterozygous mutations in the TNFRSF1A gene encoding for the TNF receptor 1 (TNFR1). TRAPS is a multi-faceted and heterogeneous disease which commonly manifests as recurrent episodes of high fever accompanied by abdominal pain, pleurisy, migratory rash, and myalgia. Disease attacks occur spontaneously or may be elicited by minor triggers. Because of a vigorous and sustained acute-phase response it may be complicated by systemic AA amyloidosis. Therapeutically interleukin-1 blockade seems even more promising than TNF blockade. Studies on the pathogenesis of TRAPS have shown TNF $\alpha$ -dependent cellular signalling to be defective, an enigmatic finding considering the hyperinflammatory phenotype of the disease. Several studies indicate that most mutated receptors never reach the cell surface but are misfolded and trapped in the endoplasmic reticulum, where they may elicit an intracellular inflammatory response, and thus lead to constitutional expression of proinflammatory cytokines. The aim of this review is to describe the current understanding of the pathogenesis of TRAPS by integrating recent clinical and laboratory data.

**Abstract** A host of clinical scenarios can be depicted in hereditary autoinflammatory diseases, and the cardiovascular system can also be involved especially in familial Mediterranean fever (FMF), caused by mutations in the MEFV gene, and tumour necrosis factor receptor-associated periodic syndrome (TRAPS), caused by mutations in the TNFRSF1A gene. Pericardial diseases are the most represented cardiovascular abnormalities, though the role of MEFV and TNFRSF1A in the initiation of heart involvement has not been demonstrated formally and will be discussed herein.

Nat Rev Rheumatol. 2011 May;7(5):254.

Reactive oxygen species (ROS) have an established role in inflammation and host defense, as they kill intracellular bacteria and have been shown to activate the NLRP3 inflammasome. Here, we find that ROS generated by mitochondrial respiration are important for normal lipopolysaccharide (LPS)-driven production of several proinflammatory cytokines and for the enhanced responsiveness to LPS seen in

cells from patients with tumor necrosis factor receptor-associated periodic syndrome (TRAPS), an autoinflammatory disorder caused by missense mutations in the type 1 TNF receptor (TNFR1). We find elevated baseline ROS in both mouse embryonic fibroblasts and human immune cells harboring TRAPS-associated TNFR1 mutations. A variety of antioxidants dampen LPS-induced MAPK phosphorylation and inflammatory cytokine production. However, gp91(phox) and p22(phox) reduced nicotinamide adenine dinucleotide phosphate (NADPH) oxidase subunits are dispensable for inflammatory cytokine production, indicating that NADPH oxidases are not the source of proinflammatory ROS. TNFR1 mutant cells exhibit altered mitochondrial function with enhanced oxidative capacity and mitochondrial ROS generation, and pharmacological blockade of mitochondrial ROS efficiently reduces inflammatory cytokine production after LPS stimulation in cells from TRAPS patients and healthy controls. These findings suggest that mitochondrial ROS may be a novel therapeutic target for TRAPS and other inflammatory diseases.

The IL-27 receptor has biphasic effects in crescentic glomerulonephritis mediated through Th1 responses.

Summers SA(1), Phoon RK, Ooi JD, Holdsworth SR, Kitching AR.

Author information:

(1)Centre for Inflammatory Diseases, Department of Medicine, Monash University, Clayton, Victoria, Australia.

Despite its initially defined role as a T-helper type 1 cell (Th1)-inducing cytokine, interleukin-27 (IL-27) has complex roles in vivo. The role of IL-27 receptor (IL-27R) was defined in experimental crescentic glomerulonephritis induced by a foreign antigen, sheep globulin, which is planted in glomeruli. This lesion is dependent on a Th1 effector cellular response. Twenty-one days after the administration of sheep anti-mouse glomerular basement membrane antibody, wild-type mice developed histologic and functional inflammatory renal injury. Injury was attenuated in the absence of IL-27R  $\alpha$  chain (IL-27R $\alpha$ ), the unique

component of the IL-27R complex. In contrast to the attenuated renal injury on day 21, IL27ra(-/-) mice exhibited enhanced systemic immune responses, including Th1 responses, with increased IL-2-dependent interferon- $\gamma$  (IFN- $\gamma$ ) production. However, earlier in the development of the nephritogenic immune response, IFN- $\gamma$  production was decreased, with reduced early immune responses translating into attenuated renal injury. Having demonstrated decreased early Th1 systemic immune responses, followed by enhanced nephritogenic Th1 immune responses, renal injury was studied at later time points. On days 28 and 35 after injection of the nephritogenic antigen, renal injury was enhanced in IL27ra(-/-) mice compared with wild-type mice in an at least partially IFN- $\gamma$ -dependent manner. In Th1-dependent autoinflammatory lesions, IL-27R $\alpha$  has a biphasic role in vivo, initially pathogenic, but ultimately playing a protective role by regulating immune responses and attenuating disease.

Shifting normalities: interactions of changing conceptions of a normal life and the normalisation of symptoms in rheumatoid arthritis.

Sanderson T(1), Calnan M, Morris M, Richards P, Hewlett S.

Author information:

(1)Faculty of Health and Life Sciences, University of the West of England, Glenside Campus, Blackberry Hill, Stapleton, Bristol. tessa2.sanderson@uwe.ac.uk

Biographical disruption and related concepts have been widely applied in chronic illness. Different conceptualisations of normalisation have also been proposed in order to explain individuals' diverse responses to illness on their biography, but as yet, not clearly related to changing bodily experience or normalisation of symptoms. This article aims to examine the relevance of these concepts in

rheumatoid arthritis (RA), an unpredictable autoinflammatory disease characterised by painful and swollen joints, disability, fatigue and joint damage. Interviews were conducted with 23 people living with RA, and analysed using Framework, to enable people's whole narratives and context to be considered. Six typologies of normality emerged from the data: disrupted; struggling to maintain; fluctuating; resetting; returning; and continuing normality. Multiple normalities were often present in individuals' narratives, with one normality typology usually dominating at the time of the interview. The typologies connect to several biographical concepts, and instances of 'biographical reinstatement' were also found, where participants described returning to normal life, through perceived effective medication rather than reconceptualisation of health. The concept of 'shifting normalities' is proposed, providing a dynamic explanatory model of chronic illness that captures the interaction of changing conceptions of a normal life and the normalisation of symptoms.

Interleukin-1 targeting drugs in familial Mediterranean fever: a case series and a review of the literature.

Meinzer U(1), Quartier P, Alexandra JF, Hentgen V, Retornaz F, Koné-Paut I.

Author information:

(1)Division of Paediatric Rheumatology, CEREMAI, Hôpital de Bicêtre, University of Paris Sud, Le Kremlin Bicêtre Cedex, France. ulrich.meinzer@bct.aphp.fr

**OBJECTIVES:** Familial Mediterranean fever (FMF) is an autosomal-recessive autoinflammatory disorder common in Mediterranean populations. FMF is associated with mutations of the MEFV gene, which encodes pyrin. Functional studies suggest that pyrin is implicated in the maturation and secretion of IL-1. The IL-1

receptor antagonist or anti-IL1 monoclonal antibody may therefore represent a new approach to treat FMF. The aim of this report was to evaluate and discuss treatment of FMF with interleukin-1 targeting drugs.

**METHODS:** Electronic mailing lists of French pediatric and adult rheumatologist associations were used to call for FMF patients treated with interleukin-1 antagonists. A search for published FMF patients treated with interleukin-1 targeting drugs was performed by screening PubMed.

**RESULTS:** Here, we report 7 cases of FMF patients treated with anakinra and/or canakinumab and discuss the clinical situations that may indicate the use of IL-1 blocking agents in FMF. The use of interleukin-1 targeting drugs was beneficial to all patients. The reasons for using interleukin-1 targeting drugs in FMF patients were as follows: (1) incomplete control of disease activity despite colchicine treatment; (2) high serum amyloid A levels despite colchicine treatment; (3) impossibility to use colchicine treatment because of severe side effects; (4) FMF in association with vasculitis.

**CONCLUSIONS:** Interleukin-1 targeting drugs may be good candidates when looking for an alternative or supplementary treatment to colchicine. These observations highlight the need for controlled trials to further evaluate the safety and efficacy of interleukin-1 antagonists in FMF patients.

The plodding diagnosis of monogenic autoinflammatory diseases in childhood: from the clinical scenery to laboratory investigation.

Rigante D(1), Capoluongo E.

Author information:

(1)Department of Pediatric Sciences, Università Cattolica Sacro Cuore, Rome, Italy. drigante@gmail.com

Autoinflammatory diseases (AID) are inherited errors of innate immunity which,

although individually uncommon, collectively set up an emerging chapter of medicine. Careful analysis and identification of AID is essential to prompt effective treatment and improve survival and quality of life in these patients. Research into pediatric AID is lagging behind studies in adults, though a better understanding of AID in infancy could lead to improved diagnostic protocols and reduce long-term disability. This review provides a detailed summary of monogenic AID in childhood to help pediatricians correctly recognize these conditions and also highlight recent developments in the laboratory diagnostic work-up.

Effects of the histone deacetylase inhibitor ITF2357 in autoinflammatory syndromes.

Bodar EJ(1), Simon A, van der Meer JW.

Author information:

(1)Department of General Internal Medicine and Nijmegen Institute for Infection, Inflammation, and Immunity (N4i), Radboud University Nijmegen Medical Centre, Nijmegen, The Netherlands.

We explored the effects of the oral histone deacetylase (HDAC) inhibitor ITF2357 in patients with autoinflammatory syndrome. In this prospective open-label pilot study, eight patients were enrolled; one patient with tumor necrosis factor receptor-associated periodic syndrome (TRAPS), three patients with hyper-IgD and periodic fever syndrome (HIDS) and four patients with Schnitzler syndrome were closely followed during 90 d of ITF2357 treatment. Three patients with Schnitzler syndrome and one TRAPS patient experienced a partial remission. In four patients, there was no effect. In HIDS patients, there was a tendency toward a higher attack frequency and increasing attack severity. In two patients (one TRAPS and one HIDS), we observed a decrease of acute-phase response without signs of clinical improvement. One patient with Schnitzler syndrome showed a partial response despite an ongoing acute-phase response. In conclusion, ITF2357 monotherapy was able to induce partial response only in patients with Schnitzler

syndrome and no response in patients with AIDS.

Erratum in

Proc Natl Acad Sci U S A. 2013 Mar 12;110(11):4429.

Clinical studies have indicated that subvirion inactivated vaccines against avian influenza viruses, particularly H5N1, are poorly immunogenic in humans. As a consequence, the use of adjuvants has been championed for the efficient vaccination of a naïve population against avian influenza. Aluminum salts (alum) and the oil-in-water emulsion MF59 are safe and effective adjuvants that are being used with influenza vaccines, but the mechanism underlying their stimulation of the immune system remains poorly understood. It was shown recently that activation of a cytosolic innate immune-sensing complex known as "NLR-Pyrin domain containing 3" (NLRP3) inflammasome, also known as "cryopyrin," "cold-induced autoinflammatory syndrome 1" (CIAS1), or NACHT domain-, leucine-rich repeat-, and PYD-containing protein 3 (Nalp3), is essential for the adjuvant effect of alum. Here we show that the inflammasome component apoptosis-associated speck-like protein containing a caspase recruitment domain (ASC), an adapter protein within the NLRP3 inflammasome, is a crucial element in the adjuvant effect of MF59 when combined with H5N1 subunit vaccines. In the absence of ASC, H5-specific IgG antibody responses are significantly reduced, whereas the responses are intact in NLRP3(-/-) and caspase-1(-/-) mice. This

defect is caused mainly by the failure of antigen-specific B cells to switch from IgM to IgG production. We conclude that ASC plays an inflammasome-independent role in the induction of antigen-specific humoral immunity after vaccination with MF59-adjuvanted influenza vaccines. These findings have important implications for the rational design of next-generation adjuvants.

Successful treatment of renal AA amyloidosis in familial Mediterranean fever with pegylated alpha-2a interferon.

Vandecasteele SJ(1), De Paepe P, De Vriese AS.

Author information:

(1)Department of 1Nephrology and Infectious Diseases and 2Pathology, AZ Sint-Jan Brugge-Oostende AV, Brugge, Belgium. Stefaan.Vandecasteele@azbrugge.be

Renal AA amyloidosis is a severe consequence of chronic inflammatory diseases such as familial Mediterranean fever (FMF). FMF is caused by mutations in the MEFV gene, resulting in defective control of granulocyte-mediated inflammation. Interferon-alpha is known to induce MEFV expression in monocytes and granulocytes in vitro. We present the first case of colchicine-resistant FMF in which a durable disease remission and regression of renal amyloidosis was induced by chronic treatment with pegylated interferon-alpha.

dottore\_erkan@yahoo.com

**OBJECTIVES:** To analyse the demographics, main clinical and laboratory features and subtype distribution of juvenile idiopathic arthritis (JIA) in an eastern Mediterranean country, based on a multicentre registry.

**METHODS:** Between March 2008 and February 2009 with this cross-sectional study, consecutive patients seen with JIA in selected centres were registered through a web-based registry. All patients were classified according to the International League of Associations for Rheumatology (ILAR) criteria.

**RESULTS:** There were 634 patients with a mean age of  $11.84 \pm 4.66$  years and the female/male ratio was 1.2. The distributions of JIA patients according to onset of disease were as follows: systemic 92 (14.5%), oligoarticular extended 26 (4.1%), oligoarticular persistent 234 (36.9%), rheumatoid factor (RF) positive polyarthritis 20 (3.2%), RF negative polyarthritis 129 (20.3%), enthesitis-related 120 (18.9%), psoriatic 13(2.1%). The frequency of uveitis was 15.7% among all of the oligoarthritis patients. Anti-nuclear antibody (ANA) was positive mainly among the oligoarticular onset patients. Twenty-one patients also had Familial Mediterranean fever (FMF). Among systemic JIA patients, the frequency of macrophage activation syndrome (MAS) was 15.2% (n=14). At the end of the mean follow-up of  $7.6 \pm 4.4$  years, 305 (48.1%) patients were defined to have inactive disease on medication, and 106 (16.7%) were completely free of any disease symptoms without medication.

**CONCLUSIONS:** Enthesitis related arthritis had a high frequency whereas psoriatic arthritis was very rare compared to other series. We suggest that there are certain differences in the characteristics of JIA in our eastern Mediterranean population. Thus, genetic studies need to be assessed in these populations separately and findings of genome wide association studies need to be confirmed in different populations.

yosunkayafenerci@hotmail.com

Rheumatoid arthritis (RA) is an autoinflammatory disease with a genetic background. The synoviocytes in RA shows cellular transformation with tumor-like features, and RA patients have genomic instability and relaxation of DNA repair mechanisms. The polymorphisms in BER repair pathway genes, XRCC1 and OGG1, may change the response to inflammation via altered DNA repair capacity. In this study, we aimed to investigate the relationship between the risk of RA and XRCC1 Arg194Trp, Arg399Gln, and OGG1 Ser326Cys polymorphisms in a group of Turkish RA patients. XRCC1 Arg194Trp, Arg399Gln, and OGG1 Ser326Cys polymorphisms were investigated by PCR-RFLP method in 100 RA patients and 158 healthy control subjects. The results were statistically analyzed by calculating the odds ratios (OR) and their 95% confidence intervals (95% CI) using the  $\chi^2$ -tests. RA patients in this study had significantly higher frequencies of XRCC1 Arg399Gln polymorphism in both homozygote (GG) (35%, OR: 7.78 [95% CI: 3.65-16.59],  $P < 0.001$ ) and heterozygote (AG) forms (41%, OR: 2.17 [95% CI: 1.19-3.96],  $P < 0.01$ ) and also increased frequency of 399Gln (G) allele (55%, OR:2.99 [95% CI: 1.67-5.37],  $P < 0.001$ ). We conclude that XRCC1 Arg194Trp, and OGG1 Ser326Cys polymorphisms are not associated with RA; however, Arg399Gln polymorphism is a significant risk factor of RA, and carriers of 399Gln (G) allele have greater risk of RA.

Polyarteritis nodosa and Henoch-Schönlein purpura nephritis in a child with familial Mediterranean fever: a case report.

Girisgen I(1), Sonmez F, Koseoglu K, Erisen S, Yilmaz D.

Author information:

(1)Department of Pediatrics, Pediatric Nephrology, Adnan Menderes University, Aydin, Turkey. igirisgen78@hotmail.com

Familial Mediterranean fever is an autosomal recessive disease characterized by recurrent self-limited attacks of fever accompanied by peritonitis, pleuritis, and arthritis. Approximately 5% of individuals with familial Mediterranean fever have been reported to have Henoch-Schönlein purpura and about 1% to have polyarteritis nodosa. A 7-year-old girl presenting with complaints of purpuric rash, abdominal pain, arthritis, hematuria, and proteinuria and having IgA depositions on renal biopsy was diagnosed as Henoch-Schönlein nephritis. She had a history of recurrent fever, abdominal and joint pain and M694 V compound homozygote mutation. Colchicine treatment was started for the diagnosis of FMF. When constitutional symptoms such as myalgia, weight loss, fatigue, fever, and hypertension were added to the clinical picture, the diagnosis of polyarteritis nodosa HSP was thought and confirmed by the demonstration of microaneurisms on renal arteries. There was no response to corticosteroid and cyclophosphamide treatments; however, the symptoms were rapidly and dramatically reduced after the administration of intravenous immunoglobulin. In conclusion, polyarteritis nodosa and Henoch-Schönlein purpura can be seen together with familial Mediterranean fever. It is also suggested that IVIG might be an important adjunct therapy in selected patients with polyarteritis nodosa, especially in the lack of response to steroids and immunosuppressive drugs.

The inflammasomes in health and disease: from genetics to molecular mechanisms of autoinflammation and beyond.

Conforti-Andreoni C(1), Ricciardi-Castagnoli P, Mortellaro A.

Author information:

(1)Singapore Immunology Network (SIgN), Agency for Science, Technology and Research (A\*STAR), Immunos, Singapore.

Nucleotide-binding oligomerization domain (NOD)-containing protein-like receptors (NLRs) are a recently discovered class of innate immune receptors that play a crucial role in initiating the inflammatory response following pathogen recognition. Some NLRs form the framework for cytosolic platforms called inflammasomes, which orchestrate the early inflammatory process via IL-1 $\beta$  activation. Mutations and polymorphisms in NLR-coding genes or in genetic loci encoding inflammasome-related proteins correlate with a variety of autoinflammatory diseases. Moreover, the activity of certain inflammasomes is associated with susceptibility to infections as well as autoimmunity and tumorigenesis. In this review, we will discuss how identifying the genetic characteristics of inflammasomes is assisting our understanding of both autoinflammatory diseases as well as other immune system-driven disorders.

Schnitzler syndrome, an autoimmune-autoinflammatory syndrome: report of two new cases and review of the literature.

Tinazzi E(1), Puccetti A, Patuzzo G, Sorleto M, Barbieri A, Lunardi C.

Author information:

(1)Department of Medicine, Autoimmune Diseases Unit, University of Verona, Italy.

Schnitzler syndrome is a rare disorder characterized clinically by chronic

urticarial rash accompanied by fever, arthralgia or arthritis, bone pain and lymphadenopathy and biochemically by monoclonal gammopathy and elevation of inflammatory indices. The disorder is very likely under-recognized and its origin remains obscure although it may be included among the immune mediated inflammatory diseases with features of autoinflammation and autoimmunity. We describe here two patients affected by Schnitzler syndrome, both refractory to corticosteroids and immunosuppressive therapy, successfully treated with the interleukin-1 receptor antagonist Anakinra. Unfortunately after two weeks, one patient experienced an important local adverse reaction to the biological drug. We decided to discontinue Anakinra with flare of the disease after 24 h. We therefore switched to Rituximab obtaining a complete remission in two months. We searched MEDLINE in order to analyze the frequency of the disease, its pathogenesis and outcome. The electronic search was conducted using the following key words "Schnitzler syndrome" and "Treatment of Schnitzler syndrome". All the selected papers, except the clinical reviews, described at least one case of Schnitzler syndrome. The review of the literature highlighted that Schnitzler syndrome remains an enigmatic disorder hard to categorize and to treat.

Colchicine modulates oxidative stress in serum and leucocytes from remission patients with Family Mediterranean Fever through regulation of  $\text{Ca}^{2+}$  release and the antioxidant system.

Sahin M(1), Uğuz AC, Demirkan H, Nazıroğlu M.

Author information:

(1)Department of Internal Medicine, Division of Rheumatology, Faculty of Medicine, Suleyman Demirel University, Isparta, Turkey.

We investigated the effects of colchicine on oxidative stress and  $\text{Ca}^{2+}$  release in serum and polymorphonuclear leucocytes (PMNs) of Familial Mediterranean Fever

(FMF) patients with attack, remission and unremission periods. Eighteen FMF patients and six age-matched healthy subjects in four groups were used. The first group was a control. The second group included patients with active FMF. The third and fourth groups were patients with remission and unremission, respectively. Colchicine (1.5 mg/day) was given to the third and fourth groups for 1 month. PMN cells, serum lipid peroxidation and intracellular  $\text{Ca}^{2+}$ -release levels in the attack and unremission groups were higher than in those in controls, although they were lower in the remission group than in the attack group. Serum vitamin E and  $\beta$ -carotene concentrations were higher in the remission group than in the control and attack groups. However, PMN, serum lipid peroxidation and  $\text{Ca}^{2+}$ -release levels were further increased in the unremission group compared to the attack group. Glutathione peroxidase, reduced glutathione and vitamin A values in the four groups did not change by FMF and colchicine. In conclusion, we observed that colchicine induced protective effects on oxidative stress by modulating vitamin E,  $\beta$ -carotene and  $\text{Ca}^{2+}$ -release levels in FMF patients with a remission period.

Mean platelet volume: a link between thrombosis and inflammation?

Gasparyan AY(1), Ayvazyan L, Mikhailidis DP, Kitas GD.

Author information:

(1)Clinical Research Unit, Russell's Hall Hospital, Dudley Group of Hospitals NHS Foundation Trust, Dudley, West Midlands, UK. a.gasparyan@gmail.com

Platelet activation is a link in the pathophysiology of diseases prone to thrombosis and inflammation. Numerous platelet markers, including mean platelet volume (MPV), have been investigated in connection with both thrombosis and inflammation. This review considers MPV as a prognostic and therapeutic marker as well as the factors influencing its measurement. Established cardiovascular risk factors, such as smoking, hypertension, dyslipidemia, and diabetes, can influence MPV, depending on confounding factors. Low-grade inflammation is one such factor. Evidence, particularly derived from prospective studies and a meta-analysis,

suggest a correlation between an increase in MPV and the risk of thrombosis. High MPV associates with a variety of established risk factors, cardio- and cerebrovascular disorders, and low-grade inflammatory conditions prone to arterial and venous thromboses. High-grade inflammatory diseases, such as active rheumatoid arthritis or attacks of familial Mediterranean fever, present with low levels of MPV, which reverse in the course of anti-inflammatory therapy. Lifestyle modification, antihypertensive, lipid lowering and diet therapies can also affect MPV values, but these effects need to be investigated in large prospective studies with thrombotic endpoints.

MEFV mutations in Moroccan patients suffering from familial Mediterranean Fever.

Belmahi L(1), Cherkaoui IJ, Hama I, Sefiani A.

Author information:

(1)Department of Medical Genetics, National Institute of Health, 27, Avenue Ibn Battouta, BP 769, Rabat, Morocco.

Familial Mediterranean Fever (FMF, MIM 249100) is an autosomal recessive disease mainly affecting patients of the Mediterranean basin. It is an autoinflammatory periodic disorder characterised by recurrent episodes of fever and abdominal pain, synovitis and pleuritis. FMF is caused by mutations in the Mediterranean Fever (MEFV) gene located on chromosome 16p13.3. Several mutations in the MEFV gene have been characterised in different populations. However, very little is known about mutations in the MEFV gene in patients with Moroccan origin. The aim of this study is to determine the clinical components of FMF and characterise mutations in the MEFV gene in Moroccan patients. The study was carried out on 120 unrelated Moroccan patients referred to the department of medical genetics in Rabat for suspicious FMF over a period of 10 years. Patients were screened for the most common MEFV mutations by direct sequencing of exons 2 and 10. Of the 120 unrelated patients investigated, 56 patients (47%) were carriers of one or two MEFV mutations, and 64 patients (53%) had no detected mutations. Of those with

mutations, 24 were homozygous (44%), 13 were compound heterozygotes (24%), and 19 patients had only 1 identifiable mutation (32%). The most frequent mutation in Moroccan patients is M694V (47%), followed by M694I (32%), A744S (6.5%), M680L (4%), M694del (2%) and E148Q (6.5%). The R761H, K695R and I692del mutations were rarely encountered (less than 1%). The V726A mutation was not found in our study. Our data represent the first report of MEFV gene mutations causing FMF in Moroccan patients. The M694V and M694I mutations are the most common mutations found in MEFV gene in Moroccan population; while the most common mutation in Arabs from the Middle-East region, the V726A, was not found in our population.

Development and preliminary validation of a diagnostic score for identifying patients affected with adult-onset autoinflammatory disorders.

Cantarini L(1), Lucherini OM, Iacoponi F, Cimaz R, Simonini G, Rigante D, Laghi Pasini F, Baldari CT, Capecchi PL, Brizi MG, Galeazzi M.

Author information:

(1)Interdepartmental Research Center of Systemic Autoimmune and Autoinflammatory Diseases, Unit of Rheumatology, Policlinico Le Scotte, University of Siena, Italy. cantariniluca@hotmail.com

To date, the rate of detection of autoinflammatory gene mutations in patients suspected of having an autoinflammatory disorder is very low. However, most of these data refer to pediatric populations. The relative rarity and lack of information on adult-onset autoinflammatory diseases make it likely that mutations will be found in an even smaller percentage of cases. Our aim was to develop and validate a set of variables for predicting the risk that a given adult patient presenting with recurrent fever episodes carries mutations in the MEFV or TNFRSF1A genes, in order to increase the probability of obtaining positive results on genetic testing. One hundred and ten consecutive patients with a clinical history of periodic fever attacks were screened for mutations in the TNFRSF1A and the MEFV genes. The mean age at disease onset was 27.85 years. Detailed information about each patient's family history, personal history, and

clinical manifestations were retrospectively collected. A diagnostic score was constructed based on univariate and multivariate analysis in a randomly-selected dataset (training set; n=40). The score was validated on an independent set of the remaining patients (validation set; n=70). Age at onset (odds ratio 0.958, P =0.050), positive family history of recurrent fever episodes (OR 5.738, P = 0.006), thoracic pain (OR 7.390, P = 0.002), abdominal pain (OR 2.853, P = 0.038) and skin involvement (OR 8.241, P = 0.003) were independently correlated with a positive genetic test result. A diagnostic score was calculated using the linear combination of the estimated coefficients of the logistic model (cut off equal to 0.24) revealing high sensitivity (0.94), high specificity (0.94) and high accuracy (0.94). We have identified variables that appear to be strongly related to the probability of detecting gene mutations in MEF and TNFRSF1A in adults, thus improving the evaluation of patients with suspected autoinflammatory disorders.

Relapsing polychondritis and familial Mediterranean fever--an association.

Miller EB(1), Friedman JA, Lahav Y, Landau Z.

Author information:

(1)Division of Rheumatology, Department of Internal Medicine D, Kaplan Medical Center affiliated with the Hebrew University School of Medicine, POB 1, Rehovot, Israel. Edward\_m@clalit.org.il

Relapsing polychondritis (RP) and familial Mediterranean fever (FMF) are systemic inflammatory disorders with seemingly distinct genetic and pathophysiologic mechanisms. An association between these disorders has been described based on a single case report with few clinical details available. We recently encountered a patient with biopsy-proven RP and genetically confirmed FMF. Following identification of this individual, we conducted a retrospective review of all cases of RP in our institution from 2000-2009 and identified one additional patient with RP who is also a genetic heterozygote for FMF. These cases highlight

the previously reported but sparsely documented relationship between these seemingly separate disorders.

Interleukin-1 antagonists in the treatment of autoinflammatory syndromes, including cryopyrin-associated periodic syndrome.

Quartier P(1).

Author information:

(1)Unité d'Immunologie-Hématologie et Rhumatologie pédiatriques, Hôpital Necker-Enfants Malades, Assistance Publique-Hôpitaux de Paris, Paris, France.

Cryopyrin-associated periodic syndrome (CAPS) include a group of rare autoinflammatory disorders, the spectrum of which ranges from the mildest form, ie, familial cold autoinflammatory syndrome to more severe phenotypes, ie, Muckle-Wells syndrome, and chronic infantile neurological cutaneous and articular syndrome, also known as neonatal-onset multisystem inflammatory disease. Three interleukin (IL)-1 antagonists have been tested in adults and children with CAPS, ie, anakinra, a recombinant homolog of the human IL-1 receptor antagonist; rilonacept, a fusion protein comprising the extracellular domains of IL-1 receptor I and the IL-1 adaptor protein, IL-1RAcP, attached to a human immunoglobulin G molecule; and canakinumab, the anti-IL-1 $\beta$  monoclonal antibody. Following rapid clinical development, rilonacept and canakinumab were approved by both the US Food and Drug Administration and the European Medicines Agency for use in adults and children. This review describes how the study of CAPS has helped us to understand better the way the innate immune system works, the pathogenesis of autoinflammatory syndromes, and the key role of IL-1. It also reviews the effects of IL-1 blockade in CAPS and other disorders, in particular systemic juvenile idiopathic arthritis, adult-onset Still's disease, and gout. Finally, this review covers some issues addressed by very recent and ongoing work regarding treatment indications, from orphan diseases to common disorders, continuous versus intermittent treatment, the pharmacokinetics, pharmacodynamics, and optimal dosages of the different drugs, as well as the need for Phase IV

trials, exhaustive registries, and long-term follow-up of several patient cohorts.

Prevalence of MEFV gene mutations and their clinical correlations in Turkish children with Henoch-Schönlein purpura.

Bayram C(1), Demircin G, Erdoğan O, Bülbül M, Caltik A, Akyüz SG.

Author information:

(1)Department of Pediatric Nephrology, Dr. Sami Ulus Children's Hospital, Ankara, Turkey.

AIM: To investigate the frequency of MEFV mutations and their associations with the clinical and laboratory findings in children with Henoch-Schönlein purpura (HSP).

METHODS: One hundred and seven children with HSP were investigated for 12 common MEFV mutations.

RESULTS: Forty-seven patients (43.9%) were found to have one of the MEFV mutations. Eight patients (7.5%) were homozygous for one mutation, 33 (30.8%) were heterozygous for one and six (5.6%) were compound heterozygous for two mutations. There were no age and sex differences between patients with or without mutations. Scrotal involvement was statistically more frequent in patients with mutations. Leucocyte counts, erythrocyte sedimentation rates, serum C-reactive protein (CRP) concentrations, number of patients with increased CRP levels and number of patients with increased immunoglobulin A concentrations were found to be higher in patients with MEFV mutations. p.M694V was the most frequent mutation and was found to have effects on clinical and laboratory findings in children with HSP. Fifteen patients were started on colchicine with the diagnosis of familial Mediterranean fever (FMF).

CONCLUSION: MEFV mutations are more frequent in HSP than in the general population, and mutation carriers may have more severe clinical findings with

higher inflammatory response, suggesting a dysregulation of the inflammatory response because of defective gene encoding the protein pyrine. Investigation of these mutations may be beneficial to follow-up the susceptible patients more closely leading to early diagnosis and treatment of FMF.

To study the prevalence major rheumatic diseases in western Turkey. This survey was conducted in Havsa which have a total population of 18,771. Physicians and interns visited every household, interviewed face to face a questionnaire about the symptoms of rheumatic disorders. The individuals replied positively to any question were examined at the nearest health center. Those have no objective findings related to any rheumatic diseases were excluded. People could not be clinically diagnosed were asked to come to the hospital for further evaluation. A total 17,835 of 18,771 residents participated. We estimated the prevalence of Behçet's Disease (BD) as 0.019%; ankylosing spondylitis: 0.120%; rheumatoid arthritis: 0.321%; knee osteoarthritis (OA): 5.351%; hand OA: 1.110%; hand and knee OA: 1.958%; total OA: 8.420%; primary Raynaud's: 1.192%; psoriasis: 0.424 %; psoriatic arthritis: 0.050%; rheumatic fever: 0.318%; rheumatic heart disease: 0.200%; inflammatory bowel disease: 0.023%; lupus: 0.059%; gout: 0.018%; systemic sclerosis: 0.022%; juvenile rheumatoid arthritis: 0.032%; temporal arteritis: 0.020%, and familial Mediterranean fever (FMF) as 0.006%. Figures were adjusted for age-sex of the general Turkish population. The prevalence's of BD and FMF are

considerably lower in Havsa as compared to other regions in Turkey.

Long-term clinical profile of children with the low-penetrance R92Q mutation of the TNFRSF1A gene.

Pelagatti MA(1), Meini A, Caorsi R, Cattalini M, Federici S, Zulian F, Calcagno G, Tommasini A, Bossi G, Sormani MP, Caroli F, Plebani A, Ceccherini I, Martini A, Gattorno M.

Author information:

(1)Istituto G. Gaslini, Genoa, Italy.

**OBJECTIVE:** To analyze the long-term impact of the R92Q mutation of TNFRSF1A in children with periodic fever, in comparison with children with tumor necrosis factor receptor-associated periodic syndrome (TRAPS) with TNFRSF1A structural mutations and children with periodic fever of unknown origin fulfilling the criteria for periodic fever, aphthosis, pharyngitis, and adenitis syndrome (PFAPA).

**METHODS:** The extracellular region of TNFRSF1A was analyzed in 720 consecutive children with periodic fever, using denaturing high-performance liquid chromatography and DNA sequencing. Followup data on 11 pediatric patients with TNFRSF1A structural mutations (cysteine or T50M), 23 pediatric patients with an R92Q substitution, and 64 pediatric patients with PFAPA were collected during routine clinic visits. The 50-item Child Health Questionnaire was used to assess health-related quality of life (HRQOL).

**RESULTS:** The frequency of typical TRAPS-related clinical manifestations was significantly lower and the impact of the disease on HRQOL was significantly reduced in patients with the R92Q mutation compared with TRAPS patients carrying structural mutations of TNFRSF1A. Followup data on 11 TRAPS patients with TNFRSF1A structural mutations (mean followup 7.9 years), 16 patients with the R92Q substitution (mean followup 7.3 years), and 64 patients with PFAPA (mean followup 5.2 years) were available. Patients with R92Q mutations and patients with PFAPA displayed a higher rate of self-resolution or amelioration of the fever episodes

than did TRAPS patients with structural mutations.

CONCLUSION: Although some cases may progress to a more chronic disease course, the majority of children with an R92Q mutation of the TNFRSFA1 gene show a milder disease course than that in children with TNFRSFA1 structural mutations and have a high rate of spontaneous resolution and amelioration of the recurrent fever episodes.

Role of interleukin-6 in a patient with tumor necrosis factor receptor-associated periodic syndrome: assessment of outcomes following treatment with the anti-interleukin-6 receptor monoclonal antibody tocilizumab.

Vaitla PM(1), Radford PM, Tighe PJ, Powell RJ, McDermott EM, Todd I, Drewe E.

prashanthamadhuri@gmail.com

In this report, we describe treatment outcomes in the first case of a patient with tumor necrosis factor receptor-associated periodic syndrome (TRAPS) treated with the anti-interleukin-6 (anti-IL-6) receptor monoclonal antibody tocilizumab. Since IL-6 levels are elevated in TRAPS, we hypothesized that tocilizumab might be effective. The patient, a 52-year-old man with lifelong TRAPS in whom treatment with etanercept and anakinra had failed, was administered tocilizumab for 6 months, and the therapeutic response was assessed by measurement of monocyte CD16 expression and cytokine levels. Following treatment, the evolving acute attack was aborted and further attacks of TRAPS were prevented. The patient did not require corticosteroids and showed significant clinical improvement in scores for pain, stiffness, and well-being. Moreover, the acute-phase response diminished significantly with treatment. Monocyte CD16 expression was reduced and the numbers of circulating CD14+CD16+ and CD14++CD16- monocytes were transiently

decreased. However, cytokine levels were not reduced. This case supports the notion of a prominent role for IL-6 in mediating the inflammatory attacks in TRAPS, but blockade of IL-6 did not affect the underlying pathogenesis. These preliminary findings require confirmation.

Recurrent fever syndromes in patients after recovery from Kawasaki syndrome.

Broderick L(1), Tremoulet AH, Burns JC, Bastian JF, Hoffman HM.

Author information:

(1)Department of Pediatrics, University of California San Diego and Rady Children's Hospital, San Diego, California, USA. lbroderick@ucsd.edu

The recurrence of fever in a child with a history of Kawasaki syndrome (KS) poses a dilemma for clinicians who must consider the possibility of recurrent KS. In this report we present the cases of 4 patients who presented with classical symptoms of KS, were successfully treated with intravenous immunoglobulin, and later experienced a reappearance of inflammatory symptoms in a pattern consistent with a recurrent fever syndrome. The association of these syndromes within the same patient suggests that some patients may have a genetic propensity toward altered immune responses and autoinflammatory syndromes. We propose that these 2 syndromes exist within a family of febrile disorders related to innate immune dysregulation.

Nucleic acid recognition by the innate immune system.

Barbalat R(1), Ewald SE, Mouchess ML, Barton GM.

Author information:

(1)Division of Immunology & Pathogenesis, Department of Molecular and Cell Biology, University of California, Berkeley, 94720-3200, USA.

Receptors of the innate immune system recognize conserved microbial features and provide key signals that initiate immune responses. Multiple transmembrane and cytosolic receptors have evolved to recognize RNA and DNA, including members of the Toll-like receptor and RIG-I-like receptor families and several DNA sensors. This strategy enables recognition of a broad range of pathogens; however, in some cases, this benefit is weighed against the cost of potential self recognition. Recognition of self nucleic acids by the innate immune system contributes to the pathology associated with several autoimmune or autoinflammatory diseases. In this review, we highlight our current understanding of nucleic acid sensing by innate immune receptors and discuss the regulatory mechanisms that normally prevent inappropriate responses to self.

Spleen tyrosine kinase inhibition in the treatment of autoimmune, allergic and autoinflammatory diseases.

Pamuk ON(1), Tsokos GC.

Author information:

(1)Division of Rheumatology, Beth Israel Deaconess Medical Center, Harvard Medical School, 330 Brookline Avenue, CLS-928, Boston, MA 02115, USA.

Spleen tyrosine kinase (Syk) is involved in the development of the adaptive immune system and has been recognized as being important in the function of additional cell types, including platelets, phagocytes, fibroblasts, and

osteoclasts, and in the generation of the inflammasome. Preclinical studies presented compelling evidence that Syk inhibition may have therapeutic value in the treatment of rheumatoid arthritis and other forms of arthritis, systemic lupus erythematosus, autoimmune cytopenias, and allergic and autoinflammatory diseases. In addition, Syk inhibition may have a place in limiting tissue injury associated with organ transplant and revascularization procedures. Clinical trials have documented exciting success in the treatment of patients with rheumatoid arthritis, autoimmune cytopenias, and allergic rhinitis. While the extent and severity of side effects appear to be limited so far, larger studies will unravel the risk involved with the clinical benefit.

**BACKGROUND:** Constrictive pericarditis (CP) represents a rare cause of protein-losing enteropathy (PLE) resulting from intestinal lymphangiectasia (IL). In this report, we describe an 8-year-old Turkish boy with IL and PLE secondary to CP.

**METHODS:** The boy was introduced to our clinic due to bilateral pretibial edema and swelling of the eyelids caused by hypoproteinemia. Physical examination revealed a distended right jugular vein. Laboratory investigation revealed PLE with fecal concentration of alpha-1 antitrypsin of 4.87 mg/g. Histopathologic examination of random biopsies obtained from the duodenum revealed markedly dilated lymphatics compatible with IL. Constrictive pericarditis was diagnosed by tagged cine cardiac magnetic resonance imaging.

**RESULTS:** Pericardiectomy was performed for the patient. Genetic analysis was done and heterozygous mutation E148Q was detected as a disease-causing Mediterranean fever (MEFV) mutation. Colchicine was started after the operation. Six months after the initiation of regular colchicine therapy, echocardiography revealed disappearance of CP.

**CONCLUSION:** This is the first reported case of PLE with a distended right jugular vein due to CP secondary to familial Mediterranean fever associated with E148Q heterozygosity in the MEFV gene.

Interleukin-1 $\beta$  inhibitors for the treatment of cryopyrin-associated periodic syndrome.

Dhimolea E(1).

Author information:

(1)Tufts University School of Medicine, Boston, MA, USA.

Cryopyrin-associated periodic syndrome (CAPS) comprises a group of rare, but severe, inherited autoinflammatory disorders associated with aberrant secretion of interleukin (IL)-1. These distinct conditions of autoinflammatory origin include Muckle-Wells syndrome, familial cold autoinflammatory syndrome, and neonatal-onset multisystem inflammatory disease (NOMID), which is also referred to as chronic infantile neurologic cutaneous and articular syndrome. Recently, this group of diseases has been associated with mutations in the NLRP3 gene that encodes for the protein cryopyrin, a component of the inflammasome complex that regulates the maturation and secretion of inflammatory cytokine IL-1 $\beta$ . Immune cells from patients with NOMID secrete higher levels of active IL-1 $\beta$  compared with monocytes from healthy subjects. Overproduction of IL-1 is believed to promote aberrant inflammatory response in CAPS patients. Evidence supporting the clinical value of IL-1 $\beta$  in CAPS has been provided from the complete response of patients after treatment with IL-1 blocking agents.

Etanercept-induced myelopathy in a pediatric case of blau syndrome.

Caracseghi F(1), Izquierdo-Blasco J, Sanchez-Montanez A, Melendo-Perez S, Roig-Quilis M, Modesto C.

Author information:

(1)Pediatric Rheumatology Department, Vall d'Hebron University Hospital, P. Vall d'Hebron 119-129, 08035 Barcelona, Spain.

Blau syndrome is a rare autoinflammatory disorder within the group of pediatric granulomatous diseases. Mutations in nucleotide-binding oligomerization domain 2 (NOD2/CARD15) are responsible for this condition, which has an autosomal dominant pattern of inheritance and variable expressivity. The clinical picture includes arthritis, uveitis, skin rash, and granulomatous inflammation. Central nervous system involvement is seldom reported, although some isolated cases of seizures, neurosensorial hearing loss, and transient cranial nerve palsy have been described. Treatment consists of nonsteroidal anti-inflammatory drugs, corticosteroids, and immunosuppressive agents, among which anti-tumor-necrosis-factor-alpha (TNF- $\alpha$ ) biologic agents, such as etanercept, play an important role. Among the major adverse effects of TNF- $\alpha$  inhibitors, demyelinating disease, multiple sclerosis, and acute transverse myelitis have been reported in adults. We describe a case of pediatric Blau syndrome affected by etanercept-induced myelopathy, manifesting as a clinical syndrome of transverse myelitis. The patient experienced rapid recovery after etanercept was discontinued. To our knowledge, this is the first such case reported in the literature and, possibly, the one with the latest onset, following 8 years of treatment. We discuss the etiopathogenic mechanisms of this reaction and possible explanations for the imaging findings.

Skin manifestations in autoinflammatory syndromes.

[Article in English, German]

Braun-Falco M(1), Ruzicka T.

Author information:

(1)Department of Dermatology and Allergy, Ludwig Maximilian University, Munich, Germany.

Autoinflammatory diseases encompass a group of inflammatory diseases that are non-infectious, non-allergic, non-autoimmune and non-immunodeficient. The term was initially coined for a small group of familial periodic fever syndromes of which familial Mediterranean fever (FMF) is the most common and best known. Genetic and molecular analyses demonstrated for the majority of these diseases an impairment of inflammasomes to cause an increased activity of an interleukin-1-dependent inflammatory response. Over the last years an increasing number of either rare hereditary syndromes or acquired common diseases could be summarized under the designation of autoinflammatory disease, thus creating an emerging new rubric of inflammatory diseases. Many of them display cutaneous manifestations as both concomitant or more rarely main symptoms. To name some of them like erysipelas-like erythema in FMF; urticaria-like rashes in tumor necrosis factor receptor 1- or cryopyrin-associated periodic syndromes (TRAPS, CAPS), hyperimmunoglobulin D syndrome (HIDS) or Schnitzler syndrome; pyoderma gangrenosum and acne in PAPA syndrome; or behçetoid aphthous ulcerations in HIDS and PFAPA syndrome. Based on the new insights into pathogenesis one increasingly realizes the good response of these diseases to IL-1 antagonist therapies.

Role of autoimmunity and autoinflammation in the pathogenesis of idiopathic recurrent pericarditis.

Cantarini L(1), Imazio M, Brizi MG, Lucherini OM, Brucato A, Cimaz R, Galeazzi M.

Author information:

(1)Interdepartmental Research Center of Systemic Autoimmune and Autoinflammatory Diseases, Unit of Rheumatology, Policlinico Le Scotte, University of Siena, Siena, Italy. cantariniluca@hotmail.com

Idiopathic recurrent pericarditis is the most common and troublesome complication of acute pericarditis affecting about one third of such patients. The pericardium may be involved in different systemic autoimmune diseases (i.e., systemic lupus erythematosus, rheumatoid arthritis, progressive systemic sclerosis, mixed connective tissue disease, Sjogren's Syndrome, polyarteritis, giant cell arteritis, other systemic vasculitides) either in a symptomatic form (usually during the active phase of the disease) or as asymptomatic pericardial effusion. Moreover, idiopathic recurrent pericarditis mimicks hereditary periodic fever syndromes (HPFSs). HPFSs are a group of disorders characterized by primary dysfunction of the innate immune system mostly caused by mutations of genes involved in the regulation or activation of the inflammatory response, without any apparent involvement of antigen-specific T cells or significant production of autoantibodies. These disorders usually manifest in the pediatric population, with onset ranging from the first hours to the first decade of life, however a limited number of patients experience disease onset during adulthood.

Recurrent fever is a relatively common problem during childhood. Diagnosis is often easy and related to mild viral infections. However a small proportion of these cases originate from an underlying non-infectious process that is generally difficult to diagnose. In this paper we describe the differential diagnosis of recurrent or periodic fever versus other processes, with especial attention to autoinflammatory disorders (AD). AD are alterations of innate immunity, and they have been recently classified as an immunodeficiency. Anyhow, since infections are not present, these processes are different to the classic primary immunodeficiency. An important part of AD is of known genetic aetiology. The symptoms originate from an underlying inflammatory process and can have different clinical expressions. One of the most relevant groups is the hereditary syndromes of periodic fever. This group of diseases associates recurrent fever and several clinical symptoms with a relative periodicity, separated by intervals free or almost free of symptoms. We include the diagnostic criteria for some processes as well as the characteristics that should, eventually, lead to a genetic study. Although treatment should be individualised, we also include some general

recommendations.

Association analysis of Toll-like receptor 7 gene polymorphisms and Behçet's disease in Japanese patients.

Sada T(1), Ota M, Katsuyama Y, Meguro A, Nomura E, Uemoto R, Nishide T, Okada E, Ohno S, Inoko H, Mizuki N.

Author information:

(1)Department of Ophthalmology and Visual Science, Yokohama City University, Graduate School of Medicine, Kanagawa, Japan.

Action of Toll-like receptors (TLRs) is deeply associated with defense mechanisms of the innate and adaptive immune responses to microbial pathogens. There have been reports of genetic polymorphisms within the TLR7 gene being closely related to a variety of inflammatory and infectious diseases. Behçet's disease (BD) is an autoinflammatory disease, and the pathogenesis has yet to be fully discovered. We investigated whether polymorphisms of Toll-like receptor 7 (TLR7) are associated with BD by analyzing the frequency of eight single nucleotide polymorphisms (SNPs) within 200 Japanese BD patients and 102 randomized controls. We genotyped nine SNPs in the TLR7 gene and assessed the allele/genotype diversity between cases and controls for all SNPs. In all eight SNPs, statistically significant differences were not observed between cases and controls.

Inflammasomes and autoimmunity.

Shaw PJ(1), McDermott MF, Kanneganti TD.

Author information:

(1)Department of Immunology, St. Jude Children's Research Hospital, MS #351, Suite E7004, 262 Danny Thomas Place, Memphis, TN 38105, USA.

The NOD-like receptor (NLR) family members are cytosolic sensors of microbial components and danger signals. A subset of NLRs control inflammasome assembly that results in caspase-1 activation and, in turn, IL-1 $\beta$  and IL-18 production. Excessive inflammasome activation can cause autoinflammatory disorders, including the hereditary periodic fevers. Autoinflammatory and autoimmune diseases form a disease spectrum of aberrant, immune-mediated inflammation against self, through innate and adaptive immunity. However, the role of inflammasomes in autoimmune disease is less clear than in autoinflammation, despite the numerous effects IL-1 $\beta$  and IL-18 can have on shaping adaptive immunity. We summarize the role of inflammasomes in autoimmune disorders, highlight the need for a better understanding of inflammasomes in these conditions and offer suggestions for future research directions.

eseyahi@yahoo.com

**OBJECTIVES:** We investigated the prevalence of Behçet's syndrome (BS) among the ethnic Armenians in Istanbul using Familial Mediterranean Fever (FMF) as a comparator disease. We also studied HLA-B51 and MEFV mutations among a group of healthy Armenians and a non-Armenian population.

**METHODS:** The prevalence study was conducted in 2 parts in the Armenian primary schools in Istanbul, using the enrolled students as index cases to study the core family. In Part I, a questionnaire seeking only whether either parent had previously been diagnosed as having BS or FMF by a physician was distributed to a total of 1873 index students registered at 10 schools. A total of 1380 parents filled in the questionnaire, yielding a response rate of 37% (1380 / 3746). In Part II, eight schools participated with a response rate of 83 % (1183/1428). Also, genomic DNA samples of 108 healthy (14 M/94 F) Armenians and 97 (45 M/ 52 F) non-Armenians, were studied for HLAB51 and MEFV gene mutations.

**RESULTS:** In Part I, none of the parents turned out to have been diagnosed as BS, whereas a total of 12 / 1380 (870/105) had been diagnosed as FMF. In the second part the estimated prevalence of BS was 90 /105 and that of FMF was 760/ 105. HLA-B51 carrier rate was found to be similar between the Armenian (27%, 29/108) and the non-Armenian participants (19%, 18/97), ( $p=0.158$ ). Overall carrier rate of MEFV gene mutations was significantly higher in the Armenian group (36% vs. 20%,  $p=0.015$ ).

**CONCLUSIONS:** The genetic load for FMF is considerably higher among the Armenians when compared to the load for BS among the same ethnic group. On the other hand, the rather low frequency of BS among the Armenians when compared to the frequency among the general population living in the same environment is further evidence for a genetic predisposition to BS. HLA- B51 does not seem to play a dominant role in the said predisposition. Finally, as we have used an unorthodox epidemiological methodology in data collection our results might need to be further verified by more conventional methods.

Anti-cyclic citrullinated peptides positivity rate in patients with familial Mediterranean fever.

Ceri M(1), Unverdi S, Altay M, Ureten K, Oztürk MA, Gönen N, Duranay M.

Author information:

(1)Department of Nephrology, Ankara Education and Research Hospital, Ankara, Turkey. tscer@yahoo.com

**OBJECTIVES:** To investigate the prevalence and levels of anti-cyclic citrullinated peptide antibodies (anti-CCP) in patients with familial Mediterranean fever (FMF) with and without arthritis.

**METHODS:** Eighty-three patients with FMF and 43 healthy controls were included in the study. Thirty seven FMF patients had a history of arthritis, and 46 patients did not. Serum antibodies directed to the anti-CCP were assessed with a commercial enzyme-linked immunosorbent assay (ELISA) kit. Values <20U were considered negative, between 20 and 39U low, 40-99U moderate, and >100U high positive.

**RESULTS:** Positivity rate of anti-CCP in the whole FMF group (14.5%) was three-fold higher than the control group (4.7%). However, the difference failed to achieve a statistically significant level ( $p=0.09$ ). Anti-CCP levels were  $21\pm30.1$  in patients with arthritis and  $13.1\pm10.3$  in the non arthritic group ( $p<0.05$ ). Anti-CCP positivity rates were 10/37 (27%) in patients with arthritis and 2/46 (4.3%) in patients without arthritis ( $p<0.005$ ). Five FMF patients with arthritis (13.5%) had moderate-high anti-CCP levels (>40U/ml). Anti-CCP levels were between 20-39U/ ml in 2FMF patients without arthritis and in 2 healthy controls. Anti-CCP positivity rate is higher in FMF patients with arthritis (27%) than healthy controls (4.7%) ( $p<0.005$ ).

**CONCLUSIONS:** Anti-CCP prevalence is higher in FMF patients with arthritis than without arthritis, and that a significant proportion of FMF patients with arthritis (13.5%) had moderate-high titers of anti-CCP. Therefore, anti-CCP antibodies may not be a reliable indicator to differentiate between FMF arthritis and rheumatoid arthritis.

Anti-interleukin 1 treatment for patients with familial Mediterranean fever resistant to colchicine.

Ozen S(1), Bilginer Y, Aktay Ayaz N, Calguneri M.

Author information:

(1)Hacettepe University Faculty of Medicine, Ankara, Turkey.  
sezaozen@hacettepe.edu.tr

**OBJECTIVE:** Familial Mediterranean fever (FMF) is a recessively inherited autoinflammatory disorder characterized by recurrent attacks of fever and serositis. Although colchicine is the standard therapy for preventing attacks and suppressing inflammation, 5%-10% of compliant patients are colchicine-resistant. We report the effect of anti-tumor necrosis factor therapy (etanercept) and anti-interleukin 1 (IL-1) treatment (anakinra) in 6 cases resistant to colchicine therapy.

**METHODS:** Five children and an adult patient (3 female, 3 male) who were experiencing at least 2 attacks per month and had consistently elevated C-reactive protein levels despite regular colchicine therapy were given either etanercept or anakinra.

**RESULTS:** Although etanercept lowered the number of attacks (from 3-4 attacks per

month to 2 attacks per month), attacks still recurred and acute-phase reactants remained high in 2 patients; thus etanercept was considered ineffective. All 4 patients were switched to anakinra. In 2 patients anakinra completely resolved clinical and laboratory findings. The other 4 patients have been switched to anakinra recently; to date anakinra has reduced the number of attacks (to < 1 per month) and lowered the levels of acute-phase reactants.

CONCLUSION: In this small series, anakinra was successful in suppressing inflammation and decreasing the number of attacks in FMF. This may be explained by the role of pyrin in the regulation of IL-1 $\beta$  activation.

Blocking interleukin-1 $\beta$  in acute and chronic autoinflammatory diseases.

Dinarello CA(1).

Author information:

(1)Department of Medicine, University of Colorado, Aurora, CO, USA.

cdinare333@aol.com

An expanding spectrum of acute and chronic inflammatory diseases is considered 'autoinflammatory' diseases. This review considers autoinflammatory diseases as being distinct from 'autoimmune' diseases. Autoimmune diseases are associated with dysfunctional T cells and treated with 'biologicals', including antitumour necrosis factor $\alpha$ , CTLA-Ig, anti-IL-12/23, anti-CD20, anti-IL-17 and anti-IL-6 receptor. In contrast, autoinflammatory diseases are uniquely attributed to a dysfunctional monocyte caspase 1 activity and secretion of IL-1 $\beta$ ; indeed, blocking IL-1 $\beta$  results in a rapid and sustained reduction in the severity of most autoinflammatory diseases. Flares of gout, type 2 diabetes, heart failure and smouldering multiple myeloma are examples of seemingly unrelated diseases, which are uniquely responsive to IL 1 $\beta$  neutralization.

Gevokizumab, an anti-IL-1 $\beta$  mAb for the potential treatment of type 1 and 2 diabetes, rheumatoid arthritis and cardiovascular disease.

Geiler J(1), McDermott MF.

Author information:

(1)NIHR-Leeds Musculoskeletal Biomedical Research Unit, Leeds Institute of Molecular Medicine, Wellcome Trust Brenner Building, St. James's University Hospital, Beckett Street, Leeds LS9 7TF, UK.

The inflammatory cytokine IL-1 $\beta$  has an essential role in the innate immune response. High levels of IL-1 $\beta$  have been implicated in the development of many diseases, including type 1 and 2 diabetes (T1D and T2D), rheumatoid arthritis (RA) and cardiovascular disease. XOMA is developing gevokizumab (XOMA-052), an IgG2 humanized mAb against human IL-1 $\beta$ , for the potential treatment of these diseases. Gevokizumab has a high affinity for IL-1 $\beta$  and a long t<sub>1/2</sub>, which would allow for once-monthly dosing and offer a considerable advantage for patients over agents requiring more frequent dosing. Data from preclinical studies and clinical trials suggest that gevokizumab is a potentially effective and well-tolerated treatment for the indicated diseases. At the time of publication, phase II clinical trials were ongoing in patients with T1D, T2D and RA, with the T2D trials assessing key cardiovascular markers. Following promising data from a recent pilot trial, XOMA was also planning a phase I/II trial of gevokizumab for the potential treatment of uveitis in patients with the vasculitic inflammatory disorder Behçet's disease and the autoinflammatory conditions familial cold autoinflammatory syndrome and Muckle-Wells syndrome.

Familial Mediterranean Fever (FMF) is an autosomal recessive autoinflammatory disorder with the responsible gene of MEFV which primarily affects Jewish, Armenian, Turkish and Arab populations. The FMF gene (MEFV) has recently been cloned to chromosome 16 p, which encodes pyrin. In the present study, we enrolled 2,067 unrelated patients with the suspicion of FMF in Middle Anatolia between the years 2006-2009 and identified the 12 MEFV mutations. DNA was amplified by PCR and subjected to reverse hybridization for the detection of MEFV gene mutations. Among the 2,067 patients, 866 (41.9%) were males and 1,201 (58.1%) were females. The mutations were homozygous in 176 (16.85%) patients, compound heterozygous in 314 (30.1%) patients, heterozygous in 546 (52.25%) patients and the other forms of mutations were found in 8 patients (0.76%). No mutation was detected in 1,023 (49.5%) patients. The most frequent mutations were M694V, M680I (G/C), E148Q and V726A. We could not find any significant differences between the two common mutations according to the gender. The high incidence of MEFV gene mutations in the Turkish population indicated that newborn screening may be discussed in the future. Because of the ethnic origin of Anatolia, larger serial analyses are necessary to investigate the rate and coexistence of these mutations.

**OBJECTIVE:** Auto-inflammatory diseases (AIDs) are characterized by recurrent self-limiting systemic inflammation. In a multicentre effort, we set out to register genetic, epidemiological and clinical features as well as prognostic factors of these diseases by prospective longitudinal and long-term documentation, in order to define novel AIDs and to better understand treatment responses and outcome.

**METHODS:** In 2009, a federally funded clinical and research consortium (AID-Net) was established, including an online registry for AIDs (<http://www.aid-register.uk-essen.de>). Inclusion criteria are disease-associated mutations for hereditary periodic fever syndromes [FMF, hyperimmunoglobulinaemia D and periodic fever syndrome (HIDS), TNF receptor 1-associated periodic syndrome (TRAPS) and cryopyrin-associated periodic syndrome (CAPS)], or, alternatively, clinically confirmed AID, systemic-onset JIA (SoJIA) and periodic fever, aphthous stomatitis, pharyngitis and adenopathy (PFAPA) syndrome with unknown genetic background. Patients were recruited to the registry and patient material was deposited in biomaterial banks (DNA/serum). In addition, basic research projects were initiated that focus on molecular mechanisms of AID.

**RESULTS:** During the first 9 months, 117 patients (65 males, 52 females; age 1-21 years) have been recorded and classified as FMF (n=84), HIDS (n=1), TRAPS (n=3) and CAPS (n=1); clinically confirmed AID (n=5); SoJIA (n=22); and PFAPA (n=1). One hundred and fifty blood samples of 18 patients were included in biomaterial banks.

**CONCLUSION:** Recruitment and follow-up of patients with AID will enable us to comprehensively address the correlation between clinical and epidemiological data, genetics and biomarkers. The translational approach may help to identify genetic or inflammatory markers relevant for the course and outcome of diseases.

PFAPA is a periodic fever syndrome characterized by: fever, aphthous stomatitis, pharyngitis and cervical adenitis. It is one of the autoinflammatory syndromes, but yet of unknown etiology. Our aim is to report our experience, describe clinical manifestations, laboratory findings, relapses occurrence and response to treatment. We present 12 PFAPA patients. Median age at onset: 1.15 years, mean duration of febrile episodes: 4 days, and relapses at regular intervals. All children received prednisone (1-2 mg/kg/dose) one to two doses, 9 patients responded immediately after the first dose and all experienced a lower periodicity of attacks. PFAPA is the most frequent periodic fever syndrome. To our knowledge, there are no other local series of PFAPA patients published. Recognizing this syndrome will prevent from ordering unnecessary studies and will favor family coping.

We performed homozygosity mapping in two recently reported pedigrees from Portugal and Mexico with an autosomal-recessive autoinflammatory syndrome characterized by joint contractures, muscle atrophy, microcytic anemia, and panniculitis-induced lipodystrophy (JMP). This revealed only one homozygous region spanning 2.4 Mb (5818 SNPs) on chromosome 6p21 shared by all three affected individuals from both families. We directly sequenced genes involved in immune response located in this critical region, excluding the HLA complex genes. We found a homozygous missense mutation c.224C>T (p.Thr75Met) in the proteasome subunit, beta-type, 8 (PSMB8) gene in affected patients from both pedigrees. The mutation segregated in an autosomal-recessive fashion and was not detected in 275 unrelated ethnically matched healthy subjects. PSMB8 encodes a catalytic subunit of the 20S immunoproteasomes called  $\beta 5i$ . Immunoproteasome-mediated proteolysis generates immunogenic epitopes presented by major histocompatibility complex (MHC) class I molecules. Threonine at position 75 is highly conserved and its substitution with methionine disrupts the tertiary structure of PSMB8. As compared to normal lymphoblasts, those from an affected patient showed significantly reduced chymotrypsin-like proteolytic activity mediated by immunoproteasomes. We conclude that mutations in PSMB8 cause JMP syndrome, most probably by affecting MHC class I antigen processing.

(1)Unité Médicale des Maladies Auto-Inflammatoires, Laboratoire de Génétique, Hôpital A de Villeneuve, Montpellier, France.

The recent identification of genes implicated in hereditary recurrent fevers has allowed their specific diagnosis. So far however, only punctual mutations have been identified and a significant number of patients remain with no genetic confirmation of their disease after routine molecular approaches such as sequencing. The possible involvement of sequence rearrangements in these patients has only been examined in familial Mediterranean fever and was found to be unlikely. To assess the existence of larger genetic alterations in 3 other concerned genes, MVK (Mevalonate kinase), NLRP3 (Nod like receptor family, pyrin domain containing 3) and TNFRSF1A (TNF receptor superfamily 1A), we adapted the qPCR-HRM method to study possible intragenic deletions and duplications. This single-tube approach, combining both qualitative (mutations) and quantitative (rearrangement) screening, has proven effective in Lynch syndrome diagnosis. Using this approach, we studied 113 unselected (prospective group) and 88 selected (retrospective group) patients and identified no intragenic rearrangements in the 3 genes. Only qualitative alterations were found with a sensitivity similar to that obtained using classical molecular techniques for screening punctual mutations. Our results support that deleterious copy number alterations in MVK, NLRP3 and TNFRSF1A are rare or absent from the mutational spectrum of hereditary recurrent fevers, and demonstrate that a routine combined method such as qPCR-HRM provides no further help in genetic diagnosis. However, quantitative approaches such as qPCR or SQF-PCR did prove to be quick and effective and could still be useful after non contributory punctual mutation screening in the presence of clinically evocative signs.

Hemophagocytic lymphohistiocytosis (HLH) is a rare, potentially fatal, severe condition of hyperinflammation caused by the uncontrolled proliferation of activated lymphocytes and histiocytes secreting high amounts of inflammatory cytokines. Here we report a fatal hemophagocytic syndrome in a 11-year-old boy with a diagnosis of both Crohn's disease receiving immunosuppressive therapy and familial Mediterranean fever. It is important to evaluate the patients with inflammatory bowel disease receiving immunosuppressive therapy presenting with unexplained fever, cytopenia, progression of organomegaly and biochemical changes for the investigation of HLH for diagnosis and treatment.

Various secondary metabolites from plants, bacteria and fungi are redox active and able to modulate the intracellular redox equilibrium in living cells. Many of these compounds behave as antioxidants, yet some of them also cause oxidative modifications, which may ultimately result in cell death. Natural isothiocyanates and xanthohumol, for instance, appear to act specifically in and against cells with a disturbed redox balance, such as certain cancer cells. Similarly, polysulfane and pyocyanin derivatives employ the glutathione antioxidant defense system of cells to generate a lethal cocktail of reactive oxygen species. Together, these redox-modulating metabolites provide promising new leads to target selectively certain cancer cells. They may also be useful in the treatment of autoinflammatory diseases.

**OBJECTIVE:** Mendelian and complex autoinflammatory disorders frequently manifest as recurrent abdominal pain and fever. Diagnosis may be difficult and scant data are available about the interest of 2-deoxy-2-[18F]fluoro-D-glucose-positron emission tomography/computed tomography (FDG-PET/CT) in such conditions, particularly aseptic abscesses (AA).

**MATERIAL AND METHODS:** We analyzed five cases of AA in which FDG-PET/CT was performed at diagnosis (n = 2) and after a suspected relapse (n = 5). Follow-up FDG-PET/CT was performed in two patients 9 days and 6 weeks after the initiation of oral corticosteroids.

**RESULTS:** FDG-PET/CT showed intense uptake foci in the abdominal lymph nodes (n = 4), liver (n = 2) and spleen (n = 4) before treatment. A marked metabolic response was observed while patients were being treated. In a relapsing patient with abdominal pain but no raised CRP, although CT scan was unchanged, abnormal uptake of FDG was observed. By contrast, some lesions previously observed on CT scan displayed no fixation on new FDG-PET/CT and were suggestive of sequelae in three patients.

**CONCLUSION:** Although nonspecific, FDG-PET/CT may be an interesting tool for the diagnosis and management of recurrent and febrile abdominal pain in AA. At the time of relapse, it can differentiate between a sequela of previous flares and a new localization. It can be used for whole-body screening to look for other asymptomatic disease localizations.

Colchicine in clinical medicine. A guide for internists.

Cocco G(1), Chu DC, Pandolfi S.

Author information:

(1)Medical Practice, Rheinfelden, Switzerland. praxis@cocco.ch

Colchicine (COL) has been used in medicine for a long time. It is well recognized as a valid therapy in acute flares of gouty arthritis, familial Mediterranean fever (FMF), Behçet's disease, and recurring pericarditis with effusion. It has also been used to treat many inflammatory disorders prone to fibrosis, mostly with disappointing therapeutic results. The pharmacotherapeutic mechanism of action of COL in diverse diseases is not fully understood, though it is known

that the drug accumulates preferentially in neutrophils, and this effect is useful in FMF. COL shows a large interindividual bioavailability. Furthermore, interactions with drugs interfering with CYP3A4 dependent enzymes and P-glycoprotein occur and are clinically important. The dosage of COL must be reduced in patients with relevant hepatic and/or renal dysfunction. However, when appropriately used and contraindications have been excluded, oral COL is a safe treatment.

Erratum in

Ann Rheum Dis. 2012 Jul;71(7):1264. Lemelle, C [corrected to Lemelle, I].

BACKGROUND: Cryopyrin-associated periodic syndromes (CAPS) consist of a continuum

of autoinflammatory diseases caused by a defect in interleukin 1 $\beta$  regulation. Although symptoms may vary widely, the discovery, in 2001, of the gene involved (NLRP3) has dramatically helped diagnosis.

**OBJECTIVES:** To define the spectrum and prevalence of NLRP3 mutations in France and to delineate initial criteria before molecular analysis.

**METHODS:** Retrospective review (2001-9) of genetic analysis data and request forms of patients living in France with an NLRP3 mutation since the set up of CAPS molecular diagnosis by the three French laboratories providing this test (GenMAI network).

**RESULTS:** Over 800 analyses of this gene have been conducted, identifying 135 cases with an NLRP3 mutation (55 probands; 33 multiplex families); the estimated prevalence in France was equal to 1/360 000. A total of 21 different sequence variants were detected, among which four are common and nine are new mutations.

**CONCLUSIONS:** Although the number of NLRP3 test requests has doubled over the past 5 years, genetic screening has not contributed to enhanced detection of new index cases each year. There are two possible reasons for this: (i) no clinical prerequisite for genetic diagnosis and (ii) few new large families are now identified (unlike the initial study based on a selection by linkage). A set of initial clinical criteria have been drawn up which it is recommended should be fulfilled before a patient is tested: at least three recurrent bouts, age at disease onset < 20 years and elevated levels of C-reactive protein, especially in individuals with urticaria and moderate fever.

Cryopyrin-associated periodic syndrome: an update on diagnosis and treatment response.

Yu JR(1), Leslie KS.

Author information:

(1)Department of Dermatology, University of California, San Francisco, 1701 Divisadero Street, San Francisco, CA 94143-0316, USA. yuj@derm.ucsf.edu

Cryopyrin-associated periodic syndrome (CAPS) is a rare hereditary inflammatory

disorder encompassing a continuum of three phenotypes: familial cold autoinflammatory syndrome, Muckle-Wells syndrome, and neonatal-onset multisystem inflammatory disease. Distinguishing features include cutaneous, neurological, ophthalmologic, and rheumatologic manifestations. CAPS results from a gain-of-function mutation of the NLRP3 gene coding for cryopyrin, which forms intracellular protein complexes known as inflammasomes. Defects of the inflammasomes lead to overproduction of interleukin-1, resulting in inflammatory symptoms seen in CAPS. Diagnosis is often delayed and requires a thorough review of clinical symptoms. Remarkable advances in our understanding of the genetics and the molecular pathway that is responsible for the clinical phenotype of CAPS has led to the development of effective treatments. It also has become clear that the NLRP3 inflammasome plays a critical role in innate immune defense and therefore has wider implications for other inflammatory disease states.

Increased levels of circulating Annexin A5 in Familial Mediterranean fever.

Boyajyan AS(1), Mkrtchyan GM, Hovhannisyan LP, Hovsepian TJ.

Author information:

(1)Institute of Molecular Biology, National Academy of Sciences of the Republic of Armenia 7, Hasratyan St., Yerevan 0014, Armenia. aboyajyan@sci.am.

**BACKGROUND:** Familial Mediterranean fever is a genetic autoinflammatory disease most commonly affecting the ethnic groups originating from around the Mediterranean Sea. Apoptosis plays an important role in down-regulation of the inflammatory response by reducing the lifespan of activated immunocompetent cells. Thus, increased apoptosis may be associated with pathogenesis of familial Mediterranean fever.

**METHODS:** In the present study we determined the serum levels of apoptotic marker, Annexin A5, in familial Mediterranean fever patients, within an attack and attack-free, in comparison to healthy subjects and assessed the influence of colchicine treatment on this parameter. In addition, in all study subjects serum

levels of C-reactive protein and interleukine-1 $\beta$ , and the total leukocyte count were also determined.

**RESULTS:** Our results demonstrated that pathogenesis of familial Mediterranean fever is characterized by the increased levels of circulating Annexin A5, which is higher in patients within the attack and which associate with the increased levels of C-reactive protein and interleukine-1 $\beta$  and total leukocyte count.

**CONCLUSIONS:** The results obtained indicate elevated rates of apoptosis of subpopulations of leukocytes involved in autoinflammation and recurrent episodes of fever in familial Mediterranean fever. It was also revealed that regular colchicine treatment sufficiently decreases the rate of apoptosis in familial Mediterranean fever patients by affecting the intensity of autoinflammatory reactions.

Cytokines are essential coordinators of defensive immune responses for resolving the invasion of pathogens such as bacteria, virus, and fungi. However, dysregulated cytokines are the main cause of various autoinflammatory immune disorders such as rheumatoid arthritis, inflammatory bowel disease, and psoriasis. Interleukin-32 (IL-32) is a recently described cytokine and characterized as a proinflammatory cytokine. IL-32 stimulates monocytes and macrophages to induce important proinflammatory cytokines (IL-1 $\beta$ , IL-6, and TNF $\alpha$ ) and chemokines (IL-8 and MIP-2) by activating the NF- $\kappa$ B and p38 mitogen-activated

protein (MAP) kinase pathways. The biological activities of IL-32 are associated with epidemic pathogens, *Mycobacterium tuberculosis*, influenza A virus, and human immunodeficiency virus (HIV). IL-32 is transcribed as six alternative splice variants ( $\alpha$ ,  $\beta$ ,  $\gamma$ ,  $\delta$ ,  $\epsilon$ , and  $\zeta$ ), with IL-32 $\gamma$  being the most active isoform. However, it is unclear which isoform is related to specific disease activities since there are no high quality antibodies available to measure circulating IL-32 in biological samples of patients. Therefore, we developed specific anti-human IL-32 $\gamma$  monoclonal antibodies from recombinant human IL-32 $\gamma$ , which was expressed in *Escherichia coli*. The IL-32 $\gamma$  specific monoclonal antibodies recognized IL-32 in cell culture supernatants and serum of IL-32 $\gamma$  transgenic mice. The newly developed IL-32 $\gamma$  monoclonal antibodies will be a useful tool to measure IL-32 level in serum samples of various inflammatory diseases. These monoclonal antibodies will be helpful in investigating the precise function of IL-32 in immune responses and in autoinflammatory diseases.

**BACKGROUND:** The systemic autoinflammatory disorders (SAID) share many clinical manifestations, albeit with variable patterns, intensity and frequency. A common definition of disease activity would be rational and useful in the management of

these lifelong diseases. Moreover, standardised disease activity scores are required for the assessment of new therapies in constant development. The aim of this study was to develop preliminary activity scores for familial Mediterranean fever, mevalonate kinase deficiency, tumour necrosis factor receptor-1-associated periodic syndrome and cryopyrin-associated periodic syndromes (CAPS).

**METHODS:** The study was conducted using two well-recognised consensus formation methods: the Delphi technique and the nominal group technique. The results from a two-step survey and data from parent/patient interviews were used as preliminary data to develop the agenda for a consensus conference to build a provisional scoring system.

**RESULTS:** 24 of 65 experts in SAID from 20 countries answered the web questionnaire and 16 attended the consensus conference. There was consensus agreement to develop separate activity scores for each disease but with a common format based on patient diaries. Fever and disease-specific clinical variables were scored according to their severity. A final score was generated by summing the score of all the variables divided by the number of days over which the diary was completed. Scores varied from 0 to 16 (0-13 in CAPS). These scores were developed for the purpose of clinical studies but could be used in clinical practice.

**CONCLUSION:** Using widely recognised consensus formation techniques, preliminary scores were obtained to measure disease activity in four main SAID. Further prospective validation study of this instrument will follow.

Author information:

(1)First Department of Internal Medicine, Democritus University of Thrace, Alexandroupolis, Greece.

Familial Mediterranean fever (FMF) inflammatory attacks are often triggered by metabolic or physical stress. mTOR signaling and autophagy modulate cellular responses to metabolic danger signals. In this study, we investigated the implication of mTOR inhibition and autophagy in FMF pathophysiology. mTOR inhibition induced MEFV gene expression in polymorphonuclear cells (PMNs) from healthy individuals, whereas it had no effect on PMNs from attack-free FMF patients. A significant reduction in pyrin levels in PMNs from FMF patients after mTOR inhibition was also observed. Pyrin levels in control PMNs remained unaffected. Moreover, the basal autophagic status in PMNs from FMF patients was reduced, as indicated by the lower LC3B-II/I ratio and ATG mRNA expression levels. However, mTOR inhibition had similar effects on the induction of autophagy in the two groups. The differential pyrin expression after metabolic stress induction and the impaired basal autophagy suggest a potential role in the triggering of FMF attacks.

We report three familial cases of periodic fever with aphthous stomatitis, pharyngitis, and cervical adenitis syndrome, including a pair of monozygotic twins and their mother. It suggests that periodic fever with aphthous stomatitis, pharyngitis, and cervical adenitis syndrome may have a certain monogenetic background.

kolivras@gmail.com

A female newborn presented with a congenital urticarial rash that consisted of fluctuating well-demarcated pink or pale reddish macules or slightly raised papules and plaques. In addition, purulent cerebrospinal fluid was present in the absence of evidence of congenital infection. Skin biopsy revealed a sparse infiltrate throughout the entire dermis, including the eccrine adventitia. The infiltrate was composed mostly of neutrophils, but rarely lymphocytes and

eosinophils could also be seen. No vasculitis was present. Because of the presenting attributes, a diagnosis of cryopyrin-associated periodic syndrome (CAPS) was considered and the neonatal-onset multisystem inflammatory disorder (NOMID) that represents the most severe expression of the CAPS clinical spectrum was favored. Diagnosis was confirmed by identification of a mutation in the cold-induced autoinflammatory syndrome-1 gene and by an observed response to treatment with the interleukin-1 receptor antagonist anakinra. Both the clinical and histopathological findings of the presented case may represent a distinct entity within the spectrum of aseptic neutrophilic dermatitis. We refer to this spectrum as neutrophilic urticarial dermatosis (NUD), which may serve as a cutaneous marker of autoinflammation. NUD with perieccrine involvement should prompt consideration of CAPS, especially NOMID, in the context of neonatal multisystem disease.

Chronic inflammation in FMF: markers, risk factors, outcomes and therapy.

Ben-Zvi I(1), Livneh A.

Author information:

(1)Department of Medicine F, Sheba Medical Center, Tel-Hashomer 52621, Israel.

Familial Mediterranean fever (FMF) is the most common of the hereditary periodic fever syndromes. Although the typical clinical course of FMF is characterized by bouts of painful inflammation, this presentation represents only the tip of the iceberg. In many patients inflammation can persist in attack-free periods, as shown by high levels of acute-phase proteins, cytokines and inflammation-induced proteins. This subclinical inflammation puts patients at risk of developing complications such as anemia, splenomegaly, decreased bone mineral density, heart disease and life-threatening amyloid A amyloidosis, among others. In this article, we review the published data on markers and other factors involved in

the persistence of inflammation in patients with FMF during attack-free periods, examine the risk factors for the development of this subclinical inflammation, summarize the complications of chronic inflammation in FMF and propose a new strategy for treatment, based on these data.

Evaluation of nailfold capillaries in familial Mediterranean fever patients.

Aytekin S(1), Aydin F, Akpolat T, Senturk N, Turanli AY.

Author information:

(1)Department of Dermatology, Ondokuz Mayıs University School of Medicine, 55139 Kurupelit, Samsun, Turkey.

Familial Mediterranean fever (FMF) is an autosomal recessive disease characterized by recurrent inflammatory febrile attacks, abdominal, chest or joint pain, myalgia, and erysipelas-like skin lesions. Several types of vasculitis are associated with FMF such as polyarteritis nodosa and Henoch-Schönlein purpura. We aimed to determine microvascular abnormalities in FMF patients via nailfold capillaroscopy using a dermoscope. Thirty-one FMF patients were assessed; capillary enlargement, tortuosity, avascular areas and microhemorrhages were investigated. Capillary enlargement was found in five patients and microhemorrhages in one patient. Our study supports that nailfold capillary abnormalities, which are nonspecific, can be seen in FMF patients, but more studies are needed to clarify the importance of these findings.

Comment in

J Periodontol. 2012 Feb;83(2):140-2.

**BACKGROUND:** It has become increasingly clear in recent years that periodontal disease can cause a dramatic increase in the levels of markers of systemic inflammation, and that periodontal treatment can result in reduction in the levels of these markers. We have previously shown that the prevalence of moderate to severe periodontitis was significantly higher in patients with familial Mediterranean fever (FMF) with amyloidosis than in patients with FMF without amyloidosis. Thus, the aim of this study is to investigate if chronic periodontitis is associated with secondary amyloidosis in the Black Sea region of Turkey.

**METHODS:** A total of 112 patients with biopsy-proven secondary amyloidosis (59 patients with FMF, 40 patients who were either chronically infected or had malignant disease, 13 patients with periodontitis) and 22 healthy subjects, were included in this study. Periodontal health and disease were evaluated using gingival index (GI), papillary bleeding index (PBI), plaque index (PI), and periodontal disease index (PDI). The concentrations of serum acute phase reactants (APRs) were measured at baseline and at 4 to 6 weeks after completion of the non-surgical periodontal therapy.

**RESULTS:** The prevalence of moderate to severe periodontitis was 47.5% in patients with FMF, 72.5% in patients who were either chronically infected or had malignant disease, and 84.6% in patients with periodontitis. Serum levels of APRs in patients with amyloidosis were reduced significantly after non-surgical periodontal therapy ( $P < 0.01$ ).

**CONCLUSIONS:** Periodontitis can increase the levels of APRs and potentiate the development of amyloidosis either by themselves or association with traditional factors, such as FMF and other chronic inflammatory diseases. Thus, preventing or treating periodontitis might prevent or at least alleviate the progression of amyloidosis. Periodontal evaluation should be performed as part of a medical

assessment and considered as an etiologic factor for secondary amyloidosis.

Tumor suppressor death-associated protein kinase is required for full IL-1 $\beta$  production.

Chuang YT(1), Lin YC, Lin KH, Chou TF, Kuo WC, Yang KT, Wu PR, Chen RH, Kimchi A, Lai MZ.

Author information:

(1)Institute of Molecular Biology, Academia Sinica, Taipei, Taiwan, Republic of China.

Interleukin-1 $\beta$  (IL-1 $\beta$ ) is critical for inflammation and control of infection. The production of IL-1 $\beta$  depends on expression of pro-IL-1 $\beta$  and inflammasome component induced by inflammatory stimuli, followed by assembly of inflammasome to generate caspase-1 for cleavage of pro-IL-1 $\beta$ . Here we show that tumor suppressor death-associated protein kinase (DAPK) deficiency impaired IL-1 $\beta$  production in macrophages. Generation of tumor necrosis factor- $\alpha$  in macrophages, in contrast, was not affected by DAPK knockout. Two tiers of defects in IL-1 $\beta$  generation were found in DAPK-deficient macrophages: decreased pro-IL-1 $\beta$  induction by some stimuli and reduced caspase-1 activation by all inflammatory stimuli examined. With a normal NLRP3 induction in DAPK-deficient macrophages, the diminished caspase-1 generation is attributed to impaired inflammasome assembly. There is a direct binding of DAPK to NLRP3, suggesting an involvement of DAPK in inflammasome formation. We further illustrated that the formation of NLRP3 inflammasome in situ induced by inflammatory signals was impaired by DAPK deficiency. Taken together, our results identify DAPK as a molecule required for full production of IL-1 $\beta$  and functional assembly of the NLRP3 inflammasome. In addition, DAPK knockout reduced uric acid crystal-triggered peritonitis, suggesting that DAPK may serve as a target in the treatment of IL-1 $\beta$ -associated autoinflammatory diseases.

Distribution of 42-bp variable tandem repeat polymorphism of the cold-induced autoinflammatory syndrome 1 (CIAS1) gene in eight human populations.

Omi T(1), Koda Y, Soejima M, Munkhtulga L, Iwamoto S.

Author information:

(1)Department of Basic Science, School of Veterinary Nursing and Technology, Faculty of Veterinary Science, Nippon Veterinary and Life Science University, Musashisakai, Tokyo, Japan. t.omi@nvlu.ac.jp

We recently identified a 42bp Variable Number of Tandem Repeats polymorphism in intron 4 of Cold-induced autoinflammatory syndrome 1 gene (CIAS1 42bp-VNTR), which are associated with CIAS1 gene expression and some inflammatory disease. The aim of our study is to investigate whether variability of CIAS1 42bp-VNTR allele is difference among races. A total of 1291 subjects from 7 populations (178 Chinese, 95 Korean, 614 Mongolian, 49 Bangladesh, 72 Sri Lanka, 192 African and 91 European) was genotyped on CIAS1 42bp-VNTR polymorphism, which was also compared to previous genotyping data from 508 Japanese subjects. A total of 11 genotypes and 5 alleles were found in 8 populations. The range of allele frequencies of CIAS1\*6, CIAS1\*7, CIAS1\*9, CIAS1\*12, and CIAS1\*13 were 0.000-0.167, 0.056-0.248, 0.008-0.203, 0.570-0.923, and 0.000-0.104 in eight populations. The CIAS1\*12 was the most common allele among all populations. The longest allele CIAS1\*13 in African population was extremely high frequent at 0.104 compared to other population. While shortest allele CIAS1\*6 was not observed Sri Lankan and African. Frequency (0.924) in the Sri Lankan population. These results showed that the CIAS1 42bp-VNTR polymorphism could represent genetic diversity among different human populations.

**HISTORY AND ADMISSION FINDINGS:** A 37-year old patient was admitted with upper abdominal pain, vomiting and diarrhea. A 38-year-old patient was admitted for liver failure.

**INVESTIGATIONS:** Case 1 was diagnosed with an AL amyloidosis due to deposition of the immunoglobulin light chain kappa in all tissues analyzed. In the bone marrow plasma cells were increased to 20-30%. Case 2 suffered from AA amyloidosis secondary to familial mediterranean fever and underwent dialysis treatment for years. He was positive for hepatitis B and C.

**DIAGNOSIS, TREATMENT AND COURSE:** Patient 1 developed refractory nephrotic syndrome and low blood pressure. During hemodialysis circulatory failure occurred and she died during resuscitation. In patient 2 a flare of chronic hepatitis B was found and treated with antiviral therapy. He was referred to ICU for rectal bleeding and developed pulmonary arrest. After resuscitation he died because of lactate acidosis and refractory circulatory failure. Both cases were subjected to autopsy.

**CONCLUSIONS:** The vast majority (90%) of amyloidoses are due to acquired AA or AL amyloidosis. Prognosis remains poor, in particular when cardiac and vascular involvement occurs.

Our study is to determine the expression of thyroid hormone, sex hormone, insulin, and C-peptide in Chinese male patients with thyrotoxic periodic paralysis (TPP). This study covered 102 patients with hyperthyroidism from Xijing Hospital. According to whether occurrence of TPP or not, patients were divided into two groups (those that were hyperthyroid with and without TPP) that were matched with age, blood pressure, urea, and creatinine. We found the body mass index (BMI) in patients with TPP was higher than that in pure hyperthyroidism patients. The levels of the total thyroxine (T4), free triiodothyronine (FT3), and free thyroxine (FT4) were significantly lower in patients with TPP compared with pure hyperthyroidism patients, while serum testosterone levels were higher compared with pure hyperthyroidism patients. Moreover, after glucose administration, the concentration of insulin at 60, 120, and 180 min were significantly higher in patients with TPP than those in pure hyperthyroidism patients. The insulin area under the curve (AUC) was significantly increased in patients with TPP compared with pure hyperthyroidism patients. The levels of thyroid hormone, sex hormone, and insulin were different in Chinese male patients with TPP compared to those with only hyperthyroidism.

Treatment of autoinflammatory syndromes.

Gattorno M(1), Martini A.

Author information:

(1)UO Pediatria II, G. Gaslini Institute, Genova, Italy.

**PURPOSE OF REVIEW:** Inherited autoinflammatory diseases are experiments in nature in which mutations of proteins playing a pivotal role in the regulation of the innate immunity lead to unprovoked episodes of inflammation. The understanding of the molecular pathways involved in these disorders has shed a new light on the pattern of activation and maintenance of the inflammatory response and disclosed new molecular therapeutic targets. In this review, we outline the more recent novelties in the treatment of autoinflammatory diseases and their possible implications for some multifactorial pediatric conditions.

**RECENT FINDINGS:** Cryopyrin-associated periodic syndrome (CAPS) represents the prototype of autoinflammatory diseases. The study of the pathophysiological consequence of mutations of the cryopyrin gene (NLRP3) allowed the identification of the intracellular pathways thought to play a pivotal part in the activation and secretion of the potent inflammatory cytokine interleukin (IL)-1 $\beta$ . The dramatic effect of IL-1 blockade in CAPS opens new perspectives for the treatment of other inherited and multifactorial inflammatory disorders. A number of IL-1 blockers are now available on the market.

**SUMMARY:** Studies on the pathogenesis and treatment of inherited autoinflammatory diseases are also changing the approach to some multifactorial inflammatory conditions.

Periodic peritonitis due to familial Mediterranean fever in a patient with systemic lupus erythematosus.

Matsuda M(1), Kishida D, Tsuchiya-Suzuki A, Fukushima K, Shimojima Y, Yazaki M, Ikeda S.

Author information:

(1)Department of Medicine (Neurology and Rheumatology), Shinshu University School of Medicine, Matsumoto. matsuma@shinshu-u.ac.jp

We report a patient with systemic lupus erythematosus (SLE) who showed periodic peritonitis with spontaneous remission. She showed compound heterozygous mutations in the MEFV gene, leading to the diagnosis of familial Mediterranean fever (FMF). Oral colchicine successfully reduced the severity and frequency of her peritonitis. SLE occasionally manifests abdominal symptoms, but in cases with periodic peritonitis, associated FMF should be considered as a possible cause.

Canakinumab for treatment of cryopyrin-associated periodic syndrome.

Feist E(1), Burmester GR.

Author information:

(1)Department of Rheumatology and Clinical Immunology, Charité - Universitätsmedizin Berlin, Charitéplatz 1, D-10117 Berlin, Germany. gerd.burmester@charite.de

**IMPORTANCE OF THE FIELD:** Autoinflammatory syndromes such as cryopyrin-associated periodic syndromes (CAPS) place a heavy burden on affected individuals as well as on their families due to significant morbidity and increased mortality. The inflammatory response in CAPS is caused by an overwhelming activation of the pro-inflammatory cytokine IL-1, which was identified as a promising treatment target.

**AREAS COVERED IN THIS REVIEW:** This article focuses on the pathogenic background and different clinical manifestations in CAPS. Furthermore, the development program and characteristics of canakinumab, a recently approved fully human anti-IL-1 $\beta$  mAb for the treatment of CAPS, are described and compared to other available IL-1 blocking agents.

**WHAT THE READER WILL GAIN:** Canakinumab targets selectively human IL-1 $\beta$  with high affinity and prevents the cytokine from interaction to its receptor and, thus, effectively blocks the inflammatory response in CAPS. In all studies performed, canakinumab showed a rapid improvement of symptoms of CAPS and a complete clinical response was achieved in most patients. Inflammatory markers such as C-reactive protein and serum amyloid-A protein were reduced to normal levels within few days. In comparison to other IL-1 blockers, canakinumab provides a longer plasma half-life and less injection site reactions.

**TAKE HOME MESSAGE:** Canakinumab offers the possibility of permanent disease control, almost symptom-free life, and hopefully less long-term morbidity and mortality in patients with CAPS.

AA type renal amyloidosis secondary to FMF: a long-term follow-up in two patients.

Aybal Kutlugün A(1), Yildirim T, Altindal M, Arici M, Yasavul U, Turgan C.

Author information:

(1)Department of Nephrology, Faculty of Medicine, Hacettepe University, Ankara, Turkey. draysunaybal@yahoo.com

Renal amyloidosis, which leads to renal failure, is the most important long-term

complication of familial Mediterranean fever (FMF). Resolution of nephrotic syndrome secondary to amyloidosis in FMF following colchicine treatment has rarely been reported. We describe two patients with FMF and nephrotic syndrome. These patients were treated with colchicine 1.5 mg/day and had a complete remission of nephrotic syndrome with a stable clinical course over 30 years. To our knowledge, our patients have the longest follow-up time without proteinuria.

Fevers and the rheumatologist.

Manners PJ(1), Guttinger R.

Author information:

(1)School of Paediatrics and Child Health, University of Western Australia, c/- Princess Margaret Hospital for Children, Perth, Australia.  
pmanners@meddent.uwa.edu.au

Fevers in children are mainly due to infection, malignancy or inflammatory conditions. Rheumatologists have an important role in the care of inflammatory conditions, many of which are associated with fevers. Seven conditions, the hereditary recurrent fever syndromes, have been defined with the presenting symptom of recurring fever, and for which mutation of a single gene has been defined: Chronic infantile neurological articular syndrome (CINCA), Familial cold autoinflammatory syndrome (FACS), Familial Mediterranean fever (FMF), hyperimmunoglobulinemia D (HIDS), Muckle-Wells syndrome (MWS), Pyogenic sterile arthritis and Pyoderma gangrenosum (PAPA) and Tumour necrosis factor receptor-associated periodic syndrome (TRAPS) . These conditions will be discussed in detail in regard to how they fit into the wider picture of pediatric rheumatological conditions, how the diagnoses may be established and the current recommended treatments for each condition.

BACKGROUND AND PURPOSE: Oxidized low-density lipoprotein (oxLDL) induces endothelial dysfunction and antibody formation. Because endothelial dysfunction

is involved in cerebral small vessel disease (CSVD) (dilated Virchow Robin spaces, lacunar infarcts, and white matter lesions), oxLDL antibodies could play a role in CSVD pathogenesis. Therefore, we studied oxLDL antibodies in patients with high prevalence of CSVD: lacunar stroke patients and essential hypertensive patients.

**METHODS:** A total of 158 lacunar stroke patients, 158 hypertensive patients, and 43 healthy controls were included. We determined levels of IgG and IgM against hypochlorite (HOCl) and malondialdehyde (MDA) oxLDL using ELISA (values in optical density).

**RESULTS:** Patients with CSVD had higher levels of IgG-HOCl-oxLDL (0.77 versus 0.70;  $P < 0.01$ ), as well as lower levels of IgM-MDA-oxLDL (0.55 versus 0.65;  $P < 0.05$ ) than patients without such lesions. Higher IgG-HOCl-oxLDL levels were only independently associated with higher numbers of Virchow Robin spaces at the level of the basal ganglia ( $\beta = 0.218$ ;  $P < 0.001$ ).

**CONCLUSIONS:** An autoinflammatory process with lower levels of IgM antibodies and higher levels of IgG antibodies against oxLDL may be involved in CSVD.

Role of etanercept in the treatment of tumor necrosis factor receptor-associated

periodic syndrome: personal experience and review of the literature.

Cantarini L, Rigante D, Lucherini OM, Cimaz R, Laghi Pasini F, Baldari CT, Benucci M, Simonini G, Di Sabatino V, Brizi MG, Galeazzi M.

Tumor necrosis factor-alpha receptor (TNFR1)-associated periodic syndrome (TRAPS) is the most common autosomal-dominant autoinflammatory condition and is caused by mutations in the TNFRSF1A gene. TRAPS is characterized by recurrent attacks of fever typically lasting from 1 to 3 weeks; in addition to fever, common clinical features include mainly periorbital oedema, conjunctivitis, a migratory erythematous plaque simulating erysipela with underlying myalgia, and arthritis or arthralgia; serosal membrane inflammation is also possible. The identification of TNFRSF1A mutations as the genetic cause of TRAPS coincided with the wider use of biological agents in medicine and raised the possibility that blocking TNF could potentially represent the primary therapeutic goal in TRAPS, thus disclosing new treatment choices for this complex disease. In the past few years, isolated reports and case-series have been published suggesting that inhibition of TNF-alpha might represent a promising therapeutic approach in TRAPS. We present here our experience with etanercept in the treatment of patients affected with TRAPS, and we also add a review of the literature.

OBJECTIVE: To describe the most prevalent pediatric hereditary autoinflammatory

syndromes.

SOURCES: A review of the literature including relevant references from the PubMed and SciELO was carried out using the keywords autoinflammatory syndromes and child.

SUMMARY OF THE FINDINGS: The hereditary autoinflammatory syndromes are caused by monogenic defects of innate immunity and are classified as primary immunodeficiencies. These syndromes are characterized by recurrent or persistent systemic inflammatory symptoms and must be distinguished from infectious diseases, autoimmune diseases, and other primary immunodeficiencies. This review describes the epidemiological, clinical and laboratory features, prognosis, and treatment of the main autoinflammatory syndromes, namely: familial Mediterranean fever; TNF receptor associated periodic syndrome; the cryopyrinopathies; mevalonate kinase deficiency; pediatric granulomatous arthritis; pyogenic arthritis, pyoderma gangrenosum and acne syndrome; Majeed syndrome; and deficiency of interleukin 1 receptor antagonist. The cryopyrinopathies discussed include neonatal-onset multisystem inflammatory disease (also known as chronic infantile neurologic, cutaneous and articular syndrome), Muckle-Wells syndrome, and familial cold autoinflammatory syndrome.

CONCLUSIONS: Pediatricians must recognize the clinical features of the most prevalent autoinflammatory syndromes. Early referral to a pediatric rheumatologist may allow early diagnosis and institution of treatment, with improvement in the quality of life of these patients.

Familial Mediterranean fever in a large Lebanese family: multiple MEFV mutations and evidence for a Founder effect of the p.[M694I] mutation.

Medlej-Hashim M(1), Chouery E, Salem N, Delague V, Lefranc G, Loiselet J, Mégarbané A.

Author information:

(1)Unité de Génétique Médicale et Laboratoire Associé INSERM à l'Unité UMR\_S 910, Faculté de Médecine, Université Saint Joseph, Beirut, Lebanon.

Familial Mediterranean fever (FMF) is an autoinflammatory autosomal recessive disease characterized by recurrent fever crises and serous inflammation. The MEFV gene responsible for the disease was identified on chromosome 16, and 5 of the mutations discovered so far in the gene are most frequently encountered in FMF patients: p.[M694V], p.[V726A], p.[M680I] and p.[M694I] in exon 10, and p.[E148Q] in exon 2. The present work describes multiple MEFV mutations and the corresponding haplotypes for 31 FMF patients as well as 32 "healthy" individuals of a large consanguineous Lebanese family. The DNAs were screened for MEFV mutations, and determination of the corresponding haplotypes was performed for all individuals by genotyping 4 microsatellites surrounding the gene. Five different mutations were detected in this one family, which is unexpected in such a genetic isolate. A phenotypic variability was also observed. The haplotype carrying the p.[M694I] allele, detected in all the family branches, was well conserved and therefore seems to be the ancestral one.

The role of the pro-apoptotic protein Siva in the pathogenesis of Familial Mediterranean fever: A structural and functional analysis.

Goulielmos GN(1), Petraki E, Vassou D, Eliopoulos E, Iliopoulos D, Sidiropoulos P, Aksentijevich I, Kardassis D, Boumpas DT.

Author information:

(1)Laboratory of Molecular Medicine and Human Genetics, Department of Medicine, University of Crete, Heraklion, Greece. [goulielmos@med.uoc.gr](mailto:goulielmos@med.uoc.gr)

Familial Mediterranean fever (FMF) is an autosomal, recessive disease, attributed to mutations in MEFV gene encoding pyrin, which is characterized by recurrent, acute and self-limiting attacks of fever as well as an increased neutrophil and

monocyte apoptosis. Most disease-associated mutations in MEFV gene reside on the C-terminal PRYSPRY (B30.2) domain of pyrin, an area found to interact with the pro-apoptotic protein Siva. Because apoptotic events may be contributing to endogenous inflammation we hypothesized that mutations in pyrin may affect Siva-mediated apoptosis. The confirmation of this hypothesis would be of a great biological significance since it would be demonstrated a connection between apoptosis and inflammation. We used homology modeling to construct a 3-D model of Siva protein and the constructed model of Siva defined structural elements with potential of binding other proteins to induce apoptosis. Given that Siva protein binds pyrin as shown by transfection and immunoprecipitation experiments, apoptosis was assessed by FACS and Western blotting. No differences in rates of apoptosis in myeloid cells (THP-1) upon transfection with either wt pyrin or mutant forms of pyrin were found. Patients with FMF did not display any mutations in the Siva-1 (full length) gene. Siva-1 was not linked to pyrin in the major predicted FMF gene network constructed using a literature-curated gene signature for FMF. These results suggest that Siva-mediated unprovoked apoptosis is not likely to be involved in the pathogenesis of FMF.

(1)Department of Nephrology, Ankara Education and Research Hospital, Ankara, Turkey. gulaykad@hotmail.com

Eosinophilic gastroenteritis (EG) is an uncommon gastrointestinal disease affecting both children and adults. The underlying molecular mechanism predisposing to the clinical manifestation of eosinophilic gastroenteritis is unknown. A 39-year-old man who was followed up with the diagnosis of familial Mediterranean fever (FMF) was admitted to our clinic with diarrhea, abdominal

pain, and weight loss. After endoscopic and colonoscopic examinations EG was diagnosed by histopathological examination. Symptoms were resolved with the treatment of budesonide. To our knowledge, this is the first reported case of EG with the MEFV gene mutations in the literature.

Successful modulation of type 2 diabetes in db/db mice with intra-bone marrow--bone marrow transplantation plus concurrent thymic transplantation.

Li M(1), Abraham NG, Vanella L, Zhang Y, Inaba M, Hosaka N, Hoshino S, Shi M, Ambrosini YM, Gershwin ME, Ikehara S.

Author information:

(1)Department of Stem Cell Disorders, Kansai Medical University, Moriguchi City, Osaka 570-8506, Japan.

There is increasing evidence that both autoimmune and autoinflammatory mechanisms are involved in the development of not only type 1 diabetes mellitus (T1 DM), but also type 2 diabetes mellitus (T2 DM). Our laboratory has focused on this concept, and in earlier efforts replaced the bone marrow cells (BMCs) of leptin

receptor-deficient (db/db) mice, an animal model of T2DM, with those of normal C57BL/6 (B6) mice by IBM-BMT. However, the outcome was poor due to incomplete recovery of T cell function. Therefore, we hypothesized that intra-bone marrow-bone marrow transplantation plus thymus transplantation (IBM-BMT + TT) could be used to treat T2 DM by normalizing the T cell imbalance. Hence we addressed this issue by using such dual transplantation and demonstrate herein that seven weeks later, recipient db/db mice manifested improved body weight, reduced levels of blood glucose, and a reduction of plasma IL-6 and IL-1 $\beta$ . More importantly, this treatment regimen showed normal CD4/CD8 ratios, and increased plasma adiponectin levels, insulin sensitivity, and the number of insulin-producing cells. Furthermore, the expression of pancreatic pAKT, pLKB1, pAMPK and HO-1 was increased in the mice treated with IBM-BMT + TT. Our data show that IBM-BMT + TT treatment normalizes T cell subsets, cytokine imbalance and insulin sensitivity in the db/db mouse, suggesting that IBM-BMT + TT is a viable therapeutic option in the treatment of T2 DM.

Author information:

(1)Department of Pediatric Neurology and Developmental Medicine, Dr von Haunersches Children's Hospital, Ludwig-Maximilians University, Munich, Germany. astrid.blaschek@med.uni-muenchen.de

We report a 16-year-old female patient with a severe course of multiple sclerosis and concomitant symptoms suggestive of a hereditary autoinflammatory disease.

Genetic analyses revealed that she inherited a TNFRSF1A R92Q mutation from her mother and a pyrin E230K mutation from her father. To our knowledge, this is the first report of a patient with severe childhood multiple sclerosis and mutations in two genes which predispose to hereditary autoinflammatory disorders. We speculate that these mutations contribute to early multiple sclerosis manifestation and enhance the inflammatory damage inflicted by the autoimmune response.

Inflammasome-mediated autoinflammatory disorders.

Wilson SP(1), Cassel SL.

Author information:

(1)Division of Allergy and Immunology, Department of Internal Medicine, University of Iowa Hospitals and Clinics, 200 Hawkins Drive, Iowa City, IA 52242, USA.

The nucleotide-binding domain leucine-rich repeat containing (NLR) family of receptors are members of the innate immune system, and have a critical role in host defense. These molecules are key to driving inflammatory responses to abnormal cellular conditions. Many NLRs serve this role on activation by forming a multiprotein complex called an inflammasome. The inflammasome drives the processing and release of cytokines, such as the proinflammatory cytokines interleukin (IL)-1 $\beta$  and IL-18. Recently, the important function of NLR molecules in autoinflammatory disorders has been recognized, in part through the identification of the role of IL-1 $\beta$  in the pathogenesis of several autoinflammatory diseases. Cryopyrin-associated periodic syndromes were the first autoinflammatory disorders found to be directly mediated by dysfunctional inflammasome activation. This finding has subsequently led to studies in both murine models and humans that have revealed several other inflammatory conditions associated with activation of NLR-containing inflammasomes. Understanding the molecular pathophysiology of these autoinflammatory disorders has further guided the successful development of targeted therapy against IL-1. In this review, we

provide an overview of the inflammasomes and describe the important role they play in the development and manifestation of autoinflammatory diseases.

The molecular basis of autosomal recessive diseases among the Arabs and Druze in Israel.

Zlotogora J(1).

Author information:

(1)Department of Community Genetics, Public Health Services, Ministry of Health Israel, Building 67, Sheba Medical Center, Tel Hashomer, 52621 Ramat Gan, Israel. joelz@cc.huji.ac.il

The Israeli population mainly includes Jews, Muslim and Christian Arabs, and Druze. In the last decade, data on genetic diseases present in the population have been systematically collected and are available online in the Israeli national genetic database ( <http://www.goldenhelix.org/server/israeli> ). In the non-Jewish population, up to 1 July 2010, the database included molecular data on six diseases relatively frequent in the whole population: thalassemia, familial Mediterranean fever (FMF), cystic fibrosis, deafness, phenylketonuria and congenital adrenal hyperplasia, as well as data on 195 autosomal recessive diseases among Muslim Israeli Arabs, 11 among the Christian Arabs and 31 among Druze. A single mutation was characterized in 149 out of the 238 rare disorders for which the molecular basis was known. In many diseases, mutation had never been observed in any other population and was present in one family only suggesting that it occurred as a de novo event. In other diseases, the mutation was present in more than one community or even in other populations such as Bedouins from the Arab peninsula or Christians from Lebanon. In the 89 other disorders, more than one mutation was characterized either in the same gene or in more than one gene. While it is probable that most of these cases represent random events in some cases such as Bardet Biedl among the Bedouins, the reason

may be a selective advantage to the heterozygotes.

Familial Mediterranean fever (FMF) is an autosomal recessive disorder characterized by recurrent attacks of febrile peritonitis, pleuritis and synovitis. Arthritis is a common and important feature of FMF. The clinical spectrum of arthritis in 71 FMF patients was retrospectively investigated. Mutations in the familial Mediterranean (MEFV) gene were screened. Unlike the previous reports on arthritis of FMF, most of the FMF patients (59%) in this study had symmetric two-joint arthritis whereas monoarticular, oligoarticular and polyarticular arthritis was presented in 20, 8 and 10% of the patients, respectively. Knees were affected in 45 (63%) patients, ankles in 30 (42%), elbows in 11 (15%), wrists in 12 (17%), hips in 12 (17%), small joints of the hands 7 (10%), small joints of the feet 2 (3%) and sacroiliac in 1 (1%). Destruction of the hip was observed in 2 (3%) patients and required hip replacement. Amyloidosis developed in 2 (3%) of our patients. Mutations in the MEFV gene were identified in 50 (71%) patients and the most dominant mutation detected was M694V (64%). Since FMF can be diagnosed by a simple DNA mutation analysis, all arthritis patients of certain origins (Arabs, Turks, Armenians and Jews) should be tested for FMF in order to prevent the complications (amyloidosis and protracted arthritis) by introducing colchicine which is the treatment of choice for FMF.

**OBJECTIVE:** Periodic fever, aphthous stomatitis, pharyngitis, and adenopathy (PFAPA) syndrome is a sporadic disease, characterized by periodic attacks of inflammation. Mutations in the MEFV, the gene associated with familial Mediterranean fever (FMF), may lead to subclinical inflammation in asymptomatic carriers and modify the phenotype of some inflammatory diseases. We aimed at investigating the effect of MEFV gene mutations on disease phenotype in PFAPA.

**PATIENTS AND METHODS:** The cohort of this ongoing prospective study consisted of 124 children with PFAPA syndrome, followed in a single referral center, who were tested for MEFV mutations. Demographic data, clinical characteristics, and disease course of 65 PFAPA patients with and 59 without MEFV mutations (M+ and M-, respectively) were compared.

**RESULTS:** PFAPA attacks in carriers of MEFV mutations were shorter compared with patients without mutations ( $3.8 \pm 1.7$  versus  $4.8 \pm 1.9$  days,  $P < 0.01$ ). The difference was more pronounced in those carrying the M694V mutation. In M+ patients, the rates of patients with regularity of their attacks (49.2%) and oral aphthae (24.6%) were lower, compared with M- patients (74.5% and 43.9%, respectively,  $P < 0.05$  for each of the 2 comparisons). M+ patients needed a lower corticosteroid (beclomethasone) dose to abort the attacks ( $0.16 \pm 0.07$ mg/kg versus  $0.19 \pm 0.08$ ,  $P = 0.028$ ). No differences were observed in all other clinical and laboratory parameters, over a follow-up period of 4.3 years.

**CONCLUSION:** In PFAPA, MEFV is a modifier gene associated with an attenuated disease severity.

**BACKGROUND:** This study aimed to profile levels of blood cells and serum cytokines during afebrile and febrile phases of periodic fever, aphthous stomatitis, pharyngitis and adenitis (PFAPA) syndrome to advance pathophysiological understanding of this pediatric disease.

**METHODS:** A cohort of patients with a median age of 4.9 years experiencing 'typical PFAPA' episodes participated in this study. Blood cells and serum cytokines were analyzed by CBC analysis and multiplex ELISA.

**RESULTS:** Oscillations in the concentration of blood cells during the afebrile and

febrile phases of typical PFAPA syndrome were observed; novel findings include increased monocytes and decreased eosinophils during a febrile episode and increased thrombocytes in the afebrile interval. Relatively modest levels of pro-inflammatory cytokines were present in sera. IFN $\gamma$ -induced cytokine IP10/CXCL10 was increased after the onset of fever while T cell-associated cytokines IL7 and IL17 were suppressed during afebrile and febrile periods. CONCLUSIONS: Identification of dysregulated blood cells and serum cytokines is an initial step towards the identification of biomarkers of PFAPA disease and/or players in disease pathogenesis. Future investigations are required to conclusively discern which mediators are associated specifically with PFAPA syndrome.

Upon activation, neutrophils release DNA fibers decorated with antimicrobial

proteins, forming neutrophil extracellular traps (NETs). Although NETs are bactericidal and contribute to innate host defense, excessive NET formation has been linked to the pathogenesis of autoinflammatory diseases. However, the mechanisms regulating NET formation, particularly during chronic inflammation, are poorly understood. Here we show that the G protein-coupled receptor (GPCR) CXCR2 mediates NET formation. Downstream analyses showed that CXCR2-mediated NET formation was independent of NADPH oxidase and involved Src family kinases. We show the pathophysiological relevance of this mechanism in cystic fibrosis lung disease, characterized by chronic neutrophilic inflammation. We found abundant NETs in airway fluids of individuals with cystic fibrosis and mouse cystic fibrosis lung disease, and NET amounts correlated with impaired obstructive lung function. Pulmonary blockade of CXCR2 by intra-airway delivery of small-molecule antagonists inhibited NET formation and improved lung function in vivo without affecting neutrophil recruitment, proteolytic activity or antibacterial host defense. These studies establish CXCR2 as a receptor mediating NADPH oxidase-independent NET formation and provide evidence that this GPCR pathway is operative and druggable in cystic fibrosis lung disease.

Compromized geranylgeranylation of RhoA and Rac1 in mevalonate kinase deficiency.

Henneman L(1), Schneiders MS, Turkenburg M, Waterham HR.

Author information:

(1)Department of Clinical Chemistry, Academic Medical Center, University of Amsterdam, Amsterdam, The Netherlands.

Mevalonate kinase deficiency (MKD) is an autoinflammatory disorder caused by mutations in the MVK gene resulting in decreased activity of the enzyme mevalonate kinase (MK). Although MK is required for biosynthesis of all isoprenoids, in MKD, in particular, the timely synthesis of geranylgeranyl pyrophosphate appears to be compromised. Because small guanosine triphosphatases (GTPases) depend on geranylgeranylation for their proper signaling function, we

studied the effect of MK deficiency on geranylgeranylation and activation of the two small GTPases, RhoA and Rac1. We demonstrate that both geranylgeranylation and activation of the two GTPases are more easily disturbed in MKD cells than in control cells when the flux through the isoprenoid biosynthesis pathway is suppressed by low concentrations of simvastatin. The limited capacity of geranylgeranylation in MKD cells readily leads to markedly increased levels of nonisoprenylated and activated GTPases, which will affect proper signaling by these GTPases.

During the last decades the description of autoinflammatory syndromes induced great interest among the scientific community. Mainly rheumatologists, immunologists and pediatricians are involved in the discovery of etiopathogenesis of these syndromes and in the recognition of affected patients. In this paper we will discuss the most important clues of monogenic and non-genetic inflammatory syndromes to help pediatricians in the diagnosis and treatment of these diseases.

A 64-year-old Egyptian man who resides in the United States presented to the rheumatology clinic with 6 months history of episodic recurrent pauci--arthritis along with constitutional symptoms. His Mediterranean ancestry, anti-cyclic citrullinated peptide negativity, and cyclical palindromic rheumatism prompted an investigation for familial Mediterranean fever gene mutation. He was found to have heterozygous 694I gene mutation during MEFV analysis. He also met Liveneh 1 major and 1 minor criteria for the diagnosis of familial Mediterranean fever.

A rare presentation of familial mediterranean Fever; acute scrotum and hydrocele amyloidosis.

Yilmaz R(1), Ozer S.

Author information:

(1)Department of Pediatrics, School of Medicine Gaziosmanpasa University Tokat, Turkey.

**BACKGROUND:** Familial Mediterranean Fever (FMF) is a genetic disease characterized by recurrent febrile attacks and inflammation of serous membranes. Amyloidosis is frequent in untreated FMF patients and is also the most important complication of FMF. It is generally seen with renal, hepatic, gastrointestinal, spleen, testicular and thyroidal involvement.

**CASE PRESENTATION:** Herein, we report a case with acute scrotum and hydrocele amyloidosis as a presenting finding in a child with FMF.

**CONCLUSION:** Although the acute scrotum and scrotal swelling are not characteristic clinical features of FMF, this genetic disease should not be forgotten in the differential diagnosis of acute scrotum in patients of Mediterranean origins.

The periodic syndromes represent a heterogeneous group of disorders that can be very difficult for practicing physicians to diagnosis and treat. This article presents an orderly approach to hyperimmunoglobulin D syndrome; tumor necrosis factor receptor-1 periodic syndrome; familial Mediterranean fever; periodic fever with aphthous stomatitis, pharyngitis, and adenitis syndrome; and cryopyrin-associated periodic syndromes by highlighting the disease presentation, diagnosis, pathogenesis, and treatment. Recent advances are also discussed.

**OBJECTIVE:** Muckle-Wells syndrome (MWS) is an inherited autoinflammatory disease resulting in excessive interleukin-1 release. It is unknown whether demographic, clinical, or laboratory characteristics at the time of diagnosis may identify patients who are at high risk for severe disease activity. This study was undertaken to analyze clinical and laboratory features of MWS, compare genetically defined subcohorts, and identify risk factors for severe MWS.

**METHODS:** A multicenter cohort study of consecutive MWS patients was performed. Parameters assessed included clinical features, MWS Disease Activity Score (MWS-DAS), inflammation markers, and cytokine levels. E311K mutation-positive patients were compared with E311K mutation-negative patients. Putative risk factors for severe MWS (defined as an MWS-DAS score of  $\geq 10$ ) were assessed in

univariate analyses, and significant predictors were entered into a multivariate model.

**RESULTS:** Thirty-two patients (15 male and 17 female) were studied. The most frequent organ manifestations were musculoskeletal symptoms and eye and skin disorders. Renal disease and hearing loss were seen in >50% of the patients.

Genetically defined subcohorts had distinct phenotypes. Severe disease activity was documented in 19 patients (59%). Predictors of severe MWS identified at the time of diagnosis were female sex, hearing loss, musculoskeletal disease, increased erythrocyte sedimentation rate, and low hemoglobin level. Female sex and hearing loss remained significant after adjustment for age in a multivariate model (relative risk 1.8 and 2.6, respectively).

**CONCLUSION:** MWS patients at high risk for severe disease can be identified at the time of diagnosis. Female patients presenting with hearing loss have the highest likelihood of manifesting severe MWS and should be considered a high-risk group.

Amyloidosis is the major complication of familial Mediterranean fever (FMF). Toll-like receptors (TLR) are involved in the activation of an innate immune system TLR-2 and TLR-4 recognize lipoteichoic acid and lipopolysaccharides (LPS), respectively. While TLR-2 Arg753Gln polymorphism upregulates, TLR-4 Asp299Gly and Thre399Ile polymorphisms downregulate inflammation. We investigated the effect of these polymorphisms on the development of amyloidosis in FMF patients. We also investigated myeloid cell TLR-2 and TLR-4 expressions in these patients. We studied 26 FMF patients and 13 FMF patients with amyloidosis. TLR-2 Arg753Gln and TLR-4 Asp299Gly and Thr399Ile polymorphisms were analyzed with the polymerase chain reaction-restriction fragment length polymorphism method. Myeloid cell baseline TLR-2 and TLR-4 and LPS-induced TLR-4 expressions were evaluated. The TLR-2 and TLR-4 polymorphism rate was compared with the results of 100 healthy subjects in our previous study. In addition, 13 healthy controls were enrolled for leukocyte TLR-2 and TLR-4 expressions. Serum amyloid A (SAA) levels were measured in these 13 control cases and in FMF patients during attack-free periods. The frequency of TLR-2 Arg753Gln, TLR-4 Asp299Gly, and Thr399Ile polymorphisms in healthy controls in our previous study were 1%, 3%, and 2%, respectively. The frequency of these polymorphisms were not different in FMF patients (with or without amyloidosis) compared to the control group. Likewise, myeloid cell TLR-2 and TLR-4 expressions were not different among the controls

and FMF patients. However, LPS-induced TLR-4 expression in granulocytes was more prominent in FMF patients. There was no correlation between TLR-2 and TLR-4 expressions and SAA levels. Neither myeloid cell TLR-2 and TLR-4 expressions nor TLR-2 Arg753Gln, TLR-4 Asp299Gly, and Thr399Ile polymorphisms seem to affect the development of secondary amyloidosis in FMF patients in our study population.

Hyperimmunoglobulinemia D and periodic fever syndrome in children. Review on therapy with biological drugs and case report.

Korppi M(1), Van Gijn ME, Antila K.

Author information:

(1)Pediatric Research Centre, Tampere University and University Hospital, Finland. matti.korppi@uta.fi

Hyperimmunoglobulinemia D syndrome (HIDS) is a rare, autosomal recessively inherited autoinflammatory disease caused by mutations in the mevalonate kinase gene. HIDS usually starts in infancy with recurrent fever episodes lasting 3-7 days and recurring every 4-6 weeks, with only partial symptom decrease in adulthood. Fever is typically accompanied by abdominal pain, vomiting, diarrhoea and cervical lymphadenopathy, and sometimes by skin and joint symptoms. Blood leukocytes and serum C-reactive protein are elevated during the episode, and in addition, high levels of interleukine-1 (IL-1), IL-6 and tumour necrosis factor (TNF) and respective soluble receptors have been measured. Instead, serum immunoglobulin D (IgD) is usually normal until 3 years of age. Currently, there is no established treatment for HIDS. Thus far, four children have been successfully treated with etanercept, TNF-alpha inhibitor, and three children with anakinra, IL-1 receptor antagonist. CONCLUSION: This review summarizes currently available data on the use biological medicines for HIDS in children. A Finnish 1.5-year-old patient with disease onset at 6 months of age, treated successfully with anakinra, is presented.

Autoinflammatory syndromes (AIS) are a heterogeneous group of congenital diseases characterized by the presence of recurrent episodes of fever and local or generalized inflammation, in the absence of infectious agents, detectable auto-antibodies or antigen-specific autoreactive T-cells. These diseases have been much better understood during the past 15 years, mainly due to the marked advances of the Human Genoma Project and its implications in the identification and characterization of genetic mutations. In this paper we make a revision of the classification of AIS and focus our attention specially on the cryopyrin-associated periodic syndromes (CAPS), in particular the CINCA syndrome that shares many clinical characteristics with juvenile idiopathic arthritis.

Interleukin (IL)-1 plays an important role not only in the mediation of inflammation but also in the destruction of cartilage and bone. Together with TNF-alpha it is one of the most important cytokines in the pathogenesis of rheumatoid arthritis (RA) and juvenile idiopathic arthritis (JIA). The first IL-1 antagonist to be approved for RA was Anakinra, an IL-1 receptor antagonist. Anakinra appears to be less effective for RA than TNF blockers. Hence, Anakinra is rarely used for the treatment of RA, but more for the treatment of IL-1-mediated diseases such as autoinflammatory syndromes, adult-onset Still's disease and systemic onset JIA. Two newer IL-1 antagonists have recently been approved for the treatment of CAPS (cryopyrin-associated periodic syndromes): Canakinumab, a fully human IL-1beta antibody, and rilonacept, a fusion protein consisting of the ligand-binding domain of the IL-1 receptor and the IL-1-receptor accessory protein, bound to human IgG1. For RA, there is only one proof-of-concept study to date with canakinumab. There are no prospective data for the treatment of patients with RA who did not respond to or tolerate TNF antagonists; in a retrospective analysis, only 8% of anti-TNF pretreated patients achieved an ACR 20 response.

**OBJECTIVE:** We aimed to validate the new paediatric criteria for diagnosis of FMF in a mixed population of 100 French patients.

**METHODS:** The study group included 100 FMF children from the French reference centre for auto-inflammatory disorders. A control group of 40 patients with unexplained recurrent fever was reviewed in parallel. Both groups of patients were assessed for both the Tel Hashomer and the new paediatric criteria published by Yalcinkaya et al.

**RESULTS:** Comparison of Tel Hashomer vs Yalcinkaya's criteria in both groups gave a sensitivity of 99 vs 100%, a specificity of 45 vs 50%, a positive predictive value (PPV) of 81.8 vs 83.3% and a negative predictive value (NPV) of 94.7 vs 100%. However, when we used at least three Yalcinkaya's criteria we obtained a sensitivity of 77% and a specificity of 95% with a PPV of 97.3% and an NPV of 62.3%. The number of mutations in the MEFV gene did not modify results for both sets of criteria.

**CONCLUSION:** The new paediatric Turkish criteria did not make a better contribution to FMF diagnosis than the Tel Hashomer criteria in our mixed population of French children while using an appropriate control group. However, if needed, they can be applied using at least three criteria, which slightly decreases their sensitivity but markedly increases their specificity.

[A case of frosted branch angiitis associated with retinal vein occlusion as a complication of familial Mediterranean fever].

[Article in Japanese]

Satoh S(1), Itoh C, Nakamura N.

Author information:

(1)Department Ophthalmology, Odate Municipal Hospital, 3-1 Yutakacho, Odate-shi 017-8550, Japan. Satoh-s@odate-hp.odate.akita.jp

**BACKGROUND:** Familial Mediterranean fever (FMF) is characterized by recurrent episodes of fever and serositis caused by autosomal recessive inheritance MEFV gene mutations. It is reported that the onset of angiitis is high among patients with this disease, but no reports were found in the field of ophthalmology in Japan. In this paper, we report one case that developed from optic disc vasculitis to frosted branch angiitis associated with retinal vein occlusion.

**CASE:** A 39 year old male. Fever, abdominal pain and chest pain were continued from childhood. In 2006, an idiopathic fever was reported with a renal disorder. Based on the results of laboratory examinations, he was diagnosed with FMF and started oral colchicines to stabilize the symptoms. In October 2007, he complained of blurry vision in his left eye that lasted for about one week prior to his visit and decided to visit our department for an examination. Visual acuity was right 1.5 and left 1.2. Although no abnormalities were found in the anterior chamber or optic media of either eye, the left eye papilla was reddish and swollen, and varicose enlargement of the retinal veins and a small retinal hemorrhage were found. Four days later, a white vascular infiltration spread to all branches of the retinal veins at the upper-half of the left eye papilla, the hemorrhage increased in the entire retina and the visual acuity decreased to 0.1. He was hospitalized and systemic administration of an antiviral agent, an antibacterial agent and a steroidal agent (prednisolone 60 mg/day) was started. Subsequently, the left eye ocular fundus findings slowly improved and he was cured 7 months later with a visual acuity of 1.0.

**CONCLUSION:** Frosted branch angiitis may occur with systemic gene abnormalities as an underlying condition and it is important in the future to consider FMF as a causative disease.

Monogenic autoinflammatory diseases: new insights into clinical aspects and pathogenesis.

Henderson C(1), Goldbach-Mansky R.

Author information:

(1)Translational Autoinflammatory Disease Section, MSC 1560, National Institute of Arthritis and Musculoskeletal and Skin Diseases, National Institutes of Health, Bethesda, Maryland, USA.

**PURPOSE OF REVIEW:** The genetic and clinical characterizations of monogenic autoinflammatory syndromes have led to ground breaking insights into the regulation of inflammatory responses to endogenous and exogenous inducers or triggers of inflammation and continue to uncover key inflammatory pathways of the innate immune system. This article summarizes recent progress in the clinical aspects and understanding of the pathogenesis of this growing spectrum of diseases.

**RECENT FINDINGS:** The understanding of the spectrum of organ manifestations in autoinflammation was expanded by the discovery of two novel monogenic diseases both caused by the absence of an anti-inflammatory signal and added evidence that increased IL-1 signaling can cause aseptic osteolytic bone lesions and that the absence of IL-10 signaling causes inflammatory enterocolitis in neonates. New knock in animal models for TNF-receptor-associated periodic syndrome, and familial Mediterranean fever and cryopyrin-associated periodic syndromes allow insights into the complexity of the dysregulated immune pathways. Exploring 'triggers' of the NLRP3 inflammasome spurred studies of tissue inflammation in diseases including gout and those that previously have not been considered inflammatory in nature such as diabetes, fibrosing lung disease and possibly coronary artery disease.

**SUMMARY:** The genetic characterization of a growing number of monogenic autoinflammatory diseases has provided important insights into the phenotypic

expression of single gene disorders and the complexity of the dysregulated inflammatory pathways leading to clinical disease. Knowledge obtained from these disorders is pertinent to a number of common disorders and provides new targets for drug development.

[From hereditary recurrent fevers to autoinflammatory syndromes: the contribution of genetics].

[Article in French]

Delpech M(1).

Author information:

(1)Laboratoire de biochimie et génétique moléculaire, APHP Hôpital Cochin, 123 bd de Port Royal, 75014 Paris. marc.delpech@inserm.fr

Hereditary recurrent fevers are rare genetic diseases characterized by febrile periods of variable duration. Classically, four such diseases were recognized, namely familial Mediterranean fever (previously called periodic disease in France), the Muckle-Wells syndrome, Hibernian fever, and hyper IgD with recurrent fever. The discovery of culprit genes has led to an overhaul of this classification. Molecular diagnosis of these diseases, that are difficult to identify on clinical grounds alone, is now possible. Timely diagnosis is particularly important as, in the absence of treatment, there is a risk of secondary AA amyloidosis, which is fatal within 5 to 10 years. The discovery of underlying genetic mechanisms has also led to the development of new therapeutic approaches, which are currently being tested in clinical trials.

Association of familial Mediterranean fever-related MEFV variations with ankylosing spondylitis.

Cosan F(1), Ustek D, Oku B, Duymaz-Tozkiir J, Cakiris A, Abaci N, Ocal L, Aral O, Gül A.

Author information:

(1)Istanbul University, Istanbul, Turkey.

**OBJECTIVE:** The pathogenesis of ankylosing spondylitis (AS) has a strong genetic contribution. Familial Mediterranean fever (FMF) is an autosomal recessively inherited autoinflammatory disorder caused by MEFV gene missense variations, and a clinical association between FMF and AS has been reported previously. The aim of this study was to analyze the association of common MEFV variations (M694V, M680I, V726A, and E148Q) with AS in a group of Turkish patients.

**METHODS:** The study group comprised 193 patients with AS and 103 matched healthy control subjects. All individuals were genotyped for 4 MEFV variations and HLA-B27 using genomic DNA, and association of the variations with the clinical and laboratory features of the patients was analyzed.

**RESULTS:** The MEFV missense variations were significantly more frequent in patients with AS (22.3%) compared with healthy control subjects (9.7%; odds ratio [OR] 2.67, 95% confidence interval [95% CI] 1.28-5.56). This difference was more prominent for exon 10 variations (M694V, V726A, M680I) (OR 3.75, 95% CI 1.41-9.97), especially for the most-penetrant variation M694V (OR 4.73, 95% CI 1.39-16.12). MEFV variations were more frequent in HLA-B27-negative patients with AS, and the difference was statistically significant in patients carrying exon 10 variants.

**CONCLUSION:** FMF-related MEFV variations are associated with AS, and these variations may contribute to the pathogenesis of AS, especially in populations in which the prevalence of FMF is high.

Cytophagic histiocytic panniculitis and hemophagocytic lymphohistiocytosis: an overview.

Aronson IK(1), Worobec SM.

Author information:

(1)Department of Dermatology, College of Medicine, University of Illinois at Chicago, Chicago, Illinois, USA. I.Aronson@uic.edu

Cytophagic histiocytic panniculitis (CHP) is a rare panniculitis that is associated with systemic features including fevers, hepatosplenomegaly, lymphadenopathy, pancytopenia, hepatic abnormalities, hypertriglyceridemia, and coagulopathy without an elevated erythrocyte sedimentation rate. The panniculitis lesions show adipose tissue lymphocytic and histiocytic infiltration along with hemophagocytosis, which may also appear in bone marrow, spleen, lymph nodes, and liver. Patients may have a rapidly fatal disease course, a longer disease course with intermittent remissions and exacerbations for many years prior to death, or a nonfatal acute or intermittent course responsive to treatment. The cytophagocytic disorder in these patients is a hemophagocytic lymphohistiocytosis (HLH), similar to the infection-activated reaction associated with perforin mutations found in familial hemophagocytic lymphohistiocytosis. HLH is a group of autoinflammatory disorders, which include macrophage activation syndrome and infection-associated hemophagocytic syndrome, which if not treated rapidly, can be fatal. The relationship of CHP and HLH is discussed. CHP associated diseases include: subcutaneous panniculitis-like T cell lymphomas; infections, connective tissue diseases, other malignancies, and the molecular disorders that cause HLH. Treatment of CHP includes: glucocorticoids in combination with cyclosporine, combined chemotherapeutic medications and most recently, anakinra, an Interleukin-1 receptor antagonist; along with supportive care, search for underlying malignancies and treatment thereof, and control of associated infections.

[Genetic background of juvenile idiopathic arthritis].

[Article in German]

Haas JP(1).

Author information:

(1)Deutsches Zentrum für Kinder- und Jugendrheumatologie, Gehfeldstr 24, 82467 Garmisch-Partenkirchen. haas.johannes-peter@rummelsberger.net

Several genetic factors have recently been observed as having an influence on susceptibility, course and prognosis of juvenile idiopathic arthritis (JIA): 1. Affected sib pairs were observed to have a low concordance in terms of disease incidence, but significant concordance in terms of subtype and course of disease. 2. Each subtype of JIA was observed to have a distinct genetic background. 3. Some JIA patients do not carry any of the defined risk genes. 4. Most subtypes of JIA have a distinct different genetic background to rheumatoid arthritis in adults. 5. Multiple factors have been observed to be involved in pathogenesis implying genetic and environmental factors. 6. Systemic JIA differs from all other subtypes in terms of genetic background and treatment options. It is currently assumed to be an autoinflammatory disease. 7. Genetic factors not only affect the course of the disease, but also response and complication rate. Increasing knowledge on the factors involved in the pathogenesis of JIA as well as analysis of large patient cohorts in consortiums cooperating on an international level have helped define many important polymorphisms; these are currently the subject of further investigation.

J Clin Rheumatol. 2012 Dec;18(8):453-4.

Colchicine, a long established anti-inflammatory agent now used in several rheumatologic conditions, acts by inhibiting microtubular polymerization, as it binds equimolarly to tubulin molecules. Cytoskeletal microtubules are crucial in processes of cell viability, such as mitosis and intracellular vesicle motility. Gastrointestinal side effects are quite common and often minor in nature or duration, whereas neuromuscular toxicity is rare. We report 2 cases of colchicine myopathy in the context of very different clinical settings.

[Periodic fever with increased IgD].

[Article in French]

Ammar J(1), Abid H, Yaalaoui S, Hamzaoui A.

Author information:

(1)Service de pneumopédiatrie, hôpital A.-Mami, 2080 Ariana, Tunisie.  
jamelammar2000@yahoo.fr

Periodic fever or hereditary inflammatory fevers are characterized by intermittent inflammatory attacks. Many entities are well recognized today such as familial mediterranean fever (FMF) and hyperimmunoglobulinemia D syndrome (HIDS). We report on the case of a 6-year-old boy referred for evaluation of a recurrent fever associated with chest pain, pneumonitis, or pleuritis since the

age of 5 years. Laboratory data showed leukocytosis, a high erythrocyte sedimentation rate, and C-reactive protein; however, a permanent high serum level IgD was noted. Stereotypical episodes of fever appeared every 4-6 weeks, while infectious, malignant, and auto-immune causes were eliminated. A search for the most common mutations of the FMF gene in Tunisian patients (M694V, M680I, V726A, E148Q, M694I, and A744S) were negative. Likewise, urinary leukotriene E(4), which may be increased in HIDS, was normal in this patient. Mevalonate kinase activity in lymphocytes was not assayed. Ethnic origin and clinical presentation suggest FMF with an increased IgD rather than authentic HIDS, in spite of the lack of improvement under colchicine treatment and the negativity of the main mutations involved in FMF.

Assessment of heart rate recovery index in patients with familial Mediterranean fever.

Ardic I(1), Kaya MG, Yarlioglues M, Dogdu O, Celikbilek M, Akpek M, Akyol L, Torun E.

Author information:

(1)Department of Cardiology, Erciyes University School of Medicine Kayseri, 38039

Kayseri, Turkey. idrisardic@yahoo.com

Heart rate recovery after exercise is a function of vagal reactivation, and its impairment is an independent prognostic indicator for cardiovascular and all-cause mortality. The aim of our study was to evaluate heart rate recovery in patients with familial Mediterranean fever (FMF). The study population included 38 patients with FMF (14 men; mean age,  $36.2 \pm 12.1$  years, and mean disease duration =  $11.3 \pm 6.5$  years) and 35 healthy control subjects (12 men; mean age =  $34.1 \pm 9.9$  years). Basal electrocardiography, echocardiography, and treadmill exercise testing were performed in all patients and control participants. The heart rate recovery index was defined as the reduction in the heart rate from the rate at peak exercise to the rate 1st-minute (HRR(1)), 2nd-minute (HRR(2)), 3rd-minute (HRR(3)), and 5th-minute (HRR(5)) after the cessation of exercise stress testing. There are significant differences in HRR(1) and HRR(2) indices between patients with FMF and control group ( $26.4 \pm 7.4$  vs.  $35.0 \pm 8.0$ ;  $P = 0.001$  and  $47.3 \pm 11.8$  vs.  $54.8 \pm 10.3$ ;  $P = 0.002$ , respectively). Similarly, HRR(3) and

HRR(5) indices of the recovery period were lower in patients with FMF, when compared with indices in the control group ( $56.0 \pm 14.0$  vs.  $63.7 \pm 11.2$ ;  $P = 0.01$  and  $64.1 \pm 14.7$  vs.  $71.5 \pm 12.7$ ;  $P = 0.02$ , respectively). There were also remarkably positive correlations between the disease duration and HRR(1) ( $r = 0.31$ ,  $P = 0.02$ ), and HRR(2) ( $r = 0.26$ ,  $P = 0.04$ ). The heart rate recovery index impaired in patients with FMF compared to control subjects. When the prognostic significance of the heart rate recovery index is considered, a useful, simple, and noninvasive test may be clinically helpful in the recognition of high-risk patients with FMF.

Review: T helper 17 cells: their role in glomerulonephritis.

Ooi JD(1), Kitching AR, Holdsworth SR.

Author information:

(1)Centre for Inflammatory Diseases, Department of Medicine, Monash Medical Centre, Monash University, Clayton, Vic 3168, Australia.

T helper (Th) cells are an integral part of the host's immune response to eliminate invading pathogens. However, autoimmune or 'autoinflammatory' diseases can develop if Th cell responses are not effectively regulated. Several subsets of Th cells exist, including the Th17 subset that produces interleukin-17A, important in experimental models of organ-specific autoimmune inflammation. Its discovery has explained paradoxical observations in model systems thought to be Th1 mediated but were exacerbated in the absence of interferon-gamma, the prototypic Th1 effector cytokine. Th17 cells express unique transcription factors and secrete a unique pattern of cytokines. Interleukin-17A induces pro-inflammatory cytokines and chemokines and mediates neutrophil recruitment. Th17 cells have a reciprocal relationship with T regulatory cells and can also mediate suppression of Th1 responses. Recent studies also suggest that Th17 cells are not terminally differentiated but can switch into Th1 cells. Th17 cells have themselves been recently shown to induce antigen-specific cell-mediated

proliferative glomerulonephritis. There is increasing evidence implicating Th17 cells in anti-glomerular basement membrane disease, lupus nephritis and pauci-immune glomerulonephritis. This review will review the discovery of the Th17 subset, its properties, its relationship with other Th subsets and assess the current evidence implicating Th17 cells in glomerulonephritis.

Mediterranean fever (MEFV) gene mutation frequency is not increased in adults with rheumatic heart disease.

Simsek I(1), Koz C, Basar N, Sari I, Erdem H, Pay S, Kisacik B, Bahce M, Dinc A.

Author information:

(1)Division of Rheumatology, Gulhane School of Medicine, Ankara, Turkey.

isimsek1@yahoo.com

It is well established that there are people with higher risk of developing acute rheumatic fever (ARF) and rheumatic heart disease (RHD). Mediterranean fever (MEFV) gene mutations might be one of the genetic predisposition factors in the development of ARF/RHD since defect in familial Mediterranean fever (FMF) patients is proposed to be heightened inflammatory response to certain stimuli. Previous clinical observations suggested a relationship between FMF and ARF/RHD. The aim of this study was to investigate the role of the MEFV gene mutations in the susceptibility to RHD in Turkish patients. A total of 100 patients with RHD and 100 healthy controls were included in the study. Diagnosis of RHD was based on echocardiographic findings in which a predominant mitral stenosis was used as an inclusion criterion. Genetic analysis was carried out by sequence analysis investigating two hot spots (exons 2 and 10) for MEFV mutations. Mutation analysis showed that 22 RHD patients (22%) and 24 healthy controls (24%) carried at least one mutated allele. MEFV mutations were identified in 22 of 200 (11%) chromosomes in RHD patients while 26 of the 200 (13%) chromosomes of healthy controls were found to carry a mutated allele. No difference was found in allele frequencies and their distribution between the patients and healthy controls

( $p = 0.54$ ). MEFV mutations are not associated with a predisposition to develop RHD in adult Turkish patients.

Formulary review of 2 new biologic agents: tocilizumab for rheumatoid arthritis and ustekinumab for plaque psoriasis.

Schafer JA(1), Kjesbo NK, Gleason PP.

Author information:

(1)Prime Therapeutics LLC, Eagan, Minnesota 55121, USA.

jschafer@primetherapeutics.com

**BACKGROUND:** Two autoimmune biologics were recently approved by the FDA: ustekinumab in September 2009 for the treatment of moderate to severe plaque psoriasis in adults who are candidates for phototherapy or systemic therapy and tocilizumab in January 2010 for adult patients with moderate to severe rheumatoid arthritis (RA) who have not responded adequately to 1 or more tumor necrosis factor (TNF) antagonist therapies. Both agents use new mechanisms of action and add to the growing group of autoimmune biologics.

**OBJECTIVE:** To critically review the phase 3 trials for ustekinumab and tocilizumab and provide managed care considerations in the context of the 9 other biologic agents on the market in the United States that are used to treat moderate to severe RA or psoriasis.

**METHODS:** A MEDLINE review was performed for articles published and available through January 2010 using keywords "ustekinumab" and "tocilizumab" with an emphasis on phase 3 trials. The literature search was limited to articles in English, clinical trials, randomized controlled trials, and research conducted in humans. Search results for ustekinumab included 8 articles of which 4 were excluded for not being psoriasis or psoriatic arthritis trials. Search results for tocilizumab included 16 articles of which 8 were excluded for not being RA trials or using biomarkers as primary endpoints. Additional information was obtained from the FDA website.

**RESULTS:** Three phase 3 trials are available for ustekinumab. Ustekinumab

demonstrated superior efficacy to placebo in 2 trials for the treatment of psoriasis. In a 12-week trial, ustekinumab 45 milligrams (mg) and 90 mg demonstrated significantly higher rates of 75% improvement in the psoriasis area and severity index (PASI 75) (67.5% and 73.8%, respectively) compared with etanercept (56.8%) in the first phase 3 comparative psoriasis trial between autoimmune biologics ( $P < 0.05$  for both comparisons). In a phase 3 trial of RA patients who had failed prior TNF antagonist therapy, a 20% improvement in signs or symptoms according to the American College of Rheumatology criteria (ACR 20) at week 24 was achieved by significantly more study participants in the tocilizumab 8 mg per kilogram (kg) (50.0%) and 4 mg per kg (30.4%) groups than the placebo group (10.1%,  $P < 0.001$  for both tocilizumab groups compared with placebo). Safety data for ustekinumab are limited to use for less than 2 years, and the prescribing information contains warnings regarding infection and malignancy. Tocilizumab is associated with neutropenia, thrombocytopenia, and elevations in lipids and liver function tests. Tocilizumab has unique adverse events when compared with other autoimmune biologics and requires laboratory testing and careful monitoring.

**CONCLUSIONS:** Ustekinumab and tocilizumab are new additions to the treatment of autoinflammatory disease. The majority of safety data for both agents are from trials lasting 3 to 6 months. Published long-term safety data for tocilizumab are limited to less than 143 patients treated longer than 5 years, and safety data for ustekinumab are scant beyond 2 years of use; therefore, clinicians should exercise caution prior to widespread adoption. The comparative efficacy and safety trial of etanercept and ustekinumab brings important clinical information to decision makers. Tocilizumab is indicated after failure or intolerance to a TNF antagonist and has unique safety concerns. Managed care plans will consider the experience and long-term data of these agents along with efficacy data and cost when establishing management programs such as prior authorization or step therapy.

Mammalian telomeric DNA suppresses endotoxin-induced uveitis.

Yagci FC(1), Aslan O, Gursel M, Tincer G, Ozdamar Y, Karatepe K, Akcali KC, Gursel I.

Author information:

(1)Biotherapeutic Oligonucleotide Laboratory, Department of Molecular Biology and Genetics, Bilkent University, 06800 Ankara, Turkey.

Telomeric regions of mammalian chromosomes contain suppressive TTAGGG motifs that inhibit several proinflammatory and Th1-biased immune responses. Synthetic oligodeoxynucleotides (ODN) expressing suppressive motifs can reproduce the down-regulatory activity of mammalian telomeric repeats and have proven effective in the prevention and treatment of several autoimmune and autoinflammatory diseases. Endotoxin-induced uveitis (EIU) is an established animal model of acute ocular inflammation induced by LPS administration. Augmented expression of proinflammatory cytokines/chemokines such as TNF $\alpha$ , IL-6, and MCP1 and bactericidal nitric oxide production mediated by LPS contribute to the development of EIU. Suppressing these mediators using agents that are devoid of undesirable systemic side effects may help prevent the development of EIU. This study demonstrates the selective down-regulatory role of suppressive ODN after (i) local or (ii) systemic treatment in EIU-induced rabbits and mice. Our results indicate that suppressive ODN down-regulate at both the transcript and protein levels of several proinflammatory cytokines and chemokines as well as nitric oxide and co-stimulatory surface marker molecules when administered prior to, simultaneously with, or even after LPS challenge, thereby significantly reducing ocular inflammation in both rabbit and mouse eyes. These findings strongly suggest that suppressive ODN is a potent candidate for the prevention of uveitis and could be applied as a novel DNA-based immunoregulatory agent to control other

autoimmune or autoinflammatory diseases.

Internist (Berl). 2011 Jun;52(6):768-70.

Systemic lupus erythematosus (SLE) is a chronic autoinflammatory disease of unknown etiology with predominance of the female sex. Clinical criteria as well as immunological characteristics, e. g. autoantibodies, are necessary for diagnosis. The clinical course of SLE is variable and may be characterized by periods of remissions and chronic or acute relapses. New symptoms are often challenging regarding differential diagnosis. This review will discuss symptoms with a problem based approach. Parameters of activity are helpful to differentiate between disease activity and associated problems, e. g. infections. Lupus patients have a 5 times increased mortality compared to the normal population. The main reasons for mortality are infections and cardiovascular events, rather than disease manifestations. Therefore, besides the fast and precise use of immunosuppressants the consequent therapy of co-morbidities is a major issue in dealing with these patients. Cardiovascular risk factors need to be controlled, life style modifications should be started early, and diagnosis and therapy of osteoporosis should not be neglected.

Inflammasome-mediated IL-1 $\beta$  production is central to the innate immune defects that give rise to certain autoinflammatory diseases and may also be associated with the generation of IL-17-producing CD4(+) T (Th17) cells that mediate autoimmunity. However, the role of the inflammasome in driving adaptive immunity to infection has not been addressed. In this article, we demonstrate that inflammasome-mediated IL-1 $\beta$  plays a critical role in promoting Ag-specific Th17 cells and in generating protective immunity against *Bordetella pertussis* infection. Using a murine respiratory challenge model, we demonstrated that the course of *B. pertussis* infection was significantly exacerbated in IL-1R type I-defective (IL-1RI(-/-)) mice. We found that adenylate cyclase toxin (CyaA), a key virulence factor secreted by *B. pertussis*, induced robust IL-1 $\beta$  production by dendritic cells through activation of caspase-1 and the NALP3-containing inflammasome complex. Using mutant toxins, we demonstrate that CyaA-mediated activation of caspase-1 was not dependent on adenylate cyclase enzyme activity but was dependent on the pore-forming capacity of CyaA. In addition, CyaA promoted the induction of Ag-specific Th17 cells in wild-type but not IL-1RI(-/-) mice. Furthermore, the bacterial load was enhanced in IL-17-defective mice. Our findings demonstrate that CyaA, a virulence factor from *B. pertussis*, promotes innate IL-1 $\beta$  production via activation of the NALP3 inflammasome and, thereby, polarizes T cell responses toward the Th17 subtype. In addition to its known role in subverting host immunity, our findings suggest that CyaA can promote

IL-1beta-mediated Th17 cells, which promote clearance of the bacteria from the respiratory tract.

Mycobacteria in Crohn's disease: how innate immune deficiency may result in chronic inflammation.

Lalande JD(1), Behr MA.

Author information:

(1)Department of Medicine, McGill University Health Centre, A5.156, 1650 Cedar Avenue, Montreal, Quebec H3G 1A4, Canada.

Crohn's disease (CD) is often considered to be an autoimmune condition or, alternatively, an autoinflammatory condition, based on the observation of host-directed inflammatory processes. However, the underlying basis of this deleterious inflammatory response remains elusive. Recent findings from genetic and genomic studies have altered the perspective on the pathogenesis of CD, hinting at defects in innate immune sensing of intracellular bacteria and the handling of these organisms through autophagy. These findings are consistent with emerging data from immunological studies that point to a systemic immune deficiency in CD patients. Both sets of data (genetic predisposition and immunodeficiency) are consistent with the longstanding hypothesis that

mycobacteria might be involved in the etiology of CD. In this article, we discuss the convergence of these three lines of investigation and highlight important knowledge gaps required in order to address the mycobacterial hypothesis with greater clarity. In the coming years, clinical immunological investigations should focus on defining the specificity of functional immune defects with regards to microbes and their associated ligands. Should CD result from a dysfunctional host-pathogen interaction, elucidation of the microbes that can exploit such defects to induce a chronic inflammatory disease is critical for the development of subsequent diagnostic assays and clinical interventions.

Role of IL-1beta in type 2 diabetes.

Dinareello CA(1), Donath MY, Mandrup-Poulsen T.

Author information:

(1)Department of Medicine, University of Colorado, Aurora, Colorado 80045, USA. cdinare333@aol.com

**PURPOSE OF REVIEW:** To understand the role of inflammation as the fundamental cause of type 2 diabetes and specifically to examine the contribution of IL-1beta.

**RECENT FINDINGS:** Recent studies from animals, in-vitro cultures and clinical trials provide evidence that support a causative role for IL-1beta as the primary agonist in the loss of beta-cell mass in type 2 diabetes. In vitro, IL-1beta-mediated autoinflammatory process results in beta-cell death. The autoinflammation is driven by glucose, free fatty acids, leptin, and IL-1beta itself. Caspase-1 is required for IL-1beta activity and the release of free fatty acids from the adipocyte. An emerging hypothesis gains support from patients with type 2 diabetes in which an imbalance in the amount of IL-1beta agonist activity versus the specific countering by the naturally occurring IL-1 receptor antagonist (IL-1Ra) determines the outcome of islet inflammation. An important confirmation comes from clinical trials. Blockade of IL-1 receptor with anakinra,

the recombinant form of IL-1Ra, or neutralizing anti-IL-1beta antibodies, provides proof-of-principle data that reducing IL-1beta activity is sufficient for correcting dysfunctional beta-cell production of insulin in type 2 diabetes, including a possibility that suppression of IL-1beta-mediated inflammation in the microenvironment of the islet allows for regeneration.

SUMMARY: Monotherapy or add-on therapy targeting IL-1beta in type 2 diabetes holds promise for long-term benefits in glycemic control and possibly reducing cardiovascular events.

(1)Division of Clinical Pharmacology and Toxicology, The Hospital for Sick Children, University of Toronto, Toronto, ON, Canada.

yaron.finkelstein@sickkids.ca

INTRODUCTION: Colchicine is used mainly for the treatment and prevention of gout and for familial Mediterranean fever (FMF). It has a narrow therapeutic index, with no clear-cut distinction between nontoxic, toxic, and lethal doses, causing substantial confusion among clinicians. Although colchicine poisoning is sometimes intentional, unintentional toxicity is common and often associated with a poor outcome.

METHODS: We performed a systematic review by searching OVID MEDLINE between 1966 and January 2010. The search strategy included "colchicine" and "poisoning" or "overdose" or "toxicity" or "intoxication."

TOXICOKINETICS: Colchicine is readily absorbed after oral administration, but undergoes extensive first-pass metabolism. It is widely distributed and binds to intracellular elements. Colchicine is primarily metabolized by the liver, undergoes significant enterohepatic re-circulation, and is also excreted by the kidneys. THERAPEUTIC AND TOXIC DOSES: The usual adult oral doses for FMF is

1.2-2.4 mg/day; in acute gout 1.2 mg/day and for gout prophylaxis 0.5-0.6 mg/day three to four times a week. High fatality rate was reported after acute ingestions exceeding 0.5 mg/kg. The lowest reported lethal doses of oral colchicine are 7-26 mg.

**DRUG INTERACTIONS:** CYP 3A4 and P-glycoprotein inhibitors, such as clarithromycin, erythromycin, ketoconazole, ciclosporin, and natural grapefruit juice can increase colchicine concentrations. Co-administration with statins may increase the risk of myopathy.

**MECHANISMS OF TOXICITY:** Colchicine's toxicity is an extension of its mechanism of action - binding to tubulin and disrupting the microtubular network. As a result, affected cells experience impaired protein assembly, decreased endocytosis and exocytosis, altered cell morphology, decreased cellular motility, arrest of mitosis, and interrupted cardiac myocyte conduction and contractility. The culmination of these mechanisms leads to multi-organ dysfunction and failure.

**REPRODUCTIVE TOXICOLOGY AND LACTATION:** Colchicine was not shown to adversely affect reproductive potential in males or females. It crosses the placenta but there is no evidence of fetal toxicity. Colchicine is excreted into breast milk and considered compatible with lactation.

**CLINICAL FEATURES:** Colchicine poisoning presents in three sequential and usually overlapping phases: 1) 10-24 h after ingestion - gastrointestinal phase mimicking gastroenteritis may be absent after intravenous administration; 2) 24 h to 7 days after ingestion - multi-organ dysfunction. Death results from rapidly progressive multi-organ failure and sepsis. Delayed presentation, pre-existing renal or liver impairment are associated with poor prognosis. 3) Recovery typically occurs within a few weeks of ingestion, and is generally a complete recovery barring complications of the acute illness.

**DIAGNOSIS:** History of ingestion of tablets, parenteral administration, or consumption of colchicine-containing plants suggest the diagnosis. Colchicine poisoning should be suspected in patients with access to the drug and the typical toxidrome (gastroenteritis, hypotension, lactic acidosis, and prerenal azotemia).

**MANAGEMENT:** Timely gastrointestinal decontamination should be considered with activated charcoal, and very large, recent (<60 min) ingestions may warrant gastric lavage. Supportive treatments including administration of granulocyte colony-stimulating factor are the mainstay of treatment. Although a specific experimental treatment (Fab fragment antibodies) for colchicine poisoning has been used, it is not commercially available.

**CONCLUSION:** Although colchicine poisoning is relatively uncommon, it is imperative to recognize its features as it is associated with a high mortality rate when missed.

Late presentation of familial mediterranean fever: a case report.

Gomez LR(1), Mellado RH.

Author information:

(1)Internal Medicine Department, Universidad Central del Caribe, School of Medicine, Bayamón, PR 00960-6032.

Familial Mediterranean Fever (FMF) is an autosomal recessive disorder predominantly affecting people of Mediterranean origin. It is characterized by recurrent episodes of fever and polyserositis of unexplained origin. Most patients with FMF experience their first attack in early childhood with 90% suffering their first bout of pain by the age of 20. We present a case of a 68 years old woman who presented with fevers of 9 months of evolution which culminated with a diagnosis of Familial Mediterranean Fever after successful treatment with Colchicine.

Review of haemophagocytic lymphohistiocytosis.

Freeman HR(1), Ramanan AV.

Author information:

(1)Department of Paediatric Rheumatology, Bristol Royal Hospital for Children, Upper Maudlin Street, Bristol, UK.

Haemophagocytic lymphohistiocytosis (HLH) describes a clinical syndrome of hyperinflammation resulting in an uncontrolled and ineffective immune response. It may develop subsequent to a number of recognised genetic mutations or in association with infection, malignancy, autoinflammatory or metabolic conditions. Even with the published diagnostic criteria it can be difficult to make the diagnosis of HLH. Patients presenting acutely to the general paediatrician or paediatric intensivist with a clinical picture of likely sepsis, ie fever, laboratory evidence of inflammatory response, coagulopathy and thrombocytopenia should be appropriately investigated and managed for sepsis, but the possible diagnosis of HLH should be borne in mind, particularly in the child who deteriorates despite maximal therapy. This review discusses current knowledge on the classification, diagnosis and management of primary and secondary HLH, and suggests a pathway of investigation for the paediatrician faced with a potential case.

Pregnancy outcome after in utero exposure to colchicine.

Diav-Citrin O(1), Shechtman S, Schwartz V, Avgil-Tsadok M, Finkel-Pekarsky V, Wajnberg R, Arnon J, Berkovitch M, Ornoy A.

Author information:

(1)Israeli Teratology Information Service and Israel Ministry of Health, Jerusalem, Israel.

OBJECTIVE: We sought to examine the fetal safety of colchicine.

STUDY DESIGN: This was a prospective observational comparative cohort study regarding colchicine exposure during pregnancy including contacts to 2 Teratology Information Services in Israel from 1994 through 2006.

RESULTS: In all, 238 colchicine-exposed pregnancies (97.0% first trimester) and 964 pregnancies with nonteratogenic exposure were followed up. Treatment indications were: familial Mediterranean fever (87.3%), Behçet disease (7.5%), or other (5.2%). The rate of major congenital anomalies was comparable between the groups (10/221 [4.5%] vs 35/908 [3.9%];  $P = .648$ ). There were no cytogenetic anomalies in the colchicine group. The median gestational age at delivery was earlier (39 [38-40] vs 40 [38-41] weeks;  $P < .001$ ), the rate of preterm deliveries was higher (32/214 [15.0%] vs 51/867 [5.9%];  $P < .001$ ), and the median birthweight was lower (3000 [2688-3300] vs 3300 [2900-3600] g;  $P < .001$ ) in the colchicine group.

CONCLUSION: The present study suggests that colchicine does not appear to be a major human teratogen, and, probably, has no cytogenetic effect.

[TRAPS: clinical significance of genotype. A report of two cases].

[Article in French]

Lahaxe L(1), Josse S, Grateau G, Levesque H, Marie I.

Author information:

(1)Département de médecine interne, CHU de Rouen, 1 rue de Germont, 76031 Rouen cedex, France.

**INTRODUCTION:** Tumor necrosis factor receptor associated periodic fever syndrome (TRAPS) is defined as recurrent attacks of generalized inflammation for which no infectious or auto-immune cause can be identified; it is caused by dominantly inherited mutations in the gene encoding the first TNF receptor. We report two additional cases of patients with TRAPS, suggesting that mutation pattern of TNFRSF 1A gene may influence the TRAPS phenotype.

**CASE REPORTS:** The first patient, with a C30S mutation, exhibited severe digestive clinical manifestations; because the patient required high-dose corticosteroids regimen to improve TRAPS manifestations, he was further given successfully etanercept. The second patient, with a R92Q mutation of TNFRSF 1A gene, presented with moderate symptoms; TRAPS outcome was favourable after corticosteroid therapy initiation.

**CONCLUSION:** Therefore, R92Q may be associated with a mild disease phenotype. On the other hand, C30S mutation appears to be associated with a severe phenotype, leading to an increased risk of amyloidosis. These findings suggest that these latter patients may require a closer follow-up.

Evaluation of left ventricle function by strain imaging in patients with familial Mediterranean fever.

Kalkan GY(1), Bayram NA, Erten S, Keles T, Durmaz T, Akcay M, Bozkurt E.

Author information:

(1)Department of Cardiology, Ataturk Education and Research Hospital, Bilkent, Ankara, Turkey.

AIM: Familial Mediterranean Fever (FMF) is a hereditary inflammatory disease characterized by recurrent fever and serositis. We aimed to evaluate cardiac involvement in FMF patients by using strain and strain rate echocardiographic imaging method in this study.

MATERIALS AND METHODS: Echocardiographic evaluation was performed in 23 FMF patients and 22 healthy controls. FMF diagnosis was based on Tell-Hashomer diagnostic criteria. Conventional echocardiography, tissue Doppler echocardiography and longitudinal two-dimensional (2D) strain and strain rate imaging were performed in patient and control groups.

RESULTS: There were no significant differences between patient and control groups in terms of 2D, M-mode, conventional Doppler and tissue Doppler velocities. Left ventricle strain value was significantly lower in five out of eight segments in FMF patients than controls and left ventricle strain rate value was significantly lower in three out of eight segments in FMF patients than controls. Mean left ventricle strain value was significantly lower in FMF patients than controls ( $-21.1 \pm 2.2\%$  vs.  $-23.8 \pm 2.2\%$ ;  $P < 0.001$ ). No significant difference was noted between FMF patients and controls in mean left ventricle strain rate value ( $-1.61 \pm 0.23$  vs.  $-1.58 \pm 0.21$ ;  $P = 0.48$ ).

CONCLUSION: We have shown that although conventional echocardiography and tissue Doppler velocity data were similar, strain, strain rate values were significantly lower in FMF patients than controls. We know that strain and strain rate imaging

method might be useful for evaluating subclinical cardiac involvement in case of normal conventional and tissue Doppler velocity data in patients with FMF.

Common MEFV mutation analysis in 36 Iranian patients with familial Mediterranean fever: clinical and demographic significance.

Bidari A(1), Ghavidel-Parsa B, Najmabadi H, Talachian E, Haghighat-Shoar M, Broumand B, Ghalehbaghi B.

Author information:

(1)Department of Rheumatology, Iran University of Medical Sciences, Tehran, Iran.

The aim of our study was to determine the spectrum of the 12 most common familial Mediterranean fever gene (MEFV) mutations in Iranian patients with heterogeneous ethnicity, using the familial Mediterranean fever (FMF) strip assay test. A total of 36 patients were diagnosed according to established clinical criteria. Genomic DNA from all patients was tested for 12 common mutations located in exon 2 (E148Q), 3 (P369S), 5 (F479L), 10 [M680I (G>C), M680I (G>A), I692del, M694V, M694I, K695R, V726A, A744S, R761H], respectively, using the FMF strip assay test. Of the 35 patients with mutations, ten were homozygote, 20 were compound heterozygote, and five were heterozygote. The most frequent genotype was M680I/M680I (6 patients, 16.7%). The most frequent mutation was M680I, followed by M694V, and V726A. The FMF strip assay test for common these 12 mutations was positive in 90.6% of alleles in this study, indicating that it appears to be an effective method for FMF mutation screening in Iranian patients.

The innate immune system, which corresponds to the first line of defense against microorganisms, brings into play cell surface and intracellular sensors that detect pathogen ligands and danger signals. Among them, NOD-like receptors (NLRs) are intracellular proteins involved in inflammatory signaling pathways. NLRs are part of multiprotein complexes, called inflammasomes, which usually bring into play a NLR, an adaptor protein called ASC, and the pro-inflammatory caspase 1 protein. The activation of inflammasome by different stimuli triggers the proteolytic cleavage of pro-caspase 1 into active caspase 1, which, in turn, converts pro-interleukin 1 $\beta$  (pro-IL1 $\beta$ ) into the mature IL1 $\beta$ . IL1 $\beta$  plays a crucial role in systemic inflammation due to its ability to induce the expression of a large panel of pro-inflammatory genes and to act on various target organs. Mutations in NLR genes are responsible for several autoinflammatory and/or autoimmune disorders. For example, mutations in NLRP3, which are responsible for three Mendelian autoinflammatory disorders called cryopyrinopathies, lead to inflammasome autoactivation. Peripheral blood mononuclear cells from patients carrying NLRP3 mutations secrete high levels of IL1 $\beta$ ; in many patients presenting with autoinflammatory disorders, blocking IL1 activity by anti-IL1 therapy significantly improves their manifestations. The mechanisms leading to IL1 $\beta$  hypersecretion in other autoinflammatory disorders remain to be identified, as is the case for the role of each inflammasome in vivo. Better knowledge in this field should also contribute to the development of new anti-inflammatory treatments.

Activated endothelial cells induce neutrophil extracellular traps and are susceptible to NETosis-mediated cell death.

Gupta AK(1), Joshi MB, Philippova M, Erne P, Hasler P, Hahn S, Resink TJ.

Author information:

(1)University Women's Hospital, Department of Biomedicine, Basel University Hospital, Basel, Switzerland.

Neutrophil interaction with activated endothelial cells (EC) is required for transmigration. We examined consequences of this interaction on NETosis. Co-culture of activated EC with neutrophils induced neutrophil extracellular trap (NET) formation, which was partially dependent on production of IL-8 by activated EC. Extended neutrophil/EC co-culture resulted in EC damage, which could be abrogated by inclusion of either diphenyleneiodonium to inhibit the NADPH oxidase pathway required for NETosis, or DNase to disrupt NETs. These findings offer new insight into mechanisms whereby NETs trigger damage to the endothelium in sepsis, small vessel vasculitis and possibly the villous trophoblast in preeclampsia.

**CONTEXT:** Genetic lipodystrophies are rare disorders characterized by partial or complete loss of adipose tissue and predisposition to insulin resistance and its complications such as diabetes mellitus, hypertriglyceridemia, hepatic steatosis, acanthosis nigricans, and polycystic ovarian syndrome.

**OBJECTIVE:** The objective of the study was to report a novel autosomal recessive lipodystrophy syndrome.

**RESULTS:** We report the detailed phenotype of two males and one female patient, 26-34 yr old, belonging to two pedigrees with an autosomal recessive syndrome presenting with childhood-onset lipodystrophy, muscle atrophy, severe joint contractures, erythematous skin lesions, and microcytic anemia. Other variable clinical features include hypergammaglobulinemia, hepatosplenomegaly, generalized seizures, and basal ganglia calcification. None of the patients had diabetes mellitus or acanthosis nigricans. Two had mild hypertriglyceridemia and all had low levels of high-density lipoprotein cholesterol. Skin biopsy of an

erythematous nodular skin lesion from one of the patients revealed evidence of panniculitis. The lipodystrophy initially affected the upper body but later became generalized involving abdomen and lower extremities as well.

CONCLUSIONS: We conclude that these patients represent a novel autoinflammatory syndrome resulting in joint contractures, muscle atrophy, microcytic anemia, and panniculitis-induced lipodystrophy. The molecular genetic basis of this disorder remains to be elucidated.

Autoinflammatory conditions: when to suspect? How to treat?

Grateau G(1), Duruöz MT.

Author information:

(1)Service de médecine interne, Centre de référence des amyloses d'origine inflammatoire et de la fièvre méditerranéenne familiale, hôpital Tenon, Assistance publique-hôpitaux de Paris, Université Paris 6 Pierre et Marie Curie, 4 rue de la Chine, 75970 Paris cedex 20, France. gilles.grateau@tnn.aphp.fr

The term 'autoinflammatory disease' encompasses an enlarging group of inflammatory disorders defined as Mendelian genetic diseases of the innate immune system. This group is growing considering the fact that diseases sharing strong similarities with this core group can be defined as autoinflammatory. The core group consists now of six disorders also known as hereditary recurrent fever syndromes. The most common is familial Mediterranean fever, an autosomal recessive disease affecting mainly populations of Mediterranean ancestry. All these six diseases are characterised by inflammatory attacks both at the clinical and at the biological level. The diagnosis of each of these diseases relies first on clinical features and second on genetic testing, which is guided by the clinical results. Deciphering the role of interleukin-1 in the regulation of the inflammatory response through the inflammasome represents a major advance in the knowledge of the mechanisms of these diseases with, as a main consequence,

treatment with interleukin-1 inhibitors.

1Novel MEFV transcripts in Familial Mediterranean fever patients and controls.

Medlej-Hashim M(1), Nehme N, Chouery E, Jalkh N, Megarbane A.

Author information:

(1)Unité de Génétique Médicale, Faculté de Médecine, Université Saint Joseph, Beirut, Lebanon.

**BACKGROUND:** Familial Mediterranean fever is a recessive autoinflammatory disease frequently encountered in Armenians, Jews, Arabs and Turks. The MEFV gene is responsible for the disease. It encodes a protein called pyrin/marenostrin involved in the innate immune system. A large number of clinically diagnosed FMF patients carry only one MEFV mutation. This study aims at studying the MEFV gene splicing pattern in heterozygous FMF patients and healthy individuals, in an attempt to understand the mechanism underlying the disease in these patients.

**METHODS:** RNA was extracted from peripheral blood leucocytes of 41 FMF patients and 34 healthy individuals. RT-PCR was then performed, and the amplified products were migrated on a polyacrylamide electrophoresis gel, characterized by gel extraction of the corresponding bands followed by sequencing.

**RESULTS:** Five novel splicing events were observed in both patients and controls deleting either exons 3, 4 (del34), or exons 2, 3, 4 (del234), or exons 2, 3, 4, 5 (del2345) or exon7 (del7) or exons 7 and 8 (del78).

**CONCLUSIONS:** The observation of such qualitative variability in the expression of the MEFV gene suggests a complex transcriptional regulation. However, the expression of these novel transcripts in both patients and controls is not in favour of a severe pathogenic effect.

nurullah.akkoc@deu.edu.tr

**OBJECTIVE:** To assess whether there is a statistically significant difference in the frequency of common MEFV allele variants in patients with ankylosing spondylitis (AS) as compared with control patients with rheumatoid arthritis (RA) and with healthy control subjects.

**METHODS:** Sixty-two patients with AS, 50 healthy control subjects, and 46 patients with RA were assessed for the presence of MEFV variants. Exon 10 was analyzed by direct sequencing. E148Q was analyzed by restriction endonuclease enzyme digestion (REED) or by direct sequencing when REED analysis failed.

**RESULTS:** The allele frequency of all MEFV variants in the AS group was significantly higher than that in the pooled control group of healthy subjects plus RA patients (15.3% versus 6.8%;  $P = 0.021$ ). M694V was the only variant that was significantly more common in the AS group than in the combined or individual control groups ( $P = 0.026$  for AS patients versus healthy controls,  $P = 0.046$  for AS patients versus RA patient controls, and  $P = 0.008$  for AS patients versus healthy and RA patient control groups). The carriage rate of M694V was also significantly higher in the AS patient group than in the combined control group (odds ratio 7.0,  $P = 0.014$ ). Neither M694V nor any other MEFV variant showed a correlation with most of the disease-related measures examined.

**CONCLUSION:** We found an increased frequency of MEFV variants in AS patients as compared with healthy controls and with RA patient controls. This was primarily due to the presence of M694V. The roles of other exon 10 variants, as well as the relationship between the variant status and the severity and clinical course of the disease, need to be explored in further studies that include sufficiently large sample sizes.

Tumor necrosis factor (TNF) receptor-associated periodic syndrome (TRAPS) is an autosomal dominantly inherited rare autoinflammatory disease. It is caused by mutations in exons 2-3 and 4-5 of the tumor necrosing factor receptor superfamily 1A (TNFRSF1A) gene on chromosome 12p13.2. TNFRSF1A gene encodes the 55-kDa receptor for tumor necrosis factor. Attacks are associated with abdominal pain, myalgia, erythematous skin rash, conjunctivitis, and periorbital edema. Until now, more than 80 mutations have been identified. We herein report three patients with TRAPS of Turkish origin. The patients were followed up in our outpatient clinic in Kocaeli University Division of Rheumatology. Because of their TRAPS associated clinical features, we isolated genomic DNA from whole blood and sequenced the exon 2-3 and 4-5 third exon of TNFRSF1A gene after amplification with appropriate primers. One of the patients with TRAPS was 47-year-old female, who described recurrent attacks of fever, urticarial rash, conjunctivitis, arthralgia, myalgia, abdominal pain, thoracic pain, headache, fatigue, and elevated acute phase response since her childhood. With the sequencing of the TNFRSF1A gene, we identified heterozygous C29R mutation, which has not been reported before in any TRAPS patient. The other patients are her sons with similar findings and age 29 and 26. They were heterozygous for C29R mutation in TNFRSF1A gene too. We report novel C29R mutation in three TRAPS patients of Turkish origin, in which the main clinical features are recurrent fever attacks, erythematous skin rash, conjunctivitis, myalgia, and arthralgia. Treatment with steroids resolved the symptoms and lesions.

Critical appraisal of canakinumab in the treatment of adults and children with cryopyrin-associated periodic syndrome (CAPS).

Toker O(1), Hashkes PJ.

Author information:

(1)Department of Pediatrics, Shaare Zedek Medical Center, affiliated with the Hadassah-Hebrew University Medical School, Jerusalem, Israel;

The cryopyrin-associated syndromes (CAPS) include three autosomal-dominant syndromes, that are caused by a mutation in the NLRP3 gene on chromosome 1, encoding the cryopyrin protein. These syndromes, familial cold autoinflammatory syndrome, Muckle-Wells syndrome and neonatal-onset multisystem inflammatory disease, are characterized by urticaria-like rash, fever, central nervous system inflammation, an arthropathy and a risk of the development of amyloidosis in a respectively escalating degree of severity between the various syndromes. Recently the role of cryopyrin in the regulation of interleukin (IL)-1 production and activation was described and anti IL-1 therapies were found to be very effective in treating these syndromes. There are several types of anti IL-1 medications based on different mechanisms of antagonizing IL-1. This paper focuses on the efficacy and safety of canakinumab, a long-acting humanized anti IL-1 antibody, in treating these syndromes.

Author information:

(1)Division of Internal Medicine, GATA Haydarpasa Training Hospital, Uskudar, Istanbul, Turkey.

The aim of this study was to determine the rate of MEFV gene mutations, the gene responsible for familial Mediterranean fever (FMF), in patients with hematolymphoid neoplasm. The rate of the five most common MEFV gene mutations (M694V, M680I, V726A, M694I and E148Q) was determined in 46 patients with hematolymphoid neoplasm. We found a high frequency of carriers in patients with multiple myeloma (60%) and acute lymphocytic leukaemia (33.3%), whereas patients with chronic lymphocytic leukaemia (9%) and non-Hodgkin lymphoma (5%) had a low mutation carrier rate. There is no MEFV gene mutation in patients with Hodgkin lymphoma. Furthermore, the statistically significant predominance of strong heterozygous mutations such as M694V and M680I in patients with hematolymphoid neoplasm; none had own and/or family history compatible with FMF, is interesting. In conclusion, we found a high frequency of carriers for MEFV gene in patients with multiple myeloma and acute lymphocytic leukaemia. The data of our study may provide some new insights in understanding of individual genetic differences in susceptibility to these neoplasms.

Serum adiponectin levels in patients with familial Mediterranean fever.

Keskin G(1), Inal A, Ozişik L.

Author information:

(1)Department of Immunology-Rheumatology, Dişkapi Yildirim Beyazit Training and Research Hospital, Ankara, Turkey. goksalkeskin@gmail.com

Familial mediterranean fever (FMF) is a systemic disorder characterized by recurrent attacks of fever and polyserositis. In FMF, several pro-inflammatory cytokines have been found to be elevated during the attacks. In recent years, it is shown that some proteins originated from adipose tissue play important role in inflammatory process. One of them, adiponectin decreases the expression of adhesion molecules and inhibits the attachment of active macrophages to the endothelial surface, so that it acts antiinflammatory effect. In this study, we analyzed the possible role of serum adiponectin in the pathogenesis of FMF. Thirty five patients with FMF and 13 healthy controls (5 female,8 male; mean age  $22.3 \pm 4.2$  years) were enrolled in this study. Fifteen patients were in active stage (6 female, 9 male, mean age;  $22.4 \pm 4.1$  years, mean disease duration  $6.1 \pm 2.3$  years) and 20 patients were in inactive stage (6 female,14 male, mean age; $22.6 \pm 4.2$  years, mean disease duration;  $5.7 \pm 1.6$  years). Serum adiponectin and IL-6 levels were determined by ELISA. The mean serum adiponectin levels were  $5.3 \pm 1.6$  ng/ml in healthy controls,  $55.3 \pm 21.8$  ng/ml in active FMF patients and  $17.1 \pm 4.7$  ng/ml in inactive FMF patients. The mean serum IL-6 levels were  $1.9 \pm 0.4$  ng/ml in healthy controls,  $4.7 \pm 1.1$  ng/ml in active FMF patients and  $2.9 \pm 1.3$  ng/ml in inactive FMF patients. Serum adiponectin levels in patients with FMF were significantly higher than in healthy controls ( $p < 0.001$ ). Serum adiponectin levels were significantly high both in active FMF patients and in inactive FMF patients compared with healthy control ( $p < 0.001$ ,  $p < 0.001$  respectively). Serum IL-6 levels were significantly higher both in patients with active and inactive disease as compared with healthy controls ( $p < 0.01$  and  $p < 0.05$  respectively). In serum adiponectin levels were correlated with high levels of serum IL-6 in the active and inactive patients. Serum adiponectin and IL-6 levels were during both active and inactive stages in patents with FMF.

We conducted this study to determine familial Mediterranean fever (FMF)-associated central nervous system involvement including demyelinating lesions, stroke, and posterior reversible leukoencephalopathy syndrome (PRES). Patients with MEFV mutations were systematically reviewed through the Medical Biology Unit database. All samples sent for mutation analysis were screened for 10 common MEFV mutations. Patients with FMF and neurologic disorders according to the clinical records were invited for reevaluation. Lumbar puncture, electroencephalography, and evoked potentials were used to determine the type of neurologic involvement in selected cases. Electrocardiography, transthoracic and/or transesophageal echocardiography, and magnetic resonance imaging and/or angiography were performed to clarify the etiology of cerebrovascular disease. Of 8864 patients in the genetic testing database, 18 with neurologic signs were assessed. The mean age of patients was 31.0 +/- 11.8 years, mean age at first FMF symptom was 12.6 +/- 5.6 years, and mean age at neurologic involvement was 25.8 +/- 12.2 years. Fifty-five percent of patients were women. A homozygote MEFV mutation was detected in 16 of 18 patients (88.8%), and a homozygote M694V mutation was found in 72.2% of patients. We found 7 FMF patients with demyelinating lesions, 7 with cerebrovascular disease, and 4 with PRES. The mean interval between first FMF sign and neurologic involvement was 13.7 +/- 8.9 years in the demyelinating group, and 23.4 +/- 10.3 years in the group with cerebrovascular disease. Mean stroke age was 28.5 +/- 16.4 years. All patients in the PRES group had hypertension. Three different neurologic conditions in FMF patients were noticeable. Demyelinating lesions and cerebrovascular disease were

the most common clinical presentations. Approximately 70% of patients had the homozygote M694V mutation. Neurologic involvement is rare but serious in FMF.

**OBJECTIVE:** To define the frequency of the R92Q tumor necrosis factor receptor-associated periodic syndrome (TRAPS) mutation in patients with familial Mediterranean fever (FMF) and to study the role of this mutation in FMF.

**METHODS:** Ninety-two FMF patients and 250 controls were genotyped for the R92Q mutation. The frequency of R92Q was assessed among 5 groups of FMF patients.

**RESULTS:** R92Q was found in 6% of the controls, with an especially high carrier rate among Moroccan Jews (8%). R92Q was found in 3 (3.2%) of the 92 FMF patients, 1 homozygous for the MEFV M694V mutation and 2 heterozygous for M694V. All 3 patients showed partial response to colchicine. R92Q was not found in patients

unresponsive to colchicine, nor was it found in patients with amyloidosis or in patients with FMF-like disease without MEFV mutations.

CONCLUSION: The frequency of the R92Q mutation in FMF patients is comparable with that of controls. Despite the fact that TRAPS and FMF share common biochemical pathways, we found no evidence for an interaction between these two genes.

Activation of ASC induces apoptosis or necrosis, depending on the cell type, and causes tumor eradication.

Motani K(1), Kawase K, Imamura R, Kinoshita T, Kushiyaama H, Suda T.

Author information:

(1)Division of Immunology and Molecular Biology, Cancer Research Institute, Kanazawa University, Kanazawa, Ishikawa, Japan.

The adaptor protein ASC (also called TMS1) links certain NLR proteins (e.g., NLRC4, NLRP3) and caspases. It is involved in the chemosensitivity of tumor cells and inflammation. Here, we found that ASC activation using NLRC4 mimicry or an autoinflammatory disease-associated NLRP3 mutant induced necrosis in COLO205 colon adenocarcinoma cells, but induced caspase-8-dependent apoptosis in NUGC-4 stomach cancer cells. As the Fas ligand induced caspase-8-dependent apoptosis in COLO205 cells, caspase-8 was intact in this cell line. ASC-mediated necrosis was preceded by lysosomal leakage, and diminished by inhibitors for vacuolar H(+)-ATPase, cathepsins, and calpains but not by inhibitors for caspase-8, or aspartic proteases, suggesting that lysosomes and certain proteases were involved in this process. Finally, growing tumors of transplanted human cancer cells in nude mice were eradicated by the activation of endogenous ASC in the tumor cells, irrespective of the form of cell death. Thus, ASC mediates distinct forms of cell death in different cell types, and is a promising target for cancer therapy.

h.moncrieffe@ich.ucl.ac.uk

The ectonucleotidase CD39 has recently been described as being highly expressed on regulatory Foxp3(+) CD4 T cells. Through hydrolysis of proinflammatory extracellular ATP, CD39 activity represents a newly described mechanism of regulatory T cell action. We report a novel population of human CD4 T cells that express CD39 yet are Foxp3 negative. These cells produce the proinflammatory cytokines IFN-gamma and IL-17 and fail to suppress proliferation; however, they still have high ATP hydrolysis activity. In the inflammatory site in human juvenile idiopathic arthritis, the CD39(+)Foxp3(-) population is greatly increased compared with peripheral blood of patients or healthy controls. We also show that cells expressing the AMPase CD73 are less frequent in the joint than in blood. To our knowledge, this is the first study to describe and characterize CD39 function on CD4 T cells from the target site in a human autoinflammatory condition. Our data suggest that in human CD4(+) T cells from the inflamed site, CD39 can be highly expressed on two populations, one regulatory and the other of a memory phenotype.

Familial clustering of recurrent pericarditis may disclose tumour necrosis factor receptor-associated periodic syndrome.

Cantarini L(1), Lucherini OM, Baldari CT, Laghi Pasini F, Galeazzi M.

Author information:

(1)Interdepartmental Research Center of Systemic Autoimmune and Autoinflammatory Diseases, Unit of Rheumatology, Policlinico Le Scotte, University of Siena, Siena, Italy. cantariniluca@hotmail.com

**OBJECTIVES:** Although several causes of recurrent pericarditis have been identified, the etiology remains obscure in most cases. The tumour necrosis factor receptor-1 associated periodic syndrome (TRAPS) is the most common autosomal dominant autoinflammatory disorder and is caused by mutations in the TNFRSF1A gene encoding the 55-kD receptor for tumour necrosis factor-(TNF)-alpha. Serosal membrane inflammation is a common feature of TRAPS, usually in the form of polyserositis. In addition, patients affected with recurrent pericarditis as the only clinical manifestation of TRAPS have been recently described. Our aim was to investigate the possible involvement of mutations in the TNFRSF1A gene in a cohort of patients affected with idiopathic recurrent pericarditis.

**METHODS:** Twenty consecutive patients diagnosed with idiopathic recurrent pericarditis were enrolled. Each patient underwent detailed examinations in order to rule out underlying diseases such as infections, connective tissue disorders and malignancies, and mutations of the TNFRSF1A gene were searched for by amplifying, using polymerase chain reaction (PCR), genomic DNA, and direct sequencing.

**RESULTS:** TNFRSF1A mutations were found in 2 of the 20 patients. They were siblings, and they both carried a heterozygous low-penetrance R92Q mutation in the TNFRSF1A gene.

**CONCLUSIONS:** Familial clustering has been recently reported in up to 10% of patients with recurrent pericarditis, thus suggesting in some cases a possible genetic predisposition. Our study suggests that familial clustering may represent a clue for investigating mutations in the TNFRSF1A gene in these patients and eventually disclose TRAPS.

P wave dispersion in familial Mediterranean fever.

Nussinovitch N(1), Livneh A, Katz K, Nussinovitch M, Volovitz B, Lidar M, Nussinovitch U.

Author information:

(1)Hypertension Unit and Department of Internal Medicine D, Sheba Medical Center, Tel Hashomer, Israel. nussim@clalit.org.il

Familial Mediterranean fever (FMF) is a hereditary disease characterized by recurrent and self-terminated attacks of fever and polyserositis. A recent study found that FMF patients had an abnormally high P wave duration and P wave dispersion, markers for supraventricular arrhythmogenicity. The aim of our study was to further evaluate atrial dispersion in FMF patients. The study group consisted of 26 patients with uncomplicated FMF and age- and sex-matched control subjects. All participants underwent 12-lead electrocardiography under strict standards. P wave length and P wave dispersion were computed from a randomly selected beat and from an averaged beat constructed from 7 to 12 beats, included in a 10-s ECG. No statistically significant differences were found between the groups in minimal, maximal, and average P wave duration and P wave dispersion calculated either from a random beat or averaged beats. During 6 months of follow-up, no supraventricular arrhythmias were documented in either group. FMF patients who are continuously treated with colchicine and do not develop amyloidosis have normal atrial conduction parameters and therefore seemingly do not have an increased electrocardiographic risk of atrial fibrillation.

Transverse myelitis and polymyositis associated with antiphospholipid antibody syndrome.

Mori A(1), Nodera H, Nakane S, Kaji R.

Author information:

(1)Department of Neurology, Tokushima University, Tokushima, Japan.

Antiphospholipid antibody syndrome (APS) has been widely recognized to be associated with various neurological complications. In addition to the classical notion of APS as a thrombotic disorder, APS has been suggested to be an autoinflammatory disease as well. We present a previously healthy 46-year-old man who concurrently developed transverse myelitis and polymyositis whose laboratory studies were significant for the elevated antiphospholipid antibodies such as anti-cardiolipin (CL)/beta2-glycoprotein I (beta 2GPI) antibody. This report further enhances the recognized clinical phenotypes of the neurological complications of APS and the understanding of its pathomechanism.

Targeting IL-1beta in disease; the expanding role of NLRP3 inflammasome.

Mitroulis I(1), Skendros P, Ritis K.

Author information:

(1)First Department of Internal Medicine, Democritus University of Thrace, Alexandroupolis, Greece.

NLRP3 inflammasome activation and IL-1 $\beta$  secretion have recently emerged as a central mechanism in the pathogenesis of disease. Genetically defined syndromes like cryopyrin-associated periodic syndromes (CAPS, cryopyrinopathies) and familial Mediterranean fever (FMF) or diseases associated with NLRP3 activation by danger signals like gout, pseudogout, Alzheimer's disease or type 2 diabetes are included in this group of diseases. The contribution of anakinra, a recombinant, nonglycosylated human IL-1 receptor antagonist, in both the identification and treatment of such syndromes was considerable. Recently, rilonacept, a long-acting IL-1 receptor fusion protein, and canakinumab, a fully humanized anti-IL-1 $\beta$  monoclonal antibody, have been developed, with the intention to further extend IL-1 $\beta$  inhibition treatment strategies to a broader spectrum of disorders beyond the characterized autoinflammatory syndromes, offering a more favorable administration profile. On the other hand, the developed caspase-1 inhibitors, even though effective in experimental models, were not proven efficient in the treatment of inflammatory diseases.

Our immune defense depends on two specialized armed forces. The innate force acts as an alarm mechanism that senses changes in the microenvironment through the recognition of common microbial patterns by Toll-like receptors (TLR) and NOD proteins. It rapidly generates an inflammatory response aimed at neutralizing the intruder at the mucosal checkpoint. The innate arm also communicates this message with more specialized adaptive forces represented by pathogen-specific B cells and T cells. Interestingly, B cells also express some innate sensors, like TLR7 and TLR9, and may respond to bacterial hypomethylated CpG motifs and single-stranded RNA viruses. Intracellular nucleic acid sensing TLRs play an important role in the pathogenesis of Systemic Lupus Erythematosus (SLE). In this review, we describe recent achievements in the development of

oligonucleotide-(ODN)-based inhibitors of TLR9 and/or TLR7 signaling. We categorize these novel therapeutics into Classes G, R, and B based on their cellular and molecular targets. Several short ODNs have already shown promise as pathway-specific therapeutics for animal lupus. We envision their future use in human SLE, microbial DNA-dependent sepsis, and in other autoinflammatory diseases.

Genotype-phenotype studies in a large cohort of Armenian patients with familial Mediterranean fever suggest clinical disease with heterozygous MEFV mutations.

Moradian MM(1), Sarkisian T, Ajrapetyan H, Avanesian N.

Author information:

(1)Center of Medical Genetics and Primary Health Care, Department of Molecular Genetics, Yerevan, Armenia. moradian@makgene.com

Familial Mediterranean fever (FMF) is an autoinflammatory disorder generally caused by recessively inherited mutations in the MEFV gene. FMF is quite prevalent in Armenian population in which majority of patients have two mutated alleles, yet in 18% of symptomatic patients just one mutation has been detected. To explain this finding, we analyzed the symptoms and genotypes of 1,299 patients, including 236 affected heterozygous patients with definite diagnosis of FMF. We selected a subset of 63 heterozygous, homozygous and asymptomatic normal individuals and completely sequenced their MEFV genes (exons) to discover any other mutations potentially missed by currently used screening method. Besides four synonymous polymorphisms in exon two and five, we found a T267I mutation in one heterozygous patient with a severe case of FMF who should have been designated as compound heterozygous, yet the other genotypes were all accurate. We used binomial probability distribution of symptoms in homozygous FMF patients to estimate the likelihood of their occurrences in heterozygous patients and demonstrated the assemblage of patients into groups with similar clinical criteria using statistical clustering. We found extremely high probabilities for

the presence of FMF symptoms in heterozygous individuals and determined that symptoms were equally likely to occur in both analyzed genotypes. Therefore, our study supports the rising evidence that a single MEFV mutation could be associated with mild FMF symptoms. However, heterozygous patients presenting with severe phenotype should be further analyzed for less common second MEFV mutation using gene sequencing.

Comment in

J Neurol Sci. 2010 Nov 15;298(1-2):163; author reply 163-4.

**PURPOSE:** Multiple Sclerosis (MS) is a disease of the central nervous system characterized by multiple areas of inflammation and demyelination in the white matter of the brain and spinal cord. MEFV gene, which is the main factor in familial Mediterranean fever, is an intracellular regulator of inflammation. This study was designed to determine if known mutations in pyrin domain of MEFV gene are involved in MS and associated with MS morbidity.

**METHODS:** Fifty-three patients with MS and 66 healthy subjects, who were all Turkish, were included in this study. Five pyrin gene mutations (E148Q, M680I, M694V, M694I and V726A) were detected in the patients and controls by using the PRONTO FMF Basic Kit according to the manufacturer's instructions.

**RESULTS:** Pyrin gene mutations were found in 20 of the 53 MS patients (38%) and in seven of the 66 healthy subjects (11%). The frequency of total pyrin domain mutations was significantly higher in the MS patients than in the healthy subjects ( $p < 0.0001$ ). The frequencies of M694V, E148Q and V726A mutations were significantly higher in the patients than in the healthy subjects ( $p = 0.02$ ,  $p = 0.013$ ,  $p = 0.004$  respectively). The mean time to reach EDSS score 3.0 was earlier in the patients with MEFV gene mutation ( $p = 0.02$ ) and the relapse rate was slightly higher among the MS patients carrying MEFV gene mutation ( $p = 0.04$ ).

**CONCLUSION:** The results of this study supported the hypothesis that MS patients with MEFV mutation seem to have the susceptibility to develop a more progressive disease. Moreover, these data suggest that MEFV mutations may increase the risk of MS development.

Tumor necrosis factor receptor-1-associated periodic syndrome (TRAPS) is the most common autosomal dominant autoinflammatory disorder and is caused by mutations in the TNFRSF1A gene encoding the 55-kDa receptor for tumor necrosis factor (TNF)- $\alpha$ . TRAPS is characterized by recurrent attacks of fever, typically lasting from 1 to 3 weeks. In addition to fever, common clinical features include periorbital edema, a migratory erythematous plaque simulating erysipela with underlying myalgia, and arthralgia or arthritis. Serosal membrane inflammation is also a common feature, usually in the form of polyserositis. To date, at least 40 different TNFRSF1A mutations have been identified, but few patients with symptoms highly suggestive of TRAPS with no mutations in the TNFRSF1A gene have recently been described, thus suggesting that not all mutations are yet known or that alternative mechanisms might be involved in the pathogenesis of the disease. We

report on three such patients here.

Arterial distensibility in chronic inflammatory rheumatic disorders.

Yildiz M(1).

Author information:

(1)Department of Cardiology, Kartal Kosuyolu Yuksek Ihtisas Educational and Research Hospital (Kosuyolu Heart Hospital), Istanbul, Turkey.

The pulse wave velocity (PWV), as an indicator of arterial distensibility, may play an important role in the stratification of patients based on the cardiovascular risk. PWV inversely correlates with arterial distensibility and relative arterial compliance. Decreased arterial distensibility alters arterial blood pressure and flow dynamics, and disturbs coronary perfusion. Systemic immune and inflammatory diseases, such as rheumatoid arthritis (RA) and systemic lupus erythematosus (SLE) are associated with increased morbidity and mortality, predominantly due to adverse cardiovascular events. Systemic inflammation in these disorders may alter arterial compliance and arterial distensibility and, through this effect, lead to accelerated atherosclerosis. We have demonstrated an increase in the carotid-femoral (aortic) PWV that is a technique in which large artery elasticity is assessed from analysis of the peripheral arterial waveform, in patients with chronic inflammatory conditions such as RA, SLE, familial Mediterranean fever (FMF), Wegener's granulomatosis (WG), sarcoidosis, psoriasis and psoriatic arthritis except Behçet's disease (BD). In this review, the issue of arterial stiffness in RA, SLE, as well as WG, psoriasis, FMF, BD, sarcoidosis, systemic sclerosis (SS) and Takayasu's arteritis (TA) is overviewed.

Comment in

Nat Rev Rheumatol. 2010 Jul;6(7):384.

TNF, acting through p55 tumor necrosis factor receptor 1 (TNFR1), contributes to the pathogenesis of many inflammatory diseases. TNFR-associated periodic syndrome (TRAPS, OMIM 142680) is an autosomal dominant autoinflammatory disorder characterized by prolonged attacks of fevers, peritonitis, and soft tissue inflammation. TRAPS is caused by missense mutations in the extracellular domain of TNFR1 that affect receptor folding and trafficking. These mutations lead to loss of normal function rather than gain of function, and thus the pathogenesis of TRAPS is an enigma. Here we show that mutant TNFR1 accumulates intracellularly in peripheral blood mononuclear cells of TRAPS patients and in multiple cell types from two independent lines of knockin mice harboring TRAPS-associated TNFR1 mutations. Mutant TNFR1 did not function as a surface receptor for TNF but rather enhanced activation of MAPKs and secretion of proinflammatory cytokines upon stimulation with LPS. Enhanced inflammation depended on autocrine TNF secretion and WT TNFR1 in mouse and human myeloid cells but not in fibroblasts. Heterozygous TNFR1-mutant mice were hypersensitive to LPS-induced septic shock, whereas homozygous TNFR1-mutant mice resembled TNFR1-deficient mice and were resistant to septic shock. Thus WT and mutant TNFR1 act in concert from distinct cellular locations to potentiate inflammation in TRAPS. These findings establish a mechanism of pathogenesis in autosomal dominant diseases where full expression of the disease phenotype depends on functional cooperation between WT and mutant proteins and also may explain partial responses of TRAPS patients to TNF

blockade.

Altered redox state of monocytes from cryopyrin-associated periodic syndromes causes accelerated IL-1beta secretion.

Tassi S(1), Carta S, Delfino L, Caorsi R, Martini A, Gattorno M, Rubartelli A.

Author information:

(1)Cell Biology Unit, National Cancer Research Institute, 16132 Genoa, Italy.

In healthy monocytes, Toll-like receptor (TLR) engagement induces production of reactive oxygen species (ROS), followed by an antioxidant response involved in IL-1beta processing and secretion. Markers of the antioxidant response include intracellular thioredoxin and extracellular release of reduced cysteine.

Cryopyrin-associated periodic syndromes (CAPS) are autoinflammatory diseases in which Nod-like receptor family pyrin domain-containing 3 (NLRP3) gene mutations lead to increased IL-1beta secretion. We show in a large cohort of patients that IL-1beta secretion by CAPS monocytes is much faster than that by healthy monocytes. This accelerated kinetics is caused by alterations in the basal redox state, as well as in the redox response to TLR triggering displayed by CAPS monocytes. Indeed, unstimulated CAPS monocytes are under a mild oxidative stress, with elevated levels of both ROS and antioxidants. The redox response to LPS is quickened, with early generation of the reducing conditions favoring IL-1beta processing and secretion, and then rapidly exhausted. Therefore, secretion of IL-1beta is accelerated, but reaches a plateau much earlier than in healthy controls. Pharmacologic inhibition of the redox response hinders IL-1beta release, confirming the functional link between redox impairment and altered kinetics of secretion. Monocytes from patients with juvenile idiopathic arthritis display normal kinetics of redox response and IL-1beta secretion, excluding a role of chronic inflammation in the alterations observed in CAPS. We conclude that preexisting redox alterations distinct from CAPS monocytes anticipate the

pathogen-associated molecular pattern molecule-induced generation of the reducing environment favorable to inflammasome activation and IL-1 $\beta$  secretion.

Topical use of colchicine to prevent spinal epidural fibrosis in rats.

Ozdemir O(1), Calisaneller T, Sonmez E, Kiyici H, Caner H, Altinors N.

Author information:

(1)Department of Neurosurgery, Baskent University Faculty of Medicine, Ankara, Turkey. ozgurhozdemir@yahoo.com

**OBJECTIVES:** Epidural fibrosis after spinal surgery may be the cause in most cases of recurrent pain. Numerous pharmacological agents and anti-adhesive barriers have been used to prevent epidural fibrosis, but the success rates are variable. Colchicine is an historical drug extracted from the flowers of *Colchium autumnale* widely used in arthritic conditions in the past. Currently, it is used in acute gout attacks, familial mediterranean fever for its anti-inflammatory and antifibrotic effects. Also, colchicine is used locally in the cutaneous diseases (e.g. actinic keratoses, psoriasis) for its similar effects. In present study, we investigated the effect of topical colchicine on spinal epidural fibrosis in the rats.

**METHODS:** The rats were randomly divided to three groups of six animals each. Total L4-5 laminectomy was performed, and ligamentum flavum and epidural fat were removed gently. Meticulous hemostasis was achieved by using cotton pad when necessary, and no bone wax and cauterization were used. Dura was left clean with no hemorrhages. In treatment group cotton pads (5 × 5 mm) soaked with 0.005 mg/ml colchicine and applied on laminectomy sites for 10 minutes and removed, in sham group only saline irrigation was done. In control group no medication or irrigation was applied. The wound was closed in layers using the same material in each group. Four weeks later, the rats were killed, and the spinal column, including surrounding muscle tissue, was removed en bloc, decalcified, and fixed

in formaldehyde. Epidural fibrosis was evaluated histologically.

RESULTS: In colchicine-treated group, epidural fibrosis was significantly reduced compared with control and sham groups.

CONCLUSIONS: Epidural fibrosis is a well-known complication following lumbar disc surgery. Topical application of colchicine is very effective in preventing epidural fibrosis.

High frequency of MEFV gene mutations in patients with myeloid neoplasm.

Oktenli C(1), Sayan O, Celik S, Erikci AA, Tunca Y, Terekeci HM, Umur EE, Sanisoglu YS, Torun D, Tangi F, Sahan B, Nalbant S.

Author information:

(1)Division of Internal Medicine, GATA Haydarpasa Training Hospital, 34668, Kadikoy, Istanbul, Turkey. coktenli@yahoo.com

We aimed to investigate the rate of MEFV, the gene mutated in familial Mediterranean fever, mutations in patients with myeloid neoplasm and to determine if known mutations of MEFV cause a tendency for myeloid neoplasms. The frequency of the five most common MEFV gene mutations (M694V, M680I, V726A, E148Q and M694I) was determined in 26 patients with myeloid neoplasm. We identified 1 homozygous (E148Q/E148Q), 1 compound heterozygous (M694V/E148Q) and 5 heterozygous MEFV gene mutations; none had their own and/or family history compatible with familial Mediterranean fever. The mean overall mutation rate was 0.269. We found a high frequency of carriers in patients with myelodysplastic syndrome (66.6%), polycythemia vera (33.3%) and acute myeloid leukemia (28.6%). However, there was no MEFV gene mutation in patients with chronic myeloid leukemia. In conclusion, this study reports for the first time a possibly high prevalence of MEFV gene mutations in patients with myeloid neoplasm, especially myelodysplastic syndrome, polycythemia vera and acute myeloid leukemia. Our findings could open new perspectives for MEFV gene mutations in myeloid neoplasms and its association with tumor promotion. Further research is needed to determine

the actual role of MEFV gene mutations in these malignancies.

Hyperimmunoglobulin D syndrome in childhood.

van der Hilst JC(1), Frenkel J.

Author information:

(1)Department of Internal Medicine and Infectious Diseases, University Medical Centre Utrecht, Utrecht, The Netherlands. j.c.h.vanderhilst@umcutrecht.nl

Hyperimmunoglobulinemia D and periodic fever syndrome, an autoinflammatory

syndrome, is caused by mutations in the gene coding for mevalonate kinase. The disease is clinically characterized by recurrent attacks of fever accompanied by an array of inflammatory symptoms including lymphadenopathy, rash, arthritis, and gastrointestinal complaints. Most patients have their first attack in the first year of life, typically after a childhood vaccination. The frequency of attacks is highest during childhood, with a gradual decrease after adolescence. Frequent fever attacks impair quality of life and the achievement of educational milestones. Recent reports show promising results with anakinra and etanercept to treat the attacks.

Author information:

(1)Department of Nephrology, Faculty of Medicine, Cumhuriyet University, Sivas, Turkey. drgursel@yahoo.com

Clinical symptoms and findings of familial Mediterranean fever (FMF), occur as a result of autoimmune inflammation of the serous membrane which is also seen in systemic lupus erythematosus (SLE). Difficulties are sometimes encountered in the differential diagnosis of FMF because of similar clinical features with other autoimmune inflammatory diseases, and very rarely it can be seen with SLE. The association of FMF and SLE has been reported in one childhood case in Turkey. As far as we know, there is no report in the adult age group. Here, we present the first FMF and SLE association in an adult and discuss the pertinent literature in Turkey.

## Neurologic manifestations of the cryopyrin-associated periodic syndrome.

Kitley JL(1), Lachmann HJ, Pinto A, Ginsberg L.

### Author information:

(1)Wessex Neurological Centre, Southampton General Hospital, UK.

**BACKGROUND:** The cryopyrin-associated periodic syndrome (CAPS) is a rare but treatable hereditary autoinflammatory condition. Without treatment, one third of patients develop amyloidosis with consequent renal failure and death. CAPS encompasses 3 conditions: familial cold autoinflammatory syndrome, Muckle-Wells syndrome, and chronic infantile, neurologic, cutaneous, and articular syndrome. Neurologic complications are common in children with the chronic infantile, neurologic, cutaneous, and articular phenotype, but there are no previous published reports of neurologic features in adults with milder phenotypes.

**METHODS:** In this case series, we report in detail an adult case of CAPS and summarize the neurologic features seen in 12 other adults with genetically proven CAPS. These patients participated in a recent randomized study of canakinumab in CAPS and we used pretreatment data collected in this study.

**RESULTS:** Twelve of the 13 patients (92%) had headache, of whom 10 (77%) had features of migraine. Seven patients (54%) had sensorineural deafness. Nine patients (69%) reported myalgia. Six patients (46%) had papilledema and a further 2 (15%) had optic disc pallor. MRI brain scan was normal in all patients.

**CONCLUSION:** CAPS is a rare but treatable condition that may be encountered by neurologists in adult clinical practice since it can present with headache, myalgia, papilledema, sensorineural deafness, and aseptic meningitis.

Unrecognized and untreated, it can lead to significant morbidity and mortality from renal failure. Treatment with anti-interleukin-1 therapy leads to complete resolution of symptoms and should also prevent progression to amyloidosis and subsequent renal failure.

(1)Department of Medical Biology and Genetics, Faculty of Medicine, Firat University, Elazig, Turkey. ebruetem@gmail.com

Male infertility is a common barrier that prevents successful conception. There have been reports of azoospermia in men with familial Mediterranean fever, some of whom had not been treated with colchicine. Variation in this disorder could be a risk factor for amyloidosis associated with azoospermia. We determined the frequency of 6 of the most common Mediterranean fever gene mutations, M680I, M694V, M694I, V726A, P369S, and A744S, in 74 infertile men, 155 men diagnosed with familial Mediterranean fever and 55 healthy fertile men in eastern Turkey. All three groups were screened for the 6 mutations using an amplification refractory mutation system and restriction fragment length polymorphism methods. Allelic frequencies were 2.7% for M694V and 1.35% for V726A in the infertile patient group and 1.8% for M694V and 1.8% for V726A in healthy subjects. Other mutations were not detected in patients or controls. The mutation frequency was not found to be significantly higher in infertile patients when compared with healthy fertile male controls. To our knowledge, this is the first study to determine the frequency of Mediterranean fever gene mutations in infertile male and the infertility rate of male patients with familial Mediterranean fever.

Relatively few data have been published on the management of pericardial diseases during pregnancy. Pericardial involvement is sporadic during pregnancy, and pregnant women do not show any specific predisposition to pericardial diseases. The more common form of pericardial involvement is hydropericardium, usually as a benign mild effusion recorded in about 40% of pregnant women by the third trimester, followed by pericarditis as the more common disease requiring medical

therapy. The general management of these conditions is not different from those of nonpregnant women, although specific precautions should be followed for specific diagnostic and therapeutic issues during pregnancy. If possible, pregnancy should be planned in a phase of disease quiescence. Nonselective cyclooxygenase inhibitors and aspirin can be used safely during the first and second trimester, but should be withdrawn later and in any case at gestational week 32, because of the possible effects on ductus arteriosus and renal function. Low-medium doses of prednisone are allowed during all pregnancy and breastfeeding. Colchicine is generally contraindicated during pregnancy, except in women with familial Mediterranean fever. These pregnancies should be followed by a dedicated multidisciplinary teams.

Familial Mediterranean fever (FMF) is an autosomal recessive disease characterized by self-limited recurrent attacks of fever and serositis. The serious complication of FMF is AA-type amyloidosis, which can result in end-stage renal disease. Although colchicine is effective in the majority of patients, there is no established treatment for those who are resistant or intolerant to colchicine. We herein report the efficacy of anakinra in a 52-year-old Turkish patient with FMF, secondary amyloidosis and renal transplant, who was resistant to colchicine treatment.

The aim of the study was to further evaluate repolarization dispersion in familial Mediterranean fever (FMF). Findings on 12-lead electrocardiography were compared with 32 patients with uncomplicated FMF and age- and sex-matched control subjects. All procedures followed stringent standards. Repolarization and dispersion parameters were computed with designated computer software, and results of the five beats were subsequently averaged. There were no statistically significant differences between the groups in average QT and average corrected QT interval length, average QT interval dispersion, average QT corrected dispersion, or QT dispersion ratio. During 6 months of follow-up, no cases of sudden death or arrhythmia were documented in either group. Patients with FMF who are continuously treated with low-dose colchicine and have not developed amyloidosis seem to have QT dispersion parameters similar to those of healthy subjects and therefore apparently have no increased risk of adverse cardiac events associated with abnormal repolarization.

Genotype-phenotype correlation in patients with familial Mediterranean fever in East Anatolia (Turkey).

Albayrak F(1), Selcuk NY, Odabas AR, Cetinkaya R, Pirim I.

Author information:

(1)Department of Gastroenterology, School of Medicine, Ataturk University, Erzurum, Turkey. fatihalbayerkerz@gmail.com

**AIMS:** Familial Mediterranean fever (FMF) is an autosomal recessive hereditary disease. Clinical symptoms and findings (phenotypes) seen in this disease are generally fever, abdominal pain, and arthritis. Amyloidosis is also a significant complication. Phenotype-genotype correlations in FMF have not been conclusively resolved. The aims of this study were to find the most frequent mutation/genotype of FMF, as well as to investigate the role of genetic factors on the phenotype and on the development of amyloidosis in a population living in East Anatolia (Turkey). This study included 105 adult patients with FMF. DNA samples were obtained from peripheral blood lymphocytes of the patients. Mutations of the Mediterranean fever (MEFV) gene were analyzed with an FMF Strip Assay test kit (ViennaLab Labordiagnostika GmbH, Vienna, Austria). Patients were separated according to genotypes, and phenotypes were compared statistically by the chi-square test.

**RESULTS:** The most frequent mutation was M694V (53%) and the most frequent genotype was M694V/M694V (26%). In total, 81% of the patients experienced abdominal pain, 76% had fever, and 22% had arthritis. Fever and arthritis were determined in similar ratios to other genotypes (76% and 19%, respectively) in the M694V/M694V genotype (74% and 29%, respectively) ( $p > 0.50$  and  $p > 0.20$ , respectively). However, the patients without the M694V/M694V genotype (86%) had a higher abdominal pain ratio than did the patients with the M694V/M694V genotype (67%) ( $p < 0.05$ ). Renal amyloidosis was determined in 33% of both M694V/M694V and M680I(G/C)/M680I(G/C) homozygous groups and in 12% of the heterozygous groups ( $p < 0.02$  and  $p < 0.00002$ , respectively). In other words, homozygous groups had

higher ratios of renal amyloidosis.

CONCLUSIONS: The most frequent mutation in FMF was M694V and the most frequent genotype was M694V/M694V. Fever, abdominal pain, arthritis, and renal amyloidosis were determined not only in patients with M694V/M694V genotype but also in other genotypes. Therefore, genotypes may not predict phenotypes in FMF. Renal amyloidosis was seen more frequently in homozygous genotypes.

Familial Mediterranean fever and membranous glomerulonephritis: report of a case.

Ceri M(1), Unverdi S, Altay M, Unverdi H, Ensari A, Duranay M.

Author information:

(1)Department of Nephrology, Ankara Education and Research Hospital, and Department of Pathology, Faculty of Medicine, Ankara University, Ankara, Turkey.

Familial Mediterranean fever (FMF) is an autosomal recessive genetic disease characterized by recurrent attacks of fever and painful episodes of sterile polyserositis. Kidney involvement may occur as a result of secondary amyloidosis during the course of FMF. Previously, different types of glomerulopathies such as IgM and IgA nephropathy, crescentic glomerulonephritis, diffuse proliferative glomerulonephritis, minimal change disease, and membranoproliferative glomerulonephritis were rarely reported. We herein represent a first case of membranous glomerulonephritis who had complete remission with colchicine treatment in the course of familial Mediterranean fever.

Comment in

Arch Pathol Lab Med. 2011 Feb;135(2):168; author reply 168-9.

**CONTEXT:** A disease associated with amyloid deposits, called amyloidosis, is associated with characteristic electron microscopic appearance, typical x-ray pattern, and specific staining. Renal involvement mainly occurs in AA amyloidosis and AL amyloidosis and usually progresses to renal failure.

**OBJECTIVE:** The renal histopathologic changes with amyloidosis comprise a spectrum. Clear relationships between the extent of amyloid deposition and the severity of clinical manifestations have not been demonstrated. Whether there is a lack of clinicopathologic correlation is not clear, but studies have revealed the need for standardization of the renal amyloid biopsy report. With these objectives in mind, we proposed a histopathologic classification, scoring, and grading system. Renal amyloidosis was divided into 6 classes, similar to the classification of systemic lupus erythematosus. Amyloid depositions and other histopathologic lesions were scored. The sum of these scores was termed the renal amyloid prognostic score and was divided into 3 grades.

**DATA SOURCES:** AA amyloidosis was detected in 90% of cases, mostly related to familial Mediterranean fever. Positive correlations between class I and grade I, class VI and grade III, and class III and grade II were observed. Also, a positive correlation was identified between severity of glomerular amyloid depositions, interstitial fibrosis, and inflammation. Because of the inadequacy of the patients' records and outcomes, different therapy regimes, and etiologies, clinical validation of this study has not been completed.

**CONCLUSIONS:** Standardization of the renal amyloid pathology report might be critical for patients' medication and comparison of outcome and therapeutic trials between different clinics. Because of our AA to AL amyloidosis ratio and the predisposition of familial Mediterranean fever-related AA amyloidosis, there is a need for further international collaborative studies.

Familial mediterranean Fever as an emerging clinical model of atherogenesis associated with low-grade inflammation.

Yüksel S(1), Ayvazyan L, Gasparian AY.

Author information:

(1)Boğaziçi University, Department of Molecular Biology and Genetics, Istanbul, Turkey.

Numerous inflammatory and innate immune pathways are involved in atherogenesis. Elaboration of clinical models of inflammation-induced atherogenesis may further advance our knowledge of multiple inflammatory pathways implicated in atherogenesis and provide a useful tool for cardiovascular prevention. Familial Mediterranean fever (FMF) is a chronic inflammatory disorder with profiles of inflammatory markers close to that seen in the general population. In a few recent studies, it has been shown that endothelial dysfunction, increased atherosclerotic burden and activation of platelets accompany attack-free periods of FMF. Colchicine is proved to be useful in suppression of inflammation in FMF. Preliminary basic and clinical studies suggest that this relatively safe drug may be useful for cardiovascular protection in patients with FMF and in the general population. Multinational prospective studies are warranted to further elaborate clinical model of inflammation-induced atherosclerosis associated with FMF.

Familial Aicardi-Goutières syndrome due to SAMHD1 mutations is associated with chronic arthropathy and contractures.

Dale RC(1), Gornall H, Singh-Grewal D, Alcausin M, Rice GI, Crow YJ.

Author information:

(1)Institute of Neuroscience and Muscle Research, University of Sydney, Sydney, Australia. russelld@chw.edu.au

We report on two siblings doubly heterozygous for null mutations in the recently identified AGS5 gene SAMHD1. The older female child showed mild intellectual disability with microcephaly. Her brother demonstrated a significant spastic paraparesis with normal intellect and head size. Both children had an unclassified chronic inflammatory skin condition with chilblains, and recurrent mouth ulcers. One child had a chronic progressive deforming arthropathy of the small and large joints, with secondary contractures. This family illustrate the remarkable phenotypic diversity accruing from mutations in genes associated with Aicardi-Goutières syndrome (AGS). The association of arthropathy with SAMHD1 mutations highlights a phenotypic overlap of AGS with familial autoinflammatory disorders such as chronic infantile neurological cutaneous and articular syndrome (CINCA). This family therefore illustrate the need to consider mutation analysis of SAMHD1 in non-specific inflammatory phenotypes of childhood. We propose that arthropathy with progressive contractures should now be considered part of the spectrum of Aicardi-Goutières syndrome because of SAMHD1 mutations.

Modulation of inflammasome activity for the treatment of auto-inflammatory disorders.

Naik E(1), Dixit VM.

Author information:

(1)Genentech, Inc, South San Francisco, CA, USA. naik.edwina@gene.com

INTRODUCTION: The innate immune system orchestrates inflammatory responses to microorganisms or danger-associated molecular patterns generated, for example, by

the deposition of uric acid in the joints of gout patients. The innate immune system comprises multiple germ-line encoded receptors, of which the nucleotide-binding domain and leucine-rich repeat containing receptors (NLRs) are crucial for the maturation of pro-inflammatory cytokines. NLRs oligomerize to form large multi-protein complexes termed inflammasomes that generate active caspase-1 fragments leading to the cleavage and secretion of mature cytokines such as IL-1 $\beta$  and IL-18. THE REGULATION OF MULTIPLE INFLAMMASOMES: At least four independent inflammasomes have been identified, NLRP1, NLRP3, IPAF, and AIM2. These inflammasomes assemble in response to different stimuli to confer specificity and are also subject to negative regulatory mechanisms to ensure that once a productive inflammatory response has been mounted, inflammatory cytokine production is restrained. TREATMENT OF AUTO-INFLAMMATORY DISORDERS: A number of human conditions are characterized by unrestrained inflammasome activation. As much is now known about how inflammasomes are regulated, it is hoped that this can be channeled into the development of novel therapeutics, for example, those that may block the upstream activation and assembly of inflammasomes.

Monogenic IL-1 mediated autoinflammatory and immunodeficiency syndromes: finding the right balance in response to danger signals.

Henderson C(1), Goldbach-Mansky R.

Author information:

(1)National Institute of Arthritis and Musculoskeletal and Skin Diseases,  
National Institutes of Health, Translational Autoinflammatory Disease Section,  
USA. hendersoncc@mail.nih.gov

**INTRODUCTION:** Interleukin-1 was the first cytokine identified and is a powerful inducer of fever and inflammation. The biologically active receptor for IL-1, shares signaling pathways with some pathogen recognition receptors, the Toll-like receptors (TLRs) which early on suggested an important role in innate immune function.

**DISCUSSION:** The discovery that some intracellular "danger receptors", the NOD like receptors (NLRs) can assemble to form multimolecular platforms, the inflammasomes, that not only sense intracellular danger but also activate IL-1 $\beta$ , has provided the molecular basis for the integration of IL-1 as an early response mediator in danger recognition. The critical role of balancing IL-1 production and signaling in human disease has recently been demonstrated in rare human monogenic diseases with mutations that affect the meticulous control of IL-1 production, release and signaling by leading to decreased or increased TLR/IL-1 signaling. In diseases of decreased TLR/IL-1 signaling (IRAK-4 and MyD88 deficiencies) patients are at risk for infections with gram positive organisms; and in diseases of increased signaling, patients develop systemic autoinflammatory diseases (cryopyrin-associated periodic syndromes (CAPS), and deficiency of the IL-1 receptor antagonist (DIRA)).

**CONCLUSION:** Monogenic defects in a number of rare diseases that affect the balance of TLR/IL-1 signaling have provided us with opportunities to study the systemic effects of IL-1 in human diseases. The molecular defects in CAPS and DIRA provided a therapeutic rationale for targeting IL-1 and the impressive clinical results from IL-1 blocking therapies have undoubtedly confirmed the pivotal role of IL-1 in human disease and spurred the exploration of modifying IL-1 signaling in a number of genetically complex common human diseases.

(3)General Surgery, Faculty of Medicine, Atatürk University, Erzurum, Turkey.

**OBJECTIVE:** Our goal is to investigate the distribution of MEFV mutations in patients with renal amyloidosis who are in renal transplant waiting list which is prepared for transplantation.

**MATERIALS AND METHODS:** FMF was diagnosed in 25 of the 297 patients between the years 2004 and 2008, who were involved in the study (15 male, 10 female; age  $34 \pm 7.8$ ). 5 out of 25 patients were transplanted, remaining were waiting for Tx. Biopsy results were amyloidosis and taken from renal (n:16), rectal (n:8) and duodenal (1). All of them were carrier of mutations in both pyrin alleles. The primer cause of chronic renal failure in our group was secondary AA amyloidosis. DNA was isolated from 25 whole blood samples. The NanoChip Molecular Biology Workstation (Nanogen) uses electronic microarrays for mutation detection. Exon 2,3,5 and 10 of pyrin gene genotypes were identified in the NanoChip.

**RESULTS:** Genetic analysis of the patients demonstrated that each subject carries either homozygote or compound heterozygote mutations of the gene. The most common mutations were M694V, V726A, E148Q and M680I.

**CONCLUSIONS:** The clinic manifestation and complain of our patients were febrile and painful attacks such as in the abdomen, chest and joints due to inflammation of the peritoneum, pleura and synovial membrane. The major problem in FMF is the occurrence of amyloidosis that primarily affects the kidneys causing proteinuria and renal failure. Dialysis and renal transplantation can be treatment, but it is important to diagnose FMF at earliest stages. The percentage of FMF patients in our waiting list was 8.4%. Moreover, in our region FMF incidence is highly frequent, so FMF should be chased by genetically so as to prevent chronic renal

failure due to amyloidosis.

Publisher: Çalışmamızın amacı, böbrek nakli bekleme listemizdeki ailesel Akdeniz ateşi'ne (AAA) bağlı amiloidoz gelişmiş son dönem böbrek yetmezlikli hastaların sıklığı ve MEFV genindeki mutasyon dağılımını araştırmaktır. 2004–2008 yılları arasında bekleme listesinde olan toplam 297 hastadan AAA tanısı almış olan ve biyopsi ile amiloidoz tespit edilmiş olan 25 (15 erkek, 10 kadın) hasta çalışmamıza dahil edildi. AAA olan hastaların 5'ine böbrek nakli yapıldı. Hastaların 16'sına renal, 8'ine rektal ve 1'ine duodenal biyopsi yapılarak amiloidoz geliştiği belirlenmiş. Yirmibeş hastanın periferik kanından DNA izole edildi. Vakalarımızın tümünde pyrin geninin her iki allelinde de mutasyon bulundu. Çalışmada pyrin geninin exon 2, 3, 5 ve 10 bölgelerindeki mutasyonların belirlenmesi için DNA analizörü NanoChip kullanıldı. Yirmi beş hastanın herbiri için mutasyon analizi yapıldı. Her bir hastanın ya homozigot veya heterozigot MFEV gen mutasyonu taşıdığı bulundu. En sık görülen mutasyonların sırasıyla M694V, V726A, E148Q ve M680I olduğu tespit edildi. AAA'nin yaygın olduğu bir bölgede bulunduğumuz dikkate alındığında, diyaliz ve böbrek nakli tedavi seçenekleri olmasına rağmen AAA'nin erken teşhisi ve tedavisi önem arz etmektedir. Pyrin genindeki mutasyonlar ile amiloidoz güçlü bir ilişki göstermektedir.

Protracted febrile myalgia syndrome in familial Mediterranean fever.

Senel K(1), Melikoglu MA, Baykal T, Melikoglu M, Erdal A, Ugur M.

Author information:

(1)Department of Physical Medicine and Rehabilitation, Medical Faculty, Ataturk University, Erzurum, Turkey. kazimsenel@gmail.com

Familial Mediterranean fever (FMF) is an autosomal, recessively inherited multisystem disease that affects various groups of people originating from the Mediterranean Sea region, most specifically those of Jewish, Turkish, Armenian,

and Arabic ethnicity. Recurrent attacks of fever and sterile polyserositis of the peritoneum, synovial membranes, and pleura are the main clinical features, although the clinical features of FMF have been expanded in recent years to also include severe myalgia, scrotal swelling, cardiac involvement, and protracted febrile myalgia syndrome (PFMS). PFMS is seen in only a small percentage of FMF patients and is characterized by severe debilitating myalgia of the upper and lower extremities and high fever, occasionally accompanied by abdominal pain, diarrhea, arthritis/arthralgia, and transient vasculitic purpura mimicking Henoch-Schönlein purpura (HSP). Here, we report on a patient with FMF who also presents with PFMS, which is an uncommon and severe manifestation of the disease.

Author information:

(1)Department of Internal Medicine I, Division of Infectious Diseases and Tropical Medicine, Medical University of Vienna, Waehringerguertel 18-20, 1090, Vienna, Austria.

We report the case of a 35-years-old renal transplant patient known to have familial Mediterranean fever with serum amyloid A (SAA)-amyloidosis, who presented with his second episode of bilateral pneumonia. As antimicrobials failed to control the first episode of pneumonia and all studies done were non-contributory, we attributed the condition to the highly active Mediterranean fever presumably resistant to colchicine and treated the patient with the interleukin-1 receptor antagonist anakinra: the patient substantially improved by clinical symptoms, chemistry and radiological evidence within no more than 2 days and was discharged in good health after 4 days.

Fever is not only observed in the course of a bacterial or viral infection, but can be a symptom of, for instance, auto-immune, malignant or thromboembolic disease. Determining the etiology of fever in a fast and reliable way is of pivotal importance, as different causes of fever may ask for different therapies. Neither clinical signs and symptoms, nor traditional biomarkers, such as CRP, leukocytes and ESR have sufficient sensitivity and specificity to guide treatment decisions. In this review we focus on the value of traditional and newer biomarkers in non-infectious febrile diseases. Procalcitonin (PCT) seems to be the most helpful laboratory marker for the differentiation of causes of fever, particularly in autoimmune, autoinflammatory and malignant diseases.

Author information:

(1)Department of Pediatrics, University of Virginia Health System, Charlottesville, Virginia 22908, USA. fts@virginia.edu

We describe a 10-year-old child with a novel mutation, c.352A>G/p.Thr118Ala (T89A) in the tumour necrosis factor receptor superfamily 1A (TNFRSF1A) gene. The patient presented with periodic fevers beginning at 2 years of age. He had overlapping clinical and laboratory features of tumour necrosis factor receptor-associated periodic syndrome (TRAPS) and hyper-IgD syndrome (HIDS). This patient expands the clinical and genetic spectrum of TRAPS.

Possible association between NOD2 variants and joint surgery in psoriatic arthritis.

Graell E(1), Arostegui JI, Sanmartí R, Blanco FJ, Yagüe J, Pinto JA, Plaza S, Fernández-Sueiro JL, González A, Cañete JD.

Author information:

(1)Arthritis Unit, Rheumatology Department, Hospital Clínic de Barcelona, Institut d'Investigacions Biomèdiques August Pi i Sunyer (IDIBAPS), Barcelona, Spain.

BACKGROUND: Psoriatic arthritis (PsA) has been inconsistently associated with

common NOD2 gene variants, although some of these studies did not include patient stratification by clinical phenotype.

**OBJECTIVES:** To analyse the association between the three common NOD2 variants (R702W, G908R and L1007fs) and clinical phenotypes of PsA, particularly with surrogate markers of severe joint destruction.

**PATIENTS AND METHODS:** A total of 183 unrelated PsA patients and 187 controls were included. Demographic, clinical, biological and immunological characteristics were collected. Genotypes for the three common NOD2 gene variants were obtained by PCR and direct sequencing.

**RESULTS:** NOD2 variants in PsA patients (7.6%) are just as prevalent as in healthy controls (7.5%). 18.5% of PsA patients carrying at least one NOD2 variant underwent joint surgery compared with 4.5% of those without these variants ( $p=0.019$ ). Multivariate analysis confirmed this finding (OR 8.82, CI 1.7-46.3). There was no requirement for early surgery in patients carrying the NOD2 variants but there was an increased possibility of requiring surgery at similar times of disease duration. No other association with clinical features and NOD2 status carrier was found.

**CONCLUSIONS:** Common NOD2 gene variants are not associated with PsA, but might increase the risk of undergoing joint replacement surgery, suggesting that this autoinflammatory-associated gene could act as a phenotypic modifier gene in PsA patients by increasing the risk of joint destruction. Given the small number of PsA patients with joint surgery included, we consider our findings a new hypothesis that will need further testing.

nurayu@hacettepe.edu.tr

**BACKGROUND AND AIMS:** Familial Mediterranean fever (FMF) and inflammatory bowel disease (IBD) concordance has been investigated in a few studies. We investigated MEFV mutations and prevalence of FMF disease in Turkish children with IBD and their relationship with the disease severity.

**METHODS:** Sixteen patients with ulcerative colitis (UC), 14 with Crohn's disease (CD) and three with indeterminate colitis (IC) were enrolled in the study (median age 13 years, range 0.6-16 years, n = 19 boys). Demographic, clinical and laboratory characteristics of the patients were evaluated as well as the parameters of disease severity. All patients were screened for 12 common MEFV mutations.

**RESULTS:** MEFV mutations were detected in 17 of 66 (25.7%) alleles. Seven patients (four patients with CD, two with IC, and one with UC) were also diagnosed as FMF. FMF disease was found in seven of all IBD patients (21.2%) and four of them had CD. M694V was the leading mutation, and as a disease-causing mutation, it was found to be significantly more frequent in CD patients than UC patients (Fisher's exact test  $P = 0.03$ ). Demographics, laboratory evaluations, growth parameters, extraintestinal manifestations, and treatment with immunosuppressive agents other than steroids were comparable between the patients with and without FMF in most aspects.

**CONCLUSIONS:** Although this is a small cohort, disease-causing MEFV mutations and FMF disease rate were increased among our patients with IBD. The increase was prominent among CD patients, whereas in UC the rate was similar to the Turkish healthy control population.

Posterior reversible encephalopathy during an attack of familial Mediterranean fever.

Ulaşlı AM(1), Kutlu G, Kocatürk Ö, Özçakar L.

Author information:

(1)Department of Physical Medicine and Rehabilitation, Ankara Training and Research Hospital, Ankara, Turkey. alperulasli@yahoo.com

Reported here is a 19-year-old female patient with familial Mediterranean fever who was seen for altered mental status and seizures. She was eventually diagnosed to have posterior reversible leukoencephalopathy syndrome. Although a variety of conditions have been reported in association with this syndrome, to our best notice, this is the second case in whom familial Mediterranean fever and posterior reversible leukoencephalopathy coexists.

cdinarelli@mac.com

Inflammation involving the innate and adaptive immune systems is a normal response to infection. However, when allowed to continue unchecked, inflammation may result in autoimmune or autoinflammatory disorders, neurodegenerative disease, or cancer. A variety of safe and effective anti-inflammatory agents are available, including aspirin and other nonsteroidal anti-inflammatories, with many more drugs under development. In particular, the new era of anti-inflammatory agents includes "biologicals" such as anticytokine therapies and small molecules that block the activity of kinases. Other anti-inflammatories currently in use or under development include statins, histone deacetylase inhibitors, PPAR agonists, and small RNAs. This Review discusses the current status of anti-inflammatory drug research and the development of new anti-inflammatory therapeutics.

**BACKGROUND:** Many disease states are characterized by a biased cytokine profile and determining the level of certain cytokines becomes an important diagnostic and research tool in clinical medicine. We hypothesized that, despite the highly dynamic nature, the profile of cytokines may be characteristic of disease.

**METHODS:** The level of systemic cytokines was studied in an autoinflammatory condition, familial Mediterranean fever; in an autoimmune disease, systemic lupus erythematosus (SLE), and in healthy controls.

**RESULTS:** Multivariate statistics with the use of seven variables clustered the patients and control subjects into the four well separated and distinct groups, corresponding to the SLE, FMF attack, FMF remission, and healthy states.

**CONCLUSIONS:** The model suggested the existence of specific patterns in cytokine levels reflecting the healthy and specific disease states. These findings warrant further investigations to establish whether this approach may serve as a potential meta-biomarker for other inflammatory disorders.

Anti-cyclic citrullinated peptide antibodies are not associated with familial Mediterranean fever.

Karatay S(1), Yildirim K, Erdal A, Uzkeser H, Erdem FH, Yanmaz V.

Author information:

(1)Department of Physical Medicine and Rehabilitation, Medical Faculty, Ataturk University, 25240 Erzurum, Turkey. skaratay73@hotmail.com

**OBJECTIVE:** This study investigated the presence of anti-cyclic citrullinated peptide (anti-CCP) antibodies in familial Mediterranean fever (FMF) patients and controls.

**MATERIAL AND METHODS:** Forty-nine patients with FMF were enrolled (23 had a history of arthritis during attacks and 26 had no such history). Two control groups were enrolled: 20 patients with rheumatoid arthritis (RA) and 30 healthy individuals. Clinical and laboratory assessments of the FMF patients were performed during attack-free periods. Erythrocyte sedimentation rate (ESR), serum C-reactive protein (CRP), rheumatoid factor (RF), and anti-CCP antibody levels were measured.

**RESULTS:** In RA patients' ESR and CRP levels, frequency of RF, and anti-CCP antibody levels were significantly higher than in both FMF patients and healthy controls ( $p < 0.001$ ). Moreover, anti-CCP was negative in all healthy controls as well as in all FMF patients.

**CONCLUSION:** Our results show that anti-CCP antibodies are not associated with FMF.

Effect of anakinra on arthropathy in CINCA/NOMID syndrome.

Miyamae T(1), Inaba Y, Nishimura G, Kikuchi M, Kishi T, Hara R, Kaneko U, Shinoki T, Imagawa T, Yokokata S.

Author information:

(1)Department of Pediatrics, Yokohama City University, Yokohama, Japan.  
tmiyamae@med.yokohama-cu.ac.jp.

CINCA/NOMID is an autoinflammatory disorder characterized by the triad of neonatal onset of cutaneous symptoms, chronic meningitis, and recurrent fever and it presents with distinctive osteoarthropathy, synovitis mainly of the large joints and overgrowth of epimetaphyseal cartilage, particularly of the long bones. The cartilage overgrowth eventually causes osseous overgrowth and deformity that persists beyond skeletal maturity and leads to limb length discrepancy, joint contracture, and early degenerative arthropathy.

Autoinflammation in CAPS/NOMID has been proven to derive from excessive release of interleukin-1 (IL-1). It has been well documented that the IL-1 receptor antagonist anakinra (Kineret(R)) helps mitigate systemic inflammation in the

disorder. However, a general consensus has not been reached on its beneficial effect on osteoarthropathy. The case of a girl with CINCA/NOMID syndrome who showed dramatic improvement of osteoarthropathy after anakinra treatment is reported. A 4-year-old girl suffered at the age of 10 months from a generalized urticarial skin lesion with recurrent episodes of fever and growth disorder. Blood examination revealed persistent massive neutrophilia, anemia and intense acute phase response. She manifested knee joint swelling with limited ROM when she was 20 months old and was diagnosed as being CINCA/NOMID based on characteristic findings of radiograph despite negative CIAS1 mutation. Radiological examination demonstrated metaphyseal fraying and cupping and widening of the growth plate in the distal femur. MR imaging showed mottled gadolinium enhancement at the chondrosesous junction. Neither significant joint effusion nor synovitis was identified. At 2 years and 7 months of age, anakinra, 2 mg/kg/day given by regular daily subcutaneous injections, was started. A few days after the initiation of the treatment, her clinical symptoms and laboratory findings of active inflammation were promptly alleviated. She was not able to walk unaided prior to the treatment, but she walked independently 1 month after the treatment. Follow-up radiographs and MR imaging showed that growth plate widening and gadolinium enhancement at the chondrosesous junction were less conspicuous. Furthermore, longitudinal growth of the femur and tibia was identified during 20 months of observation.

Coexistence of familial Mediterranean fever and juvenile idiopathic arthritis with osteoporosis successfully treated with etanercept.

Kaya S(1), Kaptanoglu E, Elden H, Hizmetli S.

Author information:

(1)Faculty of Medicine, Department of Rheumatology, Cumhuriyet University, Sivas, Turkey.

Familial Mediterranean fever (FMF) is an autoinflammatory disorder characterized

by recurrent febrile polyserositis and arthritis attacks. Accompanying seronegative spondyloarthropathy has been reported in FMF in addition to its own joint involvement. However, the coexistence of FMF with juvenile idiopathic arthritis (JIA) is very rare, only three cases with severe joint involvement and mortal outcome have been reported in the literature. Here, we present another case with FMF and JIA with osteoporosis, successfully treated with etanercept with a four-year follow-up.

**OBJECTIVE:** To characterize the clinical and genetic features of familial Mediterranean fever (FMF).

**STUDY DESIGN:** Clinical presentation and Mediterranean Fever mutation type of all patients with FMF, who first manifested the disease at < or =2 years of age were analyzed and compared with patients who first presented with FMF between 2 and 16 years.

RESULTS: Of 814 patients with FMF, in 254 patients (31.2%) the first FMF attack was at  $< \text{ or } = 2$  years of age, with a mean age at onset of  $1.1 \pm 0.8$  years. They were compared with 242 patients who presented with their first manifestation of FMF at 2 to 16 years. The clinical manifestations of FMF were comparable in the 2 patient groups, but the delay of diagnosis was longer in patients with early presentation ( $3.2 \pm 3.2$  years vs.  $1.9 \pm 2.7$  years in the group with onset at 2-16 years,  $P < .001$ ). A subgroup of patients (60/254), who were diagnosed at  $< \text{ or } = 2$  years had the highest rate of attacks of fever alone as their sole manifestation (40.0% vs 8.4%,  $P < .05$ ), and less peritonitis (45% vs 86.1%,  $P < .05$ ) and pleuritis (3.4% vs 32.9%,  $P < .05$ ). Most of these patients were homozygous for the M694V mutation and were of North African (Sephardic Jewish) extraction.

CONCLUSION: In early life, FMF often begins with an atypical presentation, characterized by attacks of fever alone, and its diagnosis and initiation of treatment is therefore significantly delayed.

Urticarial lesions: if not urticaria, what else? The differential diagnosis of urticaria: part II. Systemic diseases.

Peroni A(1), Colato C, Zanoni G, Girolomoni G.

Author information:

(1)Department of Biomedical and Surgical Sciences, Section of Dermatology and Venereology, University of Verona, Verona, Italy.

There are a number of systemic disorders that can manifest with urticarial skin lesions, including urticarial vasculitis, connective tissue diseases, hematologic diseases, and autoinflammatory syndromes. All of these conditions may enter into the differential diagnosis of ordinary urticaria. In contrast to urticaria, urticarial syndromes may manifest with skin lesions other than wheals, such as

papules, necrosis, vesicles, and hemorrhages. Lesions may have a bilateral and symmetrical distribution; individual lesions have a long duration, and their resolution frequently leaves marks, such as hyperpigmentation or bruising. Moreover, systemic symptoms, such as fever, asthenia, and arthralgia, may be present. The most important differential diagnosis in this group is urticarial vasculitis, which is a small-vessel vasculitis with predominant cutaneous involvement. Systemic involvement in urticarial vasculitis affects multiple organs (mainly joints, the lungs, and the kidneys) and is more frequent and more severe in patients with hypocomplementemia. Clinicopathologic correlation is essential to establishing a correct diagnosis. LEARNING OBJECTIVES: After completing the learning activity, participants should be able to distinguish urticarial lesions suggesting diagnoses other than common urticaria; assess patients with urticarial lesions, and suspect systemic diseases presenting with urticarial skin lesions.

[A three-year-old girl with abdominal pain and fever].

[Article in Norwegian]

Olbjørn C(1), Fjaerli HO.

Author information:

(1)colb@ahus.no

**MATERIAL AND METHODS:** A patient with both familial Mediterranean fever and coeliac disease is discussed. We present our case and then discuss symptoms and treatment of familial Mediterranean fever.

**CASE REPORT:** A 3 1/2 year-old girl from the Middle East, parents related, was admitted to the Paediatric Department with recurrent episodes of abdominal pain and fever. During each episode the inflammatory markers ESR and CRP were significantly raised, but with no apparent focus of infection. Each episode lasted 1-4 days and subsequently became more frequent. Laboratory evaluation revealed a high titer for IgA anti-tissue transglutaminase suggestive of coeliac disease. Coeliac disease was confirmed by small-bowel biopsy. A gluten-free diet was started, but she continued to have recurrent episodes of abdominal pain and fever. Because of her genetic origin the diagnosis familial Mediterranean fever was suspected. Genetic testing was performed, and she was found to be homozygote for the most common gene encoding for the disease. Colchicine therapy was initiated and her episodes with abdominal pain and fever became less frequent.

**CONCLUSION:** Familial Mediterranean fever is a rare disorder in Norway but frequent in many Mediterranean countries. Common symptoms are recurrent episodes of abdominal pain, chest pain, joint pain and fever. Treatment with colchicine reduces inflammation and the risk of developing amyloidosis.

Comment in

Rheumatol Int. 2012 Nov;32(11):3705-6.

Familial Mediterranean fever (FMF) is a disease characterized by recurrent, self-limiting fever and serositis and caused by altered pyrin due to mutated MEFV gene. The aim of this study was to investigate clinical manifestations and MEFV mutations among patients with FMF and healthy controls in the Aegean region of Turkey. This study included 308 patients and 164 healthy controls. Patients were divided into three groups according to Tel-Hashomer criteria; definitive, probable, and suspicious. Among the patients, 146 were women (47.4%) and 162 were men (52.6%). The mean age ( $\pm$ SD) of the patients at the diagnosis was  $9.6\pm3.95$  (range 0.5-18). The mean age ( $\pm$ SD) at onset of the symptom was  $6.2\pm3.95$  (range 1-18). Symptoms were seen earlier onset in definitive group than the suspicious group in our cohort ( $4.7\pm3.9$  years,  $6.6\pm3.9$  years, respectively;  $P=0.001$ ). Clinical features were abdominal pain (83.1%), fever (55%), arthritis (17.1%), myalgia (4.5%), pleuritis (10%), and erysipelas-like erythema (7.7%). Fever, arthralgia, arthritis, chest pain, and amyloidosis were found statistically significant more in definitive group than suspicious group ( $P<0.001$ ,  $P<0.001$ ,  $P<0.001$ ,  $P<0.05$ , and  $P<0.001$ , respectively). MEFV gene mutations were identified in 199 patients (64.6%). The most commonly encountered MEFV mutation among the patients was M694V homozygote (25%). M694V homozygous mutation was found most frequently in definitive FMF group than other groups (49, 9, 8.9%, respectively). To our knowledge that FMF should be suspected in the case of non-specific but recurrent attacks of serositis and high fever, and molecular analysis should be performed in order to make diagnosis of FMF.

[A Japanese family with adult-onset familial Mediterranean fever and periodic episodes of high fever and abdominal pain].

[Article in Japanese]

Araki H(1), Onogi F, Ibuka T, Moriwaki H.

Author information:

(1)Endoscopy Center, Gifu University Hospital, Japan. araara@gifu-u.ac.jp

Familial Mediterranean fever (FMF) is an autoinflammatory disease. The patient was a 28-year-old Japanese man with attacks of fever and abdominal pain, which recurred at 1-to 3-month intervals. These symptoms usually improved spontaneously 1 week later. Physical examination showed tenderness in the right lateral abdomen. Routine laboratory tests demonstrated an increase in inflammatory reactions in the serum with leukocytosis. No abnormal findings were found on either chest, or abdominal CT scans, or endoscopic examinations of the upper or lower gastrointestinal tracts. Renal and hepatic function were within the normal limits, and no positive results were obtained for an anti-nuclear antibody. DNA analysis demonstrated a heterozygous mutation in the MEFV gene, the compound pyrin variant E148Q/M694I, leading to a diagnosis of FMF. His father had also had the same symptoms for 30 years, and was also heterozygous for the pyrin variant E148Q/M694I. They both responded dramatically to colchicine treatment and have remained in full remission until the time of writing.

New insights into the nature of autoinflammatory diseases from mice with Nlrp3 mutations.

Meng G(1), Strober W.

Author information:

(1)Mucosal Immunity Section, Laboratory of Host Defense, NIAID, NIH Bethesda, MD 20892, USA.

Mutations in the Nlrp3 (CIAS1, cryopyrin) gene are associated with cryopyrin-associated periodic syndrome, autoinflammatory diseases characterized by excessive IL-1 production and neutrophilia in blood and tissues. Recent studies with gene-targeted mice expressing mutations homologous to those found in cryopyrin-associated periodic syndrome patients have advanced the understanding of NLRP3-associated autoinflammation. In this Viewpoint, we will discuss the mechanisms of NLRP3 inflammasome activation and its induction of Th17-cell-dominant immunologic responses.

Genetics of inflammasome-associated disorders: a lesson in the guiding principals of inflammasome function.

Rodrigue-Gervais IG(1), Saleh M.

Author information:

(1)Department of Medicine, McGill University, Montréal, Canada.

Human genetics research has had a great impact on the genesis of the inflammasome field and the treatment of certain inflammasomopathies. The identification of mutations causing rare autoinflammatory syndromes, reproductive wastage disorders and of single nucleotide polymorphisms influencing susceptibility to complex diseases such as vitiligo, sepsis, and Crohn's disease has not only led to the characterization of novel proteins involved in NOD-like receptor-coupled inflammatory signaling pathways but also to greater insights into pathogenic mechanisms.

The NLRP3 inflammasome, a target for therapy in diverse disease states.

Cook GP(1), Savic S, Wittmann M, McDermott MF.

Author information:

(1)Section of Oncology and Clinical Research, Leeds Institute of Molecular Medicine, Leeds, UK.

A role for NLRP3 inflammasome in recurrent and chronic inflammation was initially described in a group of rare autoinflammatory conditions, termed cryopyrin-associated periodic syndrome. Subsequently, inflammasomes have been implicated in the pathology of many common diseases, including cancer, gout and diabetes. Despite diverse pathologies, the central role of the inflammasome in innate defences and tumour elimination suggests common therapeutic approaches to reduce inflammation where appropriate.

Sporadic Blau syndrome with onset of widespread granulomatous dermatitis in the newborn period.

Stoevesandt J(1), Morbach H, Martin TM, Zierhut M, Girschick H, Hamm H.

Author information:

(1)Department of Dermatology, University Clinics of Würzburg, Würzburg, Germany. Stoevesandt\_J@klinik.uni-wuerzburg.de

Blau syndrome is a dominantly inherited, chronic autoinflammatory disorder characterized by the clinical triad of granulomatous dermatitis, symmetric arthritis, and recurrent uveitis with onset below 4 years of age. It is caused by activating mutations in the nucleotide-binding oligomerization domain 2 (NOD2) gene, previously referred to as CARD15 gene. Noncaseating granulomas in affected tissues are the pathologic hallmark of the condition. We report the lifelong

severe disease course in a 14-year-old Caucasian boy with sporadic Blau syndrome. Unusually, granulomatous dermatitis started in the first week of life. Whereas skin involvement faded away spontaneously in subsequent years, polyarthritides and anterior uveitis appeared in the second and third year of life respectively. Mutational analysis of the NOD2 gene revealed a missense mutation (R334W) previously detected in other Blau syndrome pedigrees. With this report, we would like to stress the rare possibility of Blau syndrome in generalized papular rashes of infancy and the importance of histopathologic study for clarification. The finding of early-onset widespread granulomatous dermatitis should prompt eye and joint examination in regular intervals and entail mutational analysis of the NOD2 gene.

Familial Mediterranean fever in children presenting with attacks of fever alone.

Padeh S(1), Livneh A, Pras E, Shinar Y, Lidar M, Feld O, Berkun Y.

Author information:

(1)Department of Pediatrics A, Edmond and Lily Safra Children's Hospital, Sheba Medical Center, Tel Hashomer, Israel. Shay.pade@sheba.health.gov.il

**OBJECTIVE:** Familial Mediterranean fever (FMF) is an inherited disease characterized by attacks of febrile polyserositis. In children, attacks of fever alone, or with headache and malaise, may precede other forms of attacks. Our objective was clinical and genetic characterization of FMF and its development in pediatric patients who first presented with attacks of fever alone.

**METHODS:** Clinical characterization and MEFV genotype of all FMF patients < 16 years of age at disease onset and first presenting with attacks of fever alone were analyzed and compared for age, sex, and disease duration with matched FMF patients presenting with serositis at the onset of the disease.

**RESULTS:** There were 814 patients with FMF in our registry. Fifty patients formed the study group and 234 patients the control group. In the study group, the first (febrile) attacks appeared at a younger age than in the control group (1.7 +/- 1.6 yrs vs 5.0 +/- 4.1 yrs, respectively;  $p < 0.0001$ ), diagnosis was made earlier

(4.2 +/- 2.7 yrs vs 6.7 +/- 4.1 yrs;  $p < 0.0001$ ), despite a trend for a longer delay in diagnosis. In the study group, attacks were shorter (1.6 +/- 0.8 days vs 2.1 +/- 1.0 days;  $p = 0.023$ ) and homozygosity to the M694V mutation was more prevalent (46% vs 31%;  $p = 0.03$ ). Attack rate, colchicine dose, and the MEFV mutation carrier rates were comparable between the groups. In 40/50 (80%) of the patients with fever alone, serositis had developed over a course of 2.9 +/- 2.2 years after disease onset.

**CONCLUSION:** FMF in young children may begin with attacks of fever alone, but it progresses to typical FMF disease over the next 2.9 +/- 2.2 years. Our study demonstrates that clinical heterogeneity at presentation is more likely to indicate a feature of a disease in development, rather than to mark distinct phenotypes of FMF.

A novel missense mutation in MVK associated with MK deficiency and dyserythropoietic anemia.

Samkari A(1), Borzutzky A, Fermo E, Treaba DO, Dedeoglu F, Altura RA.

Author information:

(1)Division of Hematology-Oncology, Department of Pediatrics, Hasbro Children's Hospital and Warren Alpert Medical School of Brown University, Providence, Rhode Island 02903, USA.

Mevalonate kinase deficiency (MKD) is a rare inborn error of metabolism caused by mutations in the mevalonate kinase (MVK) gene. The clinical phenotype is variable, ranging from the hyperimmunoglobulinemia D and periodic fever syndrome (HIDS) to mevalonic aciduria (MA), a severe metabolic disease. We report here for the first time (to our knowledge) the case of a patient with MKD and congenital dyserythropoietic anemia. Clinical and laboratory characteristics of inflammatory attacks were compatible with HIDS, but mild dysmorphic features and elevated urinary mevalonic acid levels in the absence of an inflammatory attack suggested an intermediate phenotype between HIDS and MA. Genomic sequencing of the MVK gene revealed compound heterozygosity for a missense mutation previously described in

MA (V310M) and a novel missense mutation (Y116H). By contrast, sequencing of the novel CDAll (SEC23B) gene revealed no mutations, suggesting that the bone marrow abnormalities were causally related to the MKD. Treatment with corticosteroids and colchicine directed at controlling the autoinflammatory disease resulted in improvement of the anemia.

Mechanisms of uric acid crystal-mediated autoinflammation.

Martinon F(1).

Author information:

(1)Department of Immunology and Infectious Diseases, Harvard School of Public Health, Boston, MA 02115, USA. fmartino@hsph.harvard.edu

Gout is an arthritis characterized by elevated uric acid in the bloodstream. In this condition, crystals of uric acid are formed and accumulate in the synovial fluids. Crystal deposition leads to acute inflammation, which is associated with the spontaneous resolution of the disease. Recent studies have led to significant advances in the understanding of the basic biology of crystal-mediated inflammation. Uric acid has been identified as a danger signal that triggers a cytosolic sensor, the inflammasome. This signaling platform is required for the activation of interleukin-1, a cytokine that is critical to the initiation of acute inflammation in gout. Importantly, both molecular and pathological evidence support the notion that gout is a prototypical member of the growing family of autoinflammatory diseases. This review discusses the role of the inflammasome in gout and the emerging new therapeutic strategies aimed at controlling inflammation in crystal arthritis.

Pregnancy outcomes in women with familial Mediterranean fever receiving colchicine: is amniocentesis justified?

Ben-Chetrit E(1), Ben-Chetrit A, Berkun Y, Ben-Chetrit E.

Author information:

(1)Shaare Zedek Medical Center, Jerusalem, Israel. eldad@hadassah.org.il

**OBJECTIVE:** To evaluate the outcome of pregnancies in women with familial Mediterranean fever (FMF) who are taking colchicine, and to reconsider the justification for amniocentesis in these women.

**METHODS:** The outcome of 179 pregnancies in a group of women with FMF taking colchicine was compared with the outcome of 197 pregnancies in women with FMF who did not take colchicine during pregnancy and with 312 pregnancies in another cohort of healthy pregnant women of similar age and ethnicity.

**RESULTS:** There was no difference in the 3 groups regarding early abortions, late abortions, or congenital malformations. There was a mild trend towards a better outcome for the colchicine-treated group but these results did not reach statistical significance.

**CONCLUSION:** Treatment with colchicine during pregnancy in patients with FMF is beneficial in controlling the disease while not affecting the outcome of the pregnancy; therefore there is no justification for recommending amniocentesis in women taking colchicine solely because of this treatment.

The protean visage of systemic autoinflammatory syndromes: a challenge for inter-professional collaboration.

Rigante D(1).

Author information:

(1)Department of Pediatric Sciences, Catholic University of the Sacred Heart, Rome, Italy. drigante@gmail.com

Systemic autoinflammatory syndromes are a group of inherited and acquired disorders of the innate immunity characterized by recurrence of seemingly unprovoked febrile attacks of variable duration and multi-district inflammation of different severity. The vast majority of these conditions when observed in pediatrics is caused by mutations in genetic systems involved in the orchestration of inflammation and apoptosis. The group includes hereditary recurrent fevers, idiopathic febrile syndromes, hereditary pyogenic disorders, bone autoinflammatory diseases, immune-mediated granulomatous diseases, complement disorders, hemophagocytic and vasculitic syndromes. Diagnostic identification derives from the combination of genotype studies and clinical/bioluminal data showing the spontaneous activation of cells of the innate immunity in the absence of specific ligands, although diagnosis remains only clinical for idiopathic febrile syndromes such as systemic-onset juvenile idiopathic arthritis and PFAPA syndrome. Meeting the needs of patients with complex chronic diseases as systemic autoinflammatory syndromes requires the provision of collaborative multidisciplinary care and the expertise of a number of health care providers across varied health care settings.

Decrease in the rate of secondary amyloidosis in Turkish children with FMF: are we doing better?

Akse-Onal V(1), Sağ E, Ozen S, Bakkaloglu A, Cakar N, Besbas N, Gucer S.

Author information:

(1)Department of Pediatrics, Hacettepe University, Ankara 06100, Turkey.

Familial Mediterranean fever (FMF) is the most common autoinflammatory disease in the world. The most serious complication of FMF is the development of secondary amyloidosis. Besides genetic factors, environment has been implicated in the development of this complication. The main objective of this study is to analyze whether there has been a substantial decrease of secondary amyloidosis in Turkey

and possible effective factors. For this purpose, clinical features of the patients diagnosed with secondary amyloidosis between the years 1978 and 1990 were compared with those diagnosed between 2000 and 2009. Severity scores were determined by the use of a scoring system modified for children. Median ages of the group diagnosed between 1978 and 1990 (n = 115; 12.1% among a total of 947 renal biopsies) and diagnosed after 2000 (n = 19; 2% among a total of 974 renal biopsies) were 12 and 13 years, respectively. There were no significant differences between the two patient groups according to gender, age, age of onset, disease duration, and disease severity. There was, however, a clear decrease in the percentage of biopsies with secondary amyloidosis from 12.1% (1978-1990) to 2% (after 2000;  $p < 0.001$ ). Our results have shown that there has been a significant decrease in the rate of secondary amyloidosis in Turkey. The main reason for this decrease is better medical care with increased awareness and treatment of the disease. However, we suggest that the improvement of infectious milieu may possibly have had a positive effect on the course of this monogenic disease, since inflammatory pathways related to innate immunity are deregulated.

Erratum in

Open Rheumatol J. 2010;4:23.

Familial Mediterranean Fever (FMF) is an autoinflammatory periodic disorder. We aim to identify the distribution and the frequency of the Mediterranean Fever (MEFV) gene mutations in the east of Anatolia in Turkey and perform a genotype/phenotype correlation in the patients' cohort. The study was carried out

on 415 clinically diagnosed Turkish FMF patients and 103 healthy controls. The tested individuals were screened for the most common twelve MEFV mutations. The most important features were the predominance of the M694V and E148Q mutations in patient group and the earlier onset of the disease in M694V mutation carriers compared with the carriers of other mutations ( $P=0.00$ ). We discuss the high frequency of E148Q mutations in patient group compared with controls, genetic counseling in intermarriage families and the variations in mutation frequency according to regions of Turkey.

IL-1 pathways in inflammation and human diseases.

Gabay C(1), Lamacchia C, Palmer G.

Author information:

(1)Division of Rheumatology, University Hospitals of Geneva & Department of Pathology-Immunology, University of Geneva School of Medicine, 26 Avenue Beau-Séjour, 1211 Geneva 14, Switzerland. cem.gabay@hcuge.ch

Interleukin (IL)-1 was first cloned in the 1980s, and rapidly emerged as a key player in the regulation of inflammatory processes. The term IL-1 refers to two cytokines, IL-1 $\alpha$  and IL-1 $\beta$ , which are encoded by two separate genes. The effects of IL-1 are tightly controlled by several naturally occurring inhibitors, such as IL-1 receptor antagonist (IL-1Ra), IL-1 receptor type II (IL-1RII), and other soluble receptors. Numerous IL-1 inhibitors have been developed and tested primarily in rheumatoid arthritis, with only modest effects. By contrast, the use of IL-1 antagonists has been uniformly associated with beneficial effects in patients with hereditary autoinflammatory conditions associated with excessive IL-1 signaling, such as cryopyrinopathies and IL-1Ra deficiency. Successful treatment with IL-1 blockers has also been reported in other hereditary autoinflammatory diseases, as well as in nonhereditary inflammatory diseases, such as Schnitzler syndrome, systemic-onset juvenile idiopathic arthritis and

adult Still disease. The role of microcrystals in the regulation of IL-1 $\beta$  processing and release has provided the rationale for the use of IL-1 inhibitors in crystal-induced arthritis. Finally, preliminary results indicating that IL-1 targeting is efficacious in type 2 diabetes and smoldering myeloma have further broadened the spectrum of IL-1-driven diseases.

tmpo@hagedorn.dk

Interleukin 1 (IL-1) is a 17 kDa protein highly conserved through evolution and is a key mediator of inflammation, fever and the acute-phase response. IL-1 has important functions in the innate immune defense against microbes, trauma and stress, and is also an effector molecule involved in tissue destruction and fibrosis. The inhibition of IL-1 action has clinical efficacy in many inflammatory diseases, such as hereditary autoinflammatory disorders, familial hereditary fever, gout, rheumatoid arthritis and type 2 diabetes mellitus (T2DM). The latter is a common metabolic condition caused by insulin resistance and pancreatic beta-cell failure, the causes of both of which have inflammatory components. IL-1 signaling has roles in beta-cell dysfunction and destruction via the NF $\kappa$ B and mitogen-activated-protein-kinase pathways, leading to endoplasmic reticulum and mitochondrial stress and eventually activating the apoptotic machinery. In addition, IL-1 acts on T-lymphocyte regulation. The modulating effect of IL-1 on the interaction between the innate and adaptive immune systems and the effects of IL-1 on the beta-cell point to this molecule being a potential interventional target in autoimmune diabetes mellitus. Genetic or pharmacological abrogation of IL-1 action reduces disease incidence in animal models of type 1 diabetes mellitus (T1DM) and clinical trials have been started to study the feasibility, safety and efficacy of IL-1 therapy in patients with

T1DM. Here, we review the rationale for blocking IL-1 in patients with T1DM.

We report on a 33-year-old female patient with a relatively mild clinical case of TNF-receptor associated periodic syndrome (TRAPS) and her 58-year-old father in whom end-stage renal disease due to TRAPS-related AA-amyloidosis has already developed. TRAPS was caused by a I170N mutation that has previously not been associated with amyloidosis. It remains unclear if an only mildly affected patient such as ours would benefit from treatment considering her father's severe course of disease. The relevant literature on this problem is reviewed.

Autoinflammatory syndromes: report on three cases.

Matos TC(1), Terreri MT, Petry DG, Barbosa CM, Len CA, Hilário MO.

Author information:

(1)Division of Pediatric Rheumatology, Department of Pediatrics, Universidade Federal de São Paulo, São Paulo, Brazil.

CONTEXT: Autoinflammatory syndromes are diseases manifested by recurrent episodes of fever and inflammation in multiple organs. There is no production of autoantibodies, but interleukins play an important role and acute-phase reactants show abnormalities. Our aim was to report on three cases of autoinflammatory syndromes that are considered to be rare entities.

CASE REPORTS: The authors describe the clinical features of three patients whose diagnosis were the following: tumor necrosis factor receptor-associated periodic syndrome (TRAPS), chronic infantile neurological cutaneous articular (CINCA) syndrome and familial Mediterranean fever (FMF). All of the patients presented fever, joint or bone involvement and increased acute phase reactants. The genetic analysis confirmed the diagnoses of two patients. The great diversity of manifestations and the difficulties in genetic analyses make the diagnosing of these diseases a challenge.

The Familial Mediterranean Fever (FMF) shows an autosomal recessive pattern of inheritance and affects certain ethnic groups. Disease is caused by mutations in MEFV gene and more than 180 mutations have been defined in affected individuals. Current study aimed to determine the frequency-type of the mutations for MEFV gene in Sivas-middle Anatolian city. The cohort was composed of 3340 patients. MEFV gene mutations were studied by multiplex PCR based reverse hybridization stripAssay method. Patients' clinical features were; family history: 68%, erysipelas-like erythema: 17.6%, fever: 89.9%, abdominal pain: 84.2%, peritonitis: 90.2%, arthritis: 33%, pleuritis: 14.2%, parental consanguinity: 21.2%. Current results revealed that M694V is the most frequent mutation (43.12%), followed by E148Q (20.18), M680I(G/C) (15.00%) and V726A (11.32%). The study population has a high rate of carriers and the E148Q mutation frequency was found to be highest when compared to the other regions of Turkey and other Mediterranean groups.

MEFV gene mutations in Egyptian patients with familial Mediterranean fever.

El Gezery DA(1), Abou-Zeid AA, Hashad DI, El-Sayegh HK.

Author information:

(1)Department of Clinical Pathology, Alexandria University, Alexandria, Egypt.

**BACKGROUND:** Familial Mediterranean fever (FMF) is an autosomal recessive disorder characterized by recurrent attacks of fever and serositis. The disease affects mainly Mediterranean populations and is caused by mutations in the MEFV gene.

**AIM:** This work was carried out to identify and determine the frequencies of MEFV gene mutations in Egyptian patients in whom FMF was diagnosed.

**METHODS:** We investigated 316 patients with a clinical diagnosis of FMF for 12 MEFV mutations including the 5 most common known mutations M694V, V726A, M694I, M680I, and E148Q by allele-specific hybridization.

**RESULTS:** Mutations were detected in 182 (57.6%) patients: 20 were homozygous, 80 were compound heterozygous, and 82 had only one identifiable mutant allele. In patients with clinically definite FMF (n = 112), no mutations were detected in 28 patients; whereas in patients with clinically unlikely FMF (n = 48), genetic analysis established the diagnosis in 6 patients. Overall, 10 mutations were detected in our patients. The most common were M694I (34%), E148Q (22.7%), V726A (15.6%), M680I (12.1%), and M694V (7.8%). M694V was observed in severe disease and in patients with amyloidosis.

**CONCLUSION:** We were able to identify a wide spectrum of MEFV mutations in Egyptian patients in whom FMF was diagnosed. Frequencies of individual mutations showed some differences from those in other Mediterranean populations.

Actual status of antiinterleukin-1 therapies in rheumatic diseases.

Geyer M(1), Müller-Ladner U.

Author information:

(1)Department of Rheumatology and Clinical Immunology, Justus-Liebig-University Giessen, Kerckhoff-Klinik, Bad Nauheim, Germany.

**PURPOSE OF REVIEW:** Several studies have evaluated the efficacy and safety of novel therapeutic options targeting interleukin-1 (IL-1), which not only plays a significant role in rheumatoid arthritis, but also in other rheumatic diseases,

for which only limited therapeutical options exist.

RECENT FINDINGS: Three different strategies have been pursued and evaluated in the past years: preventing IL-1 binding by occupying IL-1 receptors with anakinra, an imitation of the naturally occurring IL-1 receptor antagonist, anakinra; development of the fully human monoclonal anti-IL-1 $\beta$  antibody canakinumab; and synthesis of the dimeric fusion protein rilonacept, consisting of the ligand-binding domain of interleukin-1 receptor type I and its accessory protein, bound to human IgG1. Each of these three anti-IL-1 agents proved efficacy in distinct clinical situations and disease entities.

SUMMARY: Owing to the observation that IL-1 is not only involved in signaling processes resulting in autoimmune and crystal-induced joint destruction but also in several hereditary autoinflammatory syndromes, its value both in pathophysiology as well as for novel advances in medication has significantly improved in the past years leading to an enrichment of the current therapeutic armamentarium for the affected patients.

Evidence strongly suggests that excessive or protracted signaling, or both, by cell-surface or intracellular innate immune receptors is central to the pathogenesis of most autoimmune and autoinflammatory rheumatic diseases. The initiation of aberrant innate and adaptive immune responses in autoimmune diseases can be triggered by microbes and, at times, by endogenous molecules--particularly nucleic acids and related immune complexes--under sterile

conditions. By contrast, most autoinflammatory syndromes are generally dependent on germline or de novo gene mutations that cause or facilitate inflammasome assembly. The consequent production of proinflammatory cytokines, principally interferon-alpha/beta and tumor necrosis factor in autoimmune diseases, and interleukin-1beta in autoinflammatory diseases, leads to the creation of autoamplification feedback loops and chronicity of these syndromes. These findings have resulted in a critical reappraisal of pathogenetic mechanisms, and provide a basis for the development of novel diagnostic and therapeutic modalities for these diseases.

Autoimmune hepatitis type 2 arising in PFAPA syndrome: coincidences or possible correlations?

Della Corte C(1), Ranucci G, Tufano M, Alessio M, Iorio R.

Author information:

(1)University Federico II, Department of Pediatrics, Via S Pansini 5, 80131 Naples, Italy.

PFAPA syndrome is a chronic disease classified in the group of autoinflammatory syndromes characterized by periodic fever, aphthous stomatitis, pharyngitis, and cervical adenitis in young children. The etiology of this disorder is still unknown, but a primary dysfunction of the innate immune system seems to be involved. According to Marshall criteria, it is not possible to diagnose PFAPA in the presence of autoimmune diseases. We present here the case report of an 8-month girl with PFAPA who developed autoimmune hepatitis type 2 at the age of 18 months. We suppose that the dysregulation in innate immunity that is typical of patients with PFAPA could trigger autoimmune disorders such as autoimmune hepatitis in susceptible subjects. The possible relationships between immune-system dysfunction peculiar to this syndrome and autoimmune hepatitis are discussed.

(1)Asklepios Kinderklinik Sankt Augustin, Zentrum für Allgemeine Pädiatrie und Neonatologie, Arnold-Janssen-Strasse 29, Sankt Augustin, Germany.

ar.klein@asklepios.com

Muckle Wells syndrome is an autoinflammatory disease in the group of cryopyrin associated periodic syndromes (CAPS). We report the case of an 8 year old girl with MWS who presented with remitting fever, urticaria, remitting coxitis, osteitis, bilateral uveitis anterior, elevated levels of C-reactive protein (CRP) and Serum amyloid A (SAA) and progressive sensoneurinal hearing loss. After starting treatment with anakinra, clinical symptoms dissolved almost completely for about two years now. CRP and SAA levels normalized quickly and sustained and as a consequence the risk of amyloidosis may be minimized. Notable is the complete recovery from sensoneurinal hearing loss merely two months after start of treatment. This brings up questions about pathophysiology of sensoneurinal hearing loss in MWS and emphasizes the benefits of an early diagnosis, as an early start of treatment possibly reduces long-term damage.

**OBJECTIVE:** Chronic infantile neurologic, cutaneous, articular syndrome (CINCA), also known as neonatal-onset multisystem inflammatory disease (NOMID), is a severe, early-onset autoinflammatory disease characterized by an urticaria-like rash, arthritis/arthropathy, variable neurologic involvement, and dysmorphic features, which usually respond to interleukin-1 blockade. CINCA/NOMID has been associated with dominant Mendelian inherited NLRP3 mutations. However, conventional sequencing analyses detect true disease-causing mutations in only approximately 55-60% of patients, which suggests the presence of genetic heterogeneity. We undertook the current study to assess the presence of somatic, nongermine NLRP3 mutations in a sporadic case of CINCA/NOMID.

**METHODS:** Clinical data, laboratory results, and information on treatment outcomes were gathered through direct interviews. Exhaustive genetic studies, including Sanger method sequencing, subcloning, restriction fragment length polymorphism assay, and pyrosequencing, were performed.

**RESULTS:** The patient's CINCA/NOMID was diagnosed based on clinical features (early onset of the disease, urticaria-like rash, knee arthropathy, and dysmorphic features). The patient has exhibited a successful response to anakinra within the last 28 months. Analysis of NLRP3 identified a novel heterozygous variant (p.D303H) that was detected in approximately 30-38% of circulating leukocytes. The absence of this variant in healthy controls and in the patient's parents suggested a de novo true disease-causing mutation. Additional analyses showed that this novel mutation was present in both leukocyte subpopulations and epithelial cells.

**CONCLUSION:** Our findings identify the novel p.D303H NLRP3 variant in a Spanish patient with CINCA/NOMID as a new disease-causing mutation, which was detected as a somatic, nongermine mutation in hematopoietic and nonhematopoietic cell

lineages. Our data provide new insight into the role of low-level mosaicism in NLRP3 as the pathophysiologic mechanism underlying cryopyrin-associated periodic syndrome.

**OBJECTIVE:** Blau syndrome is an autoinflammatory disease resulting from mutations in the NOD2 gene, wherein granulomatous arthritis, uveitis, and dermatitis develop. The mechanisms by which aberrant NOD2 causes joint inflammation are poorly understood. Indeed, very few studies have addressed the function of nucleotide-binding oligomerization domain 2 (NOD-2) in the joint. This study was undertaken to investigate NOD-2 function in an experimental model of arthritis and to explore the potential interplay between Toll-like receptor 2 (TLR-2) and NOD-2 in joint inflammation.

**METHODS:** Mice deficient in TLR-2, myeloid differentiation factor 88 (MyD88), or NOD-2 and their wild-type controls were given an intraarticular injection of muramyl dipeptide (MDP), peptidoglycan (PG; a metabolite of which is MDP), or palmitoyl-3-cysteine-serine-lysine-4 (Pam(3)CSK(4)), a synthetic TLR-2 agonist. Joint inflammation was assessed by near-infrared fluorescence imaging and histologic analysis.

**RESULTS:** Locally administered PG resulted in joint inflammation, which was markedly reduced in mice deficient in either TLR-2 or the TLR signaling mediator MyD88. In addition to TLR-2 signaling events, NOD-2 mediated joint inflammation, as evidenced by the fact that mice deficient in NOD-2 showed significantly reduced PG-induced arthritis. TLR-2 or MyD88 deficiency did not influence arthritis induced by the specific NOD-2 agonist MDP. In addition, NOD-2

deficiency did not alter the TLR-2-dependent joint inflammation elicited by the synthetic TLR-2 agonist Pam(3)CSK(4).

CONCLUSION: Whereas NOD-2 and TLR-2 are both critical for the development of PG-induced arthritis, they appear to elicit inflammation independently of each other. Our findings indicate that NOD-2 plays an inflammatory role in arthritis.

Comment in

Arthritis Rheum. 2010 Oct;62(10):3123-4; author reply 3124-5.

OBJECTIVE: To gain insight into the pathophysiology of an atypical familial form of an autoinflammatory disorder, characterized by autosomal-dominant sensorineural hearing loss, systemic inflammation, increased secretion of interleukin-1beta (IL-1beta), and the absence of any cutaneous manifestations, and to assess the functional consequences of a missense mutation identified in the leucine-rich repeat (LRR) domain of NLRP3.

METHODS: Microsatellite markers were used to test the familial segregation of the NLRP3 locus with the disease phenotype. All NLRP3 exons were screened for mutations by sequencing. Functional assays were performed in HEK 293T cells to determine the effects of mutated (versus normal) NLRP3 proteins on NF-kappaB activation, caspase 1 signaling, and speck formation.

**RESULTS:** A heterozygous NLRP3 missense mutation (p.Tyr859Cys) was identified in exon 6, which encodes the LRR domain of the protein. This mutation was found to segregate with the disease phenotype within the family, and had a moderate activating effect on speck formation and procaspase 1 processing and did not alter the inhibitory properties of NLRP3 on NF-kappaB signaling.

**CONCLUSION:** This report is the first to describe a familial form of a cryopyrinopathy associated with a mutation outside of exon 3 of NLRP3. This finding, together with the known efficacy of anti-IL-1 treatments in these disorders, underlines the importance of screening all exons of NLRP3 in patients who present with atypical manifestations. In addition, the gain of function associated with this mutation in terms of activation of caspase 1 signaling was consistent with the observed inflammatory phenotype. Therefore, this study of the functional consequences of an LRR mutation sheds new light on the clinical relevance of in vitro assays.

Increased serum concentrations of homocysteine and lipoprotein (a) in familial Mediterranean fever.

Karatay S(1), Yildirim K, Uyanik A, Uzkeser H, Kiziltunc A, Ugur M, Baygutalp F, Acemoglu H.

Author information:

(1)Department of Physical Medicine and Rehabilitation, Medical Faculty, Ataturk University, 25240 Erzurum, Turkey. skaratay73@hotmail.com

Serum homocysteine, folic acid, lipoprotein (a) (Lp(a)), fibrinogen, and C-reactive protein (CRP) concentrations and erythrocyte sedimentation rates (ESR) were measured in 52 patients with familial Mediterranean fever (FMF) during attack-free periods and in 30 healthy control subjects. Serum homocysteine levels were significantly higher in the FMF patients (median 17.8 microg/dl; range 5.6-80.8) than in controls (median 11.7; range 5.6-42.2;  $p = 0.013$ ). Serum homocysteine levels were elevated above the upper reference limit (15 microg/dl) in 56% of the FMF patients compared to 27% of the controls ( $p = 0.011$ ). Serum

Lp(a) levels were significantly higher in the FMF patients (median 39.3 mg/dl; range 6.6-124.5) than in controls (median 27.2; range 11.1-78.1;  $p = 0.035$ ). Serum Lp(a) levels were elevated above the upper reference limit (30 mg/dl) in 71% of the FMF patients compared to 47% of the controls ( $p = 0.028$ ). The ESR, fibrinogen, CRP, and folic acid levels were similar in both groups. In conclusion, serum homocysteine and Lp(a) concentrations are often increased in FMF patients during attack-free periods. The elevated homocysteine and Lp(a) levels, which are markers of sub-clinical inflammation, may be mediators of atherosclerotic disease in FMF patients.

Rapidly progressive Creutzfeldt-Jakob disease in patients with Familial Mediterranean Fever.

Appel SA(1), Chapman J, Kahana E, Rosenmann H, Prohovnik I, Pras E, Reznik-Wolf H, Cohen OS.

Author information:

(1)Department of Neurology, The Sagol Neuroscience Center at the Chaim Sheba Medical Center affiliated to the Sackler Faculty of Medicine, Tel-Aviv University, Tel-Hashomer, Israel.

**BACKGROUND:** The largest cluster of familial Creutzfeldt-Jakob disease (fCJD) exists in Jews of Libyan origin. Familial Mediterranean fever (FMF) is an inflammatory disease also common in this population.

**OBJECTIVES:** We hypothesized that FMF, as a pro-inflammatory condition, may affect the course of CJD.

**METHODS:** Three hundred and seventy-two consecutive patients diagnosed clinically and genetically as CJD were included in the study. Two hundred and thirty-six had fCJD, and 136 had sporadic disease (sCJD). Review of the patient's records revealed three patients with FMF-CJD co-morbidity. In addition, 50 DNA samples of patients with CJD were genotyped as homozygote, heterozygote, and non-carriers of the FMF mutation. The demographic and clinical variables of the groups were

compared.

RESULTS: The three patients with FMF had an earlier age of onset and significantly shorter disease duration than the patients without FMF.

Heterozygote carriers did not differ in disease onset and duration from patients without FMF.

CONCLUSIONS: The shorter disease duration of CJD patients with FMF may indicate the importance of pro-inflammatory factors in the disease.

Worms to the rescue: can worm glycans protect from autoimmune diseases?

Kuijk LM(1), van Die I.

Author information:

(1)Department of Molecular Cell Biology and Immunology, VU University Medical Center, Amsterdam, the Netherlands.

Autoimmune and autoinflammatory diseases represent a significant health burden, especially in Western societies. For the majority of these diseases, no cure exists. Recently, research on parasitic worms (helminths) has demonstrated great potential for whole worms, their eggs or their excretory/secretory proteins in down-regulating inflammatory responses both in vitro and in vivo, in various disease models and, in some cases, even in clinical trials. The worms are thought to induce Th2 and regulatory T cells, interfere with Toll-like receptor (TLR) signaling and to down-regulate Th17 and Th1 responses. The molecular mechanisms underlying the worms' ability to modulate the host immune response are not well understood, and many hypotheses have been proposed to explain the observed immune modulation. Increasing evidence suggests that carbohydrate structures (glycans), for example, phosphorylcholine-modified glycans or Galbeta1-4(Fucalpha1-3)GlcNAc-(Lewis X, Le(X)) containing glycans, expressed by the worms contribute to these modulating properties by their interaction with antigen presenting cells. Helminths express a broad variety of protein- and lipid-linked glycans on their surface and on secretory products. These glycans differ in amount and composition

and several of these structures are species specific. However, worms also express glycan antigens that are found in a wide variety of different species. Some of these "common" worm glycans are particularly interesting with regard to regulating host responses, because they have the potential to interact with C-type lectins on dendritic cells and thereby may interfere with T-cell polarization. Helminths and helminth-derived molecules form a novel and promising group of therapeutics for autoinflammatory diseases. However, much has to be learned about the molecular mechanisms behind the helminth-mediated antiinflammatory properties. This review will describe some of the emerging evidence in selected disease areas as well as discuss the putative role of glycans in helminth-mediated immunosuppression.

Differences in pathophysiology between rheumatoid arthritis and ankylosing spondylitis.

Lories RJ(1), Baeten DL.

Author information:

(1)Laboratory for Skeletal Development and Joint Disorders, Division of Rheumatology, Department of Musculoskeletal Sciences, Katholieke Universiteit Leuven, Belgium. Rik.Lories@uz.kuleuven.be

Rheumatoid arthritis and ankylosing spondylitis are common and severe chronic inflammatory skeletal diseases. Recognizing the differences rather than emphasizing similarities is important for a better understanding of the disease processes, the identification of specific therapeutic targets and in the long-term better treatment options for the individual patients. We discuss a number of pathophysiological differences between rheumatoid arthritis and ankylosing spondylitis by looking at the anatomical characteristics, differences and similarities in the autoimmune and autoinflammatory reactions, association with other immune mediated inflammatory diseases, structural outcome, and their potential significance for further therapeutic developments. Further research into the differences between these diseases should focus on the specific nature

of the immune/inflammatory components, the role of resident cells in the joint and joint-associated tissues, the types and mechanisms of tissue remodeling and the characteristics of the articular cartilage. Better insights into their individual characteristics may lead to better therapeutic strategies, specific targets and useful biomarkers.

Cytokine production by islets in health and diabetes: cellular origin, regulation and function.

Donath MY(1), Böni-Schnetzler M, Ellingsgaard H, Halban PA, Ehses JA.

Author information:

(1)Clinic of Endocrinology and Diabetes, Center for Integrated Human Physiology, University Hospital of Zurich, 8091 Zurich, Switzerland. marc.donath@usz.ch

Islets produce a variety of cytokines and chemokines in response to physiologic and pathologic stimulation by nutrients. The cellular source of these inflammatory mediators includes alpha-, beta-, endothelial-, ductal- and recruited immune cells. Islet-derived cytokines promote alpha- and beta-cell adaptation and repair in the short term. Eventually, chronic metabolic stress can induce a deleterious autoinflammatory process in islets leading to insulin secretion failure and type 2 diabetes. Understanding the specific role of islet derived cytokines and chemokines has opened the door to targeted clinical interventions aimed at remodeling islet inflammation from destruction to adaptation. In this article, we review the islet cellular origin of various cytokines and chemokines and describe their regulation and respective roles in physiology and diabetes.

No regression of renal amyloid mass despite remission of nephrotic syndrome in a patient with TRAPS following etanercept therapy.

Simsek I(1), Kaya A, Erdem H, Pay S, Yenicesu M, Dinc A.

Author information:

(1)Division of Rheumatology, Gulhane Military School of Medicine, Ankara, Turkey.  
isimsek1@yahoo.com

Reactive systemic (AA) amyloidosis leading to renal failure is the most severe complication of tumor necrosis factor receptor-associated periodic syndrome (TRAPS). There is now growing evidence to suggest that anti-tumor necrosis factor (anti-TNF) agents may be an attractive treatment option for amyloidosis not only in TRAPS but in several forms of secondary amyloidosis complicating inflammatory rheumatic diseases. In most of the reported cases, anti-TNF agents were deemed successful on the basis of regression of proteinuria and either improvement or stabilization of creatinine clearance, while objective proof of renal amyloid regression either by serum amyloid P scintigraphy or biopsy is limited. We herein report a case of TRAPS complicated with nephrotic syndrome due to AA amyloidosis in which treatment with etanercept was associated with remission of the nephrotic syndrome but no regression of amyloid mass on the follow-up renal biopsy. Indeed, amyloid deposition was noted to be more pronounced on the second renal biopsy, particularly at tubular basement membranes. Although the variable relation between reduction in amyloid load and changes in organ function is well-known, the basis for renal recovery in association with stable or even progressive amyloid deposition is challenging. We suggest that in patients with secondary AA amyloidosis, mechanisms other than the reduction of amyloid mass could have contributed to the observed improvement of renal function with anti-TNF agents.

Interleukin-1 (IL-1) pathway.

Weber A(1), Wasiliew P, Kracht M.

Author information:

(1)Rudolf-Buchheim-Institute of Pharmacology, Justus-Liebig-University Giessen, 35392 Giessen, Germany.

The interleukin-1 (IL-1) family of cytokines comprises 11 proteins (IL-1F1 to IL-1F11) encoded by 11 distinct genes in humans and mice. IL-1-type cytokines are major mediators of innate immune reactions, and blockade of the founding members IL-1alpha or IL-1beta by the interleukin-1 receptor antagonist (IL-1RA) has demonstrated a central role of IL-1 in a number of human autoinflammatory diseases. IL-1alpha or IL-1beta rapidly increase messenger RNA expression of hundreds of genes in multiple different cell types. The potent proinflammatory activities of IL-1alpha and IL-1beta are restricted at three major levels: (i) synthesis and release, (ii) membrane receptors, and (iii) intracellular signal transduction. This pathway summarizes extracellular and intracellular signaling of IL-1alpha or IL-1beta, including positive- and negative-feedback mechanisms that amplify or terminate the IL-1 response. In response to ligand binding of the receptor, a complex sequence of combinatorial phosphorylation and ubiquitination events results in activation of nuclear factor kappaB signaling and the JNK and p38 mitogen-activated protein kinase pathways, which, cooperatively, induce the expression of canonical IL-1 target genes (such as IL-6, IL-8, MCP-1, COX-2, IkappaBalpha, IL-1alpha, IL-1beta, MKP-1) by transcriptional and posttranscriptional mechanisms. Of note, most intracellular components that participate in the cellular response to IL-1 also mediate responses to other cytokines (IL-18 and IL-33), Toll-like-receptors (TLRs), and many forms of cytotoxic stresses.

Idiopathic recurrent pericarditis refractory to colchicine treatment can reveal tumor necrosis factor receptor-associated periodic syndrome.

Cantarini L(1), Lucherini OM, Cimaz R, Baldari CT, Bellisai F, Rossi Paccani S, Laghi Pasini F, Capecchi PL, Sebastiani GD, Galeazzi M.

Author information:

(1)Interdepartmental Research Center of Systemic Autoimmune and Autoinflammatory Diseases, Unit of Rheumatology, Policlinico Le Scotte, University of Siena, Siena, Italy. cantariniluca@hotmail.com

Recurrences develop in up to 20-50% of patients with acute pericarditis. Although different causes of recurrent pericarditis have been identified, the etiology remains obscure in most cases which are therefore labelled as idiopathic. Autoinflammatory syndromes include familial Mediterranean fever (FMF), due to mutations in the MEFV gene, and tumor necrosis factor receptor-associated periodic syndrome (TRAPS), due to mutations in the TNFRSF1A gene. Recurrent pericarditis is a common feature of both conditions, but it rarely occurs alone. Colchicine is the standard treatment for FMF, while patients with TRAPS do not respond to colchicine therapy, but are responsive to corticosteroids. Based on the proven efficacy of colchicine in preventing polyserositis in FMF, colchicine has been proposed for the treatment of recurrent pericarditis and is able to decrease the recurrence rate. Our aim was to investigate the possible involvement of TNFRSF1A mutations in a group of patients with idiopathic recurrent pericarditis who were refractory to colchicine treatment. Thirty consecutive patients (17 males, 13 females) diagnosed with idiopathic recurrent pericarditis, who were characterized by a poor response to colchicine treatment, were enrolled in the study. Mutations of the TNFRSF1A gene were searched for by amplifying, using polymerase chain reaction (PCR), genomic DNA, and direct sequencing. TNFRSF1A mutations were found in 4 of the 30 patients. None of these 4 patients had a family history of recurrent inflammatory syndromes or history of pericarditis. One of the 4 patients had a novel heterozygous deletion (DeltaY103-R104) and three patients carried a heterozygous low-penetrance R92Q mutation. Our data suggest that TRAPS should be kept in mind in the differential diagnosis of recurrent pericarditis, and mutation analysis of the TNFRSF1A gene should be considered, in addition to MEFV analysis, in patients of Mediterranean origin. A poor response to colchicine treatment and/or a steroid-dependence may be the clue to investigate TNFRSF1A mutations in patients with idiopathic recurrent pericarditis.

Blocking interleukin-1 in rheumatic diseases.

Goldbach-Mansky R(1).

Author information:

(1)National Institute of Arthritis and Musculoskeletal and Skin Diseases at the National Institutes of Health, Bethesda, Maryland 20892, USA.  
goldbacr@mail.nih.gov

The role of the potent proinflammatory cytokine IL-1 in disease could clinically be investigated with the development of the IL-1 blocking agent anakinra (Kineret), a recombinant IL-1 receptor antagonist. It was first tested in patients with sepsis without much benefit but was later FDA approved for the treatment of patients with rheumatoid arthritis. More recently IL-1 blocking therapies are used successfully to treat a new group of immune-mediated inflammatory conditions, autoinflammatory diseases. These conditions include rare hereditary fever syndromes and pediatric and adult conditions of Still's disease. Recently the FDA approved two additional longer acting IL-1 blocking agents, for the treatment of cryopyrin-associated periodic syndromes (CAPS), an IL-1 dependent autoinflammatory syndrome. The study of autoinflammatory diseases revealed mechanisms of IL-1 mediated organ damage and provided concepts to a better understanding of the pathogenesis of more common diseases such as gout and Type 2 diabetes which show initial promising results with IL-1 blocking therapy.

Comment in

Rheumatology (Oxford). 2011 Aug;50(8):1525-6; author reply 1526-9.

**OBJECTIVE:** TNF receptor-associated periodic syndrome (TRAPS) is a systemic autoinflammatory disorder caused by mutations in the type 1 TNF receptor (TNFRSF1A) gene. Because the pathomechanism of TRAPS may involve aberrant TNF-mediated intracellular signalling, we examined phosphorylation levels of nuclear factor kappaB (NF-kappaB) and p38 in response to TNF in 10 patients with three different TNFRSF1A mutations (C73R, C88Y and F112I).

**METHODS:** Phosphorylation levels of NF-kappaB p65 and p38 were determined in fresh leucocytes stimulated with TNF (0-100 ng/ml) for 2.5-20 min and permeabilized for phospho-specific antibodies in a whole blood flow cytometry assay. As control agonists, we used bacterial lipopolysaccharide (LPS) and IFN-gamma, the latter mediating phosphorylation of the signal transducer and activator of transcription 1. Areas under curve values for dose-response and time course of NF-kappaB and p38 phosphorylation were calculated for the comparison of patients and reference subjects.

**RESULTS:** NF-kappaB and p38 phosphorylation levels of monocytes, lymphocytes and neutrophils stimulated with TNF were significantly lower in TRAPS patients than in reference subjects. Phosphorylation levels induced by LPS, or by IFN-gamma, in patient and reference samples were comparable, indicating that the defect was confined to TNF-mediated signalling.

**CONCLUSIONS:** In the three families studied, TRAPS was associated with low TNF-mediated signalling in leucocytes. This deficiency of the innate immune system may result in the activation of as yet unidentified compensatory regulatory mechanisms yielding the hyperinflammatory phenotype of TRAPS.

Canakinumab for the treatment of cryopyrin-associated periodic syndromes.

Walsh GM(1).

Author information:

(1)Division of Applied Medicine, Institute of Medical Science, University of Aberdeen, Foresterhill, Aberdeen, UK. g.m.walsh@abdn.ac.uk

Familial cold-induced autoinflammatory syndrome, Muckle-Wells syndrome and neonatal-onset multisystem inflammatory disease make up cryopyrin-associated periodic syndromes (CAPS). These are autoinflammatory inherited disorders caused by autosomal dominant gain-of-function mutations in the NLRP3 gene, located on chromosome 1q44. Cryopyrin/NALP3/NLRP3 is an essential component of intracellular inflammasomes that activate caspase-1, which in turn converts interleukin-1beta (IL-1beta) to its active form. IL-1beta is a potent cytokine that activates diverse elements of the immune and inflammatory systems leading to the pathogenic changes characteristic of CAPS. There is therefore much interest in the development of IL-1beta blocking agents as novel biologic treatments for these conditions. Canakinumab (ACZ-885; Ilaris, Novartis Pharma) is a fully humanized monoclonal antibody (mAb) specific for IL-1beta and is indicated for a wide range of inflammatory disorders including CAPS. This review will assess the utility of canakinumab as a treatment for CAPS.

Interferon therapy in rheumatic diseases: state-of-the-art 2010.

Kötter I(1), Hamuryudan V, Oztürk ZE, Yazici H.

Author information:

(1)Department of Internal Medicine II, University Hospital, Tübingen, Germany.

PURPOSE OF REVIEW: Interferons are natural glycoproteins that have antiviral,

antiproliferative and immune regulatory functions. They are not only involved in the pathogenesis of certain autoimmune conditions but are also useful in the treatment of some rheumatologic disorders, notably Behçet's syndrome.

RECENT FINDINGS: Interferon alpha (IFNalpha) has been recommended for severe eye involvement in Behçet's syndrome, especially when there is a significant drop in visual acuity and/or retinal involvement. It can induce a high rate of complete remission that may also persist after its discontinuation. When given early at the beginning, interferon might be effective in ameliorating the attacks of familial Mediterranean fever resistant to colchicine treatment. The combination of PEGylated IFNalpha with ribavirin and rituximab emerges as a novel and promising treatment providing complete clinical response and viral clearance in hepatitis C virus-associated mixed cryoglobulinemia. Limited data also suggest that interferon may induce remissions in Churg-Strauss patients who fail to respond to conventional immunosuppressive treatment.

SUMMARY: Among several rheumatologic diseases, IFNalpha has found more widespread use in Behçet's syndrome and hepatitis C virus-associated mixed cryoglobulinemia despite a paucity of formal studies. Patients should be carefully monitored for the frequent and dose-dependent adverse effects.

Altered cytokine profiles of mononuclear cells after stimulation in a patient with Blau syndrome.

Son S(1), Lee J, Woo CW, Kim I, Kye Y, Lee K, Lee J.

Author information:

(1)Department of Dermatology, Korea University Medical Center, Seoul, South Korea.

Autoinflammatory Blau syndrome (BS) is associated with NOD2 gene mutations that lead to constitutive NFkappaB activation. NOD2 functions as an intracellular receptor for the muramyl dipeptide (MDP) component of peptidoglycan (PGN). The objectives of this study are to analyse whether NFkappaB activation in BS affects

immune cell functions, and whether NOD2 and toll-like receptor (TLR) pathways interact. Peripheral blood mononuclear cells (MNCs) from a BS patient and three normal donors were analyzed for their ability to produce pro- and anti-inflammatory cytokines in the presence and absence of MDP, PGN, and lipopolysaccharide (LPS). The results obtained showed that the basal TNF-alpha and IL-10 production by MNCs over 24 h of incubation was very low for both the patient and the normal donors. However, upon stimulation with MDP, LPS, and PGN, the cells from the BS patient produced much lower levels of TNF-alpha, IL-10, G-CSF, and IFN-gamma than the normal donor cells. We conclude that the pathogenic mechanism responsible for the chronic inflammation that characterizes BS may relate to the impaired production of both pro- and anti-inflammatory cytokines to stimuli. The NOD2 pathway possibly interacts with either the TLR2 or TLR4 pathways.

Respiration. 2010;80(3):260-1; author reply 262.

Familial Mediterranean fever (FMF) is a genetic autoinflammatory disease especially affecting populations of Mediterranean origin with an autosomal recessive inheritance. The cardinal manifestations consist of short febrile and painful attacks of peritonitis, arthritis and pleuritis developing during childhood. We report the case of a 26-year-old man of Tunisian descent who had febrile episodes of right-sided pleuritis without any extrathoracic complaints. Disappearance of attacks with one dose of colchicine (1 mg/day) strengthened the

presumptive diagnosis of atypical FMF, which was further confirmed by genetic testing identifying the homozygous mutation M694I/M694I of the MEFV gene.

Previous studies have suggested that inflammatory bowel disease is particularly frequent and severe in familial Mediterranean fever (FMF) families. An 8-month-old boy was admitted to our hospital with chronic bloody diarrhea, failure to thrive and high-grade fever. He was diagnosed as Crohn's disease (CD) based on clinical, laboratory and histological findings and, corticosteroid therapy was started. The patient did not respond to intensive medical therapy including intravenous corticosteroid, mesalazine, azathioprine, intravenous cyclosporine and enteral feeding. MEFV gene mutation analysis revealed homozygous M694V mutation. In addition to azathioprine and cyclosporine therapy, with the diagnosis of FMF, colchicine therapy was started and partial remission was observed within 2 weeks. To the best of our knowledge, this is the first report of association of CD and FMF in an infant. In cases of CD resistant to medical therapy, possibility of underlying FMF should be considered, especially in countries where FMF is prevalent.

Health-related quality of life and its associations with mood condition in familial Mediterranean fever patients.

Deger SM(1), Ozturk MA, Demirag MD, Aslan S, Goker B, Haznedaroglu S, Onat AM.

Author information:

(1)Department of Internal Medicine, Gazi University School of Medicine, Ankara, Turkey. [serpilmugedeger@yahoo.com](mailto:serpilmugedeger@yahoo.com)

The aim of the present study was to investigate the health-related quality of life (HRQOL) and mood conditions in familial Mediterranean fever (FMF) patients. Ninety FMF patients (F/M 60/30, median age 29) and 67 control subjects (F/M 46/21, median age 30) were included in this study. HRQOL was assessed with short form-36 (SF-36) and mood conditions were assessed with hospital anxiety depression scale (HADS). FMF patients had significantly lower mean scores on SF-36 physical components compared to the control group. However, mental components were comparable between groups. FMF patients were significantly more likely to have depression and anxiety compared to the control group [30 (33%) vs. 8 (12%), respectively,  $\chi^2(2) = 9.58$ , OR (95% CI) = 3.7 (1.5-8.7),  $p < 0.01$  for depression and 48 (53%) and 11 (16%), respectively,  $\chi^2(2) = 22.31$ , OR (95% CI) = 5.8 (2.7-12.5),  $p < 0.001$  for anxiety]. When frequency of anxious subjects was adjusted for the presence of concomitant depressive status as a confounding factor, the difference between the groups remained statistically significant [ $\chi^2(2) = 11.86$ , OR (95% CI) = 5.4 (2.1-13.7),  $p < 0.01$ ]. However, the difference of depression status between groups was not statistically significant when adjusted for the presence of concomitant anxiety status [ $\chi^2(2) = 0.08$ , OR (95% CI) = 1.3 (0.5-3.8),  $p = 0.78$ ] and FMF was found to be independently associated with only anxiety [OR (95% CI) = 7.1 (2.3-20.3)]. In addition, pure anxious FMF subgroup had significantly lower scores of mental health and mental component summary when compared to normal mood subgroup. In conclusion, FMF might adversely affect HRQOL. Depression and anxiety are more frequent in FMF patients than healthy subjects.

Anti-IL-1 molecules: new comers and new indications.

Moltó A(1), Olivé A.

Author information:

(1)Rheumatology Section, Hospital Universitari Germans Trias i Pujol, Ctra del Canyet s/n, 08916 Badalona, Spain.

The interleukin 1 family is composed by the interleukin 1 (IL-1) and its natural occurring inhibitor, the interleukin 1 receptor antagonist (IL-1Ra). The role of both molecules in rheumatoid arthritis has been widely established, and in this sense new molecules blocking IL-1 actions are under investigation. Anakinra is the recombinant form of IL-1Ra, and has proven to be well tolerated and indicated in the treatment of rheumatoid arthritis. Nevertheless, other molecules such as mAb anti-IL-1 and IL-1 Trap are being developed. Moreover, the recent relation of IL-1 in the inflammasome and pathways of innate immunity has lead to new indications of anti-IL-1 molecules, especially in the autoinflammatory syndromes as well as in other inflammatory diseases. Herein we have performed a review of the literature, limited to English language journals (PUBMED search: combination of descriptors IL-1 and anakinra, systemic juvenile idiopathic arthritis, adult's onset Still's disease, autoinflammatory syndromes, gout, pseudogout, ankylosing spondylitis, and systemic lupus erythematosus from January 1985-December 2008) emphasizing the possible new indications. Although sufficient data is not yet available to fully assess the efficacy and safety of anti-IL-1 molecules in patients with inflammatory disorders other than rheumatoid arthritis, new data is promising.

Systemic juvenile idiopathic arthritis (SJIA) is a disorder characterized by arthritis in children starting before 16 years of age associated with daily high fever, persisting for more than 2 weeks, and at least one of the following clinical features: evanescent cutaneous rash, lymphadenopathy, serositis or hepatosplenomegaly. SJIA patients carry a significantly higher frequency of MEFV mutations, the gene responsible for familial Mediterranean fever, and may be characterized by a more aggressive disease. In this line, we describe a 9-year-old girl affected with SJIA who carried a heterozygous G196W mutation in MEFV. Our patient was characterized by an aggressive disease course, resistance to conventional immunosuppressive agents and developed renal amyloidosis just 2 years after the disease onset.

Riloncept in the management of cryopyrin-associated periodic syndromes (CAPS).

Gillespie J(1), Mathews R, McDermott MF.

Author information:

(1)NIHR-Leeds Musculoskeletal Biomedical Research Unit (NIHR-LMBRU), Leeds Institute of Molecular Medicine (LIMM), St. James's University Hospital, Leeds, UK.

Cryopyrin-associated periodic syndromes (CAPS) are a subgroup of the hereditary periodic fever syndromes, which are rare autoinflammatory and inherited disorders, characterized by recurrent inflammation and varying degrees of severity. CAPS are thought to be driven by excessive production of interleukin-1 $\beta$  (IL-1 $\beta$ ), through over-activation of the inflammasome by gain of function mutations in the gene encoding cryopyrin (NLRP3). This conclusion is supported by the remarkable efficacy of IL-1 $\beta$  blockade in these conditions. Rilonacept (Arcalyst(TM); Regeneron) is the first us Food and Drug Administration-approved treatment for familial cold autoinflammatory syndrome and Muckle-Wells syndrome and the first in a new line of drugs designed for longer-acting IL-1 blockade. Rilonacept has been associated with a decrease in disease activity, high-sensitivity C-reactive protein (hsCRP) and serum amyloid A (SAA) in the treatment of CAPS. The clinical safety and efficacy of rilonacept in CAPS and non-CAPS populations will be summarized in this review. Rilonacept is also beneficial for patients who tolerate injections poorly, due to an extended half-life over the unapproved CAPS treatment, anakinra, requiring weekly rather than daily self-administration. Other autoinflammatory disorders may also benefit from rilonacept treatment, with clinical trials in progress for systemic onset juvenile idiopathic arthritis, gout and familial mediterranean fever.

Delay in diagnosis of intestinal obstruction in a patient with familial mediterranean Fever.

Kaya B(1), Eriş C, Uçtüm Y.

Author information:

(1)Department of General Surgery, Faith Sultan Mehmet Training and Research Hospital, Istanbul, Turkey.

Familial Mediterranean Fever (FMF) is a recurrent disease characterized by

inflammatory process effecting synovial membranes such as peritoneum, pericardium and joints. It usually presents with acute abdominal pain. Intestinal obstruction secondary to adhesions may be observed in FMF patients. Sometimes diagnosing intestinal obstruction can be a challenging problem. We were presented a patient with FMF and adhesive intestinal obstruction. He was operated on after 10 days of symptoms. Delay in diagnosis and treatment of the case discussed with literature review.

The human gastrointestinal tract is inhabited by a diverse and dense symbiotic microbiota, the composition of which is the result of host-microbe co-evolution and co-adaptation. This tight integration creates intense cross-talk and signaling between the host and microbiota at the cellular and metabolic levels. In many genetic or infectious diseases the balance between host and microbiota may be compromised resulting in erroneous communication. Consequently, the composition of the human metabolome, which includes the gut metabolome, may be different in health and disease states in terms of microbial products and metabolites entering systemic circulation. To test this hypothesis, we measured the level of hydroxy, branched, cyclopropyl and unsaturated fatty acids, aldehydes, and phenyl derivatives in blood of patients with a hereditary autoinflammatory disorder, familial Mediterranean fever (FMF), and in patients with peptic ulceration (PU) resulting from *Helicobacter pylori* infection.

Discriminant function analysis of a data matrix consisting of 94 cases as statistical units (37 FMF patients, 14 PU patients, and 43 healthy controls) and the concentration of 35 microbial products in the blood as statistical variables revealed a high accuracy of the proposed model (all cases were correctly classified). This suggests that the profile of microbial products and metabolites in the human metabolome is specific for a given disease and may potentially serve as a biomarker for disease.

Comorbidities of hidradenitis suppurativa (acne inversa).

Fimmel S(1), Zouboulis CC.

Author information:

(1)Laboratory for Biogerontology; Dermato-Pharmacology and Dermato-Endocrinology; Institute of Clinical Pharmacology and Toxicology; Campus Benjamin Franklin; Charité Universitaetsmedizin Berlin, Germany.

Comorbidities of hidradenitis suppurativa (acne inversa) were reviewed by extracting original and review publications included in MEDLINE, EMBASE and COCHRANE libraries using the terms "hidradenitis," "Verneuil" and "acne inversa." Follicular occlusion disorders, inflammatory bowel diseases, especially Crohn disease, spondylarthropathy, other hyperergic diseases, genetic keratin disorders associated with follicular occlusion and squamous cell carcinoma were the most common hidradenitis suppurativa comorbid diseases. A first classification of these major comorbidities and their possible genetic background reveals a list of chromosome loci and genes, which could be hidradenitis suppurativa candidates. Most of these diseases belong to the group of autoinflammatory disorders, where th17 cell cytokines seem to play a central role.

Missense mutations in the MEFV gene are associated with fibromyalgia syndrome and correlate with elevated IL-1beta plasma levels.

Feng J(1), Zhang Z, Li W, Shen X, Song W, Yang C, Chang F, Longmate J, Marek C, St Amand RP, Krontiris TG, Shively JE, Sommer SS.

Author information:

(1)Division of Molecular Genetics, Beckman Research Institute, City of Hope, Duarte, California, United States of America.

**BACKGROUND:** Fibromyalgia syndrome (FMS), a common, chronic, widespread musculoskeletal pain disorder found in 2% of the general population and with a preponderance of 85% in females, has both genetic and environmental contributions. Patients and their parents have high plasma levels of the chemokines MCP-1 and eotaxin, providing evidence for both a genetic and an immunological/inflammatory origin for the syndrome (Zhang et al., 2008, Exp. Biol. Med. 233: 1171-1180).

**METHODS AND FINDINGS:** In a search for a candidate gene affecting inflammatory pathways, among five screened in our patient samples (100 probands with FMS and their parents), we found 10 rare and one common alleles for MEFV, a gene in which various compound heterozygous mutations lead to Familial Mediterranean Fever (FMF). A total of 2.63 megabases of genomic sequence of the MEFV gene were scanned by direct sequencing. The collection of rare missense mutations (all heterozygotes and tested in the aggregate) had a significant elevated frequency of transmission to affecteds ( $p = 0.0085$ , one-sided, exact binomial test). Our data provide evidence that rare missense variants of the MEFV gene are, collectively, associated with risk of FMS and are present in a subset of 15% of FMS patients. This subset had, on average, high levels of plasma IL-1beta ( $p = 0.019$ ) compared to FMS patients without rare variants, unaffected family members with or without rare variants, and unrelated controls of unknown genotype. IL-1beta is a cytokine associated with the function of the MEFV gene and thought to be responsible for its symptoms of fever and muscle aches.

**CONCLUSIONS:** Since misregulation of IL-1beta expression has been predicted for patients with mutations in the MEFV gene, we conclude that patients heterozygous for rare missense variants of this gene may be predisposed to FMS, possibly

triggered by environmental factors.

**OBJECTIVE:** Cryopyrin-associated periodic syndromes (CAPS) are a group of rare autoinflammatory diseases. Neonatal-onset multisystem inflammatory disease (NOMID)/chronic infantile neurologic, cutaneous, articular syndrome (CINCA syndrome) is the most severe phenotype, with fever, rash, articular manifestations, and neurologic and neurosensory involvement. CAPS are caused by mutations in CIAS1, the gene encoding NLRP3, which plays a critical role in interleukin-1 (IL-1) processing. Anakinra, an IL-1 receptor antagonist, has been shown to be an effective treatment; however, data on long-term efficacy and safety have been sparse. This study was undertaken to assess the long-term efficacy and safety of anakinra treatment in patients with NOMID/CINCA syndrome. **METHODS:** We retrospectively analyzed the medical records of NOMID/CINCA syndrome patients referred to 2 centers, who had started anakinra treatment before June 2007.

**RESULTS:** There were 10 patients with NOMID/CINCA syndrome who had been treated with anakinra. The patients' ages at the time anakinra treatment was initiated ranged from 3 months to 20 years. They had been followed up for 26-42 months. Sustained efficacy in the treatment of systemic inflammation and, in some cases, neurologic involvement and growth parameters, was achieved. The dosage of

anakinra required for efficacy ranged from 1 to 3 mg/kg/day in the 8 oldest patients and from 6 to 10 mg/kg/day in the 2 youngest. Residual central nervous system inflammation and deafness persisted in some patients, especially if there had been a delay in diagnosis and treatment. Secondary amyloidosis persisted in cases in which it was present at treatment initiation, but no new lesions developed. No effect on overgrowth arthropathy was observed. Adverse events consisted of mild injection-site reactions.

CONCLUSION: The present results indicate that anakinra treatment is effective over the long term in NOMID/CINCA syndrome. However, treatment has to be initiated before irreversible lesions develop, and, particularly in very young patients, dosage adjustment is required.

Constitutively active inflammasome in human melanoma cells mediating autoinflammation via caspase-1 processing and secretion of interleukin-1beta.

Okamoto M(1), Liu W, Luo Y, Tanaka A, Cai X, Norris DA, Dinarello CA, Fujita M.

Author information:

(1)Department of Dermatology, University of Colorado Denver, Aurora, Colorado 80045, USA.

Interleukin-1beta (IL-1beta) is a pleiotropic cytokine promoting inflammation, angiogenesis, and tissue remodeling as well as regulation of immune responses. Although IL-1beta contributes to growth and metastatic spread in experimental and human cancers, the molecular mechanisms regulating the conversion of the inactive IL-1beta precursor to a secreted and active cytokine remains unclear. Here we demonstrate that NALP3 inflammasome is constitutively assembled and activated with cleavage of caspase-1 in human melanoma cells. Late stage human melanoma cells spontaneously secrete active IL-1beta via constitutive activation of the NALP3 inflammasome and IL-1 receptor signaling, exhibiting a feature of autoinflammatory diseases. Unlike human blood monocytes, these melanoma cells require no exogenous stimulation. In contrast, NALP3 functionality in

intermediate stage melanoma cells requires activation of the IL-1 receptor to secrete active IL-1 $\beta$ ; cells from an early stage of melanoma require stimulation of the IL-1 receptor plus the co-stimulant muramyl dipeptide. The spontaneous secretion of IL-1 $\beta$  from melanoma cells was reduced by inhibition of caspase-1 or the use of small interfering RNA directed against ASC. Supernatants from melanoma cell cultures enhanced macrophage chemotaxis and promoted in vitro angiogenesis, both prevented by pretreating melanoma cells with inhibitors of caspases-1 and -5 or IL-1 receptor blockade. These findings implicate IL-1-mediated autoinflammation as contributing to the development and progression of human melanoma and suggest that inhibiting the inflammasome pathway or reducing IL-1 activity can be a therapeutic option for melanoma patients.

Safety and pharmacokinetics of subcutaneously administered riloncept in patients with well-controlled end-stage renal disease (ESRD).

Radin A(1), Marbury T, Osgood G, Belomestnov P.

Author information:

(1)Regeneron Pharmaceuticals, 777 Old Saw Mill River Road, Tarrytown, NY 10591, USA. allen.radin@regeneron.com

The safety and pharmacokinetics of a single dose of the IL-1 inhibitor, riloncept (IL-1 Trap; 160 mg, subcutaneously), was studied in a group of 6 patients with well-controlled end-stage renal disease (ESRD) who were observed for a period of 42 days following dosing. The safety of riloncept administration was ascertained by regular monitoring of patients for adverse events, by periodic determination of a battery of standard laboratory and hematology tests, and by testing for binding and neutralizing antibodies to riloncept. Two of the 6 patients had treatment-emergent adverse events that were moderate in intensity and unrelated to administration of riloncept. There were no deaths, serious

adverse events, or withdrawals due to adverse events. No patient developed binding or neutralizing antibodies to rilonacept by the 42nd day postdosing. Mean C(max) estimated by a noncompartmental analysis was 17.2 mg/L; t(max,) 2.80 days; terminal t(1/2), 7.63 days; and AUC(0-infinity), 199.3 d.mg/L. Comparison of these results to those obtained in a population of patients with cryopyrin-associated periodic syndromes, a group of rare, inherited, autoinflammatory disorders (mean [SD] eGFR of 73.1 [13.3] mL/min/1.73m<sup>2</sup>), shows that ESRD and related hemodialysis procedures do not prolong the elimination of rilonacept, and therefore no dose adjustment should be needed relative to individuals with normal renal function.

Depression and anxiety in children and adolescents with familial Mediterranean fever.

Makay B(1), Emiroğlu N, Unsal E.

Author information:

(1)Department of Pediatrics, Division of Immunology-Rheumatology, Dokuz Eylül University Hospital, Balçova-Izmir, Turkey. balahan.bora@deu.edu.tr

Familial Mediterranean fever (FMF) is the most common autoinflammatory disease which requires a lifelong treatment. The aim of this study was to evaluate the depression and anxiety in pediatric FMF patients. The Children's Depression Inventory and the Screen for Child Anxiety-related Emotional Disorders were the instruments used. Forty-three patients with FMF and 53 healthy controls were compared. Both study and control groups were divided into two age groups, 7-12 and 13-18 years. The depression scores of patients with FMF were significantly higher than their healthy peers ( $p = 0.001$ ). However, there was no significant difference between patients with FMF and control group regarding the anxiety scores ( $p = 0.78$ ). The disease duration was not significantly correlated with depression and anxiety scores. There was a significant correlation between depression score and FMF severity score ( $p = 0.01$ ). The mean depression and

anxiety scores of the FMF patients were positively correlated with the number of attacks ( $p = 0.000$  and  $p = 0.001$ , respectively). This study suggested that patients with FMF were considerably more depressed than their healthy peers and that the depression scores were negatively affected from disease severity score and number of attacks. Psychosocial assessment of children with FMF has potential clinical implications and individualized counseling and interventions are needed.

The interleukin 1 receptor antagonist (IL-1ra) is an important negative regulator of the inflammatory response, whose genetic deficiency has been recently shown to cause a severe autoinflammatory syndrome in humans. In this study we characterized the molecular mechanisms whereby interleukin 10 (IL-10) potentiates IL-1ra transcription in LPS-stimulated monocytes and neutrophils. Using chromatin immunoprecipitation, we show that although NF-kappaBp65 and NF-kappaBp50 proteins accumulate into the nuclei and bind to the IkappaB alpha promoter during LPS stimulation, they are not recruited to the kappaB sites of the IL-1ra promoter. However, in response to LPS plus IL-10, which were found to induce chromatin acetylation, recruitment of both NF-kappaBp65 and NF-kappaBp50 to the IL-1ra promoter efficiently occurs in a STAT3-dependent manner. Accordingly, in neutrophils from hyper-IgE syndrome patients, who carry a nonfunctional STAT3, IL-10 failed to promote NF-kappaBp65 recruitment to the IL-1ra promoter and consequently to potentiate LPS-induced IL-1ra transcription. Altogether our findings uncover a novel mechanism whereby IL-10-activated STAT3 modulates IL-1ra transcription in LPS-treated phagocytes by making IL-1ra promoter accessible to

readily available nuclear NF-kappaB.

**OBJECTIVES:** Pyrin/marenostrin, an inhibitory regulator of inflammation, is encoded by MEditerranean FeVer (MEFV) gene. Mutations of this gene are the cause of familial Mediterranean fever (FMF). A connection between MEFV gene mutations and rheumatic diseases has been suggested. The aim of this study was to explore the frequency and clinical significance of MEFV gene mutations in a cohort of Turkish patients with rheumatoid arthritis (RA).

**METHODS:** The study included 103 patients with RA and 103 age-, sex- and origin-matched healthy controls (HC). In all participants, genomic DNA was isolated and genotyped using amplification refractory mutation system or restriction fragment length polymorphism for the eight MEFV gene mutations (E148Q, M694V, M694I, M680I, V726A, A744S, R761H, and P369S). In the RA group, disease activity was determined using the disease activity score-28 (DAS-28), and radiological damage was evaluated by the modified Larsen scoring method.

**RESULTS:** Carrier rates of MEFV gene mutations were 26/103 (25.2%) and 24/103 (23.3%) in the RA and HC groups, respectively ( $p>0.05$ , OR: 0.9, 95% CI: 0.48-1.71). In the RA group, while deformed joint count was significantly higher in the mutation carrier group than those of the non-carrier group ( $p<0.05$ ), the level of C-reactive protein, DAS-28 and modified-Larsen scores were slightly but not significantly higher in the carrier group.

**CONCLUSION:** The results of this study suggest that MEFV gene mutations appear to be an aggravating factor for the severity of RA, and consequently, patients with

RA might be screened for MEFV gene mutations in countries where FMF is frequent. Whether the searching of MEFV gene mutations in RA patients is cost-effective deserves further investigations.

Etanercept and anakinra can prolong febrile episodes in patients with hyperimmunoglobulin D and periodic fever syndrome.

Shendi HM(1), Walsh D, Edgar JD.

Author information:

(1)Royal Victoria Hospital, Belfast, Northern Ireland, UK.

hiba.shendi@belfasttrust.hscni.net

Hyperimmunoglobulin D and periodic fever syndrome (HIDS) is a rare, hereditary autoinflammatory condition, characterized by recurrent inflammatory episodes. There is no proven treatment for HIDS, but various drugs including, non-steroidal anti-inflammatory drugs, colchicine, steroids, statins and thalidomide have all been tried. Recently, some patients have demonstrated a good clinical response to either etanercept or anakinra. We report a case of a 10-year-old girl who experienced prolonged and severe inflammatory attacks, when she was treated with etanercept, and later with anakinra.

Familial Mediterranean fever (FMF) is an autosomal recessive disease, characterized by recurrent, self-limited attacks of fever with serositis involving the peritoneum, pleura, and joints. There is very scarce information on physical growth of affected children. The aim of this study was to determine whether there is significant improvement in growth parameters in FMF patients after colchicine treatment. Patient files were retrospectively evaluated and patients that used colchicine for more than 1 year were included in the study. Demographic features, clinical findings before and after colchicine therapy, duration and dosage of therapy, weight, height, parentally adjusted height, and body mass index before and after colchicine therapy were noted and transformed into standard deviation scores (SDS). The study group consisted of 50 FMF (25 male and 25 female) patients. Median age at the time of diagnosis was 6.5 years. Median follow-up period was 3.6 (1-12.5) years. Mean height SDS increased from  $-0.19 \pm 1.01$  to  $0.13 \pm 0.99$  ( $p = 0.026$ ), and mean parentally adjusted height increased from  $-0.18 \pm 1.23$  to  $0.13 \pm 1.24$  ( $p = 0.027$ ), and both of them were found to be statistically significant. Mean body mass index SDS increased from  $-0.61 \pm 1.32$  to  $-0.32 \pm 1.33$ , but this improvement was statistically insignificant ( $p = 0.18$ ). In this study, we found that colchicine significantly improved height development in FMF patients.

Comment in

J Rheumatol. 2010 Oct;37(10):2190; author reply 2190-1.

**OBJECTIVE:** To characterize familial Mediterranean fever (FMF) in Ashkenazi patients, a Jewish subgroup in which FMF has rarely been described before.

**METHODS:** A retrospective analysis, comparing demographic, clinical, and genetic measures of the cohort of Ashkenazi Jewish patients with FMF (n = 57), followed at the National Center for FMF in Israel, to age and sex matched patients of Iraqi Jewish (n = 62) and North African Jewish (NAJ; n = 61) origin.

**RESULTS:** Age at disease onset and diagnosis was earlier in NAJ than among Ashkenazi and Iraqi patients. Family history of FMF was described by only 30% of Ashkenazi patients as opposed to the majority of Iraqi and NAJ patients (p = 0.001). The frequency of abdominal and febrile attacks was similar among the 3 groups, while chest and joint attacks were far less common in Ashkenazi and Iraqi compared to NAJ patients. A good response to colchicine was noted in a similar proportion of Ashkenazi and Iraqi patients (82-84%) as opposed to only 56% of NAJ patients (p = 0.0001). Proteinuria, renal failure, and amyloidosis were most frequent among the NAJ patients (18, 6.6, and 9.8% compared to 5.3, 0, and 3.5% and 1.6, 0, and 0% in Ashkenazi and Iraqi patients, respectively).

**CONCLUSION:** Ashkenazi patients with FMF stand at the mildest end of the clinical spectrum of FMF. This is notwithstanding the tendency for amyloidosis, the frequency of which is not trivial and which deserves particular awareness.

Unresponsiveness to colchicine therapy in patients with familial Mediterranean fever homozygous for the M694V mutation.

Soylemezoglu O(1), Arga M, Fidan K, Gonen S, Emeksiz HC, Hasanoglu E, Buyan N.

Author information:

(1)Department of Pediatric Nephrology, Gazi University Medical Hospital, Ankara, Turkey.

**OBJECTIVE:** More than 50 disease-associated mutations of the Mediterranean fever gene (MEFV) have been identified in familial Mediterranean fever (FMF), some of which were shown to have different clinical, diagnostic, prognostic, and therapeutic implications. The aim of our study was to define the frequency of mutation type, genotype-phenotype correlation, and response to colchicine treatment in patients with FMF.

**METHODS:** This study included 222 pediatric FMF patients. All patients were investigated for 6 MEFV mutations. Then patients were divided into 3 groups according to the presence of M694V mutation on both of the alleles (homozygotes), on only 1 allele (heterozygotes), and on none of the alleles, and compared according to their phenotypic characteristics and response to treatment.

M694V/M694V was denoted Group A, M694V/Other Group B, and Other/Other, Group C.

**RESULTS:** Complete colchicine response was significantly lower while the rate of unresponsiveness was significantly higher in Group A compared to Groups B and C ( $p = 0.031$ ,  $p < 0.001$  and  $p = 0.005$ ,  $p = 0.029$ , respectively). No differences except proteinuria were found between the phenotypic features of 3 groups. Group C had the lowest rate of proteinuria development ( $p = 0.024$ ). All the amyloidosis patients were in Group A.

**CONCLUSION:** Our results indicate that the M694V/M694V mutation is associated with lower response to colchicine treatment. Therefore, patients homozygous for M694V/M694V may be carrying an increased risk for development of amyloidosis.

Inflammasome-associated nucleotide-binding domain, leucine-rich repeat proteins and inflammatory diseases.

Jha S(1), Ting JP.

Author information:

(1)Department of Cell and Molecular Physiology, University of North Carolina, Chapel Hill, NC 27599, USA.

The nucleotide-binding domain, leucine-rich repeat (NLR) proteins are a recently discovered family of intracellular pathogen and danger signal sensors. NLRs have emerged as important contributors to innate immunity in animals. The physiological impact of these genes is increasingly evident, underscored by the genetic association of variant family members with an array of inflammatory diseases. The association of mutations in NLR genes with autoinflammatory diseases indicates an important function of these genes in inflammation *in vivo*. This review summarizes the role of the inflammasome NLR proteins in innate immunity and inflammatory diseases and explores the possible utility of some of these NLRs as pharmacological targets.

CINCA syndrome is an autoinflammatory disease in childhood characterized by multisystemic manifestations: cutaneous, articular, and neurological including sensory organs. We report the case of homozygous twins affected by CINCA syndrome. The diagnosis was evoked on the basis of multiple systemic symptoms (multiple episodes of fever of unknown origin, mental retardation, short stature, meningitis, hearing loss, bilateral papilledema) and confirmed by the presence of a CIAS1 mutation on genetic analysis. After few months of treatment by anakinra

(an interleukin-1 receptor antagonist) the children began to grow again and we noted regression of the biological inflammatory syndrome.

Autoinflammation: the prominent role of IL-1 in monogenic autoinflammatory diseases and implications for common illnesses.

Goldbach-Mansky R(1), Kastner DL.

Author information:

(1)National Institute of Arthritis and Musculoskeletal and Skin Diseases, National Institutes of Health, Bethesda, MD 20892, USA. goldbacr@mail.nih.gov

The discovery of the genetic causes of a rare group of immune-mediated inflammatory conditions that mimic infections and allergic conditions in their clinical presentation and the molecular understanding of the function of the mutated molecules in these diseases has led to a revolution in our understanding of the pathogenesis of systemic and local inflammation. The proteins mutated in a number of these so-called autoinflammatory diseases are part of, or regulate the activity of, intracellular molecular complexes, the inflammasomes, that sense "danger" to the body and coordinate an initial immune response. Our understanding of specific triggers of the inflammasomes, coupled with the recognition that inflammasomes are critical for activation of the proinflammatory cytokine IL-1, has provided a rational and very effective target in the treatment of a number of these rare autoinflammatory diseases. In addition, the ongoing discovery of the role of inflammasomes and IL-1 activation and secretion in a number of genetically complex disorders have fundamentally changed our view of disease pathogenesis in a growing number of disorders that were heretofore not even thought of as "immunologic" diseases.

Comment in

J Allergy Clin Immunol. 2011 Dec;128(6):1352-4.

The therapy of autoinflammatory syndromes is an excellent example of the power of translational research. Recent advances in our understanding of the molecular and immunologic basis of this newly identified classification of disease have allowed for the application of novel, effective, targeted treatments with life-changing effects on patients. Although colchicine and TNF-alpha inhibitors are important therapies for specific autoinflammatory syndromes, the novel IL-1-targeted drugs are particularly effective for many of these diseases. Recently, the pharmaceutical industry has adopted a strategy of confirming the efficacy of new targeted drugs in often-ignored patients with orphan diseases, and US Food and Drug Administration policies have allowed for accelerated approval of these drugs, creating a win-win situation for patients and industry. This article reviews the general approach to the therapy of autoinflammatory diseases, focusing on current approved therapies and novel approaches that might be used in the future.

Despite a lack of robust evidence, anti-TNF therapies are in wide use for the treatment of noninfectious ocular inflammatory diseases. There is a clear rationale, based on mechanistic and preclinical efficacy data, for their use in posterior segment intraocular inflammation. However, their increasing use for other indications has been largely extrapolated from the benefit observed in autoinflammatory and autoimmune systemic diseases. Given their cost and the potential for significant adverse events, this review highlights the evidence for their continued use, possibilities for switching anti-TNF agents, and ways of reducing the risk of therapy.

(1)Department of Healthcare Systems Research, Hokkaido University, Graduate School of Medicine, Sapporo 060-8638, Japan.

A 17-year-old Japanese male with a three-year history of recurrent episodic chest pain and fever, each lasting for one to three days, was diagnosed with familial Mediterranean fever (FMF) because of the following: 1) short attacks of chest pain and fever recurring at varying intervals; 2) no symptoms with a sense of well-being between attacks; and 3) identification of the Mediterranean fever gene

(MEFV) mutation demonstrating M694I. Although FMF has been described primarily in several limited ethnic groups, a limited number of cases have been reported in Japan. No specific diagnostic tests are commercially available for FMF so identifying the characteristic clinical picture of FMF is important.

Familial Mediterranean fever (FMF) is an autosomal recessive disorder characterized by recurrent and self-limited fever attacks and serositis/arthritis. The M694V, M694I, M680I, V726A, and E148Q mutations in MEFV, the gene responsible for FMF, account for most FMF cases in Mediterranean populations. In Japan, M694I and E148Q are most frequently detected; M694V, M680I, and V726A have not been identified so far. We report the first case of FMF associated with M680I in Japan.

Erratum in

Autoimmun Rev. 2011 Nov;11(1):76. Luca, Cantarini [corrected to Cantarini, Luca]; Massimo, Imazio [corrected to Imazio, Massimo]; Antonio, Brucato [corrected to Brucato, Antonio]; Maria, Lucherini Orso [corrected to Lucherini, Orso Maria]; Mauro, Galeazzi [corrected to Galeazzi, Mauro].

The pathogenesis of recurrent pericarditis is still poorly understood and may be related either to viral infections or autoimmune and autoinflammatory disorders. The immune system plays a major role in the pathogenesis of the disease, modulating individual responses to different noxa and explaining the variable reported recurrence rate (ranging from 20% to 50% of patients) following an attack of acute or recurrent pericarditis. Increasing interest is currently being devoted to autoinflammatory disorders, a group of conditions characterized by spontaneously relapsing and remitting bouts of systemic inflammation without apparent involvement of antigen-specific T cells or significant production of auto-antibodies. Ongoing basic and clinical research is needed to provide further evidence for the understanding of this common and troublesome disease, and to develop targeted and more efficacious therapies.

**OBJECTIVE:** Celiac disease (CD) is a lifelong gluten-sensitive intestinal enteropathy that is multifactorial in its etiology. In the present study, we evaluated basic anthropometric, clinical, laboratory, and histological features of 140 Turkish children with CD. We particularly underscored the association of CD with other autoimmune diseases.

**MATERIALS AND METHODS:** During the period from 1999 to 2005, CD was diagnosed in 140 children according to ESPGAN criteria. The age, gender, clinical findings, hematological, and biochemical parameters at diagnosis were noted. Symptoms and signs were recorded. Endoscopic intestinal biopsies were taken from all children.

**RESULTS:** Of the 140 children with CD, 75 (53.6%) were female, and 65 (46.4%) were male. Mean age was  $8.56 \pm 4.43$  years (range 13 months to 18 years). The most frequent symptom was failure to thrive (81.4%), followed by chronic diarrhea (60%). Of the children with CD, nine (6.4%) had type 1 diabetes mellitus (DM), six (4.3%) had familial Mediterranean fever, three (2.1%) had alopecia areata, three (2.1%) had vitiligo, three (2.1%) had Down syndrome, two (1.4%) had lung tuberculosis, two (1.4 %) had autoimmune hepatitis, two (1.4%) had growth hormone deficiency, one (0.7%) had osteogenesis imperfecta, and one (0.7%) had Floating Harbor Syndrome. Elevated serum levels of ALT, CK and AST were detected in 48(34.8%), 50 (38.2%) and 67 (48.6%) children, respectively.

**CONCLUSION:** The spectrum of clinical findings is very wide. In order to avoid overlooking CD in patients with extra intestinal symptoms and signs, physicians, especially pediatricians, should be informed about new atypical manifestations of CD.

**Publisher:** Çölyak Hastalığı (ÇH) multifaktöryel etyolojili hayat boyu devam eden glutene duyarlı incebarsak hastalığıdır. Bu çalışmada ÇH lıklı 140 Türk çocuğunun histolojik, laboratuvar, klinik, antropometrik bulguları değerlendirildi.2000–2008 yılları arasında ESPGAN tanı kriterlerine göre 140 çocuk ÇH tanısı aldı.

Çocukların tanı anındaki yaş, cins, klinik bulguları, hematolojik ve biyokimyasal parametreleri belirlendi. Endoskopik ince barsak biyopsisi tüm olgulardan alındı.ÇH’ lıklı 140 çocuğun 75(% 53,6)’ i kız, 65 (% 46,4)’ ü erkek idi.

Olguların ortalama yaşları  $8,56 \pm 4,43$  yıl (13 ay–18 yaş). En sık görülen semptom

büyüme gelişme geriliği idi. ÇH' çocuklardan 9 (% 6,4)' unda tip 1 diabetes mellitus (DM), 6 (% 4,3)' sında ailevi akdeniz ateşi, 3 (% 2,1)' ünde alopesia areata, 3 (% 2,1)' ünde vitiligo, 3 (% 2,1)' ünde Down sendromu, 2 (% 1,4)' sinde akciğer tüberkülozu, 2 (% 1,4)' sinde otoimmün hepatit, 2 (% 1,4)' sinde büyüme hormonu eksikliği, birinde (% 0,7) osteogenezis imperfekta, birinde (% 0,7) Floathing Harbor sendromu saptandı. ALT, AST ve CK' nın serum düzeylerinde artış sırası ile şöyle idi: 48 (% 34,8), 50 (% 38,2), and 67 (% 48,6). ÇH' lıklı çocuklarda klinik bulguların dağılımı çok geniş idi. Ekstra intestinal semptomlu hastalarda ÇH tanısını gözden kaçırmamak için hekimler, özellikle çocuk hekimleri ÇH' nın yeni atipik bulguları hakkında düzenli olarak bilgilendirilmelidirler.

AHR activation by tryptophan--pathogenic hallmark of Th17-mediated inflammation in eosinophilic fasciitis, eosinophilia-myalgia-syndrome and toxic oil syndrome?

Rieber N, Belohradsky BH.

The aryl-hydrocarbon-receptor (AHR) is involved as receptor and transcription factor in dioxin toxicity. Recently, its role in Th17-mediated autoimmunity and autoinflammation has been described, yet a disease-associated AHR ligand is still elusive. L-tryptophan and its metabolites are assumed to trigger the autoinflammatory disorders eosinophilic fasciitis, eosinophilia-myalgia-syndrome and toxic oil syndrome. Since L-tryptophan and metabolites are well known as AHR ligands we hypothesize that it is their interaction with AHR that induces Th17 cell differentiation and autoinflammation in these disorders. This, for the first time would link disease-causing environmental factors to a well-defined cellular receptor and the subsequent pathogenic pathway.

**OBJECTIVES:** Familial Mediterranean fever (FMF) is caused by mutations in MEFV, which encodes pyrin. The nature of substitutions P369S and R408Q in exon 3 remains unclear. Exon 3 encoding pyrin's B-box domain is necessary for interactions with proline serine threonine phosphatase interacting protein 1 (PSTPIP1). The aim was to characterise the phenotype of patients with these substitutions and to determine their functional significance.

**METHODS:** A database of genetic tests undertaken at the US National Institutes of Health was interrogated. Symptoms and signs were classified according to Tel-Hashomer criteria. Coimmunoprecipitation techniques were employed to determine the variants' effects on pyrin/PSTPIP1 interactions.

**RESULTS:** A total of 40 symptomatic and 4 asymptomatic family members with these substitutions were identified. P369S and R408Q were found in cis, and cosegregated in all patients sequenced. Clinical details were available on 22

patients. In all, 5 patients had symptoms and signs fulfilling a clinical diagnosis of FMF, and 15 received colchicine. In patients not achieving the criteria, trials of anti-tumour necrosis factor (TNF) agents resulted in partial or no benefit; resolution of symptoms was noted in those receiving anakinra. The carrier frequency was higher in the patient cohort than in controls but was not statistically significant. Coimmunoprecipitation studies demonstrated that these pyrin variants did not affect binding to PSTPIP1.

CONCLUSIONS: P369S/R408Q substitutions are associated with a highly variable phenotype, and are infrequently associated with typical FMF symptoms, however a trial of colchicine is warranted in all. Functional and modelling studies suggest that these substitutions do not significantly affect pyrin's interaction with PSTPIP1. This study highlights the need for caution in interpreting genetic tests in patients with atypical symptoms.

MEFV gene compound heterozygous mutations in familial Mediterranean fever phenotype: a retrospective clinical and molecular study.

Caglayan AO(1), Demiryilmaz F, Ozyazgan I, Gumus H.

Author information:

(1)Department of Medical Genetics, Kayseri Education and Research Hospital, Kayseri, Turkey. aocaglayan@erciyes.edu.tr

BACKGROUND: Familial Mediterranean fever (FMF) is an autosomal-recessive inherited inflammatory disease caused by mutations in the MEFV gene that encodes pyrin/marenostrin. It is characterized by recurrent short episodes of fever, abdominal pain and serositis affecting mainly Mediterranean and Middle Eastern populations. We determined the frequency of the compound heterozygous mutations which has been rarely reported. The present study not only investigated clinical features of child-onset FMF patients with compound heterozygous mutations but also determined whether there is a phenotype-genotype correlation in the same

patient population.

**METHODS:** The medical records of 66 heterozygous patients with FMF were retrospectively reviewed and assessed. Patients were investigated regarding the mutation type, clinical characteristics at the time of inflammatory attacks such as fever, abdominal pain, arthritis, chest pain, erysipelas-like erythema and oedema, epidemiological data, consanguinity, severity score and family history of FMF and amyloidosis.

**RESULTS:** The most frequent mutation was M694V, identified in 32% of the alleles examined, followed by E148Q in 20.6%, V726A in 17% and M680I in 14.5%, respectively. Consequently, we determined that P369S (n = 10; 8%) was the most frequent rare mutation in Turkish FMF patients. Frequency of the other rare mutations were R761H (3%), F479L (3%), A744S (1.5%) and K695R (0.7%). Fever was seen in 96.5%, abdominal pain in 98.5%, arthralgia in 85%, chest pain in 45.5% and erysipelas-like lesions in 23%. None of these patients had amyloidosis, but 16 had a family history of chronic renal failure, 44% had vomiting and 35% had diarrhoea during the attack. Although regular colchicine treatment was effective in 83% of the patients, the percentage of patients that did not start colchicine therapy was 18%. In addition, the patients were divided into four groups according to the presence of the mutation types and we compared genotype-phenotype correlations.

**CONCLUSIONS:** We suggest that regular colchicine therapy may be administered to symptomatic patients with MEVF gene compound heterozygous mutations, regardless of the mutation type.

Cerebrospinal fluid neopterin and cryopyrin-associated periodic syndrome.

Serrano M(1), Ormazábal A, Antón J, Aróstegui JI, García-Cazorla A.

Author information:

(1)Department of Neurology, Hospital Sant Joan de Déu, University of Barcelona, 08950 Esplugues de Llobregat, Barcelona, Spain. mserrano@hsjdbcn.org

Cryopyrin-associated periodic syndrome is a category of autoinflammatory

disorders caused by mutations of the NLRP3 gene, with chronic infantile neurologic cutaneous and articular syndrome being the severest clinical phenotype. Various pterins have been reported as mediating immunologic functions in the central nervous system, but to date studies of pterin cerebrospinal fluid (CSF) values and cryopyrin-associated periodic syndrome have been lacking. A 2-year-old child was affected with a severe atypical form of cryopyrin-associated periodic syndrome, suspected based on the analysis of neopterin in CSF. He initially presented isolated neurologic manifestations mimicking a neuroregressive disorder. Blood and CSF analyses did not present any routine inflammatory markers, but CSF neopterin was elevated. Later, the patient developed arthritis and recurrent episodes of fever, and the cryopyrin-associated periodic syndrome diagnosis was confirmed by genetic studies. Neopterin was the most altered indicator over the time. Child neurologists should be on the alert when unexplained neurologic signs appear, giving consideration to the possibility of inflammatory or immune-mediated diseases. The present case demonstrates the clinical utility of measurement of CSF neopterin levels in screening for these immune-mediated diseases, especially when neurologic symptoms are associated with normal results on routine CSF tests.

Common Mediterranean fever gene mutations in the Azeri Turkish population of Iran.

Bonyadi M, Esmaeili M, Karimi A, Dastgiri S.

Familial Mediterranean fever (FMF) is an autosomal recessive disorder primarily affecting the Mediterranean populations. It is characterized by recurrent attacks of fever and inflammation of serosal membranes and gradual development of nephropathic amyloidosis. More than 70 disease-associated mutations have been identified in the Mediterranean fever gene (MEFV) responsible for FMF. The aim of this study was to determine the mutation carrier rate in the Iranian Azeri Turkish population. A cohort of 200 unrelated healthy individuals was screened for the five most common MEFV mutations (M694V, V726A, M680I, M694I, and E148Q) using the amplification refractory mutation system for the first four and by

polymerase chain reaction-restriction-digestion testing for E148Q. Genotyping revealed that the carrier rate in the Azeri Turkish population was 25.5%, with E148Q being the most common mutation (11.5%) followed by V726A (1.75%). The remaining common mutations were not found in this cohort. Our data indicate that the FMF carrier rate and E148Q mutation frequency are high in the Iranian Azeri Turkish population.

(1)Translational and Functional Genomics Laboratory, Department of Pathology and Laboratory Medicine, Division of Urology, Albany Medical College, Ordway Cancer Center, Ordway Research Institute, Inc., Center for Medical Science, Albany, NY, USA.

Meta-analysis of genomic coordinates of SNP variations identified in genome-wide association studies (GWAS) of up to 712,253 samples (comprising 221,158 disease cases, 322,862 controls, and 168,233 case/control subjects of obesity GWAS) reveals that 39% of SNPs associated with 22 common human disorders are located within intergenic regions. Chromatin-state maps based on H3K4me3-H3K36me3 signatures show that many intergenic disease-linked SNPs are located within the boundaries of the K4-K36 domains, suggesting that SNP-harboring genomic regions are transcribed. Here we report identification of 13 trans-regulatory RNAs (transRNAs) 100 to 200 nucleotides in length containing intergenic SNP sequences associated with Crohn's disease, rheumatoid arthritis, type 1 diabetes, vitiligo, hypertension and multiple types of epithelial malignancies (prostate, breast, ovarian and colorectal cancers). We demonstrate that NALP1 loci intergenic SNP sequence, rs2670660, is expressed in human cells and may contribute to clinical manifestations of autoimmune and autoinflammatory phenotypes by generating

distinct allelic variants of transRNAs. Stable expression of allele-specific sense and anti-sense variants of transRNAs markedly alters cellular behavior, affect cell cycle progression, and interfere with monocyte/macrophage transdifferentiation. On a molecular level, forced expression of allele-specific sense and anti-sense variants of transRNAs asserts allele-specific genome-wide effects on abundance of hundreds microRNAs and mRNAs. Using lentiviral gene transfer, microarray and Q-RT-PCR technologies, we identify rs2670660 allele-specific gene expression signatures (GES) which appear useful for detecting the activated states of innate immunity/inflammasome pathways in approximately 700 clinical samples from 185 control subjects and 350 patients diagnosed with nine common human disorders, including Crohn's disease, ulcerative colitis, rheumatoid arthritis, Huntington disease, autism, Alzheimer disease, obesity, prostate and breast cancers. Microarray analysis of clinical samples demonstrates that rs2670660 allele-specific GES are engaged in patients' peripheral blood mononuclear cells (PBMC) which encounter pathological conditions in coherent tissues of a human body during immune surveillance and homeostasis monitoring. These data indicate that expression of transRNAs encoded by specific intergenic sequences can trigger activation of innate immunity/inflammasome pathways and contribute to clinical development of autoinflammatory and autoimmune syndromes. Documented in this work single-base substitution-driven molecular and biological antagonisms of intergenic SNP-containing transRNAs suggest a guiding mechanism of selection and retention of phenotype-compatible intergenic variations during evolution. According to this model, random genetic variations which generate transRNAs asserting antagonistic phenotype-altering effects compared to ancestral alleles will be selected and retained as SNP variants.

Familial atypical cold urticaria: description of a new hereditary disease.

Gandhi C(1), Healy C, Wanderer AA, Hoffman HM.

Author information:

(1)Division of Rheumatology, Allergy, and Immunology, University of California, San Diego, La Jolla, CA, USA.

**BACKGROUND:** Acquired cold urticaria (ACU) is usually a self-limited, sporadic, cutaneous disease diagnosed based on history and a positive cold stimulation time test (CSTT) result. We describe 3 unrelated families (A, B, and C) with lifelong atypical cold urticaria distinguished from ACU and familial cold autoinflammatory syndrome.

**OBJECTIVE:** We sought to describe a new hereditary disease of cold urticaria and study its pathogenesis.

**METHODS:** Questionnaires, interviews, physical examinations, skin testing, and biopsies were performed. Absolute values, means, and prevalence percentages of data are reported.

**RESULTS:** Thirty-five subjects are described with familial atypical cold urticaria (FACU; family A, 17; family B, 8; and family C, 10) displaying an autosomal dominant pattern of inheritance. All tested subjects had negative CSTT results. Completed questionnaires from affected and unaffected members of families A and B (n = 35) revealed that all affected subjects had lifelong symptoms that began in early childhood with pruritus, erythema, and urticaria after cold exposure.

Angioedema (family A, 23%; family B, 42%) and syncope, near syncope, or both (family A, 46%; family B, 86%) were also present. Triggers included cold atmosphere (100%), aquatic activities (family A, 92%; family B, 100%), handling cold objects (family A, 54%; family B, 71%), and ingestion of cold foods or beverages (family A, 69%; family B, 100%). Skin biopsy specimens demonstrated a mast cell infiltrate with the appearance of degranulation after cold challenge.

**CONCLUSIONS:** FACU is a new cold-induced inherited disease that is different than ACU in its natural history, atmospheric cold elicitation, severity of systemic reactions, and CSTT results. FACU differs from familial cold autoinflammatory syndrome in symptom timing and the absence of fever, chills, and joint pain. The cause is suspected to be mast cell related. Treatment of reactions is similar to that for ACU. Further evaluation of pathogenesis and genetics is warranted.

**OBJECTIVES:** To describe and compare the parent proxy-reported and child self-reported physical and psychosocial HRQOL of school age children who have FMF with healthy peers.

**METHODS:** The Pediatric Quality of Life Inventory 4.0 (Peds QL 4.0) Generic Core Scales was used to measure HR-QOL. Fifty-one patients and 81 healthy peers were enrolled in the study. Patients were grouped according to their ages as : 1) Children (8-12 years) and 2) Adolescents (13-18 years). An accompanying parent completed the parent proxy-report of the Peds QL 4.0.

**RESULTS:** Peds QL scores of children (8-12 years) with FMF were significantly lower than healthy peers for physical and psychosocial functioning for both child self-report and parent proxy-report. The parent proxy-report and child self-reported Peds QL scores of adolescent patients (13-18 years) with FMF were lower than the healthy group for physical, emotional and school functioning; however no significant difference was detected regarding the social functioning. Adolescents with FMF had significantly higher social scores when compared to the younger age group (8-12 years) with FMF, 92.6 +/- 8.5 and 82.2 +/- 17.6, respectively ( $p=0.028$ ). The scores of physical, emotional and school functioning were similar in both groups ( $p=0.73$ ,  $p=0.93$ , and  $p=0.028$ ). Correlations among child self-report subscales and proxy-report subscales were all significant and varied from moderate to high.

**CONCLUSION:** This study suggested that assessment of HRQOL has potential clinical implications for the healthcare needs of children and adolescents with FMF. Given the degree of reported impairment in their health-related quality of life, individualized counseling and interventions are needed.

Mutations/polymorphisms in a monogenetic autoinflammatory disease may be susceptibility markers for certain rheumatic diseases: lessons from the bedside for the benchside.

Ozen S(1).

Author information:

(1)Pediatric Nephrology and Rheumatology, Hacettepe University, Ankara, Turkey.  
sezaozen@hacettepe.edu.tr

Certain vasculitides have an increased prevalence among patients with familial Mediterranean fever (FMF). Subsequently, it was noticed that patients with certain rheumatic diseases had an increased carrier rate for mutations in the MEFV gene including seronegative spondyloarthritis, Henoch Schönlein purpura, polyarteritis nodosa and some forms of juvenile idiopathic arthritis. Furthermore in populations where the disease is rare, certain polymorphisms have been associated with a severe inflammatory complication in arthritis. The effect of these polymorphisms are probably through the upregulation of the innate immune system which serves as the initial response to the environmental trigger. It may be suggested for the aforementioned clinical associations that mutations/polymorphisms in the MEFV gene may well be susceptibility factors for the disease or a more severe course of the disease for a number of rheumatic diseases.

Bone morphogenetic protein signaling and arthritis.

Lories RJ(1), Luyten FP.

Author information:

(1)Laboratory for Skeletal Development and Joint Disorders, Department of Musculoskeletal Sciences, Division of Rheumatology, Katholieke Universiteit Leuven, Herestraat 49, B-3000 Leuven, Belgium. Rik.Lories@uz.kuleuven.be

Chronic joint diseases have a major impact on society as patients suffer from pain and disability. The spectrum of arthritic disorders is wide including autoimmune and autoinflammatory diseases such as rheumatoid arthritis, ankylosing spondylitis and related spondyloarthritides but also the more prevalent osteoarthritic diseases. The latter appear to be mainly the consequence of injury, strain and aging in a predisposing genetic background. The therapeutic options for chronic inflammatory and immune joint diseases have greatly increased over the last decade by the use of targeted anti-cytokine or anti-immune cell drugs. However, such a shift towards successful treatment has not been achieved for osteoarthritis. In addition, control of inflammation does not equal cure of

the disease as relapse occurs as soon as the treatment is interrupted, and only limited tissue repair has been observed. Bone morphogenetic proteins are potent regulators of cell proliferation, differentiation and apoptosis and they have come into the spotlight in arthritis research. Here, we summarize the recent data on the role of bone morphogenetic proteins in joint protection and repair and but also their potential disease promoting or controlling roles. These data are presented in the context of a systems biology view of joint diseases based on their histomorphological phenotype rather than on existing clinical classifications.

**OBJECTIVES:** We developed a genetic investigation using denaturing high performance liquid chromatography (DHPLC), in order to identify polymorphisms of the gene MVK in patients with autoinflammatory syndrome suspicion.

**METHODS:** We evaluated 19 patients affected by recurrent fevers and other clinical manifestations usually found in autoinflammatory syndromes and not correlated with infections or autoimmune disease and 10 healthy controls. IgD level was measured in all patients. Molecular testing was performed in DNA extracted from PBMC and MVK gene was analysed either with DHPLC or with automatic sequencer. Primers for PCR amplifications, amplicon lengths and PCR conditions were designed in our laboratory.

**RESULTS:** IgD level was normal in 14 patients. Healthy controls did not show any

alteration of the DHPLC-profiles and of the DNA sequences. Twelve patients had at least one altered DHPLC-profile and these data have been confirmed by sequencing. In particular we detected the polymorphisms c.78+61A>G, S52N, S135S, D170D, c.632-18A>G, c.885+24G>A already described in the database INFEVERS. With DHPLC we got the results in shorter time (10 hours/patient) and with lower cost (40 euro/patient) in comparison to direct sequencing (25 hours and 150 euro/patient). CONCLUSIONS: High IgD levels do not represent an essential marker for diagnosis of MKD, as already reported in literature. DHPLC is a rapid low cost technique in order to screen mutations in patients with MKD suspicion. Twelve patients carried at the same time D170D and c.632-18A>G: such event suggests that these SNPs could be in linkage disequilibrium and that such polymorphisms could predispose to MKD.

Involvement of the modifier gene of a human Mendelian disorder in a negative selection process.

Author information:

(1)INSERM, U933, Paris, France.

BACKGROUND: Identification of modifier genes and characterization of their effects represent major challenges in human genetics. SAA1 is one of the few modifiers identified in humans: this gene influences the risk of renal amyloidosis (RA) in patients with familial Mediterranean fever (FMF), a Mendelian autoinflammatory disorder associated with mutations in MEFV. Indeed, the SAA1 alpha homozygous genotype and the p.Met694Val homozygous genotype at the MEFV locus are two main risk factors for RA.

METHODOLOGY/PRINCIPAL FINDINGS: HERE, WE INVESTIGATED ARMENIAN FMF PATIENTS AND

CONTROLS FROM TWO NEIGHBORING COUNTRIES: Armenia, where RA is frequent (24%), and Karabakh, where RA is rare (2.5%). Sequencing of MEFV revealed similar frequencies of p.Met694Val homozygotes in the two groups of patients. However, a

major deficit of SAA1 alpha homozygotes was found among Karabakhian patients (4%) as compared to Armenian patients (24%) ( $p = 5.10(-5)$ ). Most importantly, we observed deviations from Hardy-Weinberg equilibrium (HWE) in the two groups of patients, and unexpectedly, in opposite directions, whereas, in the two control populations, genotype distributions at this locus were similar and complied with (HWE).

**CONCLUSIONS/SIGNIFICANCE:** The excess of SAA1alpha homozygotes among Armenian patients could be explained by the recruitment of patients with severe phenotypes. In contrast, a population-based study revealed that the deficit of alpha/alpha among Karabakhian patients would result from a negative selection against carriers of this genotype. This study, which provides new insights into the role of SAA1 in the pathophysiology of FMF, represents the first example of deviations from HWE and selection involving the modifier gene of a Mendelian disorder.

Heart rate variability in familial Mediterranean fever.

Nussinovitch N(1), Livneh A, Katz K, Langevitz P, Feld O, Nussinovitch M, Volovitz B, Lidar M, Nussinovitch U.

Author information:

(1)Hypertension Unit, Department of Internal Medicine D, Chaim Sheba Medical Center, Tel Hashomer, Israel. nussim@clalit.org.il

Familial Mediterranean fever (FMF) is a hereditary disease, characterized by recurrent episodes of fever and polyserositis. Heart rate variability (HRV) is a powerful, simple and reliable technique to evaluate autonomic nervous system function. Previous studies of physiologic parameters during tilt-test have suggested that patients with FMF have abnormal cardiovascular reactivity and occult dysautonomia. Prompted by these findings, the present study sought to evaluate HRV in patients with FMF, at rest and in the standing position. The

study sample included 34 patients with FMF and 34 sex- and age-matched control subjects. All underwent electrocardiography according to strict criteria. HRV parameters were computed with custom-made software. There was no significant difference in HRV parameters, in either the supine or standing position, between the FMF and control groups. In both groups, the upright position was associated with a significant decrease, when compared with the supine position, in maximal RR interval, minimal RR, average RR, root square of successive differences in RR interval, number of intervals differing by >50 ms from preceding interval (NN50), NN50 divided by total number of intervals (pNN50) and high-frequency components as well as a significant increase in average heart rate, very low frequency or low-frequency components, low-frequency/high-frequency components ratio and total power. In conclusion, patients with FMF who are continuously treated with low-dose colchicine have not developed amyloidosis and have normal HRV parameters in the supine and upright position. Further investigation of occult dysautonomia in FMF is needed.

Familial Mediterranean fever (FMF) is a recessive autosomal disease, predominantly affecting the population around the Mediterranean. The main clinical signs consist of attacks of fever associated with abdominal, articular and thoracic pain. Based on a case report, the authors describe the main thoracic forms of this illness comprising pleural pain, pleural effusion and pulmonary

amyloidosis. The authors also discuss the association of mesothelioma and FMF. Colchicine is successfully used in the treatment of FMF.

**OBJECTIVE:** Hereditary periodic fever syndromes (HPFs) develop as a result of uncontrolled activation of the inflammatory response, with a substantial contribution from interleukin-1 $\beta$  or tumor necrosis factor  $\alpha$  (TNF $\alpha$ ). The HPFs include familial Mediterranean fever (FMF), hyperimmunoglobulinemia D with periodic fever syndrome (HIDS), TNF receptor-associated syndrome (TRAPS), and cryopyrinopathies, which are attributable to mutations of the MEFV, MVK, TNFRSF1A, and CIAS1 genes, respectively. However, in many patients, the mutated gene has not been determined; therefore, the condition in these patients with an HPF-like clinical picture is referred to as idiopathic periodic fever (IPF). The aim of this study was to assess involvement of X-linked inhibitor of apoptosis (XIAP), which plays a role in caspase inhibition and NF-kappaB signaling, both of which are processes that influence the development of inflammatory cells.

**METHODS:** The XIAP gene (X-linked) was sequenced in 87 patients with IPF, 46 patients with HPF (13 with HIDS, 17 with TRAPS, and 16 with FMF), and 182 healthy control subjects. The expression of different alleles was evaluated by sequencing XIAP-specific complementary DNA mini-libraries and by real-time polymerase chain reaction and Western blot analyses. The functional effect of XIAP on caspase 9 activity was assessed by a fluorimetric assay, and cytokine secretion was evaluated by enzyme-linked immunosorbent assay.

**RESULTS:** Sequencing disclosed a 1268A>C variation that caused a Q423P amino acid substitution. The frequency of 423Q-homozygous female patients and 423Q-hemizygous male patients was significantly higher in the IPF group than in the control group (69% versus 51%; odds ratio 2.17, 95% confidence interval 1.23-3.87,  $P = 0.007$ ), whereas no significant difference was detected in the HPF group (59%) compared with controls. In primary lymphocytes and transfected cell lines, 423Q, as compared with 423P, was associated with higher XIAP protein and messenger RNA expression and lower caspase 9 activation. In lipopolysaccharide-activated monocytes, 423Q was associated with higher secretion of TNF $\alpha$ .

**CONCLUSION:** These results suggest that 423Q is a predisposing factor for IPF development, possibly through its influence on monocyte function.

Familial Mediterranean fever (FMF) is an autosomal recessive autoinflammatory disorder with more than 60 disease-associated mutations in the responsible gene, MEFV. In the present study, we determined 15 MEFV mutations in Iranian Azeri Turkish FMF patients. Five hundred and twenty-four unrelated patients were tested for 15 known mutations in the MEFV gene using amplification refractory mutation system-polymerase chain reaction and polymerase chain reaction-restriction fragment length polymorphism methods. Thirty-five different genotypes were characterized among the studied patients. Of the alleles investigated, the most common mutation was p.M694V (42.4%), followed by p.V726A (17%), p.E148Q (16.2%), and p.M680I (c.2040G>C) (15.2%). The p.R761H mutation (4.7%) was found to be the

most frequent among the rare mutations. The mutations p.M680I (c.2040G>A), p.I692del, p.M694del and p.K695R were not found in this cohort. The remaining mutations account for 7.7% of the identifiable mutations. Five different types of complex alleles were also identified. The results show the diversity and the frequency of the mutations in the Iranian Azeri Turkish FMF patients. The p.R761H mutation is rather prevalent in Azeri Turks; therefore, it should be included in the routine molecular diagnosis of FMF patients from this ethnic group.

(1)Department of Pediatric Immunology Wilhelmina Children s Hospital, University Medical Center Utrecht, Lundlaan 6, 3584 EA, Utrecht, the Netherlands.

b.vastert@umcutrecht.nl

Systemic juvenile idiopathic arthritis (sJIA) is a rare, systemic inflammatory disease classified as a subtype of JIA. Besides arthritis, it is characterised by systemic features such as spiking fever, skin rash, hepatosplenomegaly or serositis. It is becoming clear now that abnormalities in the innate immunity (cytokines such as interleukin (IL)-1, IL-6 and IL-18, and neutrophils and monocytes/macrophages rather than lymphocytes) play a major role in the pathogenesis of sJIA, distinguishing it from other JIA subtypes. Another distinctive feature of sJIA is its strong association with macrophage activation syndrome (MAS). Based on this, consensus is emerging that sJIA should be viewed as an autoinflammatory syndrome rather than a classic auto-immune disease. As a consequence of the progression in understanding the underlying mechanisms of sJIA, major changes in the management are evolving. So far, treatment has been based on glucocorticosteroids in combination with disease-modifying drugs such as methotrexate. Recently, remarkable improvement has been observed with IL-1 and

IL-6 targeted therapies. These therapies might also change the long-term outcome of this disease. However, controlled trials set up in international collaboration are needed to determine the optimal treatment strategies for all sJIA patients.

(1)Department of Pediatrics, School of Medicine, Gaziosmanpasa University, Tokat, Turkey. drresul@hotmail.com

**AIM:** Familial Mediterranean fever (FMF) is an autosomal recessive disorder characterised by recurrent episodes of fever, polyserositis and rash. The aim of this study was to determine the most common mutations and clinical features, and their relationships.

**METHODS:** The medical records of 78 patients were evaluated retrospectively. All of the patients had been diagnosed with FMF according to Tel Hashomer criteria between January 2005 and May 2008 in general paediatric clinics of the School of Medicine at Gaziosmanpasa University. Twelve mutations were detected in the 78 patients by polymerase chain reaction-enzyme-linked immunosorbent assay. The patients were classified into three groups according to allele status.

**RESULTS:** The most prominent clinical symptoms were abdominal pain (95%), fever (90%), arthritis (33%) and pleuritis (31%). Seventeen different genotypes were identified. The mutations were homozygous in 25 (32%) patients, compound heterozygous in 28 (36%) patients and heterozygous in 22 (28%) patients. No mutation was detected in three (4%) patients. The most frequent mutations were M694V (55%), M680I (16%), E148Q (10%) and P369S (4%). The mean symptom severity score was highest in the homozygous group, and high levels of C-reactive protein were also detected in this group.

**CONCLUSIONS:** In addition to clinical criteria, molecular studies for detecting disease-causing mutations are needed to establish the diagnosis of FMF. FMF patients who were homozygous for MEFV gene mutations had a higher symptom severity score and higher incidence of appendectomy. The broad spectrum of mutations may reflect intercultural interactions of ethnic groups in Anatolia. Nation-wide studies may help to determine the relationships among demographic, clinical and genetic features of FMF.

Autoinflammatory diseases are a group of monogenic inflammatory diseases with an early onset in childhood. Previously these diseases were summarized as "periodic fever syndromes." Included in this spectrum are familial Mediterranean fever, mevalonate kinase deficiency, and tumor necrosis factor receptor-associated disease. They are characterized by periodic or recurrent episodes of systemic inflammation causing fever, accompanied by rash, serositis, lymphadenopathy, arthritis, and other clinical manifestations. The other large group of autoinflammatory diseases consists of the cryopyrin-associated periodic syndromes, which include the cryopyrinopathies. The mildest form is familial cold-associated syndrome, a more severe form is Muckle-Wells syndrome, and the most severe is neonatal-onset multisystem inflammatory disease/chronic infantile neurological cutaneous and articular syndrome. These are characterized by chronic or recurrent systemic inflammation associated with various clinical

presentations, including urticaria-like rash, arthritis, sensorineural deafness, and central nervous system and bone involvement. In our review we focus on the clinical presentation of these diseases.

Crystals in tissues lead the innate immune system to the same kind of acute response seen with pathogens. Via activation of the inflammasome, interleukin-1 (IL-1) is released, which upregulates mediators such as cyclooxygenase, tumor necrosis factor, and IL-8 and induces an acute granulocytic inflammation. Therefore, in addition to nonsteroidal anti-inflammatory drugs (NSAIDs), steroids, and colchicine, IL-1 blockers appear to be effective. Large clinical trials have already been initiated. Such an approach could constitute a valuable alternative for patients with contraindications or insufficient response to NSAIDs. After the attack has subsided, control of uric acid metabolism is central. At least several of the responsible urate transporters have been unraveled, which could lead to more focused therapy in the future. At present, diet and blockade of uric acid synthesis remain the main pillars of therapy. The new xanthine oxidase inhibitor febuxostat constitutes a novel option for patients with renal insufficiency or intolerance to allopurinol.

[Adult-onset Still's disease, Schnitzler syndrome, and autoinflammatory syndromes in adulthood].

[Article in German]

Lamprecht P(1).

Author information:

(1)Poliklinik für Rheumatologie, Vaskulitzszentrum UKSH, Universität zu Lübeck & Klinikum Bad Bramstedt, 23538 Lübeck. peter.lamprecht@uk-sh.de

Adult-onset Still's disease (AoSD), Schnitzler syndrome, and cases of adult-onset autoinflammatory syndromes [10-15% of cases of familial Mediterranean fever (FMF) and tumor necrosis factor (TNF) receptor-associated periodic syndrome (TRAPS)] are characterized by a genetic predisposition, with increased interleukin (IL)-1beta and IL-18 production and TNF-alpha signaling, respectively. As a result, periodic fever and inflammation at barrier tissues (synovial tissues, serous membranes, and the skin) are encountered in such patients.

Pathophysiological insights into these diseases have renewed interest in research on IL-1beta in rheumatic diseases and have opened new therapeutic avenues. Recently published studies have shown that patients with Schnitzler syndrome, methotrexate-refractory AoSD, and colchicine-refractory FMF or contraindications to colchicines in FMF respond well to treatment with the soluble IL-1 receptor antagonist anakinra. For TRAPS patients, the p75 TNF-alpha receptor/Fc-IgG1 fusion protein etanercept is the treatment of first choice.

The spectrum of MEFV clinical presentations--is it familial Mediterranean fever only?

Ben-Chetrit E(1), Peleg H, Aamar S, Heyman SN.

Author information:

(1)Department of Medicine, Hadassah-Hebrew University Hospital, Ein Kerem, Israel. eldad@hadassah.org.il

**OBJECTIVE:** FMF is an autosomal recessive hereditary disease, associated with a single gene named MEFV. This gene is considered to be responsible only for FMF. In the present study, we tried to find out whether the MEFV gene is associated with or responsible for clinical conditions other than FMF.

**METHODS:** We looked for patients who presented with signs and symptoms not typical for FMF but carried MEFV mutations. We also searched for reports about similar conditions in the English medical literature, and we surveyed the website 'Infervers' for MEFV mutations defined as associated with 'atypical FMF'.

**RESULTS:** We encountered three patients carrying MEFV mutations who presented with distinct clinical presentations not typical of FMF. We identified additional reports about MEFV-related non-FMF disease entities such as palindromic rheumatism. By screening the 'Infervers' website, we further disclosed 13 cases with MEFV mutations that were defined as 'atypical FMF' and 4 cases categorized as 'recurrent arthritis'.

**CONCLUSIONS:** These findings suggest that the MEFV gene is associated with clinical conditions other than FMF. Changing our concept regarding the MEFV gene and its link to such clinical phenotypes may call for a higher awareness of the existence of additional autoinflammatory diseases. Furthermore, a correct diagnosis of these MEFV gene mutation-associated syndromes will justify a therapeutic trial with colchicine, thereby relieving suffering of many patients who up to now have been misdiagnosed.

Periodic episodes of fever and inflammation can have a genetic origin. Nowadays, the identification of the causative genetic variants in the majority of cases allows molecular genetic confirmation of the clinical diagnosis, which enables approaches with specific drug treatment and improves patient compliance as well as genetic counseling. Besides a detailed clinical examination a medical history including family history and an assessment of the ethnic origin are required. In order to make genetic testing straightforward and cost effective an iterative procedure should be followed which should include, in addition to clinical data, the frequencies of causative mutations in the various gene segments involved.

The understanding of the genetic and immunological basis of human periodic fever syndromes, in particular cryopyrin-associated periodic syndromes (CAPS), has led to important new insights into the pathogenesis of monogenic and complex interleukin-1beta-associated autoinflammatory diseases. Currently the focus of attention is on the nucleotide-binding oligomerization domain (NOD)-like receptors (NLR), which take part in the regulation of the synthesis and

maturation of cytokines in the IL-1 families, NOD-signalosomes and inflammasomes.

Free circulating interleukin-18 is increased in Schnitzler syndrome: a new autoinflammatory disease?

Migliorini P(1), Del Corso I, Tommasi C, Boraschi D.

Author information:

(1)Clinical Immunology and Allergy Unit, University of Pisa, Pisa, Italy.

p.migliorini@med.unipi.it

Schnitzler syndrome is a rare disease characterised by chronic urticaria and arthralgia. The recent evidence that the IL-1 receptor antagonist IL-1Ra could induce rapid and complete remission of Schnitzler symptoms has pointed to IL-1 as a major pathological factor in this disease. To examine the possibility that Schnitzler syndrome may be considered to be an autoinflammatory disease, in this study we measured the serum levels of IL-18, another cytokine of the IL-1 family that is cleaved by caspase-1, in two recently diagnosed Schnitzler patients before and after treatment with IL-1Ra. In parallel, mRNA expression of IL-1 family cytokines and caspase-1 were assessed in isolated blood monocytes. Treatment with IL-1Ra significantly inhibited IL-1beta gene expression, indicating that IL-1beta activity in Schnitzler syndrome is central to IL-1beta gene upregulation in a type of auto-amplification loop. While no IL-1beta was detected in serum, free circulating IL-18 was increased in patients with Schnitzler syndrome, despite low IL-18 gene expression in monocytes. This suggests constitutive activation of the IL-1beta/IL-18-producing inflammasome, and supports the hypothesis that Schnitzler's syndrome is a new autoinflammatory disease.

Author information:

(1)Laboratoire Inflammation, Tissus Epithéliaux et Cytokines, EA 4331, Université de Poitiers, Poitiers, France. jean-claude.lecron@univ-poitiers.fr

The mevalonate kinase deficiency (MKD), including hyperimmunoglobulinemia D periodic fever syndrome (HIDS) and the more severe mevalonic aciduria are rare, autosomal recessive, autoinflammatory diseases belonging to the hereditary periodic fever (HPF) family. Other members include: familial mediterranean fever (FMF), the cryopyrin-associated periodic syndromes (CAPS) and TNFR-associated periodic syndromes (TRAPS). MKD is caused by mutations in the gene encoding mevalonate kinase (MK), an enzyme of the cholesterol pathway, leading to its inactivation. The molecular mechanisms linking MKD and abnormalities of isoprenoid biosynthesis to cytokine production and inflammation have yet to be fully elucidated. Statins, which are extensively prescribed for lowering cholesterol, are potent inhibitors of 3-hydroxy-3-methylglutaryl-CoA reductase, the enzyme directly upstream of MK. In this review, we discuss recent reports demonstrating that in vitro inhibition of the mevalonate pathway by statins specifically increases the production, by activated monocytes, of cytokines of the IL-1 family, by enhancing caspase-1 activity, the enzyme responsible for IL-1 $\beta$  and IL-18 maturation. The molecular mechanisms involve geranylgeranylation and the enhancement of the activity of G proteins such as Rac-1. Interestingly, activated fibroblasts from MKD patients secrete more IL-1 $\beta$  than fibroblasts from healthy donors. Taken together, these data highlight the specific enhancement of the IL-1 family of cytokines, the maturation of which is caspase-1-dependent in MKD. Finally, the spectacular decrease in febrile attacks in patients with severe HIDS under IL-1 receptor antagonist (anakinra) treatment, reinforces this hypothesis. Deregulated caspase-1 activation could be responsible for the inflammatory component of MKD, thereby mechanistically linking MKD to FMF and CAPS through cytokines of the IL-1 family.

TNF receptor-associated periodic fever syndrome caused by sequence alterations in exonic splicing enhancers: comment on the article by Trübenbach et al.

Martorana D, Neri TM.

Comment on

Rheumatol Int. 2010 Apr;30(6):805-9.

Tumor necrosis factor receptor-associated periodic syndrome (TRAPS), an autosomal disease belonging to human autoinflammatory syndromes, is caused by mutations in Tumor Necrosis Factor Receptor Superfamily Member 1A (TNFRSF1A) gene. Trübenbach and colleagues described a patient with two heterozygotic nucleotide transversions in exon 4 of TNFRSF1A gene: the first is a substitution from guanine to cytosine at position 263 of the nucleotide sequence (c.263 G>C); the second is a substitution from cytosine to adenine at position 264 (c.264 C>A); the two mutations affect the amino acid number 88 of the protein. To date, this was the first report of a double monoallelic mutation in a gene related to autoinflammatory syndromes. Using two web interfaces (ESEfinder and RESCUE-ESE), we provide evidence that the double nucleotide change may affect an exonic splicing enhancer (ESE), a sequence element distinct from the canonical splice sites that are needed for normal splicing. ESEs are short and degenerate sequences found within coding exons and required for efficient splicing and splice site recognition. In order to verify if these changes really affect an ESE, it would be useful to analyze the described index case TNFRSF1A cDNA, because if this analysis will evidence an exon skipping in the TNFRSF1A coding sequence, it would then represent the first mutation in autoinflammatory syndromes demonstrated to be caused by ESE elements alteration.

halesamli@gmail.com

**OBJECTIVES:** Familial Mediterranean Fever (FMF) is an autosomal recessive disease characterized by recurrent fever, peritonitis, arthritis, pleuritis, and

secondary amyloidosis. In the current study, we sought to determine the frequency of acute surgical abdominal intervention and MEFV gene mutations in FMF patients.

**PATIENTS AND METHODS:** A total of 159 patients were referred to our department with a diagnosis of FMF. Twenty-six patients (16.4%) had a history of surgical intervention. Of these, 17 (10.7%) were operated on due to appendicitis, and 9 (5.7%) were operated on due to other acute abdomen reasons. Genomic DNA was isolated from the blood samples, and in the isolated DNA samples, 12 MEFV gene mutations were studied.

**RESULTS:** Mutation frequency was detected to be 80.8% in the patients with acute abdomen surgery intervention and 56.4% in the patients without acute abdomen surgical intervention. Upon mutational evaluation of these patients, we noted that the M694V (40.5%) and E148Q (21.4%) mutations occurred most frequently.

**CONCLUSIONS:** The MEFV gene mutation frequency in FMF patients with acute abdomen surgical intervention was significantly higher than that in patients without such intervention. Increased mutation scanning in FMF patients will significantly decrease unnecessary surgical interventions in this patient group.

Diffusion-weighted MRI of the kidneys in patients with familial Mediterranean fever: initial experience.

Karadeli E(1), Ulu EM, Yilmaz S, Durukan E.

Author information:

(1)Department of Radiology, Başkent University School of Medicine, Ankara, Turkey. elifkaradeli@gmail.com

**PURPOSE:** To evaluate the feasibility of diffusion-weighted magnetic resonance imaging (DW-MRI) in the assessment of renal function in patients with familial Mediterranean fever (FMF).

**MATERIALS AND METHODS:** Thirty healthy volunteers who had no history of renal disease, hypertension or vascular disease and 60 patients with FMF were included in the study. Transverse diffusion-weighted multisection echo-planar MRI was performed with the following diffusion gradient b values: 0, 111, 222, 333, 444, 556, 667, 778, 889 and 1000 s/mm<sup>2</sup>. The apparent diffusion coefficient (ADC) values, urine protein and serum creatinine levels, and glomerular filtration rates of the healthy volunteers, patients with renal involvement, and patients without were compared by using ANOVA test. ADCs of the kidneys were calculated separately for low (ADC(low); b = 0, 111, 222, 333 s/mm<sup>2</sup>), average (ADC(avg); of all b values), and high (ADC(high); b = 778, 889, 1000 s/mm<sup>2</sup>) b values to

enable the differentiation of the relative influence of perfusion fraction and true diffusion. ADC(high) reflects almost only diffusion, whereas ADC(low) is composed of both diffusion and perfusion.

RESULTS: There was statistically significant difference between ADC(low) values of the FMF patients with renal involvement and the control group ( $P < 0.05$ ).

Negative correlation was found between the duration of disease and ADC(low) values of the kidneys ( $r = -0.223$ ,  $P = 0.087$ ).

CONCLUSION: DW-MRI of the kidneys might allow early detection of the renal changes in patients with FMF. This might prevent the progression of disease by giving proper medical treatment. Further studies with larger numbers of FMF patients and more experience on MRI technique are required to help define more conclusively the precise role of DW imaging in detection of renal changes.

Glyburide inhibits the Cryopyrin/Nalp3 inflammasome.

Lamkanfi M(1), Mueller JL, Vitari AC, Misaghi S, Fedorova A, Deshayes K, Lee WP, Hoffman HM, Dixit VM.

Author information:

(1)Department of Physiological Chemistry, Genentech, South San Francisco, CA 94080, USA.

Inflammasomes activate caspase-1 for processing and secretion of the cytokines interleukin-1beta (IL-1beta) and IL-18. Cryopyrin/NALP3/NLRP3 is an essential component of inflammasomes triggered by microbial ligands, danger-associated molecular patterns (DAMPs), and crystals. Inappropriate Cryopyrin activity has been incriminated in the pathogenesis of gouty arthritis, Alzheimer's, and silicosis. Therefore, inhibitors of the Nalp3 inflammasome offer considerable therapeutic promise. In this study, we show that the type 2 diabetes drug glyburide prevented activation of the Cryopyrin inflammasome. Glyburide's cyclohexylurea group, which binds to adenosine triphosphatase (ATP)-sensitive K(+) (K(ATP)) channels for insulin secretion, is dispensable for inflammasome inhibition. Macrophages lacking K(ATP) subunits or ATP-binding cassette transporters also activate the Cryopyrin inflammasome normally. Glyburide analogues inhibit ATP- but not hypothermia-induced IL-1beta secretion from human monocytes expressing familial cold-associated autoinflammatory syndrome-associated Cryopyrin mutations, thus suggesting that inhibition occurs upstream of Cryopyrin. Concurrent with the role of Cryopyrin in endotoxemia, glyburide significantly delays lipopolysaccharide-induced lethality in mice. Therefore, glyburide is the first identified compound to prevent Cryopyrin activation and microbial ligand-, DAMP-, and crystal-induced IL-1beta secretion.

necil.kutukculer@ege.edu.tr

The autoinflammatory disorders differ in severity, as well as age of onset, duration, and manifestations, but they all share some common features: recurring fever peaks, inflammation of serosal membranes, musculoskeletal involvement, varying types of skin rash, amyloidosis as a sequel of the disease. TRAPS is very rare in Turkish population and we present two unrelated Turkish children with similar clinical phenotypes and laboratory findings related with autoinflammatory disorders and with novel p. Y331X mutation in TNFRSF1A gene. Both of the patients were male and they had recurrent fever without abdominal pain and arthralgia. Full cDNA and exon-intron binding regions of TNFRSF1A, MEFV, MVK, CIAS1 genes were analysed by direct DNA sequencing methods in order to differentiate TRAPS, FMF, HIDS, CINCA/MWS/FCAS respectively. We screened ten exons of TNFRSF1A gene, and detected a heterozygous c.1080C>G nucleotide substitution in exon 10 in both of the unrelated patients, resulting p.Y360X nonsense (protein truncated) mutation. According to classical TNFRSF1A gene nomenclature and the agreement of 30th amino acid as the first one, it is accepted as p.Y331X. It was interesting to determine same mutations in fathers of two patients. In one of the cases, E148Q heterozygous mutation, which is one of the disease-causing mutations of MEFV gene, was detected. No nucleotide substitution was identified in exon and exon-intron splicing regions encoding 396 amino acid of MVK gene in both of the patients. In CIAS1 gene, two different nucleotide substitutions resulting synonymous amino acid mutation were detected in exon 3: c.[732G>A] and c.[786A>G] nucleotide substitutions and compatible p.A242A (according to c.DNA p.A244A) and p.R260R (according to c.DNA p.R262R) synonymous amino acid mutations. These nucleotide substitutions were also detected in parents and were reported to be normal variations in Turkish population. In conclusion, in Turkish patients, with dominantly inherited recurrent fever, TRAPS is a diagnosis worthy of attention and novel mutations have to be reported with phenotype associations.

Colchicine for the treatment of pericarditis.

Imazio M(1), Trinchero R, Adler Y.

Author information:

(1)Cardiology Department, Maria Vittoria Hospital, Torino, Italy.

massimo\_imazio@yahoo.it

Colchicine has been effectively used in the treatment of several inflammatory conditions, such as gouty attacks, serositis related to familial Mediterranean fever, Behçet syndrome and more recently, in acute and recurrent pericarditis. Colchicine concentrates in white blood cells, particularly polymorphonuclear cells, inhibiting tubulin polymerization, thus interfering with migration and phagocytosis, and reducing the inflammatory cycle. Although the exact number of responders is unknown, the drug has been successfully used for the treatment and prevention of recurrences and to taper corticosteroids in patients with recurrent pericarditis in several retrospective studies and an open-label, randomized trial, where the recurrence rate was halved in the treatment arm. Less evidence supports the use of the drug for the treatment of acute pericarditis, where colchicine remains optional and requires further multicenter confirmatory studies. At present, colchicine has been recommended by the 2004 European guidelines on the management of pericardial diseases for acute (class IIa) and recurrent pericarditis (class I), but its use is still unlabeled and informed consent is required for prescription. A careful monitoring of possible contraindications, drug interactions and side effects is necessary. The aim of this paper is to review the evidence that supports the use of the drug in acute and recurrent pericarditis, as well as dosing and precautions for clinical use.

Author information:

(1)American University of Armenia, Yerevan, Republic of Armenia.

maria\_sevoyan@yahoo.co.uk

**OBJECTIVE:** To determine whether or not the use of colchicine decreases the risk of amyloidosis among Armenian patients with familial Mediterranean fever (FMF).

**SUBJECTS AND METHODS:** The study included 99 Armenian patients from the Center of Medical Genetics database with genetically ascertained FMF; 33 had renal amyloidosis and 66 were randomly selected control patients without renal amyloidosis. Self-reported colchicine use was assessed by interviewer-based questionnaire.

**RESULTS:** The patients with incident amyloidosis were more likely to be older men, but younger at the time of disease onset, and more likely to have had a family history of amyloidosis and M694F mutation in the MEFV gene compared to patients without amyloidosis. The risk of amyloidosis decreased with adequate colchicine use rather than nonadequate use (adjusted odds ratio, OR, 0.48, 95% confidence interval, CI, 0.16-1.43), continuous colchicine use rather than interrupted use (adjusted OR 0.15, 95% CI 0.04-0.53), earlier rather than later initiation age of colchicine treatment (adjusted OR 0.95, 95% CI 0.90-1.01), current colchicine rather than ever/never colchicine use (adjusted OR 0.20, 95% CI 0.05-0.89).

**CONCLUSION:** The study demonstrated that colchicine treatment is effective in preventing amyloidosis among Armenian patients with FMF and that earlier initiation and continuous therapy at an adequate dose of 1.2-1.8 mg/day may be associated with a decreased amyloidosis risk among Armenian patients with FMF.

TNF receptor-associated periodic syndrome (TRAPS): a new cause of joint destruction?

Schoindre Y(1), Feydy A, Giraudet-Lequintrec JS, Kahan A, Allanore Y.

Author information:

(1)Service de Rhumatologie A, Hôpital Cochin, AP-HP, Université Paris-Descartes, 75014 Paris, France.

TNF receptor-associated periodic syndrome (TRAPS) is a highly polymorphic autoinflammatory syndrome related to mutations in the TNFRSF1A gene encoding the type 1 TNF receptor. Arthralgia and nonerosive synovitis are among the most common manifestations. We report the case of a 73-year-old woman who presented with chronic erosive joint disease that progressed by flare-ups. Moderate nonspecific abdominal and cutaneous abnormalities were noted, suggesting TRAPS. This diagnosis was confirmed when genetic tests identified the R92Q mutation in the TNFRSF1A gene. Although glucocorticoid therapy was effective in alleviating the symptoms, combination therapy with methotrexate and etanercept neither decreased the frequency of the flare-ups nor slowed the pace of joint destruction. Treatment with anakinra is being considered. To our knowledge, this is the first reported case of joint destruction related to TRAPS. In patients with refractory inflammatory joint disease, the presence of extraarticular manifestations, however mundane, should suggest TRAPS.

A genome-wide association study has identified the R92Q variant of the TNFRSF1A gene as a new susceptibility locus for multiple sclerosis. This locus is of special interest because the R92Q substitution was previously detected in a group of multiple sclerosis patients who had additional symptoms compatible with the autoinflammatory syndrome TRAPS.

Differentiating PFAPA syndrome from monogenic periodic fevers.

Gattorno M(1), Caorsi R, Meini A, Cattalini M, Federici S, Zulian F, Cortis E, Calcagno G, Tommasini A, Consolini R, Simonini G, Pelagatti MA, Baldi M, Ceccherini I, Plebani A, Frenkel J, Sormani MP, Martini A.

Author information:

(1)UO Pediatria II, G. Gaslini Institute, Largo G. Gaslini 5, 16146, Genova, Italy. marcogattorno@ospedale-gaslini.ge.it

**OBJECTIVES:** To analyze whether there were clinical differences between genetically positive and negative patients fulfilling periodic fever, aphthous stomatitis, pharyngitis, and cervical adenitis (PFAPA) syndrome criteria and to test the accuracy of the Gaslini diagnostic score for identifying patients with PFAPA syndrome with higher probabilities of carrying relevant mutations in genes associated with periodic fevers.

**METHODS:** Complete clinical and genetic information was available for 393 children

with periodic fever; 82 had positive genetic test results, 75 had incomplete genetic test results, and 236 had negative results for MVK, TNFRSF1A, and MEFV mutations. Current diagnostic criteria for PFAPA syndrome were applied.

RESULTS: Of 393 children, 210 satisfied PFAPA syndrome criteria; 43 carried diagnostic mutations (mevalonate kinase deficiency:  $n = 33$ ; tumor necrosis factor receptor-associated periodic syndrome:  $n = 3$ ; familial Mediterranean fever:  $n = 7$ ), 37 displayed low-penetrance mutations or incomplete genotypes, and 130 demonstrated negative genetic testing results. Genetically positive patients had higher frequencies of abdominal pain and diarrhea ( $P < .001$ ), vomiting ( $P = .006$ ), and cutaneous rash and arthralgia ( $P = .01$ ). Genetically negative patients had a higher frequency of exudative pharyngitis ( $P = .010$ ). Genetically undetermined patients showed the same pattern of symptom frequency as genetically negative patients. The Gaslini diagnostic score was able to identify 91% of genetically positive patients correctly, with a global accuracy of 66%.

CONCLUSION: The Gaslini diagnostic score represents a useful tool to identify patients meeting PFAPA syndrome criteria and at low risk of carrying relevant mutations in genes associated with periodic fevers.

alexandra-chloe.villani@mail.mcgill.ca

BACKGROUND AND AIMS: The familial Mediterranean fever (FMF) gene (MEFV) encodes pyrin, a major regulator of the inflammasome platform controlling caspase-1

activation and IL-1 $\beta$  processing. Pyrin has been shown to interact with the gene product of NLRP3, NALP3/cryopyrin, also an important active member of the inflammasome. The NLRP3 region was recently reported to be associated with Crohn's disease (CD) susceptibility. We therefore sought to evaluate MEFV as an inflammatory bowel disease (IBD) susceptibility gene.

**METHODOLOGY AND RESULTS:** MEFV colonic mucosal gene expression was significantly increased in experimental colitis mice models (TNBS  $p < 0.0003$ ; DSS  $p < 0.006$ ), in biopsies from CD ( $p < 0.02$ ) and severe ulcerative colitis (UC) patients ( $p < 0.008$ ). Comprehensive genetic screening of the MEFV region in the Belgian exploratory sample set (440 CD trios, 137 UC trios, 239 CD cases, 96 UC cases, and 107 healthy controls) identified SNPs located in the MEFV 5' haplotype block that were significantly associated with UC (rs224217;  $p = 0.003$ ; A allele frequency: 56% cases, 45% controls), while no CD associations were observed. Sequencing and subsequent genotyping of variants located in this associated haplotype block identified three synonymous variants (D102D/rs224225, G138G/rs224224, A165A/rs224223) and one non-synonymous variant (R202Q/rs224222) located in MEFV exon 2 that were significantly associated with UC (rs224222:  $p = 0.0005$ ; A allele frequency: 32% in cases, 23% in controls). No consistent associations were observed in additional Canadian (256 CD trios, 91 UC trios) and Scottish (495 UC, 370 controls) sample sets. We note that rs224222 showed marginal association ( $p = 0.012$ ; G allele frequency: 82% in cases, 70% in controls) in the Canadian sample, but with a different risk allele. None of the NLRP3 common variants were associated with UC in the Belgian-Canadian UC samples and no significant interactions were observed between NLRP3 and MEFV that could explain the observed flip-flop of the rs224222 risk allele.

**CONCLUSION:** The differences in association levels observed between the sample sets may be a consequence of distinct founder effects or of the relative small sample size of the cohorts evaluated in this study. However, the results suggest that common variants in the MEFV region do not contribute to CD and UC susceptibility.

Periodic fever responds to vitamin B12 treatment.

Naimer S(1), Volkov I.

Author information:

(1)Department of Family Medicine, Siaal Research Center for Family Medicine and Primary Care, Faculty of Health Sciences, Ben-Gurion University of the Negev Beer-Sheva, Hogla street, 6, Lehavim, 85338, Beersheba, Israel.

Periodic fever of childhood is a group of diseases that cause repeated febrile illnesses with various associated symptoms. In our article, we present the case of a 6-year-old girl with unusual appearance of periodic fever syndrome. Our patient suffered from repeated episodes of high fever from the age of 2 years old. Each episode usually lasted 24-48 h, the interval between events was 1-3 weeks long. During high fever episodes the child usually felt well, without associated accompanying complaints. As a rule, the physical examination did not reveal any pathologic finding explaining the fever. During the 4 years of follow-up the patient sustained treatment attempts with prednisone for a number of months and half a year with colchicine without any response. We considered treatment with sublingual tablets of vitamin B12 (VIT B12). Beyond all expectation, we witnessed complete resolution of attacks during the first 2 months following treatment. After a long episode-free period, the parents withheld the treatment on their own accord, and in a short time the disease recurred. We advised to renew the treatment with VIT B12, and during approximately half year of follow-up there were no recurrences of periodic fever. CONCLUSION: we believe that our observation raises interest in systematic evaluation of the therapeutic role of VIT B12 as a treatment option for disorders of the periodic fever spectrum.

MEFV mutations in Egyptian patients suffering from familial Mediterranean fever: analysis of 12 gene mutations.

el-Garf A(1), Salah S, Iskander I, Salah H, Amin SN.

Author information:

(1)Department of Rheumatology, Faculty of Medicine, Cairo University, Cairo, Egypt. agarf@ritsec1.com.eg

The objective of the study is to screen 12 MEFV gene mutations in Egyptian patients with familial Mediterranean fever (FMF) and to study the initial hypothesis that the phenotypic expression of the disease may be attributable to the existence of a particular mutation. We enrolled 136 Egyptian patients (74 males, and 62 females) with a clinical diagnosis of FMF. DNA was amplified by PCR and subjected to reverse hybridization for the detection of 12 MEFV gene mutations. The phenotypic expression of the disease was compared in two subgroups according to the presence of homozygote E148Q and M694V gene mutations. The most frequent gene mutations in the studied group were V726A, M694V, M680I, E148Q and M694I in 41.2, 32.4, 29.4, 25 and 20.6%, respectively. At least one of these main five founder mutations was present in 132 patients (97.1%). Thirty-two patients (23.5%) were homozygote for one of the main five founder mutations. The most common homozygote gene mutations were E148Q and M694V, each in 12 patients (8.8%). Significant increase in abdominal pain and arthritis was found in patients with homozygote M694V mutation compared to those with E148Q mutation. All patients with amyloidosis had M694V gene mutation. The increased frequency of V726A gene mutation and the rarity of amyloidosis in this study suggest that Egyptian patients may have a milder form of FMF compared to other populations. The five main founder mutations account for the vast majority of cases of FMF. M694V gene mutation may be associated with increased frequency of abdominal pain, arthritis and the presence of amyloidosis.

Anti-IL-1 treatment for secondary amyloidosis in an adolescent with FMF and Behçet's disease.

Bilginer Y(1), Ayaz NA, Ozen S.

Author information:

(1)Department of Pediatrics, Nephrology and Rheumatology Unit, Hacettepe University School of Medicine, Sıhhiye, 06100, Ankara, Turkey.

Familial Mediterranean fever (FMF) is associated with mutations in the gene coding for pyrin which lead to accentuated innate immune responses resulting in increased production of IL-1. We present a teenager who had severe FMF and Behçet's disease and developed moderate proteinuria. Renal biopsy showed secondary amyloidosis. Anakinra was started at 1 mg/kg/day subcutaneously along with colchicine treatment. The clinical response was excellent. Acute phase reactants decreased. The level of proteinuria and renal functions remained stable and the hypoalbuminemia returned to normal. Her clinical and laboratory symptoms returned when anakinra had to be stopped at 6 months. Thus, the drug was restarted and she is now clinically in excellent condition a year after the start of therapy. She has normal renal functions, normal serum proteins, and normal acute-phase reactants. However, recently, after 18 months of anakinra treatment, her proteinuria gradually increased and albumin levels decreased. We suggest that anti-IL-1 treatment is beneficial for the suppression of inflammation; however, long-term studies are needed to understand whether progressive renal disease will be prevented.

The inherited autoinflammatory syndrome: a decade of discovery.

Goldfinger S(1).

Author information:

(1)Massachusetts General Hospital, 55 Fruit St., Boston, MA 02114, USA.  
sgoldfinger@partners.org

The hereditary autoinflammatory diseases arise from mutations of genes regulating the innate immune system. These rare disorders are well characterized, both clinically and in terms of their molecular pathogenesis. The recurrent attacks of

febrile polyserositis of Familial Mediterranean Fever (FMF) are due to defective pyrin, a protein that down-regulates inflammation. The Hyperimmunoglobulinemia D Syndrome (HIDS), which mimics FMF, results from a genetically conferred deficiency of mevalonate kinase. TRAPS (TNF Receptor Associated Periodic Syndrome), formerly known as Familial Hibernian Fever, is caused by a defective membrane receptor for TNF. Three other hereditary disorders which overlap in their clinical expression - Familial Cold Autoinflammatory Syndrome, the Muckle Wells syndrome, and Neonatal Onset Multisystem Inflammatory Disease (NOMID) - are a consequence of gain-of-function mutations of the gene encoding cryopyrin, the scaffolding protein of the inflammasome. The PAPA syndrome (Pyogenic Arthritis, Pyoderma gangrenosum, Acne) results from mutations of a gene that increases the binding of its product (PSPSTPIP1) to pyrin, thereby blunting the inhibitory effect of pyrin on inflammasome activation.

Intestinal effector T cells in health and disease.

Maynard CL(1), Weaver CT.

Author information:

(1)Department of Pathology, University of Alabama at Birmingham, Birmingham, AL 35294, USA. clmaynard@uab.edu

Crohn's disease and ulcerative colitis are the two major forms of chronic relapsing inflammatory disorders of the human intestines collectively referred to as inflammatory bowel disease (IBD). Though a complex set of autoinflammatory disorders that can be precipitated by diverse genetic and environmental factors, a feature that appears common to IBD pathogenesis is a dysregulated effector T cell response to the commensal microbiota. Due to the heightened effector T cell activity in IBD, developmental and functional pathways that give rise to these cells are potential targets for therapeutic intervention. In this review, we highlight recent advances in our understanding of effector T cell biology in the context of intestinal immune regulation and speculate on their potential clinical

significance.

Neutrophil-derived S100A12 as novel biomarker of inflammation in familial Mediterranean fever.

Kallinich T(1), Wittkowski H, Keitzer R, Roth J, Foell D.

Author information:

(1)Department of Pediatric Pneumology and Immunology,  
Charité-Universitätsmedizin Berlin, Augustenburger Platz 1, Berlin, Germany.  
tilmann.kallinich@charite.de

**OBJECTIVE:** Familial Mediterranean fever (FMF) is characterised by recurrent periodic febrile attacks and persistent subclinical inflammation. The damage-associated molecular pattern (DAMP) protein S100A12 has proven to be a sensitive marker for disease activity and inflammation in numerous inflammatory disorders. The aim of this study was to analyse the role of S100A12 in the detection of inflammation in patients with FMF.

**METHODS:** 52 children and adolescents with a clinical and/or genetic diagnosis of FMF were prospectively followed-up over 18 months (in total 196 visits). During clinical visits, erythrocyte sedimentation rate, C reactive protein, serum amyloid A and S100A12 serum concentrations were determined. Patients were categorised into four groups according to the clinical activity of FMF.

**RESULTS:** Serum concentrations of S100A12 were excessively increased in patients with a mean increase of about 290-fold in active FMF above normal controls. S100A12 decreased significantly after introduction of colchicine therapy. Serum concentrations of S100A12 were significantly higher in patients treated with colchicine with persistent symptoms (mean $\pm$ -SEM, 6260 $\pm$ -2120 ng/ml) than in those with clinically controlled disease (440 $\pm$ -80 ng/ml,  $p$ <0.001). In contrast to classical markers of inflammation, S100A12 was significantly elevated in clinically unaffected homozygous MEFV gene mutation carriers, indicating

subclinical inflammation.

CONCLUSIONS: S100A12 is a valuable biomarker for monitoring disease activity, inflammation and response to colchicine treatment in patients with FMF. It might even be more sensitive in detecting subclinical inflammation than other available indicators.

Colchicine revisited.

Bhat A(1), Naguwa SM, Cheema GS, Gershwin ME.

Author information:

(1)Division of Rheumatology, Allergy and Clinical Immunology, University of California at Davis, Davis, California 95616, USA.

Purified from a Mediterranean plant nearly two centuries ago, colchicine has been discovered to inhibit many steps in the inflammatory process. The drug has good oral bioavailability and some enterohepatic recirculation, requiring dose adjustments for kidney disease and avoidance in liver disease. Toxicities are primarily gastrointestinal, hepatic, and hematologic. Colchicine is approved by the U.S. Federal Drug Administration for the treatment and prophylaxis of gout flares but has also been tried with varying success in the treatment of familial Mediterranean fever, primary biliary cirrhosis, psoriasis, Behçet's disease, aphthous stomatitis, linear IgA dermatosis, relapsing polychondritis, Sweet's syndrome, scleroderma, amyloidosis, leukocytoclastic vasculitis, epidermolysis bullosa, and dermatomyositis.

The rationale for comparative studies of accelerated atherosclerosis in rheumatic

diseases.

Gasparyan AY(1), Stavropoulos-Kalinoglou A, Mikhailidis DP, Toms TE, Douglas KM, Kitas GD.

Author information:

(1)Department of Rheumatology, Clinical Research Unit, Russells Hall Hospital, Dudley Group of Hospitals NHS Foundation Trust, Dudley DY1 2HQ, West Midlands, UK.

The inflammatory pathogenesis of atherosclerosis is now well-established, owing to in vitro and in vivo studies and the application of high sensitivity assays for C-reactive protein (CRP) in the general population and specific groups at risk for cardiovascular disease (CVD). In view of the complexity of inflammation-induced atherosclerosis, the rationale for comparative studies of atherogenesis in rheumatic diseases with diverse inflammatory pathogenesis seems obvious; they are human in vivo models to study inflammatory mechanisms involved in atherosclerosis and the impact of treatment. Factors implicated in atherogenesis in systemic lupus erythematosus (SLE), rheumatoid arthritis (RA), familial Mediterranean fever (FMF) and Behçet's disease (BD) are discussed in this review. Evidence suggests that enhanced atherosclerosis causes premature cardiovascular events in the autoimmune disease, SLE, and the "high-grade" inflammatory rheumatic disease, RA. Preliminary data suggest that enhanced atherogenesis may accompany FMF in the absence of sufficient suppression of inflammation by colchicine. In the setting of BD, the role of atherosclerosis in the premature manifestation of coronary pathology has not been confirmed; coronary vasculitis and aneurysms appear to constitute the basis of myocardial infarction (MI) in BD. A variety of established and novel risk factors are believed to influence enhanced atherogenesis in rheumatic diseases. Antiphospholipid antibodies are thought to be intimately involved in atherogenesis in SLE and to a lesser extent in RA. CRP may play a more universal role in all rheumatic diseases. The application of high resolution ultrasound of peripheral arteries and other non-invasive techniques may allow targeted use of statins, ACE inhibitors, antiplatelet agents and other cardioprotective drugs in patients with rheumatic diseases, but this needs to be evaluated specifically in prospective studies.

In Germany, the only available interleukin-1beta (IL-1beta) blocking agent is anakinra (ANR) (as of August 2009) which is given subcutaneously at a dosage of 100 mg/day (adults) and 1-2 mg/kg body weight/day (maximum 100 mg/day) (children), respectively. Based on published data and clinical experience the German Society of Rheumatology (Deutsche Gesellschaft für Rheumatologie) recommends the following indications for ANR: (1) Rheumatoid arthritis, if treatment with two DMARDs (one of the two being methotrexate, MTX) for at least 6 months has failed. (2) Adult-onset and juvenile-onset Still's disease (systemic juvenile idiopathic arthritis) in the case of insufficient response to glucocorticoids or inadequate long-term dosage, as well as failure of a conventional DMARD, usually MTX. For both indications the treatment should be supervised and documented by a rheumatologist or paediatric rheumatologist. Cryopyrin-associated periodic syndromes (CAPS) are recommended as an additional treatment option for IL-1 blocking therapy. The efficacy of the fusion protein rilonacept (RIC) and the monoclonal antibody canakinumab in the treatment of CAPS has been proven by randomized, placebo-controlled trials. In the US, RIL was recently approved by the FDA for the treatment of CAPS under the "Orphan Drug Status".

Expression of the familial Mediterranean fever gene is regulated by nonsense-mediated decay.

Grandemange S(1), Soler S, Touitou I.

Author information:

(1)Génétique des Maladies Auto-Inflammatoires, Institut de Génétique Humaine, CNRS-UPR1142, Montpellier, France.

Mutations in the MEditerranean FeVer (MEFV) gene are responsible for familial Mediterranean fever (FMF), a recessively inherited auto-inflammatory disease. Cases of dominant inheritance and phenotype-genotype heterogeneity have been reported; however, the underlying molecular mechanism is not currently understood. The FMF protein named pyrin or marenostrin (P/M) is thought to be involved in regulating innate immunity but its function remains subject to controversy. Recent studies postulate that a defect in MEFV expression regulation may play a role in FMF physiopathology. Our group, along with others, has identified several alternatively spliced MEFV transcripts in leukocytes. Since alternative splicing and nonsense-mediated decay (NMD) pathways are usually coupled in the post-transcriptional regulation of gene expression, we hypothesized that NMD could contribute to the regulation of the MEFV gene. To address this issue, we examined the effect of indirect and direct inhibition of NMD on expression of the MEFV transcripts in THP1, monocyte and neutrophil cells. We showed that MEFV is the first auto-inflammatory gene regulated by NMD in both a cell- and transcript-specific manner. These results and preliminary western-blot analyses suggest the possible translation of alternatively spliced MEFV transcripts into several P/M variants according to cell type and inflammatory state. Our results introduce the novel hypothesis that variation of NMD efficiency could play an important role in FMF physiopathology as a potent phenotypic modifier.

Pericarditis is usually a complication of viral or bacterial infection. In addition, it can be associated to systemic diseases such as autoimmune disorders, rheumatic fever, cancer, tuberculosis and AIDS. It can also be related to familial Mediterranean fever, an autosomic recessive inflammatory disease, characterized by fever, abdominal pain, and pleuritis mainly seen in persons from the Mediterranean area. In this study, we described the evolution and treatment response to colchicine in three patients with pericarditis associated to familial Mediterranean fever. Two of the patients had a pericardiectomy showing in their biopsy nonspecified inflammatory changes. Later their diagnosis were confirmed by genetic markers, echocardiogram and EKG. They were treated with antiviral and antibiotics without any improvement; subsequently they had good results with colchicine.

The role of inflammatory cytokines and NF-kappaB/MAPK signaling pathways in the evolution of familial Mediterranean fever: current clinical perspectives and potential therapeutic approaches.

Haddad JJ(1).

Author information:

(1)Cellular and Molecular Signaling Research Group, Department of Clinical Laboratory Science, Faculty of Health Sciences, American University of Science and Technology, Aschrafieh, Beirut, Lebanon. john.haddad@yahoo.co.uk

Familial Mediterranean fever (FMF) is one of the social and health care problems for several populations that is known as a historically endemic disease of inflammatory nature. FMF, albeit a rare disorder, is characterized by recurrent fevers and painful inflammation of various body parts, especially the abdomen, lungs, and joints. FMF is typically characterized by inflammation of the abdominal lining (peritonitis), inflammation of the lining surrounding the lungs (pleurisy), painful, swollen joints (arthralgia and occasionally arthritis), and a characteristic ankle rash, a condition that is referred to as recurrent polyserositis, or familial paroxysmal polyserositis. Moreover, FMF is an inherited inflammatory disorder usually occurring in people of Mediterranean origin - including Sephardic Jews, Arabs, Armenians, and Turks; but it may ostensibly affect any other ethnic group, however, rarely. While there's no cure for this disorder, FMF is typically diagnosed during childhood, and signs and symptoms are treatable - or even preventable - by specialized medical attrition. The inflammatory signaling pathways associated with the evolution of FMF are currently being unraveled has that has therapeutic repercussions. In this review, I recap major concepts associated with the cellular and molecular immunology of FMF, especially shedding light on the likely roles of inflammatory cytokines, the transcription factor nuclear factor (NF)-kappaB, and the superfamily of mitogen-activated protein kinases (MAPKs). Furthermore, I summarize current advances for the clinical treatments available for FMF.

The crystal structure of human pyrin b30.2 domain: implications for mutations associated with familial Mediterranean fever.

Weinert C(1), Grütter C, Roschitzki-Voser H, Mittl PR, Grütter MG.

Author information:

(1)Department for Biochemistry, University of Zürich, Winterthurer Str. 190,  
CH-8057 Zürich, Switzerland.

The inherited autoinflammatory syndrome familial Mediterranean fever (FMF) is characterized by recurrent episodes of fever, which are independent of any bacterial or viral infections. This disease is associated with point mutations in the *mefv* gene product pyrin. Although the precise molecular functions of pyrin are unknown, it seems to be involved in the maturation and secretion of interleukin-1 $\beta$ . Approximately two thirds of all FMF-associated mutations cluster in the C-terminal B30.2 domain of pyrin. To investigate the molecular consequences of FMF-associated mutations, we determined the crystal structure of the pyrin B30.2 domain at 1.35-Å resolution. The comparison with other B30.2/ligand complex structures revealed a shallow cavity, which seems to be involved in binding the pyrin ligand. The bottom of this cavity is covered mainly with hydrophobic amino acids, suggesting that pyrin recognizes its ligand by hydrophobic contacts and surface complementarities. FMF-associated mutations cluster around two sites on the B30.2 surface. Approximately two thirds, including those mutations with the most severe disease outcomes, are observed in the vicinity of the predicted peptide binding site, suggesting that they will have a direct impact on ligand binding. A second mutational hot spot was observed on the opposite side of the B30.2 domain in the neighbourhood of its artificial N-terminus. Although most FMF-associated mutations are solvent exposed, several will modify the main-chain conformation of loops. The experimental crystal structure of the pyrin B30.2 domain serves as a basis for an accurate modelling of these mutations.

Republished from

J Allergy Clin Immunol. 2008 Aug;122(2):261-6.

Our skin is constantly challenged by microbes but is rarely infected. Cutaneous production of antimicrobial peptides (AMPs) is a primary system for protection, and expression of some AMPs further increases in response to microbial invasion. Cathelicidins are unique AMPs that protect the skin through 2 distinct pathways: (1) direct antimicrobial activity and (2) initiation of a host response resulting in cytokine release, inflammation, angiogenesis, and reepithelialization. Cathelicidin dysfunction emerges as a central factor in the pathogenesis of several cutaneous diseases, including atopic dermatitis, in which cathelicidin is suppressed; rosacea, in which cathelicidin peptides are abnormally processed to forms that induce inflammation; and psoriasis, in which cathelicidin peptide converts self-DNA to a potent stimulus in an autoinflammatory cascade. Recent work identified vitamin D3 as a major factor involved in the regulation of cathelicidin. Therapies targeting control of cathelicidin and other AMPs might provide new approaches in the management of infectious and inflammatory skin diseases.

Author information:

(1)First Department of Internal Medicine, Democritus University of Thrace, Alexandroupolis, Greece. vaspapmd@otenet.gr

Turkey is one of the few countries in the world where Familial Mediterranean Fever (FMF), an autoinflammatory disease caused by mutations in MEFV, the gene encoding pyrin, is not rare. Many interesting studies regarding the genetics of Familial Mediterranean Fever in Turkey have been already published. Despite that different MEFV genetic profiles have been revealed for Turkish FMF patients, deriving from different regions of Turkey, a systematic population genetics analysis has not been carried out yet. The present study aims to investigate the population genetics of MEFV in Turkish FMF patients so as to additionally facilitate the clinical interpretation of individualized genetic data. All relevant studies have been recruited by searching PubMed with the terms "MEFV", "FMF", and "Turkey". Seven of them, including 3,061 FMF patients, contained all necessary data concerning allelic and genotypic frequencies of the 4 commonest MEFV mutations in Turkey (M694V, V726A, M680I, E148Q). From all 6,122 MEFV alleles analyzed, the M694V mutation was recognized in 15.6-52.2% (mean 29.3%), the V726A in 1.5-9.7% (mean 4.8%), the M680I in 1.5-15.5% (mean 7.6%), and the E148Q in 3.2-13.9% (mean 5.5%). Unidentified mutations ranged from 0-42.9% (mean 16.8%). No mutations were found in 0-54.5% (mean 36.0%) of the patients. The allelic and genotypic frequencies of the most frequent mutation (M694V) showed aberration of the Hardy-Weinberg law for all 7 populations studied. By application of the Arlequin 2.0 population genetics software, the Fixation index (F<sub>ST</sub>) was found to be 0.09994, thus demonstrating that the observed variability is mainly within (90.006%) and not among (9.994%) populations (P < 0.00001). Moreover, the global test of differentiation demonstrated that every population differs from each other (P < 0.00325). Finally, the Ewens-Watterson test of selective neutrality yielded to statistical significance in only 3 populations. In conclusion, Turkish FMF patients are characterized by an increased genetic heterogeneity, explained by the intrapopulation differentiation. Thus, the regional origin should be regarded as a determining factor in the diagnosis of FMF in Turkish patients.

Esophageal motor function in Familial Mediterranean Fever: a prospective evaluation of motility in 31 patients.

Bektaş M(1), Doğanay B, Alkan M, Ustun Y, Soykan I.

Author information:

(1)Ankara University Medical School, Ibni Sina Hospital, Department of Gastroenterology, 06100 Sıhhiye, Ankara, Turkey.

**BACKGROUND:** The aims of this study were to evaluate esophageal motor function in patients with Familial Mediterranean Fever (FMF) who had upper gastrointestinal symptoms and to compare esophageal motor function between FMF patients who developed amyloidosis and patients without amyloidosis.

**METHODS:** 31 FMF patients with dyspeptic symptoms and 31 healthy age-matched individuals were included in the study. Endoscopic examination and esophageal motility testing were performed.

**RESULTS:** Esophageal motor abnormalities were detected in 25.8% (8/31) of these patients [incomplete Lower esophageal sphincter (LES) relaxation: n=4, esophageal hypomotility: n=2, and hypotensive LES: n=2]. Median LES relaxation (%) (min-max) was significantly lower in patients with FMF compared to control group 94% (54-100) vs. 98% (80-100), p=0.019 respectively). However, mean LES pressure (mmHg) (19.5+/-8.9 vs. 19.7+/-5.6, p=0.813), duration of LES relaxation (s) (7.9+/-1.7 vs. 8.7+/-1.7, p=0.068), contraction amplitude of esophageal body (mmHg) (60.4+/-23.3 vs. 58.2+/-19.7, p=0.691) and median (min-max) peak velocity (s) [3.1(-1.43-50.3) vs. 3.1 (0.9-8.7), p=0.435] were similar in patients with FMF compared to control group. There were no significant differences with regard to LES pressure, LES relaxation, LES relaxation duration, contraction amplitude (mmHg) and peak velocity (sc) among patients with FMF and amyloidosis, amyloidosis negative FMF patients and healthy controls.

**CONCLUSIONS:** Abnormal esophageal manometric findings can be observed at least in a subgroup of patients with FMF regardless of amyloid status. Investigation of esophageal motor function in patients with FMF who exhibit unexplained upper gastrointestinal symptoms between attacks may be a helpful tool in order to delineate esophageal motor dysfunction.

Acute adrenal crisis mimicking familial Mediterranean fever attack in a renal transplant FMF patient with amyloid goiter.

Emeksiz H(1), Bakkaloglu S, Camurdan O, Boyraz M, Soylemezoglu O, Hasanoglu E, Buyan N.

Author information:

(1)Gazi University, Ankara, Turkey. hcemeksiz@gmail.com

The most devastating complication of familial Mediterranean fever (FMF) is amyloidosis which is capable of resulting in chronic renal failure. Although amyloid deposits are frequent in adrenal glands based on the autopsies of FMF patients however; to our knowledge, symptomatic adrenal insufficiency has not been reported yet. We describe a 21-year-old-FMF amyloidosis case with a well-functioning allograft who presented to the emergency clinic with the complaints of abdominal pain, vomiting and diarrhea mimicking FMF attack. adrenocorticotrophic hormone stimulation test was performed due to resistant hyponatremia and disclosed Addison disease. In countries with a high prevalence of FMF, adrenal crisis should be borne in mind in long standing FMF patients.

Long term management of patients with cryopyrin-associated periodic syndromes (CAPS): focus on rilonacept (IL-1 Trap).

Church LD(1), Savic S, McDermott MF.

Author information:

(1)Department of Rheumatology, Division of Immunity, Infection and Inflammation, Institute for Biomedical Research, The University of Birmingham, Birmingham, UK.

Cryopyrin-associated periodic syndromes (CAPS) are a group of inherited inflammatory disorders consisting of familial cold-induced autoinflammatory syndrome (FCAS), Muckle-Wells syndrome (MWS), and neonatal-onset multisystem inflammatory disease (NOMID; also known as chronic infantile neurologic, cutaneous, articular [CINCA] syndrome). These rare disorders are associated with heterozygous mutations in the NLRP3 (CIAS1) gene, which encodes the protein NALP3 or cryopyrin, and inflammation driven by excessive production of the cytokine interleukin-1beta (IL-1beta). Amyloidosis is a serious complication with 25% of MWS patients developing amyloidosis, with occasional fatal consequences, whilst up to 20% of CINCA/NOMID patients die from various complications, before reaching the early adulthood. In some CINCA/NOMID adult survivors amyloidosis can also occur. Prior to the discovery of the CIAS1 gene mutations and the advent of IL-1 targeted therapy, treatment was aimed at suppressing inflammation, with limited success. The selective blockade of IL-1beta, with anakinra (IL-1 receptor antagonist), not only provided supportive evidence for the role of IL-1beta in CAPS, but also demonstrated the efficacy of targeting IL-1beta for treatment of these conditions. In February, 2008, 'Orphan Drug' approval from the Food and Drug Administration (FDA) for rilonacept (IL-1 Trap/Arcalyst(), Regeneron Pharmaceuticals, Inc) was given for the treatment of two CAPS disorders, FCAS and MWS in adults and children 12 years and older, making rilonacept the first therapy approved for the treatment of CAPS.

Does breast-feeding affect severity of familial Mediterranean fever?

Makay B(1), Unsal E.

Author information:

(1)Department of Pediatrics, Division of Immunology-Rheumatology, Dokuz Eylul University Hospital, 35340 Balçova, Izmir, Turkey. balahan.bora@deu.edu.tr

Familial Mediterranean fever (FMF) is the most common inherited autoinflammatory disease, which is caused by an inborn error in innate immune system. It was shown that disease severity of patients of the same ethnic origin differed according to different country of residence, suggesting an influence of environment on phenotype of FMF. Different microbial milieus of the countries were accused. Breast-feeding has an important role on innate immunity and protects the infant from infections. The aim of this study is to investigate whether being breast-fed and duration of breast-feeding has an impact on disease severity of FMF. The mothers of patients were asked to fill a questionnaire about the feeding type in infancy. Mode of delivery, gestational age, and age at onset of FMF symptoms were also asked. The disease severity score of each patient was calculated according to the scoring system suggested by Pras et al. (Am J Med Genet 75:216-219, 1998). MEFV mutations were noted. The mothers of 81 FMF patients completed the questionnaire. Fifteen patients (18.5%) had mild, 49 (60.5%) had moderate, and 17 (21%) had severe disease. All the patients except four were breast-fed for some period. The duration of breast-feeding was similar between three severity groups. Time to introduce cow's milk and complementary foods also did not differ between groups. Longer duration of breast-feeding did not delay the onset of FMF symptoms. Mode of delivery and gestational age had no effect on disease severity. Patients homozygous for M694V had higher severity scores. This preliminary study suggests that breast-feeding is not an exogenous factor having an influence on phenotype of FMF. M694V genotype seems to cause more severe disease.

Enthesitis: an autoinflammatory lesion linking nail and joint involvement in psoriatic disease.

McGonagle D(1).

#### Author information:

(1)NIHR, Leeds Biomedical Research Unit, Leeds Institute of Molecular Medicine (LIMM), Wellcome Trust Brenner Building, St James' University Hospital, Leeds, LS9 7TF, UK. d.g.mcgonagle@leeds.ac.uk

The traditional model for psoriasis and psoriatic arthritis (PsA) is that autoimmunity directed against a common skin and joint autoantigen leads to chronic autoreactive T cell driven inflammation. However, recent imaging, histological and genetic studies have challenged this view, especially with respect to joint and nail disease, and provide a broader insight into the pathogenesis of PsA and associated nail involvement. Clinically unrecognized enthesitis (inflammation at tendon and ligament attachments) is commonly seen in early PsA at all sites of the disease. Specifically, enthesitis is associated with adjacent osteitis or bone and synovial inflammation. Even in normal joints, normal insertions are associated with microdamage and inflammatory change, strongly suggesting that local tissue specific, or what has been described as autoinflammatory factors, may dictate disease expression. Distal interphalangeal (DIP) joint disease in PsA is associated with diffuse inflammation that envelops the nail root and adjacent bone. In fact, the nail is intimately linked to entheses, with the extension tendon of the DIP joint sending fibres from bone that envelop the nail root in an interdigitating fashion. Furthermore, the joint collateral ligament enthesis has fibres that merge with the lateral borders of the nail. Other anchorage mechanisms include fibres that directly tether the nail plate to the underlying periosteum, which itself is closely anchored to the extension tendon. The frequent microdamage and tissue repair at normal enthesis attachment sites in healthy joints has resulted in a proposed new model of PsA pathogenesis embracing the concept of autoinflammation, whereby tissue specific factors, including microtrauma, lead to regional innate immune activation and persistent inflammation, as an alternative to primary immunopathology driven by T and B cell abnormalities. Unlike the classical autoimmune diseases, which may attack a completely normal organ, autoimmunity in psoriatic disease is likely to involve tissues where there is intrinsic dysregulation of the target tissues. These tissue specific factors related to the enthesis appear to be key to the phenotypic expression of diseases hitherto regarded as autoimmune. The pathogenesis of PsA, nail disease and to a lesser extent psoriasis therefore appear to have an autoinflammatory (innate immune driven) rather than autoimmune basis. Taken together, these findings are important for better understanding PsA, nail disease and psoriasis, and for conceptualizing the immunopathogenic basis of

these diseases and further exploring the role of enthesitis in their pathophysiology.

Cytokine imbalance with increased production of interferon-alpha in psoriasiform eruptions associated with antitumour necrosis factor-alpha treatments.

Seneschal J(1), Milpied B, Vergier B, Lepreux S, Schaeffer T, Taïeb A.

Author information:

(1)Department of Dermatology and Pediatric Dermatology, Saint André and Pellegrin Hospitals, Bordeaux University Hospitals, 33075 Bordeaux Cedex, France.

**BACKGROUND:** Psoriasiform eruptions occur in association with antitumour necrosis factor (TNF)-alpha treatments in autoinflammatory diseases. The major reported clinical presentation is palmoplantar pustulosis, sometimes accompanied with plaque-like psoriasis. In some reports, histological findings suggest psoriasis whereas others favour a lichenoid drug reaction. We present a case series with a comprehensive clinical, histopathological and immunohistochemical study.

**OBJECTIVES:** To investigate the mechanism involved in psoriasiform eruptions in patients receiving anti-TNF-alpha inhibitors.

**METHODS:** Between July 2004 and May 2008, 13 patients with psoriasiform eruptions arising under anti-TNF-alpha treatment were enrolled in the study. Punch biopsy specimens of lesions were processed for standard and immunohistochemical analyses using antibodies against CD3, CD4, CD8, CD20, CD1a, KP1, CXCR3, CXCL9, Tia1 and MxA, which is specifically induced by type I interferons (IFNs). Additionally, we analysed biopsies from lesional skin of patients with cutaneous discoid lupus erythematosus, lichen planus and psoriasis. Control biopsies were taken from unaffected skin.

**RESULTS:** All patients developed psoriasiform plaques on the body accompanied with palmoplantar keratoderma or pustulosis in three patients. Histological and immunohistochemical findings showed a psoriasiform pattern with focal lichenoid and spongiotic features. We detected strong production of the MxA protein in

inflammatory cells, indicating involvement of type I IFNs, and the expression was higher than in control psoriasis samples. Expression of MxA was closely associated with the recruitment of CXCR3+ lymphocytes in the skin bearing markers of cytotoxic capacity.

CONCLUSIONS: Results support the hypothesis that psoriasiform eruptions are a new model of drug reaction characterized by an increased expression of type I IFNs induced by anti-TNF-alpha.

Familial Mediterranean Fever (FMF) is a recessively inherited systemic autoinflammatory disease caused by mutations in the MEFV gene. The frequency of different disease alleles is extremely high in multiple populations from the Mediterranean region, suggesting heterozygote advantage. Here, we characterize the sequence variation and haplotype structure of the MEFV 3' gene region (from exon 5 to the 3' UTR) in seven human populations. In non-African populations, we observed high levels of nucleotide variation, an excess of intermediate-frequency alleles, reduced population differentiation and a genealogy with two common haplotypes separated by deep branches. These features are suggestive of balancing selection having acted on this region to maintain one or more selected alleles. In line with this finding, an excess of heterozygotes was observed in Europeans and Asians, suggesting an overdominance regime. Our data, together with the earlier demonstration that the MEFV exon 10 has been subjected to episodic positive selection over primate evolution, provide evidence for an adaptive role of nucleotide variation in this gene region. Our data suggest that further studies aimed at clarifying the role of MEFV variants might benefit from the integration of molecular evolutionary and functional analyses.

Investigation of C5a receptor gene 450 C/T polymorphism in Turkish patients with familial Mediterranean fever.

Erken E(1), Gunesacar R, Ozer HT.

Author information:

(1)Department of Rheumatology-Immunology, Cukurova University Faculty of Medicine, Adana, Turkey. eerken@cu.edu.tr

Familial Mediterranean fever (FMF) is a genetic disorder with acute inflammatory serosal attacks due to MEFV gene mutations which resides in chromosome 16. Lack of a C5a inhibitor activity in the peritoneum has previously been proposed in

part to contribute in propagation of the serosal inflammation in FMF attacks. The aim of this study is to investigate C5a receptor (C5aR) gene polymorphism in patients with FMF and its relation to the main features of the disease. A polymorphism in the coding region of C5aR gene leading to C to T transition at nucleotide position 450 has been investigated in 85 non-related Turkish FMF patients and 160 non-related healthy controls by using PCR-RFLP. The frequencies of C5aR gene 450 CT genotype and T allele were not significantly different between Turkish FMF patients and healthy subjects (14.12 and 8.24% for FMF vs. 10 and 5% for controls, respectively). C5aR gene 450 CT genotype tended to associate with the presence Henoch-Schonlein purpura (OR: 1.25, 95% CI: 0.917-1.704, P = 0.017) but with no other clinical findings of the disease. C5aR polymorphism might be searched in populations having high prevalence of FMF.

Riloncept in the treatment of chronic inflammatory disorders.

McDermott MF(1).

Author information:

(1)NIHR-Leeds Musculoskeletal Biomedical Research Unit, Leeds Institute of Molecular Medicine, St. James's University Hospital, Leeds, UK.

medmmc@leeds.ac.uk

Riloncept (IL-1 Trap/Arcalyst) is a long-acting interleukin-1 (IL-1) blocker developed by Regeneron Pharmaceuticals. Initially, Regeneron entered into a joint development effort with Novartis to develop riloncept for the treatment of rheumatoid arthritis (RA) but this was discontinued following the review of phase II clinical data showing that IL-1 blockade appeared to have limited benefit in RA. In February 2008, Regeneron received Orphan Drug approval from the Food and Drug Administration for riloncept in the treatment of two cryopyrin-associated periodic syndromes (CAPS) disorders, namely, familial cold-induced autoinflammatory syndrome (FCAS) and Muckle-Wells syndrome (MWS), for children and adults 12 years and older. CAPS is a group of inherited inflammatory disorders consisting of FCAS, MWS, neonatal-onset multisystem inflammatory

disease (NOMID), also known as chronic infantile neurologic, cutaneous and articular (CINCA) syndrome, all associated with heterozygous mutations in the NLRP3 (CIAS1) gene, which encodes the protein NLRP3 or cryopyrin. Prior to the discovery of the NLRP3 (CIAS1) mutations and the advent of IL-1-targeted therapy, treatment was aimed at suppressing inflammation but with limited success. The dramatic success of selective blockade of IL-1beta, initially with the IL-1 receptor antagonist (IL-1Ra; Kineret(R) or anakinra/ Amgen, Inc.), not only provided supportive evidence for the role of IL-1beta in CAPS but also demonstrated the efficacy of targeting IL-1beta for treatment of these conditions. A high-affinity protein called rilonacept has been produced by cytokine Trap technology and was developed by Regeneron. The desirable longer half-life of rilonacept offers potential alternatives to patients who do not tolerate daily injections very well or have difficulty with drug compliance. The initial evidence for the beneficial effects of rilonacept for MWS and FCAS suggests that it would also be a suitable treatment for CNICA/NOMID. It is yet to be determined whether rilonacept would be an effective treatment for other chronic inflammatory conditions such as gout, familial Mediterranean fever and systemic juvenile idiopathic arthritis.

Autoinflammatory syndromes behind the scenes of recurrent fevers in children.

Rigante D(1).

Author information:

(1)Department of Pediatric Sciences, Università Cattolica Sacro Cuore, Largo A Gemelli, Rome, Italy.

Many children experience recurrent fevers with no easily identifiable source and only a careful follow-up helps in the early identification of other presenting symptoms of other defined conditions which require medical intervention. Autoinflammatory syndromes are rare childhood-onset disorders of the innate immunity in which recurrent flares of fever and inflammation affecting skin, joints, the gastrointestinal tube, or serous membranes are the most striking signs, without any evidence of autoantibody production or underlying infections. Among the pediatric conditions belonging to this group we can consider hereditary recurrent fevers (familial Mediterranean fever, mevalonate kinase deficiency syndrome, tumor necrosis factor receptor-associated periodic syndrome, cryopyrin-associated periodic syndromes), pyogenic disorders (PAPA syndrome, CRMO syndrome, Majeed syndrome), immune-mediated granulomatous diseases (Blau syndrome, Crohn's disease), and idiopathic febrile syndromes (systemic-onset juvenile idiopathic arthritis, PFAPA syndrome, Behçet syndrome). Their genetic background has only been partially elucidated and advances in their molecular pathogenesis are shedding new light on the innate immune system, whilst more and more diseases are being reconsidered at a pathogenetic level and included in this new chapter of postgenomic medicine. The diagnosis of most autoinflammatory syndromes relies on clinical history, demonstration of an increased acute-phase response during inflammatory attacks, and, possibly, genetic confirmation, which is still elusive especially for idiopathic febrile syndromes. This astonishing progress in the awareness and knowledge of autoinflammatory syndromes has anticipated the actual possibilities of medical intervention and rationalized treatment with targeted biologic agents.

Theoretical and practical basis for early aggressive therapy in paediatric autoimmune disorders.

Woo P(1).

Author information:

(1)Centre for Paediatric and Adolescent Rheumatology, University College London, London, UK. Patricia.woo@ucl.ac.uk

**PURPOSE OF REVIEW:** The clinical practice of introducing anti-inflammatory therapies in paediatric autoimmune disorders has changed substantially in the last two decades. This is partly due to the fact that we are able to put disease into remission with potent drugs, and so the issue of when to introduce these drugs is important. This review will seek to highlight the consequences of chronic inflammation and the change to outcomes if adequate or 'aggressive' treatment is given early to induce remission.

**RECENT FINDINGS:** The review not only highlights publications on this topic over the past 12-18 months but also refers to key publications before when appropriate. The disorders reviewed are juvenile idiopathic arthritis, systemic lupus erythematosus, Wegener's granulomatosis, juvenile dermatomyositis, juvenile scleroderma and autoinflammatory syndromes.

**SUMMARY:** Outcomes can be influenced by potent anti-inflammatory therapies. Their use early in the evolution of the disorder in question can limit damage and allow the possibility of normal life and function in the child.

Clinical and genetic findings of familial Mediterranean fever (FMF) may be variable in different populations. Environmental factors may also affect phenotypic features of FMF. In this study, we investigated demographic, clinical and mutational features of FMF patients who were treated in a single reference hospital in Turkey. Two hundred and sixty patients (169 females, 91 males, mean age 30.44 +/- 10.29 years) were included in this study. All patients were evaluated regarding MEFV gene mutations. The mean age of disease onset was 17.21 +/- 8.66 years (range 2-40 years). The mean duration between the disease onset and diagnosis was 9.39 +/- 8.92 years. Seventy percent of patients had symptoms before 20 years of age (early onset FMF). Arthritis and erysipelas like erythema (ELE) were more common, and the mean duration between the disease onset and diagnosis was longer in early onset FMF patients. The frequency of attacks per year, and disease severity score (DSS) was higher in early onset patients. Homozygote mutation of M694V was detected in 37 (20.2%) and 4 (5.2%) patients in early onset FMF and adult onset FMF groups, respectively ( $p < 0.05$ ). Histological diagnosis of amyloidosis was established in 7 patients (2.7%). The age of disease onset was earlier, and arthritis and ELE were more frequent, and DSS was higher in patients with M694V/M694V mutation. In conclusion, mean delay to diagnosis in our FMF population is quite high. Early and adult onset forms may differ regarding some clinical, molecular and prognostic characteristics. Disease activity was higher in patients with homozygote mutation of M694V.

Evaluation of pathergy test positivity in familial Mediterranean fever patients and comparison of clinical manifestations of FMF with Behçet's disease.

Aydin F(1), Akpolat T, Senturk N, Bagci H, Yasar Turanli A.

Author information:

(1)Department of Dermatology, School of Medicine, Ondokuz Mayıs University, TR-55139 Kurupelit, Samsun, Turkey. bennet@mynet.com

Familial Mediterranean fever (FMF) shares a number of features with Behçet's disease (BD), such as their common ethnic origin, etiopathogenetic mechanisms, symptoms, and treatment. Pathergy reaction is accepted as a major criterion in BD. We aimed to determine the frequency of pathergy positivity in FMF patients and compared clinical features between FMF and BD. Pathergy test was performed in patients with FMF, BD, and healthy controls. Diagnostic criteria for FMF and BD were screened in both groups. None of the FMF patients or healthy controls yielded positive pathergy test. Pathergy test was positive in 13 out of 31 (41.9%) of the patients with BD. None of the FMF patients fulfilled the International Study Group criteria for BD. None of the BD patients fulfilled the Livneh diagnostic criteria for FMF. BD and FMF are associated with neutrophilic dermatoses and neutrophil hyper-reactivity. Although pathergy test and erysipelas-like erythema share some histological findings, pathergy test was negative among FMF patients.

Manipulation of T(H)17 responses in pulmonary immunity and disease through vaccination.

Sonnenberg GF(1), Weiner DB.

Author information:

(1)Department of Pathobiology, University of Pennsylvania School of Medicine, Philadelphia, PA, USA.

Since the discovery of a novel subset of CD4(+) T helper cells, T(H)17 cells have been implicated in a wide range of human diseases, including autoimmunity, allergic reactions and autoinflammatory diseases. Conversely, it has also been determined that T(H)17 cells are required to mount a protective immune response to a number of pathogens. It has therefore been of great interest to manipulate T(H)17 responses to either prevent disease or promote immunity. Vaccination is a particularly attractive approach for this manipulation. With a focus on the pulmonary mucosal environment, we herein review T(H)17 responses and potential methods for manipulation.

Primed innate immunity leads to autoinflammatory disease in PSTPIP2-deficient cmo mice.

Chitu V(1), Ferguson PJ, de Bruijn R, Schlueter AJ, Ochoa LA, Waldschmidt TJ, Yeung YG, Stanley ER.

Author information:

(1)Department of Developmental and Molecular Biology, Albert Einstein College of Medicine, Bronx, NY 10461, USA. vchitu@aecom.yu.edu

The mouse Lupo (I282N) mutation in proline-serine-threonine phosphatase-interacting protein 2 (PSTPIP2) leads to reduced expression of PSTPIP2 that is associated with a macrophage-mediated autoinflammatory disease. Another mutation in PSTPIP2, L98P, termed chronic multifocal osteomyelitis (cmo), leads to a disease in mice that resembles chronic recurrent multifocal osteomyelitis in humans. The cellular basis of cmo disease was investigated. cmo disease develops independently of lymphocytes and is cured by bone marrow transplantation. Macrophages, mast cells, and osteoclasts from cmo mice fail to express detectable PSTPIP2 protein. Asymptomatic Pstpip2(cmo/cmo) mice have increased circulating levels of macrophage inflammatory protein 1-alpha and interleukin-6, and their macrophages exhibit increased production of these inflammatory mediators, which is normalized by retroviral expression of wild-type PSTPIP2. Spleens of asymptomatic cmo mice contain increased numbers of macrophage precursors, and cmo mice mobilize more macrophage precursors in response to a sterile inflammatory stimulus. Signal transducer and activator of transcription 1 is elevated in cmo splenic macrophages, which also exhibit increased colony-stimulating factor-1-stimulated proliferation and increased extracellular signal-regulated kinase 1/2 phosphorylation. PSTPIP2 overexpression in macrophages leads to the opposite phenotype. Thus, PSTPIP2 deficiency causes both an expansion of macrophage progenitors and increased responsiveness of mature macrophages to activating stimuli, which together prime the organism for

exaggerated and sustained responses leading to autoinflammatory disease.

(1)Mallinckrodt Institute of Radiology, Washington University School of Medicine, Campus Box 8131, St Louis, MO 63110, USA. khannag@mir.wustl.edu

Chronic recurrent multifocal osteomyelitis (CRMO) is an autoinflammatory disorder of children and young adults that is characterized by nonbacterial osteomyelitis. Patients typically present with multifocal bone pain secondary to sterile osseous inflammation, and the disease has a relapsing and remitting course. The cause of CRMO remains unclear, although the results of several studies have suggested a genetic component. The typical imaging findings of CRMO include lytic and sclerotic lesions in the metaphyses of long bones and the medial clavicles. Other common sites of disease are the vertebral bodies, pelvis, ribs, and mandible. CRMO is often bilateral and multifocal at presentation. Owing to the lack of a diagnostic test, CRMO remains a diagnosis of exclusion. Although generally a self-limiting disease, CRMO can have a prolonged course and result in significant morbidity. Radiologists can be the first to suggest this diagnosis given its characteristic radiographic appearance and distribution of disease. Radiologists should be familiar with the typical imaging findings of CRMO to prevent unnecessary multiple biopsies and long-term antibiotic treatment in children with CRMO.

Plasma ghrelin levels in patients with Familial Mediterranean Fever.

Keskin G(1), Inal A, Ilikçi R, Baysal O.

Author information:

(1)DYBEA Hospital Immunology, Department, Ankara, Turkey. goksalkeskin@gmail.com

Familial mediterranean fever (FMF) is a familial disease characterized by recurrent episodes of febrile serositis, peritonitis, arthritis and pleuritis. Many studies have been performed is an attempt to understand the basis of the inflammatory attacks in FMF. Ghrelin, a recently described orexigene peptide is predominantly produced by stomach. Ghrelin also exerts multiple regulatory effects on immune system. It has reported that grelin has anti-inflammatory effects. There is currently no published evidence demonstrating a role for anti-inflammatory effects of ghrelin in FMF. For this reason, we investigated the role of plasma ghrelin levels in patients with FMF. Thirty seven patients with FMF and 10 healthy controls (5 female, 5 male; mean age 35.4 +/- 5.6 years) were enrolled in this study. Twenty-one patients were in active stage (10 female, 11 male, mean age; 31.0 +/- 5.4 years, mean disease duration 7.2 +/- 3.3 years) and 16 patients were in inactive stage (7 female, 9 male, mean age; 33.0 +/- 6.0 years, mean disease duration; 8.7 +/- 3.2 years). Plasma ghrelin levels were determined by EIA. The mean plasma ghrelin levels were 158.4 +/- 52.9 pg/ml in patients with FMF and 56.7 +/- 7.5 pg/ml in healthy controls. The mean plasma ghrelin levels were 190.5 +/- 49.4 pg/ml in the active patients and 116.2 +/-

11.7 pg/ml in the inactive patients. Plasma ghrelin levels were significantly high in patients with FMF compared to healthy controls ( $p<0.001$ ). Plasma ghrelin levels were significantly high in the active patients compared to in the inactive patients and healthy controls ( $p<0.001$  and  $p<0.001$  respectively). There was significantly difference between in active and inactive patients with FMF ( $p<0.001$ ). As a results; Plasma ghrelin levels were high both in active and inactive patients with FMF. It is showed that ghrelin may play significant role of the pathogenesis of FMF.

TLR-2 Arg753Gln, TLR-4 Asp299Gly, and TLR-4 Thr399Ile polymorphisms in Henoch Schonlein purpura with and without renal involvement.

Soylu A(1), Kizildağ S, Kavukçu S, Cingöz S, Türkmen M, Demir BK, Sakizli M.

Author information:

(1)Department of Pediatrics, Medical Faculty, Dokuz Eylul University, Izmir, Turkey. alper.soylu@deu.edu.tr

Infections may trigger or aggravate glomerulonephritidis and renal vasculitis like Henoch Schonlein purpura (HSP). HSP is seen more frequently in patients with familial Mediterranean fever in which TLR-2 Arg753Gln polymorphism frequency is increased. Although renal involvement is the most important factor affecting the prognosis in HSP, it is not known which patients will have renal disease or why some patients have severe renal involvement while some others have mild renal disease. We investigated the role of TLR-2 and TLR-4 polymorphisms on the incidence and severity of renal involvement in HSP patients. We studied HSP patients with and without nephritis ( $n = 15$  for each group) and healthy controls ( $n = 100$ ). TLR-2 Arg753Gln and TLR-4 Asp299Gly/Thr399Ile polymorphisms were analyzed with polymerase chain reaction-restriction fragment length polymorphism method. The frequency of TLR-2 Arg753Gln, TLR-4 Asp299Gly, and Thr399Ile polymorphisms in healthy controls were 1, 3, and 2%, respectively. The frequencies of these polymorphisms were not different in HSP patients with or

without nephritis compared to healthy controls. TLR-2 Arg753Gln, TLR-4 Asp299Gly, and Thr399Ile polymorphisms are not increased in HSP or HSP nephritis patients.

Syndrome of periodic fever, aphthous stomatitis, pharyngitis, and adenitis (PFAPA) in siblings.

Valenzuela PM(1), Majerson D, Tapia JL, Talesnik E.

Author information:

(1)Department of Pediatrics, Pontificia Universidad Católica de Chile, Lira 85, 5th floor, Santiago, Chile. pvalenzu@med.puc.cl

PFAPA syndrome is characterized by episodes of periodic fever, aphthous stomatitis, pharyngitis, and cervical adenitis. PFAPA syndrome usually begins in children under 5 years old and normally has self-resolution. The etiology of PFAPA syndrome remains unknown. In this paper, we report the cases of two different families with siblings with PFAPA syndrome: two sisters and two brothers. To our knowledge, this is the first report of siblings with PFAPA syndrome.

Uncommon clinical pattern of FMF: protracted febrile myalgia syndrome.

Tufan G(1), Demir S.

Author information:

(1)Department of Internal Medicine, Faculty of Medicine, Afyon Kocatepe University, Afyon, Turkey. gntufan@yahoo.com

Familial Mediterranean fever (FMF) is a genetic multisystem disorder of unknown etiology characterized by recurrent episodes of fever and pain due to acute inflammation of the peritoneum, synovia, or pleura. Up to 25% of patients with FMF report muscle pain. Myalgia may be a spontaneous pattern, exercise-induced pattern, or protracted febrile myalgia syndrome (PFMS). PFMS is characterized by severe paralyzing myalgia, high fever, abdominal pain, diarrhea, arthritis/arthritis, and transient vasculitic rashes mimicking Henoch-Schonlein purpura. The episodes last for 4-6 weeks, except in those patients treated with corticosteroids. The PFMS may recur even under colchicine prophylaxis. We describe a 30-year-old pregnant Turkish woman with known FMF and under colchicine prophylaxis, with severe myalgia for 8 weeks, emphasizing the importance of a different clinical pattern of PFMS even in the absence of other symptoms.

Sweet's syndrome in familial Mediterranean fever: possible continuum of the neutrophilic reaction as a new cutaneous feature of FMF.

Oskay T(1), Anadolu R.

Author information:

(1)Department of Dermatology, Bayindir Hospital, Ankara, Turkey. oskayt@gmail.com

Sweet's syndrome (SS) or acute febrile neutrophilic dermatosis is an uncommon disorder that often occurs in association with other systemic diseases. In its systemic manifestation, SS resembles familial Mediterranean fever (FMF) in many aspects. Although the exact pathogenesis of SS and FMF is not yet clear, their clinical similarities and simultaneous occurrence suggest a possible common underlying mechanism and may represent a continuum of a reactive neutrophilic condition.

PSTPIP1 is a cytoskeleton-associated adaptor protein that links PEST-type phosphatases to their substrates. Mutations in PSTPIP1 cause PAPA syndrome (Pyogenic sterile Arthritis, Pyoderma gangrenosum, and Acne), an autoinflammatory disease. PSTPIP1 binds to pyrin and mutations in pyrin result in familial Mediterranean fever (FMF), a related autoinflammatory disorder. Since disease-associated mutations in PSTPIP1 enhance pyrin binding, PAPA syndrome and FMF are thought to share a common pathoetiology. The studies outlined here describe several new aspects of PSTPIP1 and pyrin biology. We document that PSTPIP1, which has homology to membrane-deforming BAR proteins, forms homodimers and generates membrane-associated filaments in native and transfected cells. An extended FCH (Fes-Cip4 homology) domain in PSTPIP1 is necessary and sufficient for its self-aggregation. We further show that the PSTPIP1 filament network is dependent upon an intact tubulin cytoskeleton and that the distribution of this network can be modulated by pyrin, indicating that this is a dynamic structure. Finally, we demonstrate that pyrin can recruit PSTPIP1 into aggregations (specks) of ASC, another pyrin binding protein. ASC specks are associated with inflammasome activity. PSTPIP1 molecules with PAPA-associated mutations are recruited by pyrin to ASC specks with particularly high efficiency, suggesting a unique mechanism underlying the robust inflammatory phenotype of PAPA syndrome.

Morbach\_H@klinik.uni-wuerzburg.de

Chronic non-bacterial osteomyelitis (CNO) is an inflammatory, non-infectious disorder of the skeletal system with unknown etiology. Besides bone-inflammation, patients may present with inflammatory involvement of other tissues. Chronic recurrent multifocal osteomyelitis (CRMO) is the most severe form of CNO. We describe the occurrence of Crohn's disease (CD) in four patients, previously diagnosed with CRMO. Mutations in CARD15, encoding the NOD2 protein, have recently been found in patients with CD. Based on the occurrence of CNO and CD in these four and several reported patients, we hypothesized that CD and CRMO might share a common autoinflammatory process. Thus, we searched for CD associated CARD15 gene variants R702W, G908R and 1007fs in 29 CNO patients, 4 of them additionally diagnosed with CD. In the latter one out of the four showed compound heterozygosity for the gene variants R702W and 1007fs. The allele frequency in the 25 patients diagnosed with CNO but not CD was not different from that already reported in healthy people (R702W 4.0%, G908R 2.0%, 1007fs 2.0%). The occurrence of non-bacterial bone inflammation and granulomatous intestinal inflammation seems to represent an extended phenotype of CD, which partly might be explained by potential disease causing mutations in CARD15. However, CNO without intestinal inflammation is not associated with common CARD15 gene variants. Therefore, other variants of genes coding for proteins involved in innate immunity and inflammation might predispose for the occurrence of CNO.

PFAPA is a periodic fever disease, of unknown etiology, characterized by aphthous stomatitis, pharyngitis and cervical adenitis. To inquire whether genes implicated in other auto-inflammatory diseases might be involved in its pathogenesis, predominant mutations in the genes causing familial Mediterranean fever, TNF receptor-associated periodic fever syndrome, Crohn's disease and Muckle-Wells syndrome were analyzed in PFAPA patients. Patients (n = 57) with PFAPA, according to previously published criteria were recruited, at the Meyer Children Hospital during 2006-2007. Clinical information was complemented during physicians-parents encounter. Predominant mutations in MEFV, TNF1rA, CARD15/NOD2 and NLRP3 genes were tested. Mean age at diagnosis was 30.64 +/- 16.4 months. Boys (n = 33; 58%) were diagnosed earlier than girls (n = 21; 42%) at 26.18 +/- 13.83 and 36.41 +/- 18.32 months, respectively (P = 0.05). Fifteen patients (27%) carried an MEFV mutation; two patients (3.6%) a CARD15 mutation, one patient (1.8%) a variance in TNF1rA and another had both an MEFV and a CARD15 mutation. Clinical symptoms were equally manifested in carriers and non-carriers. The high carrier rate of MEFV mutations in our PFAPA cases compares well with that of the general population in Israel. It is debated whether MEFV mutations, when mediated by the presence of additional modifiers, may expose a transient fever condition, namely PFAPA.

QT dispersion and transmural dispersion of repolarization in patients with familial Mediterranean fever.

Akcay A(1), Acar G, Sayarlioglu M, Sokmen A, Kaya H, Ispiroglu M, Koroglu S.

Author information:

(1)Department of Cardiology, Faculty of Medicine, Kahramanmaras Sutcuimam University, Kahramanmaras, Turkey. dr.akcay@yahoo.com.tr

Familial Mediterranean fever (FMF) is a disease characterized by sporadic, paroxysmal attacks of fever and serosal inflammation. QT dispersion (QTd) and transmural dispersion of repolarization (TDR), simple noninvasive arrhythmogenic markers, that can be used to assess homogeneity of cardiac repolarization, have not been studied in FMF patients before. The aim of our study was to evaluate the QTd and TDR in FMF patients without overt cardiac involvement. A total of 50 patients with FMF (30 men, 20 women, 29.4 +/- 11.8 years) and 50 controls (30 men, 20 women; mean age 31.3 +/- 11.9 years) were included. QTd, corrected QTd (cQTd), maximum QT (QTmax), maximum corrected QT (cQTmax), minimum QT (QTmin), and minimum corrected QT intervals (cQTmin) and TDR were measured from standard 12-lead electrocardiography (ECG). We found that QTd, QTmax, and TDR were greater in FMF patients than in the control group (36.0 +/- 11.4 vs. 20 +/- 11.2,  $P < 0.001$  and 354.8 +/- 30.9 vs. 342.8 +/- 18.0,  $P = 0.02$ ; 62.0 +/- 16.0 vs. 49.0 +/- 9.5  $P < 0.001$ , respectively), as were cQTd and cQTmax (40.4 +/- 13.5 vs. 21.9 +/- 12.4,  $P < 0.001$  and 397.7 +/- 40.2 vs. 375.5 +/- 25.4  $P = 0.001$ ). A modest positive correlation was found between cQTd and C-reactive protein (CRP) and erythrocyte sedimentation rate (ESR) ( $r = 0.30$ ,  $P < 0.001$ ;  $r = 0.40$ ,  $P < 0.001$ ; respectively). QTd, which is an index of inhomogeneity of ventricular repolarization and an important predictor of cardiovascular mortality, and TDR, which is a better marker of cardiac repolarization, increased in FMF patients similarly as in other rheumatologic diseases.

Childhood stroke in a child with familial Mediterranean fever carrying several prothrombotic risk factors.

Aoun EG(1), Musallam KM, Uthman I, Beydoun A, El-Hajj T, Taher AT.

Author information:

(1)Division of Hematology-Oncology, Department of Internal Medicine, American University of Beirut Medical Center, Beirut, Lebanon.

Familial Mediterranean fever (FMF) was recently associated with a hypercoagulable state. However, clinically overt thrombosis remains a rare event limited to patients with other predisposing factors. We herein present a child with FMF who experienced a stroke. An extensive thrombophilia work-up revealed multiple inherited and acquired risk factors. In areas with high prevalence of prothrombotic mutations and in children who are products of consanguineous marriages, early screening for concurrent thrombotic risk factors is warranted; as this may help design an optimal management plan and prevent unfavourable outcomes.

Progress in pediatric vasculitis.

O'Neil KM(1).

Author information:

(1)Division of Pediatric Rheumatology, University of Oklahoma Health Sciences Center, Oklahoma City, Oklahoma 73104, USA. kathleen-oneil@ouhsc.edu

**PURPOSE OF REVIEW:** To examine recent advances in the pathophysiology and therapy of pediatric vasculitis.

**RECENT FINDINGS:** The past 2 years have been marked by significant progress in extending novel techniques to the investigation of the two most common pediatric vasculitis syndromes, Henoch-Schonlein purpura and Kawasaki disease. Study of other vasculitides, such as Wegener granulomatosis, Churg-Strauss syndrome, and microscopic polyangiitis, is impeded by the small number of pediatric patients. Nonetheless, national and international registries are beginning to provide the foundation for generation of testable hypotheses regarding pathogenesis and optimal treatment. Thus, recent data from the study of children suggest that

disorders in the control of inflammation, such as those that underlie familial Mediterranean fever and other autoinflammatory diseases, may predispose to vasculitis. Improved knowledge of mechanisms of disease, in turn, should pave the way for more targeted, effective, and tolerable therapies for children with systemic vasculitis.

SUMMARY: International collaboration to study rare disorders such as pediatric vasculitis are demonstrating disorders of inflammatory regulation that predispose to these diseases and may point toward new treatment approaches.

Neurological manifestations of the Mendelian-inherited autoinflammatory syndromes.

Montealegre Sanchez GA(1), Hashkes PJ.

Author information:

(1)Rainbow Babies and Children's Hospital/Cleveland Clinic Joint Fellowship Program, Department of Pediatrics, Division of Infectious Diseases and Rheumatology, Cleveland, OH 44106, USA.

Autoinflammatory syndromes include an expanding list of conditions characterized by unprovoked recurrent attacks of systemic inflammation with lack of auto-antibodies or autoreactive T cells. Many of these syndromes are genetic diseases with a Mendelian inheritance. Neurological manifestations may be one of the major clinical features and, in some cases, the presenting symptom of these syndromes. The purpose of this review is to increase the recognition among neurologists of the Mendelian-inherited autoinflammatory syndromes by highlighting the neurological manifestations in the context of other symptoms that should lead physicians to suspect these syndromes. Most important for neurologists are the cryopyrin-associated periodic syndromes that include familial cold autoinflammatory syndrome, Muckle-Wells syndrome and neonatal-onset multisystem inflammatory disease (called chronic infantile neurological cutaneous and articular syndrome in Europe). We also review other syndromes with less

common neurological involvement, including familial Mediterranean fever, tumor necrosis factor receptor-associated periodic syndrome, and hyperimmunoglobulinemia D syndrome. Because these syndromes are often treatable and irreversible damage is prevented if they are treated early, it is important to recognize the features that may result in these syndromes presenting to a neurologist, especially in early childhood.

CTLA4 gene polymorphisms and soluble CTLA4 protein in Behcet's disease.

Park KS(1), Baek JA, Do JE, Bang D, Lee ES.

Author information:

(1)Department of Biology, Institute of Basic Science, Sungshin Women's University, Seoul, Korea.

Cytotoxic T lymphocyte antigen 4 (CTLA4; CD152) is a costimulatory molecule expressed on activated T cells that plays a key inhibitory role during T lymphocyte activation. The gene encoding for CTLA4 has been suggested as a candidate for conferring susceptibility to autoinflammatory diseases. We investigated the polymorphisms of the CTLA4 gene [promoter region (-1722 T/C, -1661 A/G and -318 C/T) and exon 1 (+49 G/A)] and the differences of serum soluble sCTLA4 levels in 285 patients with Behcet's disease (BD) and 287 controls. The frequency of the CTLA4 -1661 GG genotype was significantly higher in BD patients than in controls [ $P = 0.019$ , odds ratio (OR) = 5.2, 95% confidence interval (CI) = 1.13-23.86]. Also, the genotype frequency for CTLA4 -1722 TC was significantly higher ( $P = 0.014$ , OR = 1.8, 95% CI = 1.13-2.99), while CTLA4 -1722 CC was significantly lower ( $P = 0.018$ , OR = 0.4, 95% CI = 0.20-0.87) in BD patients with ocular lesions compared with patients without this symptom. Serum sCTLA4 levels in BD patients were significantly lower, especially in BD patients with the CTLA4 +49 G allele, than those in healthy controls ( $P < 0.05$ ). Although our understanding of the role of the CTLA4 gene and its protein product in BD is incomplete, these results suggest that single nucleotide polymorphisms of the

promoter and exon regions in the CTLA4 gene are candidates that predispose to BD and that sCTLA4 may be related to the immunological abnormalities and disease expressions associated with BD.

Immunoglobulin D (IgD) is an enigmatic antibody isotype that mature B cells express together with IgM through alternative RNA splicing. Here we report active T cell-dependent and T cell-independent IgM-to-IgD class switching in B cells of the human upper respiratory mucosa. This process required activation-induced cytidine deaminase (AID) and generated local and circulating IgD-producing plasmablasts reactive to respiratory bacteria. Circulating IgD bound to basophils through a calcium-mobilizing receptor that induced antimicrobial, opsonizing, inflammatory and B cell-stimulating factors, including cathelicidin, interleukin 1 (IL-1), IL-4 and B cell-activating factor (BAFF), after IgD crosslinking. By showing dysregulation of IgD class-switched B cells and 'IgD-armed' basophils in autoinflammatory syndromes with periodic fever, our data indicate that IgD orchestrates an ancestral surveillance system at the interface between immunity and inflammation.

Hereditary periodic fever syndromes (HPFSs) are a subset of human autoinflammatory diseases characterized by periodic episodes of fever and signs of inflammation with or without involvement of inner organs. In this paper, we report phenotypic features of an index patient and affected family members that present a previously not described mutation type in the TNFRSF1A gene. The phenotype of a HPFS of affected family members was shown to be associated with two monoallelic mutations in TNFRSF1A. Primarily, the index patient was clinically diagnosed as being affected by familial Mediterranean fever (FMF). However, with molecular genetic analyses, it could be shown that the patient was in fact affected by tumor necrosis factor receptor-associated periodic syndrome, which requires a different therapy when compared with FMF. Thus, molecular genetic analyses of currently known disease loci enable the most precise diagnosis presently available and are consequently the basis for the most effective therapeutic intervention.

**OBJECTIVE:** TNF receptor 1-associated periodic syndrome (TRAPS) is a rare disease belonging to the heterogeneous group of hereditary periodic fever (HPF) syndromes. By their monogenic origins, the HPF syndromes are clearly differentiated from other periodic inflammatory episodes occurring in autoimmune, neoplastic and infectious diseases. We aim to determine the incidence of TRAPS and the spectrum of mutations in the TNFRSF1A gene, and to give a brief survey of clinical signs.

**METHODS:** A prospective surveillance of children with TRAPS was conducted in Germany during a time period of 3 years (2003-06). Monthly inquiries were sent to 370 children's hospitals by the German Pediatric Surveillance Unit (Clinic-ESPED, n1) and to 23 laboratories (Laboratory-ESPED, n2). Inclusion criteria were TNFRSF1A mutation-positive patients < or =16 years of age, more than three self-limiting episodes of fever >38.5 degrees C, and increased inflammation markers. Clinical, epidemiological and genetic data were evaluated via questionnaires.

**RESULTS:** Of the 23 cases included, 19 were identical in 20 clinical and 22 laboratory reports. The incidence of TRAPS in German children was estimated to be approximately 5.6 per 10(7) person-years. In 20 TRAPS patients of the Clinic-ESPED, median age of onset and duration of fever periods were 6 (range 1-16) years and 6.3 (range 2-24) days, respectively. Main symptoms were

arthralgia, abdominal pain, lymphadenopathy, headache and skin involvement. The R92Q substitution was found in 19 (83%) of 23 cases.

CONCLUSION: The incidence of TRAPS is low and corresponds to 6-10 newly diagnosed patients < or =16 years per year in Germany.

Managing Behçet's disease: An update on current and emerging treatment options.

van Daele PL(1), Kappen JH, van Hagen PM, van Laar JA.

Author information:

(1)Department of Internal Medicine, Department of Immunology, Erasmus MC, 's Gravendijkwal 230, 3015 CE Rotterdam, The Netherlands.

Behçet's disease is an autoinflammatory vasculitis of unknown origin characterized by recurrent oral and genital ulcers, uveitis, arthritis and skin lesions. Additionally, involvement of the gastrointestinal tract, central nervous system and large vessels may occur. The disease is prevalent in countries along the ancient Silk Road from Eastern Asia to the Mediterranean Basin. Many treatment modalities are currently available. The choice of treatment depends on organ involvement and severity of disease. Topical treatment with corticosteroids is often sufficient for mucocutaneous involvement, however for more severe disease with vasculitis or neurological involvement a more aggressive approach is warranted. Newer drugs (biologicals) influencing cytokines and thereby T-cell function are promising with an acceptable side effect profile. Unfortunately, reimbursement of the costs of biologicals for rare disease is still a problem in various countries. In this report we discuss the current treatment modalities for Behçet's disease.

Antibodies directed to cyclic citrullinated peptides in familial Mediterranean fever.

Uyanik A(1), Albayrak F, Uyanik MH, Dursun H, Keles M, Cetinkaya R.

Author information:

(1)Division of Nephrology, Department of Internal Medicine, School of Medicine, Ataturk University, Erzurum, Turkey.

The aim of this study was to find the prevalence of anti-cyclic citrullinated peptide (anti-CCP) in patients with familial Mediterranean fever (FMF) and to examine the relationship between anti-CCP and joint findings. We measured the serum levels of the anti-CCP antibodies in patients with FMF (n = 55) and healthy

controls (n = 43). Serum levels of rheumatoid factor (RF), erythrocyte sedimentation rate (ESR), C-reactive protein (CRP), fibrinogen, ferritin, erythrocyte sedimentation rate (ESR), and white blood cell (WBC) were also measured in all the samples. Fibrinogen, ferritin, erythrocyte sedimentation rate (ESR), and RF levels were normal in the patient and the control groups ( $P > 0.05$ ). There was a significant difference in anti-CCP between the patient and the control groups ( $P = 0.008$ ). There was a positive correlation between arthritis and anti-CCP ( $P = 0.001$ ). In patients without arthritis, there was no significant relationship between abdominal pain or fever and anti-CCP ( $P > 0.05$ ). Anti-CCP levels increased in FMF patients with arthritis independent from acute phase reactants such as CRP, ESR, and fibrinogen. We conclude that in patients who are under investigation for arthritis, the ones with positive anti-CCP and negative RF, may be examined for FMF. In addition, we also conclude that it is very likely that FMF patients with anti-CCP antibodies will have signs of arthritis. On the other hand, it is possible that long-term follow-up of the FMF patients with anti-CCP antibodies may reveal the eventual development of inflammatory joint disease.

A clinical criterion to exclude the hyperimmunoglobulin D syndrome (mild mevalonate kinase deficiency) in patients with recurrent fever.

Steichen O(1), van der Hilst J, Simon A, Cuisset L, Grateau G.

Author information:

(1)Service de médecine interne, Hôpital Tenon, 4 rue de la Chine, F-75020 Paris, France. olivier.steichen@tnn.aphp.fr

**OBJECTIVE:** The hyperimmunoglobulin D syndrome (HIDS) is an autosomal recessive autoinflammatory disease caused by mutations in the mevalonate kinase gene. Our objective was to define a clinical criterion able to exclude HIDS without the need of genetic testing.

**METHODS:** A recursive partitioning algorithm was applied to derive the clinical

criterion in 149 patients with genetic testing in a French laboratory, among whom 35 had HIDS. The criterion was validated in 93 patients with genetic testing in a Dutch laboratory, among whom 28 had HIDS.

RESULTS: The most discriminatory composite clinical criterion satisfied by all patients with HIDS in the derivation group was [onset age < 5 years old OR (joint pain during attacks AND length of attacks < 14 days)]. It had a sensitivity of 100% (95% confidence interval 88% to 100%) and a specificity of 28% (95% CI 17% to 40%) in the validation group. If genetic testing had been limited to patients fulfilling this criterion, 18 tests (19%) would have been avoided in this highly selected validation sample, without missing a single patient with HIDS.

CONCLUSION: Even among patients already selected by expert physicians, this criterion could help prevent unnecessary genetic testing, which is resource- and time-consuming.

Clinical and genetic features of familial Mediterranean fever in Japan.

Tsuchiya-Suzuki A(1), Yazaki M, Nakamura A, Yamazaki K, Agematsu K, Matsuda M, Ikeda S.

Author information:

(1)Departments of Medicine (Neurology and Rheumatology) and Pediatrics, Shinshu University School of Medicine, Matsumoto; and the National Center of Neurology and Psychiatry, Tokyo, Japan.

OBJECTIVE: Familial Mediterranean fever (FMF) is thought to be a rare disorder in Japan, and the clinical features of Japanese patients with FMF remain unclear. Our aim was to elucidate the clinical characteristics of FMF in Japanese patients.

METHODS: We analyzed clinical and genetic data of 80 patients based on the results of a nationwide questionnaire survey and review of the literature.

RESULTS: From clinical findings of 80 Japanese patients, high-grade fever was observed in 98.8%, chest attacks (pleuritis symptoms) in 61.2%, abdominal attacks (peritonitis symptoms) in 55.0%, and arthritis in 27.5%. Twenty-four percent of

patients experienced their first attacks before 10 years of age, 40% in their teens, and 36% after age 20 years. Colchicine was effective in many patients at a relatively low dose (< 1.0 mg/day). AA amyloidosis was seen in only 1 patient. Common MEFV mutation patterns were E148Q/M694I (25.0%), M694I alone (17.5%), and L110P/E148Q/M694I (17.5%), and no patient carried the M694V mutation, the most common mutation in Mediterranean patients with FMF.

CONCLUSION: A larger than expected number of patients with FMF exist in Japan, and the clinical presentation of Japanese FMF patients seems to be relatively milder than those of Mediterranean FMF patients. AA amyloidosis rarely occurs in Japanese patients, probably due to difference in patterns of the MEFV genotype between Japanese and Mediterranean patients.

Familial Mediterranean Fever (FMF) is the most frequent periodic febrile syndrome among the autoinflammatory syndromes (AS), nowadays considered as innate immunity disorders, characterized by absence of autoantibodies and autoreactive T lymphocytes. FMF is a hereditary autosomal recessive disorder, characterized by recurrent, self-limiting episodes of short duration (mean 24e72 h) of fever and serositis. In FMF, periodic attacks show inter- and intra-individual variability in terms of frequency and severity. Usually, they are triggered by apparently innocuous stimuli and may be preceded by a prodromal period. The Mediterranean FeVer gene (MEFV) responsible gene maps on chromosome 16 (16p13) encoding the Pyrine/Marenostrin protein. The precise pathologic mechanism is still to be definitively elucidated; however a new macromolecular complex, called inflammasome, seems to play a major role in the control of inflammation and it

might be involved in the pathogenesis of FMF. The most severe long-term complication is type AA amyloidosis, causing chronic renal failure. Two types of risk factors, genetic and non-genetic, have been identified for this complication. Currently, the only effective treatment of FMF is the colchicine. New drugs in a few colchicine resistant patients are under evaluation

Weber-Christian Disease (WCD), also known as relapsing febrile lobular non-suppurative panniculitis, is a rare condition characterized by recurrent subcutaneous inflammatory nodules in the adipose tissue in addition to fever, malaise and other systemic manifestations such as polyarthralgia and polymyalgia. The association with small vessel vasculitis has been rarely reported. We report here an unusual case of WCD associated with small vessels vasculitis also describing the efficacy of Cyclosporin A treatment.

Association between familial mediterranean fever and retroperitoneal fibrosis:

retroperitoneal fibrosis regression after colchicine therapy.

De Socio G, Cerquaglia C, Curigliano V, Fonnesu C, Giovinale M, Verrecchia E, Marino GM, Natale L, Gasbarrini GB, Manna R.

Retroperitoneal fibrosis (RPF) is a disease characterized by inflammatory fibrotic processes affecting the retroperitoneal structures. Familial Mediterranean Fever (FMF) is an autosomal recessive disorder, characterized by fever and attacks of sterile serositis. Colchicine is the only suitable drug for prevention of acute episodes. We describe a case of association between RPF and FMF in a 48-year-old male, in whom therapy with colchicine, besides preventing acute episodes, allowed RPF regression. To date the association between FMF and RPF and the use of colchicine therapy alone for RPF has not been described.

Missense mutations of the gene encoding NLRP3 are associated with autoinflammatory disorders characterized with excessive production of interleukin-1beta (IL-1beta). Here we analyzed the immune responses of gene-targeted mice carrying a mutation in the Nlrp3 gene equivalent to the human mutation associated with Muckle-Wells Syndrome. We found that antigen-presenting

cells (APCs) from such mice produced massive amounts of IL-1beta upon stimulation with microbial stimuli in the absence of ATP. This was likely due to a diminished inflammasome activation threshold that allowed a response to the small amount of agonist. Moreover, the Nlrp3 gene-targeted mice exhibited skin inflammation characterized by neutrophil infiltration and a Th17 cytokine-dominant response, which originated from hematopoietic cells. The inflammation of Nlrp3 gene-targeted mice resulted from excess IL-1beta production from APCs, which augmented Th17 cell differentiation. These results demonstrate that the NLRP3 mutation leads to inflammasome hyperactivation and consequently Th17 cell-dominant immunopathology in autoinflammation.

NLRP3 nucleates the inflammasome, a protein complex responsible for cleavage of prointerleukin-1beta (IL-1beta) to its active form. Mutations in the NLRP3 gene cause the autoinflammatory disease spectrum cryopyrin-associated periodic syndromes (CAPS). The central role of IL-1beta in CAPS is supported by the response to IL-1-targeted therapy. We developed two Nlrp3 mutant knockin mouse

strains to model CAPS to examine the role of other inflammatory mediators and adaptive immune responses in an innate immune-driven disease. These mice had systemic inflammation and poor growth, similar to some human CAPS patients, and demonstrated early mortality, primarily mediated by myeloid cells. Mating these mutant mice to various gene mutant backgrounds showed that the mouse disease phenotype required an intact inflammasome, was only partially dependent on IL-1 $\beta$ , and was independent of T cells. These data suggest that CAPS are true inflammasome-mediated diseases and provide insight for more common inflammatory disorders.

We describe a patient with an autoinflammatory disease in which the main clinical features are pustular rash, marked osteopenia, lytic bone lesions, respiratory insufficiency, and thrombosis. Genetic studies revealed a 175-kb homozygous deletion at chromosome 2q13, which encompasses several interleukin-1 family members, including the gene encoding the interleukin-1-receptor antagonist (IL1RN). Mononuclear cells, obtained from the patient and cultured, produced large amounts of inflammatory cytokines, with increasing amounts secreted after stimulation with lipopolysaccharide. A similar increase was not observed in peripheral-blood mononuclear cells from a patient with neonatal-onset multisystem inflammatory disorder (NOMID). Treatment with anakinra completely resolved the symptoms and lesions.

Comment in

N Engl J Med. 2009 Jun 4;360(23):2467-70.

**BACKGROUND:** Autoinflammatory diseases manifest inflammation without evidence of infection, high-titer autoantibodies, or autoreactive T cells. We report a disorder caused by mutations of IL1RN, which encodes the interleukin-1-receptor antagonist, with prominent involvement of skin and bone.

**METHODS:** We studied nine children from six families who had neonatal onset of sterile multifocal osteomyelitis, periostitis, and pustulosis. Response to empirical treatment with the recombinant interleukin-1-receptor antagonist anakinra in the first patient prompted us to test for the presence of mutations and changes in proteins and their function in interleukin-1-pathway genes including IL1RN.

**RESULTS:** We identified homozygous mutations of IL1RN in nine affected children, from one family from Newfoundland, Canada, three families from The Netherlands, and one consanguineous family from Lebanon. A nonconsanguineous patient from Puerto Rico was homozygous for a genomic deletion that includes IL1RN and five other interleukin-1-family members. At least three of the mutations are founder mutations; heterozygous carriers were asymptomatic, with no cytokine abnormalities in vitro. The IL1RN mutations resulted in a truncated protein that is not secreted, thereby rendering cells hyperresponsive to interleukin-1 $\beta$  stimulation. Patients treated with anakinra responded rapidly.

**CONCLUSIONS:** We propose the term deficiency of the interleukin-1-receptor antagonist, or DIRA, to denote this autosomal recessive autoinflammatory disease caused by mutations affecting IL1RN. The absence of interleukin-1-receptor antagonist allows unopposed action of interleukin-1, resulting in life-threatening systemic inflammation with skin and bone involvement.

**BACKGROUND:** The cryopyrin-associated periodic syndrome (CAPS) is a rare inherited inflammatory disease associated with overproduction of interleukin-1. Canakinumab is a human anti-interleukin-1beta monoclonal antibody.

**METHODS:** We performed a three-part, 48-week, double-blind, placebo-controlled, randomized withdrawal study of canakinumab in patients with CAPS. In part 1, 35 patients received 150 mg of canakinumab subcutaneously. Those with a complete response to treatment entered part 2 and were randomly assigned to receive either 150 mg of canakinumab or placebo every 8 weeks for up to 24 weeks. After the completion of part 2 or at the time of relapse, whichever occurred first, patients proceeded to part 3 and received at least two more doses of canakinumab. We evaluated therapeutic responses using disease-activity scores and analysis of levels of C-reactive protein (CRP) and serum amyloid A protein (SAA).

**RESULTS:** In part 1 of the study, 34 of the 35 patients (97%) had a complete response to canakinumab. Of these patients, 31 entered part 2, and all 15 patients receiving canakinumab remained in remission. Disease flares occurred in 13 of the 16 patients (81%) receiving placebo ( $P<0.001$ ). At the end of part 2, median CRP and SAA values were normal ( $<10$  mg per liter for both measures) in patients receiving canakinumab but were elevated in those receiving placebo ( $P<0.001$  and  $P=0.002$ , respectively). Of the 31 patients, 28 (90%) completed part 3 in remission. In part 2, the incidence of suspected infections was greater in the canakinumab group than in the placebo group ( $P=0.03$ ). Two serious adverse events occurred during treatment with canakinumab: one case of urosepsis and an episode of vertigo.

**CONCLUSIONS:** Treatment with subcutaneous canakinumab once every 8 weeks was associated with a rapid remission of symptoms in most patients with CAPS.

Familial Mediterranean fever (FMF) is the most common of the hereditary periodic fevers. FMF is an autosomal recessive disease that affects populations among non-Ashkenazi Jews, Arabs, Turks, and Armenians. Yet, it is observed worldwide, and approximately 90 FMF patients have been reported in Japan. FMF is caused by mutations in the MEFV gene, which encodes the pyrin protein. Pyrin protein is associated with the interleukin (IL)-1-related inflammation cascade and involved in the regulation of apoptosis and inflammation. The clinical characteristics of FMF attacks are fever, abdominal pain, chest pain, and arthritis as symptoms of serositis. Reactive or secondary AA amyloidosis is the most devastating complication of FMF. As amyloid slowly accumulates in various organs and tissues, organ dysfunction ensues prominently in the kidneys. Colchicine has been used in the treatment of FMF, and has markedly changed the course of the disease. Although over 80 mutations in the MEFV gene have been reported, the majority of cases are caused by four mutations in exon 10: M694V, M694I, V726A, and M680I. The majority of Japanese FMF patients are compound heterozygous for M694I/E148Q. E148Q, which is found in populations of Japanese and Chinese, is considered to be a functional polymorphism. It is intriguing that about 10% of Japanese FMF patients have the L110P mutation in addition to E148Q in the same allele. Allelic frequencies of MEFV mutations and polymorphisms in 500 normal Japanese individuals were 0% for M694I and 23% for E148Q, respectively. In conclusion, FMF

is not a rare disease in Japan, and it is necessary to consider FMF when a patient experiences recurrent attacks of fever and serositis.

It is known that type 1 diabetes mellitus (type 1 DM) may be associated with other autoimmune diseases. Recently, a patient with an association of type 1 DM and familial Mediterranean fever (FMF) was reported in the medical literature. A 10.5-year-old boy was brought to our clinic with complaints of polydipsia, polyuria and weight loss and was diagnosed as diabetic ketoacidosis due to autoimmune type 1 DM. Insulin therapy was started. Elevated thyroid antibodies associated with diffuse goiter and hypothyroidism led to the diagnosis of autoimmune thyroid disease (ATD), and elevated antiendomysial antibodies and abnormal intestinal biopsy findings led to the diagnosis of celiac disease (CD).

L-thyroxine therapy and gluten-free diet were initiated accordingly. At the third-year of follow-up, acute attacks of fever, abdominal pain and chest pain developed. Laboratory investigations, which were normal between the attacks, revealed elevated erythrocyte sedimentation rate, fibrinogen, white blood cell count and pleural effusion on chest X-ray during the attacks. Molecular analysis for FMF revealed compound heterozygous M694I and V726A. The patient responded well to colchicine therapy started at a dose of 1.5 mg/day. We present the second patient with type 1 DM associated with FMF who also had ATD and CD.

Comment in

Arthritis Rheum. 2009 Jun;60(6):1575-7.

**OBJECTIVE:** To define the molecular basis of familial Mediterranean fever (FMF) in patients with only 1 mutation in the MEFV gene.

**METHODS:** Genetic analysis was performed in 20 FMF patients, including full sequencing of complementary DNA (cDNA) samples and multiplex ligation-dependent probe amplification analysis. In patients with first-degree relatives with FMF, haplotype analysis was also performed.

**RESULTS:** A second mutation was found in 2 patients. In the other 18 patients, we could not identify additional mutations, large genomic deletions, or duplications. Analysis of single-nucleotide polymorphisms along the cDNA ruled out a lack of expression of 1 of the alleles. In 2 of the 3 families in which more than 1 sibling had FMF, we showed that the affected siblings inherited a different MEFV allele from the parent who did not have the MEFV mutation.

**CONCLUSION:** These findings are highly consistent with the existence of a clinical phenotype among some patients who are heterozygous for FMF and could explain the vertical transmission in some families. A single mutation in the MEFV gene may be much more common than was previously thought and may include up to 25% of patients who are diagnosed as having FMF.

Comment in

Arthritis Rheum. 2009 Jun;60(6):1575-7.

**OBJECTIVE:** Familial Mediterranean fever (FMF) has traditionally been considered an autosomal-recessive disease; however, it has been observed that a substantial number of patients with clinical FMF possess only 1 demonstrable MEFV mutation. The purpose of this study was to perform an extensive search for a second MEFV mutation in 46 patients diagnosed clinically as having FMF and carrying only 1 high-penetrance FMF mutation.

**METHODS:** MEFV and other candidate genes were sequenced by standard capillary electrophoresis. In 10 patients, the entire 15-kb MEFV genomic region was resequenced using hybridization-based chip technology. MEFV gene expression levels were determined by quantitative reverse transcription-polymerase chain reaction. Pyrin protein levels were examined by Western blotting.

**RESULTS:** A second MEFV mutation was not identified in any of the patients who were screened. Haplotype analysis did not identify a common haplotype that might be associated with the transmission of a second FMF allele. Western blots did not

demonstrate a significant difference in pyrin levels between patients with a single mutation and those with a double mutation; however, FMF patients of both types showed higher protein expression as compared with controls and with non-FMF patients with active inflammation. Screening of genes encoding pyrin-interacting proteins identified rare mutations in a small number of patients, suggesting the possibility of digenic inheritance.

CONCLUSION: Our data underscore the existence of a significant subset of FMF patients who are carriers of only 1 MEFV mutation and demonstrate that complete MEFV sequencing is not likely to yield a second mutation. Screening for the set of the most common mutations and detection of a single mutation appears to be sufficient in the presence of clinical symptoms for the diagnosis of FMF and the initiation of a trial of colchicine.

Author information:

(1)Department of Internal Medicine, Medical Faculty of Cumhuriyet University, Sivas, Turkey.

**OBJECTIVE:** The aim of this study was to assess the frequency of atherosclerotic plaques and intima-media thickness (IMT) in patients with FMF and suitable controls.

**METHODS:** We studied 100 (46 males, 54 females; mean age: 40 +/- 6 years) patients with FMF. Also 94 (15 males, 79 females; mean age: 41 +/- 7 years) patients with SLE and 103 (44 males, 59 females; mean age: 40 +/- 5 years) apparently healthy volunteers were included as the control groups. Subclinical atherosclerosis was assessed by investigating atherosclerotic plaques and measuring IMT from carotid and common femoral arteries using B-mode ultrasonography (USG). Traditional atherosclerotic risk factors were also assessed.

**RESULTS:** Both FMF and SLE patients had significantly higher carotid (C-IMT) and femoral artery IMT (F-IMT) compared with healthy controls. This was also true after adjustment for atherosclerotic risk factors. Only patients with SLE were found to have higher frequency of atherosclerotic plaques in the carotid and in the carotid and/or femoral artery. When all atherosclerotic risk factors were adjusted, again only patients with SLE were found to have risk for atherosclerotic plaques. In FMF, whereas the presence of atherosclerotic plaques was only associated significantly with diabetes mellitus; C-IMT was correlated with age, BMI and fasting glucose; and F-IMT with age and BMI.

**CONCLUSIONS:** Increased atherosclerosis defined as the presence of plaques was not observed in patients with FMF. The significance of increased C- and F-IMT among patients with FMF must be further assessed.

The discovery of MEFV as the susceptibility gene for autosomal recessive Familial Mediterranean Fever (FMF) in 1997 represents the beginning of the new era of the monogenic autoinflammatory diseases. During the last decade, the increasing knowledge on the pathogenic mechanisms related to a number of diseases associated to mutations of genes associated to autoinflammatory diseases had a terrific impact on the understanding of pivotal mechanisms regulating the inflammatory response and therefore represents one of the major advance in the field of inflammation. The International Congress on Familial Mediterranean Fever and Systemic Autoinflammatory Diseases brings together the experts in the field every two and a half years and represents a unique opportunity for an update on the recent progress in this growing field. The fifth edition of the congress was held in Rome (Italy, 4-8 April 2008). Most of the contributions to this meeting have been published during the course of the present year. Thus, the aim of the present article is to report the main highlights from the above-mentioned meeting and to give a general update of the more recent advances in this field.

Familial Mediterranean fever (FMF) is a systemic autoinflammatory disorder characterized by seemingly unprovoked recurrent episodes of fever and serosal, synovial, or cutaneous inflammation. FMF is caused by recessively inherited mutations in MEFV, which encodes pyrin, and most of the mutations are present in the C-terminal end of the protein encoding B30.2 domain. The FMF carrier frequencies are extremely high in several eastern Mediterranean populations. Pyrin is expressed in granulocytes, monocytes, dendritic cells, and synovial fibroblasts. Pyrin regulates caspase-1 activation and consequently interleukin-1 $\beta$  production through the interactions of its N-terminal PYRIN domain and C-terminal B30.2 domain with an adaptor protein, apoptosis-associated speck-like protein with a caspase-recruitment domain (ASC) and caspase-1 respectively. Pyrin is cleaved by caspase-1 and the cleaved N-terminal fragment translocates to nucleus and enhances ASC-independent nuclear factor (NF)- $\kappa$ B activation through interactions with p65 NF- $\kappa$ B and I $\kappa$ B- $\alpha$ . In addition to the regulatory role of pyrin for caspase-1, the cleavage of pyrin provides an important clue not only in understanding the molecular pathogenesis of FMF but also in developing new therapeutic targets for FMF.

kinukom-tky@umin.ac.jp.

Familial Mediterranean fever (FMF) is a recessively inherited disease characterized by recurrent episodes of systemic inflammation. The cause of this disease is the mutations affecting both the alleles of MEFV gene. We describe here a case in a heterozygous MEFV mutation complicated with myelodysplastic syndrome (MDS). Clinical symptoms and the effectiveness of colchicines in this patient are typical for FMF. The first attack of FMF in this patient was observed during immunosuppressive therapy for MDS. This case suggests the possibility that certain immunosuppressants may trigger FMF attack in asymptomatic cases carrying MEFV heterozygous mutation.

Comment in

Rheumatol Int. 2011 Jul;31(7):979-80.

Familial Mediterranean fever (FMF) is hereditary episodic febrile syndrome characterized by acute attacks of fever and serosal inflammation, generally lasting 1-3 days and resolves spontaneously. Apart from abdominal pain, patients may present with variety of abdominal manifestations such as acute peritonitis, mechanical intestinal obstruction, diarrhea, bowel infarction, amyloidosis and small amounts of peritoneal fluid during the acute attacks. A 6-year-old boy was admitted with massive ascites. After extensive laboratory investigations, no causative agent could be identified. On subsequent days, he developed fever and skin eruptions. Acute-phase reactants were increased. A second tomography revealed cystic fluid collection near the anterior side of spleen that invades the stomach. An exploratory was performed and histopathological examination of the all resected specimens revealed mix inflammatory cell infiltrate associated with severe myofibroblast proliferation suggesting chronic inflammatory process on the mesenteric region. A diagnosis of FMF was suspected based on the clinical, laboratory and histopathological findings, and a trial of colchicine therapy initiated. Ascites and other serosal inflammations improved within 1 week without any recurrence during the next 12-month period on colchicine treatment. Atypical presentations of FMF have been increasingly reported. Pediatricians should keep FMF in mind in the differential diagnosis of massive ascites especially in regions where hereditary inflammatory disease are common.

**OBJECTIVE:** To assess the clinical characteristics of patients living in France and carrying a single MEFV mutation.

**METHOD:** A retrospective chart review of patients referred to us for recurrent fevers. Genetic testing: systematic screening of exons 2 and 10 was performed in the MEFV gene. A subset of patients was also investigated for other auto-inflammatory genes.

**RESULTS:** We analysed 94 patients (sex ratio:1). Forty-two percent of them were Jews and 17% were Arabs. The median age of onset was 2 years (3 months-47 years). Fever was >39 degrees C in 80% of them, while the duration and frequency of an attack varied (<24 h: 8%; 1-3 days: 56%; >3 days: 36%; >2 months: 15%; 1-2 months: 48%; and <1 month: 37%, respectively). Peritonitis occurred in 97%, pleuritis in 25%, arthralgia in 53%; skin rashes in 20%, aphthosis in 18% and lymphadenopathy in 9%. MEFV mutations were M694V (60%) and M694I (7%). The R92Q TRAPS mutation was retrieved in 3/21 patients tested and the V377I MKD mutation in 1/6. Associated diseases in these patients were periodic fever, aphthosis pharyngitis and adenitis syndrome (4), AS (5), Crohn's disease (2) and Castleman's disease (1).

**CONCLUSION:** The clinical picture of French heterozygote patients with recurrent fevers resembles that of homozygote patients. Most of them required colchicine treatment.

MEFV mutations in patients with Familial Mediterranean Fever from the Aegean region of Turkey.

Akin H(1), Onay H, Turker E, Cogulu O, Ozkinay F.

Author information:

(1)Medical Faculty, Department of Medical Genetics, Ege University, Izmir, Turkey. akin63@yahoo.com

Familial Mediterranean Fever (FMF) which is frequently present in Mediterranean populations is caused by mutations in the MEFV gene. According to recent data, MEFV mutations are not the only cause of FMF, but these are major genetic determinants which cause FMF. It has also been suggested that there may be a number of other genes causing FMF. The MEFV gene is located at 16p13.3 and encodes a protein, pyrin/marenostrin. More than 70 disease associated mutations and totally 186 mutations and polymorphisms have been defined in affected individuals. We have retrospectively evaluated the molecular test results of 1,201 patients identified as having FMF clinical symptoms referred to the Molecular Genetics Laboratory of the Department of Medical Genetics, Faculty of Medicine, Ege University, Izmir/Turkey over the last 4 years. Patients were tested for 12 common mutations in the MEFV gene using a strip assay method (Innogenetics, Belgium). Out of the 1,201 patients tested (2,402 chromosomes) in the Aegean region in Turkey, 654 (54.45%) did not carry any mutations, among the 547 (45.55%) patients with mutations 246 patients were either homozygous (101) or compound heterozygous (145), 296 carried only one detected mutation, and five patients had three mutations. Allelic frequencies for the four most common mutations in the mutation positive groups were 47.60% (M694V), 16.75% (E148Q), 12.95% (V726A), 11.94% (M680I G/C). The remaining alleles (10.76%) showed rare mutations which were R761H, P369S, A744S, K695R, F479L, M694I. When the frequencies of mutations detected in our group were compared to the frequencies reported in the other regions of Turkey, an increase in V726A mutation frequency was observed. No patient showed a I692del mutation which is sometimes evident in other Mediterranean populations.

(1)Department of Physical Medicine, Medical Faculty, Ataturk University, Erzurum, Turkey. kadiryildirim88@hotmail.com

This study was carried out to determine lumbar and femoral bone mineral density (BMD) in patients with familial Mediterranean fever (FMF), an autosomal-recessive disease characterized by recurrent episodes of peritonitis, pleuritis, and arthritis, which are usually associated with fever. In patients with FMF and control subjects, erythrocyte sedimentation rate (ESR) and C-reactive protein (CRP) were measured. BMD was determined at the lumbar spine (L1-4) and the femoral regions (neck and total) using dual energy X-ray absorptiometry. Twenty-eight FMF patients and 30 control subjects without a history of inflammatory disease participated in our study. The demographic variables, such as age, sex and body mass index were similar between patients and controls ( $P > 0.05$ ). We found statistically significant difference in ESR and CRP between FMF patients and controls ( $P < 0.01$ ,  $P < 0.05$  respectively). There was statistically significant difference in lumbar spine, femoral neck, and total femur BMD between FMF patients and control groups ( $P < 0.001$ ,  $P < 0.01$ ,  $P < 0.01$  respectively). Our study indicates that lumbar spine and femoral neck and total femur BMD in patients with FMF may be lower than in healthy subjects.

J Am Soc Nephrol. 2009 Aug;20(8):1654-6.

Small-vessel vasculitis (SVV) is a chronic autoinflammatory condition linked to antineutrophil cytoplasm autoantibodies (ANCA). Here we show that chromatin fibers, so-called neutrophil extracellular traps (NETs), are released by ANCA-stimulated neutrophils and contain the targeted autoantigens proteinase-3 (PR3) and myeloperoxidase (MPO). Deposition of NETs in inflamed kidneys and circulating MPO-DNA complexes suggest that NET formation triggers vasculitis and promotes the autoimmune response against neutrophil components in individuals with SVV.

It has been suggested that MEVF mutations offer advantage against infections, including tuberculosis. Bearing in mind the central role of TLR-2 and TLR-4 in the recognition of pathogens, we conducted this study to examine whether the TLR2-R753Q, TLR4-D299G, TLR4-T399I common polymorphisms are associated with susceptibility to familial Mediterranean fever (FMF) or affect the course of the disease. A cohort of 169 FMF patients and 245 healthy bone marrow donors were enrolled in the study. FMF patients appeared with a significantly lower frequency

of the TLR4-D299G mutated allele (3.2% vs 6.9%,  $p = 0.032$ ). No association was observed with the other analyzed polymorphisms. Moreover, we found no association between polymorphisms and the frequency of attacks or the development of amyloidosis. Our results may reinforce the hypothesis that FMF patients display a better defense against pathogens, providing an additional mechanism and suggesting a positive selection advantage in the area of the Mediterranean basin.

Author information:

(1)Division of Clinical Immunology, 3rd Department of Medicine, Medical and Health Science Center, University of Debrecen, Moricz Zs. Str. 22, Debrecen 4004, Hungary. zold\_eva@yahoo.com

Crohn's disease (CD) is a chronic relapsing and remitting autoinflammatory disorder of the gastrointestinal tract that has many intestinal and extraintestinal complications. The purpose of treatment is long-term remission, reduction of complications, and improvement of patients' quality of life. In many cases, this can be quite challenging and it is necessary to have a well thought out management strategy. We present the case of a 38-year-old woman with fistulizing CD that manifested as diffuse abdominal pain and bloody diarrhea accompanied by arthralgia. In addition, there were ulcerative lesions surrounded by cutaneous inflammation and erythema on her extremities, indicative of pyoderma gangrenosum. The patient was treated with high doses of parenteral methylprednisolone without any improvement and was started on adalimumab. A positive response to adalimumab therapy was observed: after 2 mo of therapy, the ulcerative skin lesion healed completely and the enterogastric fistula was closed after 5 mo adalimumab treatment. Adalimumab might be a suitable initial as well as maintenance therapy in patients with complicated CD.

[Autoinflammatory syndromes].

[Article in German]

Lamprecht P(1), Gross WL.

Author information:

(1)Poliklinik für Rheumatologie, Vaskulitzszentrum UKSH & Klinikum Bad Bramstedt, Universität zu Lübeck, Ratzeburger Allee 160, 23538 Lübeck.

In its strict sense, the term "autoinflammatory syndromes" comprises the hereditary periodic fever syndromes (HPF), which are caused by mutations of pattern-recognition receptors (PRR) and perturbations of the cytokine balance. These include the cryopyrinopathies, familial Mediterranean fever, TNF-receptor associated periodic fever syndrome (TRAPS), hyper-IgD and periodic syndrome (HIDS), pyogenic sterile arthritis, pyoderma gangrenosum and acne (PAPA) syndrome, NALP12-HPF, and the Blau syndrome. The diseases are characterized by spontaneous activation of cells of the innate immunity in the absence of ligands. Autoantibodies are usually not found. HPF clinically present with recurrent fever episodes and inflammation, especially of serosal and synovial interfaces and the skin. Intriguingly, PRR-mediated autoinflammatory mechanisms also play a role in a number of chronic inflammatory and autoimmune diseases.

Consanguineous marriages in Morocco and the consequence for the incidence of autosomal recessive disorders.

Jaouad IC(1), Elalaoui SC, Sbiti A, Elkerh F, Belmahi L, Sefiani A.

Author information:

(1)Department of Medical Genetics, National Institute of Health, Rabat, Morocco.

Consanguineous marriage is traditionally common throughout Arab countries. This leads to an increased birth prevalence of infants with recessive disorders, congenital malformations, morbidity and mortality. The aim of this study was to evaluate the rate of consanguineous marriage in families with autosomal recessive diseases, and to compare it with the average rate of consanguinity in the Moroccan population. The study was conducted in the Department of Medical Genetics in Rabat on 176 families with autosomal recessive diseases diagnosed and confirmed by clinical, radiological, enzymatic or molecular investigations. The rate of consanguinity was also studied in 852 families who had infants with trisomy 21 confirmed by karyotyping. These families were chosen because: (i) there is no association between trisomy 21 and consanguinity, (ii) these cases are referred from different regions of Morocco and (iii) they concern all social statuses. Among 176 families with autosomal recessive disorders, consanguineous marriages comprised 59.09% of all marriages. The prevalence of consanguinity in Morocco was found to be 15.25% with a mean inbreeding coefficient of 0.0065. The differences in the rates of consanguineous marriages were highly significant when comparing the general population and couples with offspring affected by autosomal recessive conditions. These results place Morocco among the countries in the world with high rates of consanguinity. Autosomal recessive disorders are strongly associated with consanguinity. This study better defines the health risks associated with consanguinity for the development of genetic educational guidelines targeted at the public and the health sector.

Rapidly progressive glomerulonephritis in a child with Henoch-Schönlein Vasculitis and familial Mediterranean fever.

Sozeri B(1), Mir S, Ertan P, Kara OD, Sen S.

Author information:

(1)Department of Pediatric Nephrology, Faculty of Medicine, Ege University, Izmir, Turkey. betulsozeri@yahoo.com.

Henoch-Schonlein Vasculitis (HSV) is systemic small vessel vasculitis involving the skin, kidney, joints, and gastrointestinal tract. The proportion of patients reported to have renal involvement varies between 20% and 80%. Rapidly progressive glomerulonephritis (RPGN) is rare syndrome in children, characterized by clinical features of glomerulonephritis (GN) and rapid loss of renal function. We present a severe kidney involvement in a 14 year old boy with HSV in who is carrying MEFV mutation. A 14 year old boy had developed sudden onset of palpable purpuric rash on his extensor surfaces of lower extremities. He had elevated an erythrocyte sedimentation rate (ESR) (45 mm/h), C-reactive protein (3.74 mg/dl), serum urea 66 mg/dl, serum creatinine 1.8 mg/dl. Also, he had hypocomplementemia. Antinuclear antibody, anti ds DNA, antineutrophil cytoplasmic antibody, anticardiolipine antibodies were negative. Urinalysis revealed macroscopic hematuria and proteinuria with a 24-h urinary protein excretion of 55 mg/m<sup>2</sup>/h. The renal biopsy specimen showed crescentic and necrotizing glomerulonephritis. He had also M694V/E148Q compound heterozygote mutation. Clinical symptoms and renal failure resolved with intermittent hemodialysis and medical therapy.

Recurrent febrile syndromes: what a rheumatologist needs to know.

Hoffman HM(1), Simon A.

Author information:

(1)University of California at San Diego, La Jolla, CA 92093, USA.  
hahoffman@ucsd.edu

Rheumatologists are likely to be asked to evaluate patients with recurrent febrile syndromes, so it is important that they are familiar with the clinical

and diagnostic features, pathophysiology and therapeutic options for these rare autoinflammatory disorders. These syndromes are all characterized by recurrent episodes of fever and systemic inflammation; however, some syndromes have unique historical and physical features that can help with making a diagnosis. The primary associated morbidity is systemic amyloidosis, usually with renal involvement. Diagnostic testing is mostly limited to genetic testing. NSAIDs, colchicine and corticosteroids have roles in the treatment of some of these disorders, but biologic drugs that target interleukin-1beta are emerging as consistently effective therapies.

Screening for Familial Mediterranean Fever M694V and V726A mutations in the Greek population.

Gkretsi V, Deltas C, Yapijakis C, Lamnissou K.

Familial Mediterranean Fever (FMF) is an autosomal recessive genetic disease that primarily affects populations surrounding the Mediterranean basin. FMF patients suffer from recurrent episodes of fever accompanied by abdominal pain, pleuritis, and arthritis. Missense mutations in the gene for FMF (MEFV) have been shown to

be responsible for the disease, while more than 70 mutations have been identified to date. The aim of the present study was to determine the carrier rates of two of the most common MEFV mutations, M694V and V726A, in the general Greek population. A cohort of 220 healthy and unrelated individuals of Greek descent was screened for the two MEFV mutations using the Amplification Refractory Mutation System. Our results showed that none of the healthy individuals tested were carriers of any of the two mutations. In conclusion, our study independently confirms that the carrier rate for the MEFV mutations M694V and V726A is extremely low in the general Greek population.

Alhopuro P(1), Klimenko T, Aittomäki K.

Author information:

(1)HUSLAB, perinnöllisyyslääketieteen yksikkö, PL 140, 00029 HUS.

Familial cold autoinflammatory syndrome (FCAS) is a dominantly inherited syndrome caused by mutations of the CIAS1 gene. It is characterized by recurrent episodes involving fever, urticaria, articular symptoms and conjunctivitis. The episodes may be associated with exposure to cold. In some families, association with reactive AA amyloidosis has been described for the syndrome. We describe a Finnish family, in which at least 16 persons were affected with FCAS, and one person had been diagnosed with renal amyloidosis.

Morbach\_h@kinderklinik.uni-wuerzburg.de

The objectives of this study are autoinflammatory syndromes which are usually characterized by repeated attacks of fever, especially in children. The presentation of these diseases, however, varies between entities and between patients of a particular syndrome. We report a 16-year-old female patient, who suffered from periodic erythema and myositis/fasciitis. She experienced at least nine attacks of dermatitis and myositis, while no fever episodes were noted over a 3-year period. A delay of puberty with amenorrhea and a short stature were also present. Laboratory investigations consistently showed markedly increased inflammatory parameters (especially a high serum amyloid A) and dysproteinemia. Because the patient's mother complained about chronic and periodic abdominal pain with also persistently elevated inflammatory parameters, the differential diagnosis included hereditary disorders resulting in chronic inflammation. The diagnosis of an inherited tumor necrosis factor receptor (TNFR) 1-associated periodic syndrome (TRAPS) was confirmed by genetic analyses. Long-term anti-inflammatory treatment with etanercept resulted in a significant clinical improvement and reduction of the inflammatory parameters ESR, CRP, interleukin-6, TNF- $\alpha$ , and soluble TNF- $\alpha$  receptor 1, but not of interleukin-12. Monitoring of the cytokine profile suggested partial effectiveness of etanercept in the treatment of TRAPS. Hereditary fever syndromes have to be considered in case of chronic unexplained inflammation even if fever is no presenting symptom.

MEFV mutation carriage in Israeli Jewish individuals from ethnicities with low risk for familial Mediterranean fever.

Feld O(1), Livneh A, Shinar Y, Berkun Y, Lidar M.

Author information:

(1)Department of Medicine F, Sheba Medical Center, Heller Institute of Medical Research, Ramat Gan, Israel.

Familial Mediterranean fever (FMF) is a disease caused by mutations in the MEditerranean FeVer gene (MEFV), and in Israel it most commonly affects Jews of North African extraction, in whom the mutation carrier rate is as high as 1 in 5. To assess the protective as well as the modulating affect of MEFV mutation carriage on various inflammatory disease states, we sought to define the frequency of MEFV mutations in Israeli Jewish individuals of various ethnicities, including those with low frequency of FMF, which were not in the focus of our attention hitherto. A total of 163 adults of Bucharian, Turkish, Georgian, Yemenite and Bulgarian origin comprised the study group. The prevalence of the most frequent MEFV mutations in the Israeli Jewish population, namely: M694V, V726A and E148Q, was assessed. The association of mutation carriage with a personal history of FMF-like phenomena, as well as various inflammatory and non-inflammatory diseases, was evaluated. A high MEFV mutation frequency was found among Jews of Bucharian, Georgian and Bulgarian origin (20%), whereas intermediate and low rates were detected in Jews of Turkish and Yemenite extraction (14 and 8%, respectively). FMF-like manifestations and related diseases were observed more often in MEFV mutation carriers than in their counterparts. MEFV mutation frequency, directly assessed by DNA analysis, exceeds the rate calculated from disease prevalence in Israeli Jewish individuals originated from ethnicities with a low prevalence of FMF. MEFV mutation carriage in this subgroup is associated with various inflammatory disorders.

Erratum in

J Exp Med. 2009 May 11;206(5):1205. Nishikomori, Ryuta [corrected to Nishikomori, Ryuta].

Urticarial rash observed in cryopyrin-associated periodic syndrome (CAPS) caused by nucleotide-binding oligomerization domain-leucine-rich repeats containing pyrin domain 3 (NLRP3) mutations is effectively suppressed by anti-interleukin (IL)-1 treatment, suggesting a pathophysiological role of IL-1beta in the skin. However, the cellular mechanisms regulating IL-1beta production in the skin of CAPS patients remain unclear. We identified mast cells (MCs) as the main cell population responsible for IL-1beta production in the skin of CAPS patients. Unlike normal MCs that required stimulation with proinflammatory stimuli for

IL-1 $\beta$  production, resident MCs from CAPS patients constitutively produced IL-1 $\beta$ . Primary MCs expressed inflammasome components and secreted IL-1 $\beta$  via NLRP3 and apoptosis-associated speck-like protein containing a caspase recruitment domain when stimulated with microbial stimuli known to activate caspase-1. Furthermore, MCs expressing disease-associated but not wild-type NLRP3 secreted IL-1 $\beta$  and induced neutrophil migration and vascular leakage, the histological hallmarks of urticarial rash, when transplanted into mouse skin. Our findings implicate MCs as IL-1 $\beta$  producers in the skin and mediators of histamine-independent urticaria through the NLRP3 inflammasome.

The investigation of interleukin 1 $\beta$  (IL-1 $\beta$ ) in human inflammatory diseases is hampered by the fact that it is virtually undetectable in human plasma. We demonstrate that by administering the anti-human IL-1 $\beta$  antibody canakinumab (ACZ885) to humans, the resulting formation of IL-1 $\beta$ -antibody complexes allowed the detection of in vivo-produced IL-1 $\beta$ . A two-compartment mathematical model was generated that predicted a constitutive production rate of 6 ng/d IL-1 $\beta$  in healthy subjects. In contrast, patients with cryopyrin-associated periodic syndromes (CAPS), a rare monogenetic disease driven by uncontrolled caspase-1 activity and IL-1 production, produced a mean of 31 ng/d. Treatment with canakinumab not only induced long-lasting complete clinical response but also reduced the production rate of IL-1 $\beta$  to normal levels within

8 wk of treatment, suggesting that IL-1beta production in these patients was mainly IL-1beta driven. The model further indicated that IL-1beta is the only cytokine driving disease severity and duration of response to canakinumab. A correction for natural IL-1 antagonists was not required to fit the data. Together, the study allowed new insights into the production and regulation of IL-1beta in man. It also indicated that CAPS is entirely mediated by IL-1beta and that canakinumab treatment restores physiological IL-1beta production.

OBJECTIVE: The objective of this article is to educate military physicians and providers about rare, endemic rheumatic diseases that may be encountered in

deployments to the Middle East region, specifically Familial Mediterranean Fever (FMF), Behcet's disease (BD), and tumor necrosis factor-associated periodic syndrome (TRAPS).

METHODS: We found review articles using MDConsult and Ovid.

RESULTS: Suitable articles were employed to describe the characteristics of each disease.

CONCLUSIONS: Although these diseases are considered rare, they can be endemic to current areas of deployment. Awareness of these conditions may prevent unnecessary and invasive treatment as well as make the clinician aware of possible disease complications.

Familial Mediterranean fever (FMF) is an autosomal recessively-transmitted disease characterised by attacks of fever and serositis. Articular involvement is the second most common manifestation following abdominal pain. Patients with FMF are considered to have an increased risk of sacroiliitis, while the association of such abnormalities with FMF has not been accepted uniformly. We report two cases of FMF with accompanying seronegative spondyloarthropathy, a 18-year-old boy and a 29-year-old man, and review the literature for FMF-related seronegative spondyloarthropathy.

Comment in

JAMA Dermatol. 2013 Oct;149(10):1245.

JAMA Dermatol. 2013 Oct;149(10):1244-5.

We conducted the current study to define within the spectrum of the neutrophilic dermatoses a group of patients with an urticarial rash clinically and a neutrophilic dermatosis histopathologically. We reviewed the literature on neutrophilic urticaria and we report here a series of patients with this unique presentation. We reviewed all cutaneous biopsies submitted to our department between 2000 and 2006 in which histopathologic evaluation was compatible with this entity. We then retrieved the patient medical records and obtained information about follow-up and associated diseases. This allowed us to identify 9 patients with an urticarial eruption that was characterized histopathologically by a perivascular and interstitial neutrophilic infiltrate with intense leukocytoclasia but without vasculitis and without dermal edema. Four patients also had small foci of necrobiotic collagen bundles. The eruption consisted of pale, flat or only slightly raised, nonpruritic macules, papules, or plaques. Elementary lesions resolved within 24 hours. Purpura, angioedema, and facial swelling were not seen, but dermographism was present in 1 patient. Six patients had fever, 7 had polyarthritis, and 6 had leukocytosis. Seven patients had associated systemic diseases: adult-onset Still disease (3 patients), systemic lupus erythematosus (3 patients), and Schnitzler syndrome (1 patient). A similar rash has been reported previously in the literature, mostly in patients with systemic inflammatory diseases, but the majority of patients reported under the undefined designation of "neutrophilic urticaria" did have a different clinicopathologic presentation. Thus, we suggest naming this eruption "neutrophilic urticarial dermatosis," to emphasize that this entity expands the broad group of cutaneous manifestations of neutrophilic aseptic disease. This entity bears important medical significance as it is strongly indicative of an

associated systemic disease, mainly Schnitzler syndrome, adult-onset Still disease, lupus erythematosus, and the hereditary autoinflammatory fever syndromes.

Insights into the heterogeneity of human B cells: diverse functions, roles in autoimmunity, and use as therapeutic targets.

Anolik JH(1), Looney RJ, Lund FE, Randall TD, Sanz I.

Author information:

(1)Department of Medicine, Division of Allergy, Immunology, and Rheumatology, University of Rochester Medical Center, NY 14642, USA.

B cells are critical players in the orchestration of properly regulated immune responses, providing protection against infectious agents without inflicting autoinflammatory damage. A balanced B cell compartment is also essential to create protective immunity in response to vaccines. This difficult compromise is achieved through the finely regulated participation of multiple B cell populations with different antibody-dependent and independent functions. Both types of functions allow B cells to powerfully modulate other components of the innate and adaptive immune system. For the most part, however, the necessary division of labor among different B cell populations is poorly understood. B cell dysfunction has been implicated in multiple autoimmune conditions. The physiological importance and complexity of B cell functions has been brought to the fore in recent years by the success of rituximab-based B cell depletion therapy (BCDT) in multiple autoimmune diseases including rheumatoid arthritis (RA) and multiple sclerosis (MS) which are conventionally viewed as T-cell mediated conditions. Given the widespread utilization of BCDT in malignant and autoimmune diseases and the key role of B cells in both protective immunity and pathogenic autoimmunity, a better understanding of B cell functions is of the essence and a focus of the research in our division. We are investigating these issues through a variety of approaches, including the study of the phenotype and

function of human B cell populations in health, their perturbation in autoimmune disease states, the effects of targeted biologic therapies, and the study of relevant murine models.

Familial Mediterranean fever (FMF) has episodic or subclinical inflammation that may lead to a decrease in bone mineral density (BMD). The aim of this study was to evaluate the effect of FMF on bone metabolism and to investigate the factors that can influence bone metabolism, such as body mass index (BMI), mutations in Mediterranean fever (MEFV) gene, osteoprotegerin (OPG), leptin and inflammatory cytokines, including interleukin (IL)-1beta, IL-6 and tumor necrosis factor-alpha (TNF-alpha). OPG, a soluble protein produced by osteoblasts, favors increased bone mass. Leptin may influence bone metabolism by acting on differentiated osteoblasts, having anabolic effects on bone. Thirty-one FMF patients in attack-free period (12 females and 19 males; mean age 31.4 +/- 9.3 years) and 18 healthy controls (11 females and 7 males; mean age 34.6 +/- 9.5 years) were compared according to the above parameters. BMD (g/cm(2)) and standard deviation scores (Z-score) were measured at the lumbar spine L(1)-L(4) (BMD-L(1-4)) and proximal femur by dual X-ray absorptiometry. Osteopenia is defined as a Z-score between -1 and -2.5 and osteoporosis is equal or below -2.5. FMF patients showed statistically significant reduction in BMD-L(1-4) and Z-score-L(1-4). Moreover, serum OPG concentration was significantly elevated in FMF patients. In contrast, MEFV gene mutations, leptin and the inflammatory cytokines did not differ between

the patient and control groups. In conclusion, BMD was decreased and OPG was increased in our FMF patients. The high OPG levels may reflect a preventive mechanism against bone loss; namely, OPG might protect the FMF patients from excessive osteoporosis.

Rilonacept for the treatment of cryopyrin-associated periodic syndromes (CAPS).

Hoffman HM(1).

Author information:

(1)University of California at San Diego, Division of Rheumatology and Allergy/Immunology, Mail Code 0635, 9500 Gilman Drive, La Jolla, CA 92093-0635, USA. hahoffman@ucsd.edu

**BACKGROUND:** Cryopyrin-associated periodic syndromes (CAPS) encompass a group of rare inherited, autoinflammatory disorders that represent a spectrum of one disease with varying degrees of severity. Until recently, there was no effective treatment for CAPS, but identification of the genetic basis of CAPS highlighted the pathogenic role of IL-1beta.

**OBJECTIVES:** Rilonacept is a recently FDA approved biologic therapy for CAPS with high affinity for IL-1beta. Limited pharmacological data has been reported to date.

**METHODS:** A review of the pharmacokinetics and pharmacodynamics data as well as the results of a pilot study and Phase III placebo-controlled trials of rilonacept in CAPS. Unpublished data on an open-label extension study in adult and pediatric subjects is also reviewed.

**RESULTS:** Rilonacept produced rapid and profound improvements in symptoms and also reduced high-sensitivity C-reactive protein levels and normalized elevated serum amyloid A concentrations, an important risk factor for amyloidosis. The primary adverse events were injection- site reactions and upper respiratory tract infections.

**CONCLUSION:** Rilonacept, the only IL-1 Trap, is the first of many novel IL-1-targeted therapies being developed. In a very short time it has changed the

lives of CAPS patients.

Current perspectives on familial Mediterranean fever.

Guz G(1), Kanbay M, Ozturk MA.

Author information:

(1)Department of Internal Medicine/Nephrology, Gazi University Faculty of Medicine, Ankara, Turkey. galip\_guz@hotmail.com

**PURPOSE OF REVIEW:** The gene responsible for familial Mediterranean Fever (FMF), MEditerranean FeVer (MEFV), was identified two decades ago; however, only recent studies have shed light on its pathogenesis. This review focuses on recent studies that have led us to more fully understand FMF pathogenesis.

**RECENT FINDINGS:** The vast majority of FMF-associated mutations are located in the B30.2 (SPRY) domain, which functions as a ligand binding or a signal transduction domain, at the carboxy terminus of the protein. As a result, B30.2 mutations may lead to postponed apoptosis and inflammation due to the reduced ability of pyrin to control interleukin-1beta (IL-1beta) activation. Development of AA amyloidosis is rare in FMF patients without amyloidogenic single nucleotide polymorphisms (SNPs) (713T allele) of the SAA1 gene. High macrophage inflammatory protein-1alpha levels during FMF attacks might be responsible for the enhancement of T-cell mediated immunity in FMF. IL-1beta-511 (C/T), IL-1beta+3953 (C/T) and IL-1Ra VNTR polymorphisms were not associated with the development of amyloid in FMF patients.

**SUMMARY:** Future studies should focus on defining the impact of MEFV and other mutations on the pathological course of FMF, and to understand the exact pathophysiology of those patients who are unresponsive to colchicine, which may help to develop novel therapeutic options for the management and improvement of prognosis.

Frequency of abdominal surgery in patients with familial Mediterranean fever.

Kaşifoğlu T(1), Cansu DU, Korkmaz C.

Author information:

(1)Division of Rheumatology, Department of Internal Medicine, Eskişehir Osmangazi University Medical Faculty, Eskişehir, Turkey. [tkas@mynet.com](mailto:tkas@mynet.com)

**OBJECTIVE:** Familial Mediterranean fever (FMF) is characterized by recurrent episodes of peritonitis. Abdominal FMF attacks can be indistinguishable from those of an acute abdominal emergency, and patients may undergo one or more laparotomies before the true nature of their disease is documented. The objectives of this study were to investigate the frequency and reasons for abdominal surgeries performed on patients with FMF.

**METHODS:** We retrospectively reviewed the files of 254 patients with FMF (127 males, 127 females, mean age 27.2+/-6.3 years). We also included 182 healthy individuals for this study (89 males, 93 females, mean age 27.6+/-5 years; range 11-43) to make a comparison between FMF and healthy controls (HC) with respect to frequency of abdominal operations.

**RESULTS:** The number of patients with abdominal surgery in FMF group was 74 (29.1%). The number of surgeries performed in 74 patients with FMF was 92. The first abdominal surgery before the diagnosis of FMF was appendectomy in 68 patients (26.6%). In HC group, the number of abdominal operations was found to be 16 (8.7%). Of these abdominal operations, 9 (4.9%) were due to appendectomy. The

rate of total abdominal operations and appendectomy were significantly higher in FMF group than in HC group ( $p=0.0001$ ).

CONCLUSION: Abdominal attacks of FMF patients may cause an unnecessary laparotomy prior to the diagnosis of FMF. FMF patients can present with abdominal emergency while they are receiving colchicine. Therefore, each abdominal pain should be carefully determined according to clinical findings. The purpose of this study was to emphasize the misdiagnosis of appendicitis.

Chronic recurrent multifocal osteomyelitis mimicked in childhood hypophosphatasia.

Whyte MP(1), Wenkert D, McAlister WH, Mughal MZ, Freemont AJ, Whitehouse R, Baildam EM, Coburn SP, Ryan LM, Mumm S.

Author information:

(1)Center for Metabolic Bone Disease and Molecular Research, Shriners Hospitals for Children, St. Louis, Missouri 63131-3597, USA. mwhyte@shrinenet.org

Hypophosphatasia (HPP) is the inborn error of metabolism characterized by low serum alkaline phosphatase (ALP) activity caused by inactivating mutations within TNSALP, the gene that encodes the "tissue-nonspecific" isoenzyme of ALP (TNSALP). In HPP, extracellular accumulation of inorganic pyrophosphate, a TNSALP substrate, inhibits hydroxyapatite crystal growth leading to rickets or osteomalacia. Chronic recurrent multifocal osteomyelitis (CRMO) is the pediatric syndrome of periarticular pain and radiographic changes resembling infectious osteomyelitis but without lesional pathogens. Some consider CRMO to be an autoinflammatory disease. An unrelated boy and girl with the childhood form of HPP suffered chronic, multifocal, periarticular pain, and soft tissue swelling. To investigate this unusual complication, we evaluated their cumulative clinical, biochemical, radiological, and histopathological findings and performed mutation analysis of their TNSALP alleles. The earliest radiographic disturbances were typical of childhood HPP. Subsequently, changes consistent with CRMO developed at sites where there was pain, including lucencies, osteosclerosis, and marked

expansion of the underlying metaphyses. Bone marrow edema was shown by MRI. Biopsies of affected bone showed nonspecific histopathological findings and no pathogens. The boy was heterozygous (c.1133A>T, p.D378V) and the girl compound heterozygous (c.350A>G, p.Y117C, c.400\_401AC>CA, p.T134H) for different TNSALP missense mutations. Nonsteroidal anti-inflammatory drugs diminished their pain, which improved or resolved at maturity. HPP should be considered when CRMO is a diagnostic possibility. Metaphyseal radiographic changes and marrow edema associated with periarticular bone pain and soft tissue swelling suggestive of osteomyelitis can complicate childhood HPP.

Norbert.Blank@med.uni-heidelberg.de

AA amyloidosis can be the consequence of any chronic inflammatory disorder. It is most commonly associated with chronic inflammatory rheumatic, pulmonary or gastrointestinal diseases, familial Mediterranean fever or other rare periodic syndromes. AA amyloidosis often affects the kidneys, gastrointestinal tract and the heart. Effective therapy of the underlying disease can normalize the inflammatory reaction and can slow or inhibit the deterioration of organ function if the diagnosis is made at an early stage of the disease. In rheumatoid diseases and in some periodic syndromes the use of antibodies against TNFalpha or IL-1 beta might be helpful. Patients with familial Mediterranean fever should regularly take colchicine to prevent attacks and to reduce the risk for development or progression of AA amyloidosis. Eprodisate is currently being investigated for AA amyloidosis and renal involvement.

Amyloid goiter: two cases and a review of the literature.

Yildiz L(1), Kefeli M, Kose B, Baris S.

Author information:

(1)Department of Pathology, Ondokuz Mayıs University, Samsun, Turkey.

Although involvement of the thyroid gland by amyloid is a relatively common phenomenon, clinically significant enlargement of the thyroid owing to amyloid deposition is an extremely rare occurrence. We describe two cases of amyloid goiter and review the relevant literature. The first case was systemic amyloidosis secondary to familial Mediterranean fever. The second case was a chronic renal failure patient who presented with an enlarged thyroid and upper airway obstructive symptoms. To date, true amyloid goiter secondary to amyloidosis associated with familial Mediterranean fever has only been reported in twelve patients.

Genotypic profiles of the natural killer cell immunoglobulin-like receptors (KIR) have been reported to vary among different ethnic groups and variable clinical entities. This study represents the first report on its distribution among patients with familial Mediterranean fever (FMF). We studied 56 unrelated Lebanese FMF patients, had their DNA typed using sequence-specific primer (SSP) technique for the presence of 16 KIR gene and pseudogene loci, and compared them to the general Lebanese population. The AA1 genotype was the most frequent in both the FMF and control groups. Six new KIR profiles were identified. The FMF group showed a higher prevalence of KIR 3DP1\*003 ( $p < 0.05$ ) and an increase in the BB genotype compared with controls. The results lead to an interesting future research question of whether or not KIR genotype is involved in the predisposition to or pathogenesis of FMF. This is the first report that describes the KIR genotypic profile in this important clinical disease.

Detection of MEFV gene mutations in patients with inflammatory bowel disease.

Yurtcu E(1), Gokcan H, Yilmaz U, Sahin FI.

Author information:

(1)Department of Medical Biology and Genetics, Baskent University Faculty of Medicine, Ankara, Turkey.

Inflammatory bowel disease (IBD) with ulcerative colitis (UC) and Crohn's disease (CD) as the most common forms is an inflammation of the gastrointestinal tract. Familial Mediterranean fever (FMF) is another inflammatory disease as well. In

the current study we studied FMF gene mutations in 47 patients with IBD and 25 healthy individuals to investigate the effects of these mutations on the clinical status of IBD. Twelve mutations were analyzed by reverse hybridization after multiplex PCR amplification of DNA samples. We did not find an association between FMF gene mutations and IBD phenotypic characteristics. However, in patients without Mediterranean fever (MEFV) mutations, extraintestinal disease frequencies were higher ( $p < 0.05$ ). IBD has a genetic basis with multiple genes probably playing a role via several pathways during disease progression. Studying other genes interacting with FMF gene in a larger group of patients will add to the knowledge of disease pathogenesis.

Bacterial osteomyelitis in children must be diagnosed quickly and requires immediate and adequate antibiotic treatment. Surgical interventions may be necessary. Infants as well as immunodeficient patients suffer more often from hematogenic bone infections than immunocompetent patients. According to recent findings, autoinflammatory nonbacterial osteitis is more probable in immunocompetent patients in good general condition and should always be considered as a differential diagnosis. Diagnostic and therapeutic approaches are presented when childhood osteomyelitis is suspected.

(1)The National Institute of Arthritis and Musculoskeletal and Skin Diseases,  
National Institutes of Health, Bethesda, Maryland 20892, USA.  
masterss@mail.nih.gov

The autoinflammatory diseases are characterized by seemingly unprovoked episodes of inflammation, without high-titer autoantibodies or antigen-specific T cells. The concept was proposed ten years ago with the identification of the genes underlying hereditary periodic fever syndromes. This nosology has taken root because of the dramatic advances in our knowledge of the genetic basis of both mendelian and complex autoinflammatory diseases, and with the recognition that these illnesses derive from genetic variants of the innate immune system. Herein we propose an updated classification scheme based on the molecular insights garnered over the past decade, supplanting a clinical classification that has served well but is opaque to the genetic, immunologic, and therapeutic interrelationships now before us. We define six categories of autoinflammatory disease: IL-1beta activation disorders (inflammasomopathies), NF-kappaB activation syndromes, protein misfolding disorders, complement regulatory diseases, disturbances in cytokine signaling, and macrophage activation syndromes. A system based on molecular pathophysiology will bring greater clarity to our discourse while catalyzing new hypotheses both at the bench and at the bedside.

Immunological and inflammatory functions of the interleukin-1 family.

Dinareello CA(1).

Author information:

(1)Department of Medicine, Division of Infectious Diseases, University of Colorado Denver, Aurora, Colorado 80045, USA. cdinareello@mac.com

More than any other cytokine family, the interleukin (IL)-1 family is closely linked to the innate immune response. This linkage became evident upon the discovery that the cytoplasmic domain of the IL-1 receptor type I is highly homologous to the cytoplasmic domains of all Toll-like receptors (TLRs). Thus, fundamental inflammatory responses such as the induction of cyclooxygenase type 2, increased expression of adhesion molecules, or synthesis of nitric oxide are indistinguishable responses of both IL-1 and TLR ligands. Both families nonspecifically affect antigen recognition and lymphocyte function. IL-1 $\beta$  is the most studied member of the IL-1 family because of its role in mediating autoinflammatory diseases. Although the TLR and IL-1 families evolved to assist in host defense against infection, unlike the TLR family, the IL-1 family also includes members that suppress inflammation, both specifically within the IL-1 family but also nonspecifically for TLR ligands and the innate immune response.

The inflammasomes: guardians of the body.

Martinon F(1), Mayor A, Tschopp J.

Author information:

(1)Department of Immunology and Infectious Diseases, Harvard School of Public Health, Boston, Massachusetts 02115, USA.

The innate immune system relies on its capacity to rapidly detect invading pathogenic microbes as foreign and to eliminate them. The discovery of Toll-like receptors (TLRs) provided a class of membrane receptors that sense extracellular microbes and trigger antipathogen signaling cascades. More recently,

intracellular microbial sensors have been identified, including NOD-like receptors (NLRs). Some of the NLRs also sense nonmicrobial danger signals and form large cytoplasmic complexes called inflammasomes that link the sensing of microbial products and metabolic stress to the proteolytic activation of the proinflammatory cytokines IL-1 $\beta$  and IL-18. The NALP3 inflammasome has been associated with several autoinflammatory conditions including gout. Likewise, the NALP3 inflammasome is a crucial element in the adjuvant effect of aluminum and can direct a humoral adaptive immune response. In this review, we discuss the role of NLRs, and in particular the inflammasomes, in the recognition of microbial and danger components and the role they play in health and disease.

Concomitant amyloidosis, renal papillary carcinoma and ipsilateral pelvicalyceal urothelial carcinoma in a patient with familial Mediterranean fever.

Kirkpantur A, Baydar DE, Altun B, Karcaaltincaba M, Aki T, Yuksel S, Turgan C.

We report a case of a 58-year-old man with a history of long standing familial Mediterranean fever (FMF) and AA amyloidosis, who developed renal papillary carcinoma and renal pelvic urothelial carcinoma simultaneously. Although the association between chronic inflammatory states like FMF and AA amyloidosis has been well established, the relationship between amyloidosis and solid tumors is not defined as clearly. Furthermore, to the best of our knowledge, co-existence of two different types of kidney malignancy with amyloidosis in a patient with FMF has not been reported. Our patient was admitted to hospital with gross hematuria and renal insufficiency. Imaging studies revealed mass lesions in the middle portion of the right kidney. Right radical nephrectomy showed extensive amyloid deposition, co-existing with renal papillary carcinoma and poorly differentiated invasive urothelial carcinoma.

Kristen.hayward@seattlechildrens.org

Juvenile idiopathic arthritis (JIA) is the most common autoimmune-autoinflammatory disease in childhood and affects approximately 1 in 1,000 children. Despite advances in diagnosis and treatment options, JIA remains a chronic condition for most affected children. Recent evidence suggests that disease control at onset may determine the tempo of subsequent disease course and long-term outcomes, and raises the concept of a therapeutic window of opportunity in patients with JIA. This underscores the importance of early aggressive treatment in patients with JIA. With the advent of novel biologic therapeutics, the repertoire of agents available for treatment of children with JIA has greatly increased. The present article will summarize recent developments in the medical treatment of children with JIA and will offer insights into emerging therapies.

PEST family phosphatases in immunity, autoimmunity, and autoinflammatory disorders.

Veillette A(1), Rhee I, Souza CM, Davidson D.

Author information:

(1)Laboratory of Molecular Oncology, Clinical Research Institute of Montréal, Montréal, Québec, Canada. veillea@ircm.qc.ca

The proline-, glutamic acid-, serine- and threonine-rich (PEST) family of protein tyrosine phosphatases (PTPs) includes proline-enriched phosphatase (PEP)/lymphoid tyrosine phosphatase (LYP), PTP-PEST, and PTP-hematopoietic stem cell fraction (HSCF). PEP/LYP is a potent inhibitor of T-cell activation, principally by suppressing the activity of Src family protein tyrosine kinases (PTKs). This function seems to be dependent, at least in part, on the ability of PEP to bind C-terminal Src kinase (Csk), a PTK also involved in inactivating Src kinases. Interestingly, a polymorphism of LYP in humans (R620W) is a significant risk factor for autoimmune diseases including type 1 diabetes, rheumatoid arthritis, and lupus. The R620W mutation may be a 'gain-of-function' mutation. In non-hematopoietic cells, PTP-PEST is a critical regulator of adhesion and migration. This effect correlates with the aptitude of PTP-PEST to dephosphorylate cytoskeletal proteins such as Cas, focal adhesion associated-kinase (FAK), Pyk2, and PSTPIP. While not established, a similar function may also exist in immune cells. Additionally, overexpression studies provided an indication that PTP-PEST may be a negative regulator of lymphocyte activation. Interestingly, mutations in a PTP-PEST- and PTP-HSCF-interacting protein, PSTPIP1, were identified in humans with pyogenic sterile arthritis, pyoderma gangrenosum, and acne (PAPA) syndrome and familial recurrent arthritis, two autoinflammatory diseases. These mutations abrogate the ability of PSTPIP1 to bind PTP-PEST and PTP-HSCF, suggesting that these two PTPs may be negative regulators of inflammation.

balahan.bora@deu.edu.tr

Familial Mediterranean fever (FMF) is the most common inherited periodic fever syndrome characterized by recurrent episodes of serositis. Recently, a few studies have suggested that FMF is related to increased risk of atherosclerosis. Mean platelet volume (MPV) is a marker of platelet activation. Larger platelets are associated with increased atherosclerosis risk. The aim of the study is to evaluate levels of MPV in pediatric FMF patients during and between attacks. The study consisted of 48 patients during an attack (group 1), 63 patients in attack-free period (at least 2 weeks after an attack, group 2), and 49 healthy controls (group 3). Erythrocyte sedimentation rate, C-reactive protein, white blood cell count, platelet count (PLT), and MPV levels were retrospectively recorded from the computerized patient database. Mean platelet volume was significantly lower in FMF patients during attack than in attack-free period ( $p = 0.00$ ); however, there was no difference among attack-free patients and healthy controls ( $p = 0.38$ ). The mean platelet counts of FMF patients during attack were higher than the healthy controls ( $p = 0.02$ ). There was an inverse correlation between MPV and mean PLT in the attack-free period ( $r = -0.446$ ,  $p = 0.01$ ). This study suggests that an early atherosclerosis marker, MPV, is not elevated in pediatric FMF patients on colchicine treatment.

The autoinflammatory syndromes include a group of inherited diseases that are characterized by 1) seemingly unprovoked episodes of systemic inflammations, 2) absence of high titer of autoantibody or auto-reactive T cell, and 3) inborn

error of innate immunity. In this article, we will focus on the clinical features, the pathogenesis related the genetic defects, and the therapeutic strategies in the representative disorders including familial Mediterranean fever (FMF), TNF receptor associated periodic syndrome (TRAPS), cryopyrin-associated periodic syndrome (CAPS), hyper-IgD with periodic fever syndrome (HIDS), syndrome of pyogenic arthritis with pyoderma gangrenosum and acne (PAPA), and Blau syndrome. Recent advances in genetics and molecular biology have proceeded our understanding of the pathogenesis of autoinflammatory syndromes.

**BACKGROUND:** Increased inflammatory activity is known to be a pathophysiologic characteristic of atrial fibrillation. Familial Mediterranean fever (FMF) is a disease characterized by recurrent and sustained increased inflammatory activity. Atrial conduction abnormalities in these patients have not been investigated in terms of P-wave duration, P-wave dispersion (Pd), and atrial electromechanical delay measured by tissue Doppler echocardiography (TDE). We aimed to assess atrial conduction time in patients with FMF.

**METHODS:** A total of 33 patients with FMF (13 males/20 females, 28.4 +/- 12.5 years), and 33 controls (13 males/20 females, 28.5 +/- 12.1 years) were included. Atrial electromechanical coupling (PA) and intra- and interatrial electromechanical delay were measured with TDE. From the 12-lead electrocardiogram Pd was calculated.

**RESULTS:** Atrial electromechanical coupling at the left lateral mitral annulus (PA

lateral) was significantly higher in FMF patients (58.0 +/- 9.0 vs 51.0 +/- 5.8,  $P < 0.001$ ). Interatrial (PA lateral-PA tricuspid) and intraatrial electromechanical delay (PA septum-PA tricuspid) were significantly longer in FMF patients (21.3 +/- 7.4 vs 12.9 +/- 4.6,  $P < 0.001$  and 4.7 +/- 5.5 vs 2.1 +/- 1.7,  $P = 0.01$ , respectively). Also, Pd and maximum P-wave duration were significantly higher in FMF patients (42.8 +/- 7.9 vs 35.3 +/- 6.1,  $P < 0.001$  and 98.6 +/- 9.0 vs 93.1 +/- 8.5,  $P = 0.01$ , respectively). A positive correlation was detected between interatrial electromechanical delay and Pd ( $r = 0.622$ ,  $P < 0.001$ ). Plasma level of C-reactive protein (CRP) correlated with interatrial electromechanical delay and Pd ( $r = 0.733$ ,  $P < 0.001$ ; and  $r = 0.427$ ,  $P < 0.001$ , respectively).  
CONCLUSION: This study shows that atrial electromechanical delay and Pd are prolonged in FMF patients. Atrial electromechanical delay is closely associated with Pd and plasma level of CRP.

Secondary (amyloid A [AA]) amyloidosis is a systemic disease characterized by amyloid deposition in many organs, leading to impaired function. Although cardiac involvement may occur with AA amyloidosis, significant deposition of amyloid in the heart is considered an infrequent observation and is rarely the cause of death. It occurs in 5% of patients with poorly controlled chronic inflammatory disease, mainly rheumatoid arthritis, ankylosing spondylitis, and familial Mediterranean fever. The authors report a case of AA amyloidosis diagnosed by rectal and skin biopsies, with cardiac involvement demonstrated by typical echocardiographic features in the presence of low voltage on electrocardiography.

Periodic fever is uncommon in children. The differential diagnosis is large, even though associated symptoms such as rash may help narrow the differential diagnosis. Atypical presentations require thoughtful evaluation. This article describes a case of a 4-year-old boy who presented to the emergency department with recurrent fever, vomiting, abdominal pain, myalgias, and rash. His hospital course is described along with a review on the background, evaluation, management, and complications of tumor necrosis receptor-1 alpha periodic syndrome.

Familial Mediterranean fever (FMF) is a recessive autoinflammatory disease commonly found in the Mediterranean populations. Genetic diagnosis has developed since the discovery of the causative gene MEFV in 1997. As many patients could not be confirmed genetically by routine exon screening, we searched for mutations in the 5'-flanking region of this gene. Using denaturing gradient gel electrophoresis, we screened DNA from 108 patients with clinical FMF and 91 asymptomatic individuals. We found six novel sequence variants in a region extending -825 bp upstream of the first translated codon. To investigate the potential role of these variants in altering MEFV gene expression, we first characterized the MEFV promoter. Promoter mapping assays revealed that the region located between nucleotides -949 and -152 of the initiation codon was important for regulating expression of the gene. We identified a putative enhancer element between -571 and -414. Investigation of the sequence variants found in two patients demonstrated that c.-614C>G resulted in a 70% decrease in promoter activity, whereas c.-382C>T induced a 100% increase in activity, when compared to the wild type. We observed specific DNA-protein binding to both wild-type sites, suggesting that transcription factors may bind to these sequences to modulate MEFV expression.

Hereditary periodic fever syndromes (autoinflammatory syndromes) are characterised by relapsing fevers and additional manifestations such as skin rashes, mucosal manifestations, and joint pain. Some of these disorders only present with organ manifestations and serological signs of inflammation without obvious fever (e.g. PAPA and Blau syndrome). There is a strong serological inflammatory response with an elevation of serum amyloid A (risk of secondary amyloidosis). There are monogenic disorders for which the mode of inheritance and gene mutation are known, but probably also polygenic diseases which present with similar symptoms to the classic autoinflammatory syndromes. Gene mutations have been described for the monogenic disorders (FMF, HIDS, CAPS, PAPA and Blau syndrome), which lead to an induction of the production of IL-1ss.

Therapeutically, the IL-1-receptor antagonist anakinra is mainly used. In the case of TRAPS and Blau syndrome, TNF antagonists may also be used. PFAPA syndrome, the Schnitzler syndrome, Still's disease of adult and pediatric onset, Behçet's disease and Crohn's disease also are mentioned as additional possible autoinflammatory syndromes.

Familial Mediterranean fever in Syrian patients: MEFV gene mutations and genotype-phenotype correlation.

Jarjour RA(1).

Author information:

(1)Clinical Genetics Unit, Molecular Biology and Biotechnology Department, Atomic Energy Commission of Syria, Damascus, Syria. scientific@aec.org.sy

Familial Mediterranean fever is an autosomal recessive disorder characterized by recurrent attacks of abdominal pain, synovitis and pleuritis. MEFV gene mutations are responsible for the disease. The objective of this study was to identify the frequency and distribution of 12 MEFV mutations in 153 Syrian patients and perform a genotype-phenotype correlation in the patients' cohort. Of the 153 unrelated patients investigated, 97 (63.4%) had at least one mutation. The most frequent mutation was M694V (36.5%), followed by V726A (15.2%), E148Q (14.5%), M680I (G/C) (13.2%), and M694I (10.2%) mutations. Rare mutations (R761H, A744S, M680I (G/A), K695R, P369S, F479L and I692del) were also detected in the patients. M694V was associated with the severe form of the disease. The identification of a significant number of FMF patients with no mutations or only one known mutation identified indicates the presence of new mutations in the MEFV gene which will be investigated in the future.

Co-existence of Hashimoto's thyroiditis with familial Mediterranean fever: is there a pathophysiological association between the two diseases?

Gulcan E(1), Gulcan A, Koplay M, Alcelik A, Korkmaz U.

Author information:

(1)Department of Internal Medicine, Dumlupinar University School of Medicine, Kutaya, Turkey. dreringulcan@gmail.com

Familial Mediterranean fever is an autosomal recessive disease characterized by periodic attacks of fever and polyserositis, while Hashimoto's thyroiditis is the most common cause of hypothyroidism. We suggest that common autoimmune mechanisms

may underlie both disorders, describe their clinical co-existence in a patient, and discuss a possible causal link between them.

Laboratory tests in the diagnosis and follow-up of pediatric rheumatic diseases: an update.

Breda L(1), Nozzi M, De Sanctis S, Chiarelli F.

Author information:

(1)Department of Pediatrics, Reumatology Unit, University of Chieti, Chieti, Italy. luciana.breda@yahoo.it

**OBJECTIVES:** We reviewed the literature to evaluate the role of common laboratory tests and to examine the recent progress in the laboratory diagnosis of pediatric rheumatic diseases.

**METHODS:** We used the PubMed database (1950-2008) to search for the keywords "laboratory," "erythrocyte sedimentation rate" (ESR), "C-reactive protein" (CRP), "blood cytology," "procalcitonin" (PCT), "complement system," "ferritin," "antistreptolysin O titer" (ASO), "autoantibodies," "genetic studies," in conjunction with "rheumatic disease in children" and "pediatric autoimmune diseases." All relevant original and review articles in English were reviewed as well as textbooks of pediatric rheumatology.

**RESULTS:** Laboratory tests (ESR, CRP, blood cytology, complement system, ferritin, ASO titer) play an important role in confirming a diagnosis and in the follow-up of rheumatic diseases in the pediatric age group. The ESR is probably the most widely measured index of the acute phase response. Measurement of CRP is very useful in the rapid diagnosis of infection as a progressive increase can be shown in the first 48 hours. Also, the subsequent fall in serum CRP concentration on resolution of inflammation is useful for monitoring the efficacy of treatment. In chronic diseases, a combination of CRP and ESR may provide the most useful information. Cytopenia and different forms of anemia can be encountered in many

rheumatic diseases: they can be related to disease activity or to therapeutic side effects. Determination of complement levels (C3 and/or C4) is useful in the follow-up of systemic lupus erythematosus (SLE) and membranoproliferative glomerulonephritis. Ferritin is a laboratory hallmark of primary and secondary hemophagocytic lymphohistiocytosis. ASO titer should be obtained to confirm a diagnosis of acute rheumatic fever; other important antibody markers of streptococcal infection include antihyaluronidase, antideoxyribonuclease B, and antistreptokinase antibodies. We also found that, in the pediatric age, the main indication for synovial fluid analysis is suspected joint infection. Antinuclear antibodies, anti-Smith antigen, and anti-double-stranded DNA antibodies are important in the diagnosis of SLE, are useful prognostic markers, and facilitate clinical and treatment follow-up. Anti-SSA/Ro and anti-SSB/La antibodies are associated with Sjögren's syndrome and congenital heart block, while the anti-U1 small nuclear ribonucleoprotein antibodies show high specificity for mixed connective tissue disease. Repetitive spontaneous abortions, thrombocytopenia, and many types of venous or arterial thrombosis are associated with antiphospholipid antibodies. The presence of cytoplasmic antineutrophil antibodies is essential in the diagnosis of Wegener granulomatosis. The discovery of underlying single causative gene defects led to the identification of several autoinflammatory diseases, a group of genetic disorders characterized by recurrent attacks of inflammation (hereditary periodic fever syndromes). These include familial Mediterranean fever due to mutations in the Mediterranean fever (MEFV) gene, hyperimmunoglobulinemia D syndrome due to mutations in the MK gene for mevalonate kinase, cryopyrinopathies such as Muckle-Wells syndrome or neonatal-onset multisystemic inflammatory disease (neonatal-onset multisystemic inflammatory disease or chronic infantile neurological cutaneous and articular (CINCA)) associated with cold-induced autoinflammatory syndrome 1 gene mutations, and tumor necrosis factor receptor-associated periodic syndrome due to mutation of TNF receptor I gene.

**CONCLUSIONS:** Laboratory investigations play an important role in the diagnosis and follow-up of inflammatory rheumatic diseases in children. A good history and a complete physical examination are the best screening tests. Routine laboratory tests are useful to confirm a suspected diagnosis, to assess disease activity, and to measure the response and toxicity to treatment. Only a few tests represent diagnostic criteria such as antinuclear antibodies and anti-double-stranded DNA in SLE or cytoplasmic antineutrophil cytoplasmic autoantibodies in Wegener's granulomatosis. Recent advances in molecular genetics have impacted diagnosis, pathogenesis, and treatment in genetic fever syndromes.

Familial Mediterranean fever (FMF) is an autosomal recessive disorder characterized by recurrent attacks of fever and polyserositis. It is the most frequent periodic fever syndrome. In FMF, sterile peritonitis, pleuritis and arthritis are frequently seen in addition to recurrent febrile attacks. Skin and muscle involvement is less common. Here, we report four patients presented with skin lesions or myalgia. Most striking findings in those patients are the absence of other major criteria for FMF and dominance of skin lesions or myalgia. All four patients had MEFV gene mutations on both alleles. In patients with erysipelas-like lesions or erythema nodosum along with arthritis/arthritis or recurrent myalgia, FMF should be kept in mind.

**BACKGROUND:** Familial Mediterranean Fever (FMF) is a systemic relapsing autoinflammatory disorder. Adenosine deaminase (ADA) is an enzyme widely distribute in tissues and body fluids. Circulating levels of ADA have been shown to increase in several inflammatory conditions. This study was designed to evaluate the serum ADA in patients with FMF during acute attacks and attack-free periods.

**METHODS:** The study groups comprised 23 FMF patients in attack-free period (male/female: 11/12), 30 FMF patients in attack period (male/female: 11/19) and 20 healthy control (male/female:10/10). The groups were similar for age, gender and disease duration.

**RESULTS:** The mean age of FMF patients in attack-free period, patient with acute attack were 34.3+/-11.7 and 29.4+/-11.1 respectively. The disease durations were 13.1+/-10.2 and 8.2+/-7.6 years for patients in attack-free periods and patients with acute FMF attack, respectively. Patients with acute attack had significantly higher ADA levels than both patients with attack-free periods and healthy controls (for each,  $p<0.001$ ).

**CONCLUSION:** In this study we demonstrated that FMF patients with acute attacks had higher serum ADA levels than attack-free periods and healthy controls. It is likely that ADA may have a role in the cytokine network of the inflammatory cascade of FMF. Also, elevated ADA levels may be a part of the activated Th1 response in the disease. ADA may be used as a supportive marker to differentiate FMF attacks from attack-free periods. Further larger-scale studies are needed to support this result.

The autoinflammatory diseases, also known as periodic fever syndromes, are disorders of innate immunity which can be inherited or acquired and which cause recurrent, self-limiting, seemingly spontaneous episodes of systemic inflammation and fever in the absence of autoantibody production or infection. There has been much recent progress in elucidating their aetiologies and treatment. With the exception of familial Mediterranean fever, which is common in certain populations, autoinflammatory diseases are mostly rare but should not be overlooked in the differential diagnosis of recurrent fevers since DNA diagnosis and effective therapies are available for many of them.

Rare monogenetic syndromes in rheumatology practice.

Manger K(1), Nüsslein H, Schett G, Manger B.

Author information:

(1)Rheumatology Practice, Bamberg, Germany.

The EULAR Executive Committee defined eight overall objectives for EULAR to achieve by 2012. The first of these objectives is to strengthen activities in areas that are currently less prioritized, such as non-inflammatory and orphan diseases. This study aims to increase awareness of rheumatologists towards rare hereditary musculoskeletal disorders, by describing their genetics, pathogenesis, and typical clinical and radiological features. We analyzed patient charts from the recent 5 years from the Rheumatology Outpatient Department of the University Erlangen-Nuremberg and of two rheumatologic practices, all joined in a regional network ("Rheumazentrum Erlangen") retrospectively for hereditary musculoskeletal disorders other than hemochromatosis, autoinflammatory syndromes, lysosomal storage diseases, and hypermobility syndromes. We were able to identify four patients with trichorhinophalangeal syndrome type I, multiple exostoses, Kirner's deformity, and osteopoikilosis. In addition, a PubMed and OMIM ("Online Mendelian Inheritance in Man") database search was carried out using these as key words and all relevant articles were reviewed for each of these diseases. Our findings show that rare hereditary musculoskeletal disorders occur in a routine rheumatological setting and that rheumatologists should know the clinical and radiological features of these diseases in order to adequately counsel the patient.

Comment in

Curr Opin Immunol. 2009 Feb;21(1):1-2.

The NLR (nucleotide-binding domain leucine-rich repeat containing) family of intracellular sensors is a crucial component of the innate immune system. A number of NLR family members can form multiprotein complexes, called inflammasomes, and are capable of activating the cysteine protease caspase-1 in response to a wide range of stimuli including both microbial and self-molecules. Caspase-1 activation leads to processing and secretion of the proinflammatory cytokines interleukin-1beta (IL-1beta) and IL-18, which play crucial roles in host defense to infectious insults. Dysregulation of the inflammasome has also been linked to a number of autoinflammatory and autoimmune disorders. Recent advances in the inflammasome field will be discussed in this review.

**OBJECTIVE:** Familial Mediterranean Fever (FMF) is common among Mediterranean populations, while other populations are rarely affected. The aim of this study was to assess the involvement of MEFV gene mutations among Japanese rheumatoid arthritis patients with or without amyloid A (AA) amyloidosis.

**METHODS:** The frequency of the MEFV mutations, which were identified in Japanese FMF patients, was determined in 126 Japanese RA patients and 76 Japanese healthy subjects.

**RESULTS:** The M694I mutation was not observed among RA patients and healthy

subjects. Allele frequency of R408Q, P369S, E148Q, L110P mutations account respectively for 3.3%, 3.9%, 23.7%, 9.2% in healthy subjects and 5.6%, 6.7%, 24.2%, 9.5% in RA patients. The overall mutation rate was comparable between the RA patients and healthy subjects, as well as between the RA patients with and without amyloidosis.

**CONCLUSION:** This study shows the high prevalence of mutations of the MEFV genes in Japanese RA patients. However, our data suggest that the MEFV gene mutations may not be a genetic factor affecting the susceptibility of RA or the development of amyloidosis in a Japanese population.

**OBJECTIVES:** Several sets of criteria mainly for adults have been proposed for the diagnosis of FMF. The aim of the present study is to validate the most widely used diagnostic 'Tel Hashomer' criteria in children and to establish a new set of criteria for use in childhood.

**METHODS:** The study group consisted of 170 recently diagnosed FMF patients who had mutations at both alleles. They were interviewed about the presence of 35 features and manifestations of FMF at the time of diagnosis. Controls were consecutive patients without FMF (n = 141) who had episodes of fever and clinical features mimicking that of FMF. The diagnostic performance of the candidate features was assessed by multiple logistic regression analysis.

**RESULTS:** The sensitivity and specificity of Tel Hashomer criteria in our study group were 98.8 and 54.6%, respectively. The multiple logistic regression analysis showed that 5 (fever, abdominal pain, chest pain, arthritis and family history of FMF) of the 35 candidate criteria discriminate FMF from controls with a sensitivity and specificity of 88.8 and 92.2%, respectively. The presence of two or more of these five criteria diagnosed FMF with a sensitivity of 86.5% and a specificity of 93.6%.

**CONCLUSION:** It was demonstrated that although the Tel Hashomer criteria were successful in diagnosing the FMF patients in childhood, its specificity was definitely low in children. The new set of criteria has a high sensitivity and specificity for the diagnosis of FMF and is practical to use on an everyday basis.

Auto-inflammatory syndromes and oral health.

Scully C(1), Hodgson T, Lachmann H.

Author information:

(1)UCL Eastman Dental Institute, London, UK. [crispian.scully@eastman.ucl.ac.uk](mailto:crispian.scully@eastman.ucl.ac.uk)

Auto-inflammatory diseases (periodic syndromes) are rare childhood-onset disorders which are characterized by fluctuating or recurrent episodes of fever and inflammation affecting serosal surfaces, joints, eyes and/or skin without significant autoantibody production or an identifiable underlying infection. They are disorders of innate immunity and the underlying genetic defect has been identified in most of the syndromes. Diagnosis relies on clinical symptoms and evidence of an elevated acute phase response during attacks, supported by finding mutations in the relevant genes. Several syndromes can lead to systemic AA amyloidosis. Aphthous-like oral ulceration has been reported as one manifestation in several of the syndromes, including periodic fever, aphthous-stomatitis, pharyngitis, adenitis (PFAPA) familial Mediterranean fever (FMF), hyperimmunoglobulinaemia D and periodic fever syndrome, tumour necrosis factor receptor associated periodic syndrome and pyogenic sterile arthritis, pyoderma gangrenosum, acne (PAPA). Chronic jaw recurrent osteomyelitis has been recorded in chronic recurrent multifocal osteomyelitis. Advances in the molecular pathogenesis of these syndromes and the regulation of innate immunity have enhanced diagnosis, and rationalized therapies. This article reviews the periodic fever syndromes relevant to oral health and the suggested association of FMF with Behçet's disease.

An integrated classification of pediatric inflammatory diseases, based on the concepts of autoinflammation and the immunological disease continuum.

McGonagle D(1), Aziz A, Dickie LJ, McDermott MF.

Author information:

(1)NIHR-Leeds Molecular Biology Research Unit (NIHR-LMBRU), University of Leeds, Leeds LS9 7TF, United Kingdom.

Historically, pediatric inflammatory diseases were viewed as autoimmune but

developments in genetics of monogenic disease have supported our proposal that "inflammation against self" be viewed as an immunologic disease continuum (IDC), with genetic disorders of adaptive and innate immunity at either end. Innate immune-mediated diseases may be associated with significant tissue destruction without evident adaptive immune responses and are designated as autoinflammatory due to distinct immunopathologic features. However, the majority of pediatric inflammatory disorders are situated along this IDC. Innate immunity has been demonstrated in polygenic disorders, particularly Crohn's disease (CD). A genetic overlap exists between CD and some major histocompatibility complex (MHC) class I-associated diseases, including psoriasis; these diseases seem to represent a true intermediate between autoinflammation and autoimmunity. Conversely, classical autoimmune diseases, with autoantibody and MHC class II associations, including celiac disease and rheumatoid arthritis (RA), have adaptive immune genetic associations, including Cytotoxic T-Lymphocyte Antigen-4 (CTLA4) and PTPN22. This proposed classification is clinically relevant, because innate immune-mediated disorders may respond to cytokine antagonism whereas autoimmune-mediated diseases respond better to anti-T and B cell therapies. Furthermore, the etiopathogenesis of poorly defined "autoimmune" diseases, such as juvenile idiopathic arthritis, may be inferred to have substantial innate immune involvement, based on response to IL-1 antagonism.

Colchicine for pericarditis: hype or hope?

Imazio M(1), Brucato A, Trinchero R, Spodick D, Adler Y.

Author information:

(1)Cardiology Department, Maria Vittoria Hospital, Torino, Italy.

massimo\_imazio@yahoo.it

Colchicine has been effectively used in the treatment of several inflammatory conditions, such as gouty attacks, serositis related to familial Mediterranean fever, Behçet syndrome, and more recently also in acute and recurrent

pericarditis. Growing evidence has shown that the drug may be useful to treat an acute attack and may be a way to cope with the prevention of pericarditis in acute and recurrent cases and after cardiac surgery. Nevertheless, clinicians are often sceptical about the efficacy of the drug, and concerns have risen on possible side effects and tolerability. In this review, we analyse current evidence to support the use of the drug, as well as possible harms and risks related to drug interactions, reaching the conclusion that colchicine is safe and useful in recurrent pericarditis, if specific precautions are followed, although less evidence supports its use for the treatment of acute pericarditis, where colchicine remains optional and there is a need for further multicentre confirmatory studies. This paper also reviews specific dosing and precautions for the clinical use.

Author information:

(1)Departments of Dermatology and Venerology, School of Medicine, Antalya, Turkey. aakman@akdeniz.edu.tr

Familial Mediterranean fever (FMF) is an inherited, recurrent, inflammatory disease. Of its various cutaneous features, erysipelas-like erythema is the best known and most common skin lesion. We present a new case of FMF with recurrent bullous lesions. A 41-year-old woman was admitted to our clinic with tense bullae, 20 x 20 mm in diameter on the left shin. The patient had a history of fever, abdominal pain, peritonitis attacks and infertility. A lesional skin biopsy revealed subepidermal bullae and neutrophilic infiltration around dermal vessels. Direct immunofluorescence analysis was negative. Over the period of investigation, the lesion regressed spontaneously; 1 month later, a similar lesion appeared on the right wrist. Diagnosis of FMF was made according to the Tel-Hashomer criteria. Recognition of this peculiar skin lesion may lead to an

earlier diagnosis of the disease.

(1)Oregon Health & Science University, Portland, OR 97239, USA. martint@ohsu.edu

Comment in

Arthritis Rheum. 2009 Aug;60(8):2544-5.

**OBJECTIVE:** Blau syndrome is a rare, autosomal-dominant, autoinflammatory disorder characterized by granulomatous arthritis, uveitis, and dermatitis. Genetics studies have shown that the disease is caused by single nonsynonymous substitutions in NOD-2, a member of the NOD-like receptor or NACHT-leucine-rich repeat (NLR) family of intracellular proteins. Several NLRs function in the innate immune system as sensors of pathogen components and participate in immune-mediated cellular responses via the caspase 1 inflammasome. Mutations in a gene related to NOD-2, NLRP3, are responsible for excess caspase 1-dependent interleukin-1beta (IL-1beta) in cryopyrinopathies such as Muckle-Wells syndrome. Furthermore, functional studies demonstrate that caspase 1-mediated release of IL-1beta also involves NOD-2. The aim of this study was to test the hypothesis that IL-1beta may mediate the inflammation seen in patients with Blau syndrome. **METHODS:** IL-1beta release was measured in peripheral blood mononuclear cells cultured in vitro, obtained from 5 Blau syndrome individuals with a NOD2 (CARD15) mutation.

**RESULTS:** We observed no evidence for increased IL-1beta production in cells obtained from subjects with Blau syndrome compared with healthy control subjects. Furthermore, we presented 2 cases of Blau syndrome in which recombinant human IL-1 receptor antagonist (anakinra) was ineffective treatment.

**CONCLUSION:** Taken together, these data suggest that in contrast to related IL-1beta-dependent autoinflammatory cryopyrinopathies, Blau syndrome is not mediated by excess IL-1beta or other IL-1 activity.

Proinflammatory action of the antiinflammatory drug infliximab in tumor necrosis factor receptor-associated periodic syndrome.

Nedjai B(1), Hitman GA, Quillinan N, Coughlan RJ, Church L, McDermott MF, Turner MD.

Author information:

(1)Institute of Cell and Molecular Science, Barts and The London School of Medicine and Dentistry, London, UK.

**OBJECTIVE:** Tumor necrosis factor receptor (TNFR)-associated periodic syndrome (TRAPS) is an autosomal-dominant autoinflammatory condition caused by mutations in the TNFRSF1A gene. Unlike other autoinflammatory diseases in which anti-TNF therapy is largely a successful treatment option, therapy with the anti-TNF drug infliximab is often ineffective in patients with TRAPS. Moreover, in certain cases, infliximab actually triggers severe episodes of inflammation. The aim of this study was to elucidate the mechanisms underlying such a reaction.

**METHODS:** Peripheral blood mononuclear cells (PBMCs) were obtained from patients with TRAPS. Both caspase 3 activity and NF-kappaB subunit activity were determined by enzyme-linked immunosorbent assay. Cytokine secretion was assessed using a specific customized human multiplex bead immunoassay kit.

**RESULTS:** Unlike findings in controls, cells from a family of 9 patients, all of whom carried the T50M mutation in TNFRSF1A, failed to respond to infliximab through proapoptotic induction of caspase 3 activity. Instead, we observed enhanced antiapoptotic c-Rel subunit activity, accompanied by a significant increase in secretion of the proinflammatory cytokines interleukin- 1beta (IL-1beta), IL-1 receptor, IL-6, IL-8, and IL-12.

**CONCLUSION:** Altered extracellular conformation of TNFR1, resulting from the T50M

mutation in TNFRSF1A, results in failure of PBMCs to induce an apoptotic response to infliximab. We hypothesize that failure to shed infliximab-bound TNF/TNFR1 from the cell surface of cells from patients with the T50M mutation triggers c-Rel activation, and that this leads to a marked increase in cytokine secretion and an increased proinflammatory response. In light of these findings, we strongly advise caution when prescribing infliximab as anti-TNF therapy to patients with TRAPS.

Genotype analysis of polymorphisms in autoimmune susceptibility genes, CTLA-4 and PTPN22, in an acute anterior uveitis cohort.

Martin TM(1), Bye L, Modi N, Stanford MR, Vaughan R, Smith JR, Wade NK, Mackensen F, Suhler EB, Rosenbaum JT, Wallace GR.

Author information:

(1)Oregon Health & Science University, Portland, OR, USA.

**PURPOSE:** Acute anterior uveitis (AAU) is the most common form of uveitis and is thought to be autoimmune in nature. Recent studies have described genes that act as master controllers of autoimmunity. Protein tyrosine phosphatase type 22 (PTPN22) and Cytotoxic T lymphocyte antigen-4 (CTLA-4) are two of these genes, and single nucleotide polymorphisms (SNPs) in the genes encoding these molecules have been associated with several autoimmune diseases. In this study we have analyzed SNPs in PTPN22 and CTLA-4 in patients with AAU.

**METHODS:** The functional protein tyrosine phosphatase type 22 (PTPN22) SNP (R620W rs2476601, 1858C/T), and two CTLA-4 SNPs (rs5742909, -318C/T and rs231775, 49A/G) were analyzed in 140 patients with AAU and 92 healthy controls by sequence-specific primer -polymerase chain reaction (SSP-PCR). Data was analyzed by chi(2) analysis and Fisher's exact test.

**RESULTS:** There was no significant association between PTPN22 620W, CTLA-4 -318C/T, or CTLA-4 49A/G and AAU. Similarly, there was no association with the three SNPs when patients were classified by race or gender. Finally, there was no association with the presence of ankylosing spondylitis in the patient cohort.

**CONCLUSIONS:** The data do not support an association between SNPs in PTPN22 and CTLA-4, genes regarded as genetic master switches of autoimmunity. This raises the issue of the etiology of AAU and the possibility that it should be regarded as an autoinflammatory rather than an autoimmune condition.

[Thyroid disorders and childhood rheumatic diseases].

[Article in Spanish]

Alvarez Madrid C(1), González Fernández A, Lisbona Muñoz M, Molina Rodríguez MA, Merino Muñoz R, García-Consuegra Molina J.

Author information:

(1)Sección de Reumatología Pediátrica, Hospital Universitario La Paz, Madrid, España.

**INTRODUCTION:** The relationship between thyroid dysfunction and autoimmune diseases has mainly been described in adults. The aim of this study was to analyse the prevalence and characteristics of thyroid abnormalities in children with rheumatic diseases.

**PATIENTS AND METHOD:** One hundred and forty-five patients (109 girls and 36 boys) from a rheumatology paediatric unit were studied for two years. The diagnoses were: juvenile idiopathic arthritis (JIA) (n=115), lupus (n=17), juvenile dermatomyositis (n=5), scleroderma (n=4), and one case each of the following: mixed connective mixed disease, CINCA syndrome (chronic infantile neurological, cutaneous and articular), TRAPS (tumour necrosis factor receptor-associated periodic syndrome), and familial mediterranean fever. T4 and TSH levels were carried out, and if these showed abnormalities, antithyroid antibodies (ATA) were determined.

**RESULTS:** Six girls aged between 2 and 17 years old had thyroid abnormalities. Three had JIA and three had lupus. Five were diagnosed with autoimmune

hypothyroidism, with high ATA levels, and there was one case of hyperthyroidism. All of the patients with thyroid dysfunction had positive antinuclear antibodies (ANA), compared to 34.5% of the rest of the patients ( $p=0.003$ ).

CONCLUSIONS: The prevalence of thyroid abnormalities in children with rheumatic disease was 4.14% to 7.9% in JIA patients with positive ANA, and up to 17.6% with lupus. The majority of patients were asymptomatic. Thyroid hormones should be determined when rheumatic disease is diagnosed and periodically afterwards.

An invariant surface patch on the TRIM5alpha PRYSPRY domain is required for retroviral restriction but dispensable for capsid binding.

Sebastian S(1), Grütter C, Strambio de Castillia C, Pertel T, Olivari S, Grütter MG, Luban J.

Author information:

(1)Department of Microbiology, Columbia University, New York, New York 10032, USA.

TRIM5alpha is a retrovirus restriction factor in the host cell cytoplasm that blocks infection before provirus establishment. Restriction activity requires capsid (CA)-specific recognition by the PRYSPRY domain of TRIM5alpha. To better understand the restriction mechanism, nine charge-cluster-to-triple-alanine mutants in the TRIM5alpha PRYSPRY domain were assessed for CA-specific restriction activity. Five mutants distributed along the TRIM5alpha PRYSPRY primary sequence disrupted restriction activity against N-tropic murine leukemia virus and equine infectious anemia virus. Modeling of the TRIM5alpha PRYSPRY domain based on the crystal structures of PRYSPRY-19q13.4.1, GUSTAVUS, and TRIM21 identified a surface patch where disruptive mutants clustered. All mutants in this patch retained CA-binding activity, a reticular distribution in the cytoplasm, and steady-state protein levels comparable to those of the wild type. Residues in the essential patch are conserved in TRIM5alpha orthologues and in closely related paralogues. The same surface patch in the TRIM18 and TRIM20 PRYSPRY domains is the site of mutants causing Opitz syndrome and familial

Mediterranean fever. These results indicate that, in addition to CA-specific binding, the PRYSPRY domain possesses a second function, possibly binding of a cofactor, that is essential for retroviral restriction activity by TRIM5alpha.

Increased frequency of familial Mediterranean fever in northern Turkey: a population-based study.

Kisacik B(1), Yildirim B, Tasliyurt T, Ozyurt H, Ozyurt B, Yuce S, Kaya S, Ertenli I, Kiraz S.

Author information:

(1)Division of Rheumatology, Department of Internal Medicine, Faculty of Medicine, Gaziosmanpasa University, Tokat, Turkey. bunyamin\_k@hotmail.com

Familial Mediterranean fever (FMF) is a systemic relapsing autoinflammatory disorder occurring in populations originating from the Mediterranean basin, mainly Turks, Levantine Arabs, Sephardic Jews, Druze, and Armenians. The prevalence of FMF shows considerable geographical variation. In Turkey, the prevalence rates were reported as 0.0027-0.25%. This field survey was conducted in different regions to investigate the frequency of FMF in a northern province of Turkey. This study was conducted in 70 areas (12 urban and 58 rural) in the province of Tokat, which is in northern Turkey. The population of Tokat was reported to be 828,000 at the last census in Turkey in 2000, about 530,000 for individuals aged >18 years ( <http://www.die.gov.tr> ). Mean age of 1,095 (541 male and 554 female; urban 555 and rural 540) subjects was 41 +/- 17 (range 18-95 years). FMF frequency in this study was 1/123 (0.82%, 95 CI: 0.40-1.61). Mean age of patients were 27 years (20-41) and mean age of symptoms were 16.3 years (11-23). In conclusion, the frequency of FMF in this study was 1/123 (0.82%) which was higher than expected. This rate is the highest frequency of FMF reported from Turkey. Further large sample studies are needed to define to true prevalence of FMF in Turkey.

kemalureten@yahoo.com

Familial Mediterranean fever (FMF) is an autosomal recessive inflammatory disease especially seen in Turks, Sephardic Jews, Armenians, and Arabs. Peritoneal and pleural inflammation, arthritis, erysipelas-like erythema, and arthralgia are well-known features of FMF. A small amount of peritoneal fluid collection can be seen during peritoneal attacks in FMF patients, but chronic ascites is a rather rare complication. We herein report a female FMF patient who developed chronic ascites. She was compound heterozygote for M694V/M680I mutation of the MEFV gene. Aspiration of the ascites fluid revealed a small amount of erythrocytes and mesothelial cells. After dose adjustment of colchicine the amount of ascites decreased. In conclusion, FMF should be considered in the differential diagnosis of chronic ascites in populations where the disease is endemic.

Is the urinary protein excretion pattern compatible with renal morphological findings in renal amyloidosis?

Erdoğan O(1), Demircin G, Bülbül M, Memiş L, Oner A.

Author information:

(1)Department of Pediatric Nephrology, Dr. Sami Ulus Children's Hospital, Ankara, Turkey. erdogan65@yahoo.com

The aims of this study are to compare urinary protein excretion pattern with renal morphological findings and to find out whether urinary protein excretion pattern is a prognostic indicator of renal amyloidosis. Fifteen children with renal amyloidosis secondary to familial Mediterranean fever were included in the study. The patients were classified into three groups according to the degree of tubulointerstitial injury in renal biopsy (group 1, <25%; group 2, 25-50%; and group 3, >50%). In all patients, urinary protein electrophoresis were performed. Levels of urinary beta(2)-microglobulin, retinol binding protein, and beta.N-acetyl-D glucosaminidase were measured as markers for tubular injury, and urinary excretions of protein and albumin and plasma albumin levels were measured as markers of glomerular injury. While urinary excretions of protein and albumin and plasma albumin levels were not different between groups, higher urinary beta(2)-microglobulin and retinol binding protein values and lower creatinine clearance values were found in group 3 than in groups 1 and 2 ( $p < 0.05$ ). We concluded that analysis of urinary protein excretion pattern is a non-invasive and reliable method to detect the degree of tubulointerstitial injury as the most important prognostic factor in renal amyloidosis and may be used to determine the changes during the follow-up period of the patients.

Eosinophilia-associated muscle disorders: an immunohistological study with tissue localisation of major basic protein in distinct clinicopathological forms.

Cantarini L(1), Volpi N, Carbotti P, Greco G, Aglianò M, Bellisai F, Giannini F, Alessandrini C, Grasso G, Galeazzi M.

Author information:

(1)Interdepartmental Research Center of Systemic Autoimmune and Autoinflammatory Diseases, Unit of Rheumatology, Policlinico Le Scotte, University of Siena, Siena, Italy. cantariniluca@hotmail.com

AIMS: (a) To evaluate tissue eosinophil density, location of eosinophil cytotoxic products, histopathological muscle changes and inflammatory cell types in different eosinophilia-associated myopathies that are clinicopathologically heterogeneous. (b) To determine the immunohistological range of tissue eosinophil density in non-eosinophilic inflammatory myopathies.

METHODS: Muscle biopsy specimens from seven patients with blood and/or tissue eosinophilia and clinicolaboratory myopathic signs (five chronic course myopathies, one subacute onset fasciitis/myositis, one acute myositis), and from 18 non-eosinophilic inflammatory myopathies, underwent routine staining, inflammatory infiltrate immunophenotyping, immunostaining for eosinophil major basic protein (MBP) and transmission electron microscopy examination. Eosinophil and total inflammatory cell counts were statistically analysed.

RESULTS: Histological examination showed occasional or no infiltrating eosinophils in all cases. MBP staining showed that tissue eosinophil density and percentages in eosinophilia-associated myopathies were significantly higher than in idiopathic myositides. Extracellular MBP diffusion, the hallmark of eosinophil cytotoxicity, was recurrent on sarcolemma and endothelium. Electron microscopy showed eosinophils close to sarcolemma, abundant mast cells, and capillary endothelial swelling. Immunostaining detected a higher mean eosinophil density in idiopathic myositides than previously assessed histologically.

CONCLUSIONS: MBP immunohistology on skeletal muscle, previously performed only for acute eosinophilic polymyositis, suggests that eosinophil-mediated injury of muscle cells may occur in a wider spectrum of less aggressive eosinophilia-associated myopathies than previously thought. As conventional histology is likely to underestimate this leucocyte subset, MBP staining may be a useful tool in the analysis of tissue infiltration of eosinophils as a possible treatment target.

The molecular apparatus that protects us against infection can also injure us by causing autoimmune or autoinflammatory disease. It now seems that at times, defects within the sensing arm of innate immunity contribute to diseases of this type. The initiation of an immune response is often microbe dependent and, in many cases, Toll-like receptor (TLR) dependent. Positive feedback loops triggering immune activation may occur when TLR signaling pathways stimulate host cells in an unchecked manner. Or, immune activation may persist because of failure to eradicate an inciting infection. Or on occasion, endogenous DNA may trigger specific immune responses that beget further responses in a TLR-dependent autoamplification loop. Specific biochemical defects that cause loop-related autoimmunity have been revealed by random germline mutagenesis and by gene targeting. We have also developed some insight into critical points at which feedback loops can be interrupted.

Inflammasomes: guardians of cytosolic sanctity.

Lamkanfi M(1), Dixit VM.

Author information:

(1)Department of Physiological Chemistry, Genentech, South San Francisco, CA 94080, USA.

The innate immune system is critical in recognizing bacterial and viral infections to evoke a proper immune response. Certain members of the

intracellular nucleotide-binding and oligomerization domain (NOD)-like receptor (NLR) family detect microbial components in the cytosol and trigger the assembly of large caspase-1-activating complexes termed inflammasomes. Autoproteolytic maturation of caspase-1 zymogens within these inflammasomes leads to maturation and secretion of the pro-inflammatory cytokines interleukin-1 beta (IL-1 beta) and IL-18. The NLR proteins ICE protease-activating factor (IPAF), NALP1b (NACHT domain-, leucine-rich repeat-, and PYD-containing protein 1b), and cryopyrin/NALP3 assemble caspase-1-activating inflammasomes in a stimulus-dependent manner. Bacterial flagellin is sensed by IPAF, whereas mouse NALP1b detects anthrax lethal toxin. Cryopyrin/NALP3 mediates caspase-1 activation in response to a wide variety of microbial components and in response to crystalline substances such as the endogenous danger signal uric acid. Genetic variations in Nalp1 and cryopyrin/Nalp3 are associated with autoinflammatory disorders and increased susceptibility to microbial infection. Further understanding of inflammasomes and their role in innate immunity should provide new insights into the mechanisms of host defense and the pathogenesis of autoimmune diseases.

Dysregulation of innate immunity: hereditary periodic fever syndromes.

Bodar EJ(1), Drenth JP, van der Meer JW, Simon A.

Author information:

(1)Department of General Internal Medicine, Radboud University Nijmegen Medical Centre, Nijmegen, The Netherlands.

The hereditary periodic fever syndromes encompass a rare group of diseases that have lifelong recurrent episodes of inflammatory symptoms and an acute phase response in common. Clinical presentation can mimic that of lymphoproliferative disorders and patients often go undiagnosed for many years. These syndromes follow an autosomal inheritance pattern, and the major syndromes are linked to specific genes, most of which are involved in regulation of the innate immune

response through pathways of apoptosis, nuclear factor kappaBeta activation and cytokine production. In others, the link between the protein involved and inflammation is less clear. The recurrent inflammation can lead to complications, such as renal impairment due to amyloidosis and vasculitis, visual impairment, hearing loss, and joint destruction, depending on the specific syndrome. In recent years, treatment options for these diseases have improved significantly. Early establishment of an accurate diagnosis and start of appropriate therapy improves prognosis in these patients.

Arthritis Rheum. 2009 Aug;60(8):2543; author reply 2543-4.

Recurrent pericarditis occurs in association with various medical conditions, but in most cases the condition appears to be idiopathic. Although high-dose steroid treatment is often effective, it may have serious side effects. Herein we describe 3 children with recurrent pericarditis who were treated at our hospital, during flares, with the interleukin-1beta receptor antagonist anakinra, with immediate response. Pericarditis recurred when anakinra treatment was discontinued, and no further episodes occurred after it was resumed. Idiopathic recurrent pericarditis shares several features with autoinflammatory diseases, and anakinra has been efficacious in the treatment of the latter diseases. The findings in these patients suggest that idiopathic recurrent pericarditis may be a previously unrecognized autoinflammatory disease.

Comment in

Arthritis Rheum. 2009 Jan;60(1):8-11.

**OBJECTIVE:** To analyze the effects of tumor necrosis factor receptor-associated periodic syndrome (TRAPS)-associated mutant tumor necrosis factor receptor type I (TNFRI) expression in a cell type directly relevant to the inflammation in TRAPS, and to identify novel markers associated with mutant TNFRI expression.

**METHODS:** Transcriptome analysis on 30,000 human genes was performed on SK-Hep-1 human endothelial cells transfected with either wild-type (WT) or TRAPS-associated mutant TNFRI. Quantitative reverse transcriptase-polymerase chain reaction and protein expression levels measured by enzyme-linked immunosorbent assay verified transcriptional changes for selected genes both in supernatants from cells expressing mutant TNFRI and in patient plasma.

**RESULTS:** Cells expressing mutant TNFRI showed up-regulation of multiple proinflammatory genes relative to WT transfectants, including genes for pentraxin 3, granulocyte-macrophage colony-stimulating factor, granulocyte colony-stimulating factor, CCL2, and CCL5, which were also expressed as proteins. In addition, the expression of most of these markers was increased in the plasma and peripheral blood mononuclear cells from TRAPS patients relative to those from healthy controls. The cysteine mutations (C33Y and C52F), which are associated

with a more severe clinical phenotype, induced more genes than the low-penetrance mutation R92Q, which is associated with a milder phenotype. The expression of most genes was induced by a death domain (DD)-dependent mechanism, since they were not induced by expression of TNFRI mutants with an inactivated DD.

CONCLUSION: TRAPS-associated TNFRI mutants induce the expression of multiple genes encoding inflammatory molecules, cellular receptors, transcription factors, and regulators of apoptosis in endothelial cells that require the cytoplasmic signaling properties of the receptor. Different mutants have specific expression profiles, indicating mutation-specific effects. The expression of some of these markers was also elevated in samples from TRAPS patients.

Author information:

(1)Fatih University, Department of Obstetrics and Gynecology, Ankara, Turkey.

Familial Mediterranean Fever (FMF) is an autosomal recessive disease which is characterized by recurrent, self-limiting, short attacks of serositis while abdominal pain is the most common symptom. The underlying clinical and pathological picture is that of acute peritonitis. These abdominal signs are often so striking that they mimic an acute abdominal calamity suggesting several possible gastrointestinal, gynecologic or urologic diagnoses. Diagnosis of acute abdomen in pregnancy also remains one of the most challenging conditions as the physiological consequence of pregnancy and nonspecific laboratory parameters. A limited number of studies addressed FMF in pregnancy and none of them mentioned the diagnostic challenging of FMF during pregnancy because the patients had al been diagnosed previously. In this paper, we discussed a 20 year old, gravida 1, parity 0 patient whose twin pregnancy wash complicated by an acute abdominal condition after amniocentesis and the difficulties of making the diagnosis of FMF with the complications during this diagnostic period in pregnancy.

Cytological vitreous findings in a patient with infantile neurological cutaneous and articular (CINCA) syndrome.

Adán A(1), Solé M, Corcostegui B, Navarro R, Burés A.

Author information:

(1)Instituto de Microcirugía Ocular Barcelona, Barcelona, Spain.

The CINCA syndrome is an inflammatory disease characterised by persistent rash and chronic aseptic meningitis, with extensive infiltration of polymorphonuclear and macrophage cells at the sites of inflammation. The CINCA syndrome belongs to the group of systemic autoinflammatory diseases characterised by episodic or fluctuating degrees of inflammation, without evidence of high-titre autoantibodies or antigen-specific T cells. The disease is caused by mutations in the CIAS1 gene that encodes a protein cryopyrin, NALP3 or PYPAF1. Mutations in cryopyrin have a profound pro-inflammatory effect. Cryopyrin is a caspase 1 activator, which in turn causes the activation of interleukin (IL)1 $\beta$ . The activating mutations of cryopyrin induce an excessive activation of IL1 $\beta$ , which causes an influx of macrophages and polymorphonuclear cells to the site of inflammation, in our patient, in his eye.

The inflammasomes: the key regulators of inflammation.

Fietta P(1), Delsante G.

Author information:

(1)Dipartimento Medico-Specialistico 2 - S.D. di Medicina Interna e Reumatologia Azienda Ospedaliero-Universitaria di Parma, Via Gramsci 14, 43100 Parma (Italy).

Following any threat to tissutal integrity, innate immune system promptly recognizes foreign/damage-associated molecules and orchestrates the global immune response, inducing inflammation, chemotaxis, phagocytosis and production of antimicrobial effector molecules, as well as providing instruction to the adaptive immune system. Innate immune cells detect both exogenous and endogenous

danger signals through invariant germline-encoded pattern recognition receptors, including Toll-like receptors, retinoic acid-inducible gene I-like receptors, and nucleotide binding domain and leucine rich repeat containing receptors (NLRs). The recruitment of NLRs, namely IPAF, NAIPs and NALPs, by various potentially harmful stimuli leads to the assembly of inflammasomes, multimeric caspase-activating complexes entailing the sensor NLR, intracellular adaptor proteins, and procaspase-1 and -5. The caspase activation is necessarily required for the processing and secretion of proinflammatory cytokines, such as interleukin (IL)-1 $\beta$ , IL-18, and IL-33. Therefore, the inflammasomes are critical regulators of the inflammatory response. Dysregulation of such a versatile sentry system is involved in the pathogenesis of human autoinflammatory diseases, autoimmune disorders, and microcrystalline arthritides. A better knowledge of the inflammasome crucial role in the immune response may provide possible future therapeutic improvements in protection against invading pathogens and in vaccine efficacy, as well as in the treatment of human inflammatory diseases.

Author information:

(1)Division of Pediatric Allergy and Immunology, Faculty of Medicine, Balcali Hospital, University of Cukurova, 01330 Adana, Turkey. ainal@cu.edu.tr

The aim of the present study was to evaluate the clinical features of childhood-onset Familial Mediterranean fever (FMF) patients and to assess the phenotype-genotype correlation. The study included patients with childhood-onset FMF that followed up over a period of 18 years in the Division of Pediatric Allergy and Immunology clinic. Twelve MEFV mutations were investigated in all patients. The patients were classified into four groups according to mutations: 1, M694V homozygote; 2, M694V heterozygote; 3, compound heterozygote for M694V;

and 4, other-other gene mutation group. The following parameters were evaluated: gender, age of onset, age at diagnosis, time interval between disease onset and diagnosis, fever, abdominal pain, chest pain, arthralgia, arthritis, myalgia, vomiting, diarrhea, constipation, headache, erysipela-like erythema, protracted febrile myalgia, splenomegaly, hepatomegaly, consanguinity, number of attacks before and after treatment, severity score, response to colchicine treatment. Of the 124 patients included in the study, 105 had at least one MEFV gene mutation. M694V homozygosity was the most common mutation, followed by M694V heterozygotes and M694V-M680I compound heterozygotes. Severity score was found significantly higher in patients with M694V homozygote and compound heterozygote for M694V compared with other groups. The data supported the findings in literature that FMF patients with M694V homozygote and compound heterozygote for M694V gene mutations experience a more severe clinical course.

Lymphoid tissue inducer-like cells are an innate source of IL-17 and IL-22.

Takatori H(1), Kanno Y, Watford WT, Tato CM, Weiss G, Ivanov II, Littman DR, O'Shea JJ.

Author information:

(1)Lymphocyte Cell Biology Section, Molecular Immunology and Inflammation Branch, National Institute of Arthritis and Musculoskeletal and Skin Diseases, Bethesda, MD 20892, USA. takatorih@mail.nih.gov

The interleukin (IL) 17 family of cytokines has emerged to be critical for host defense as well as the pathogenesis of autoimmune and autoinflammatory disorders, and serves to link adaptive and innate responses. Recent studies have identified a new subset of T cells that selectively produce IL-17 (Th17 cells; Bettelli, E., T. Korn, and V.K. Kuchroo. 2007. Curr. Opin. Immunol. 19:652-657; Kolls, J.K., and A. Linden. 2004. Immunity. 21:467-476), but the regulation of IL-17 production by innate immune cells is less well understood. We report that in vitro stimulation with IL-23 induced IL-17 production by recombination activating gene (Rag) 2(-/-) splenocytes but not Rag2(-/-) common gamma chain(-/-)

splenocytes. We found that a major source of IL-17 was CD4(+)CD3(-)NK1.1(-)CD11b(-)Gr1(-)CD11c(-)B220(-) cells, a phenotype that corresponds to lymphoid tissue inducer-like cells (LTi-like cells), which constitutively expressed the IL-23 receptor, aryl hydrocarbon receptor, and CCR6. In vivo challenge with the yeast cell wall product zymosan rapidly induced IL-17 production in these cells. Genetic deletion of signal transducer and activator of transcription 3 reduced but did not abrogate IL-17 production in LTi-like cells. Thus, it appears that splenic LTi-like cells are a rapid source of IL-17 and IL-22, which might contribute to dynamic organization of secondary lymphoid organ structure or host defense.

Pyrin and ASC co-localize to cellular sites that are rich in polymerizing actin.

Waite AL(1), Schaner P, Hu C, Richards N, Balci-Peynircioglu B, Hong A, Fox M, Gumucio DL.

Author information:

(1)Department of Cell and Developmental Biology, University of Michigan Medical School, 109 Zina Pitcher Place, Box 2200, Ann Arbor, MI 48109-2200, USA.

Familial Mediterranean fever (FMF) is an autoinflammatory disease caused by mutations in the MEFV locus, which encodes the protein pyrin. While it is known that pyrin is expressed in myeloid cells and several fibroblastic cell types, the exact function of pyrin in these cells and the mechanism underlying the pathological effect of pyrin mutations have yet to be revealed. Here, we document that in migrating human monocytes, pyrin protein is dramatically polarized at the leading edge, where it co-localizes with polymerizing actin. ASC (Apoptosis-associated Speck protein with CARD domain), a known pyrin-interacting protein and a critical component of the inflammasome, is also located at the leading edge in migrating monocytes. Similarly, both pyrin and ASC concentrate in dynamically polymerizing actin-rich tails generated by *Listeria monocytogenes*. Pyrin's B-box and coiled-coil region is required for its association with

Listeria tails. Pyrin also binds, with low affinity and via the same domains, to actin, VASP, and Arp3. Though disease-causing mutations in pyrin do not appear to alter its localization to the leading edge or to Listeria rocket tails, they could potentially have important functional consequences in the context of processes such as migration and cell synapse formation. The co-localization of pyrin and ASC together at such sites may provide an important link between cytoskeletal signaling and inflammasome function.

Screening of family members of children with Familial Mediterranean Fever: true-autosomal and pseudo-autosomal inheritance.

Caglar MK(1), Altugan FS, Ozyurt H, Atasoy HI.

Author information:

(1)Department of Pediatrics, Faculty of Medicine, Abant Izzet Baysal University, Bolu, Turkey. caglar\_m@ibu.edu.tr

**OBJECTIVES:** Screening of family members of children with Familial Mediterranean Fever (FMF) has been carried out to detect new potential patients and to analyze the type of inheritance other than autosomal recessive.

**METHODS:** Marenostin encoding fever gene mutational analysis has been performed in 83 subjects - including 19 newly diagnosed children with FMF and their family members.

**RESULTS:** Fourteen additional patients with FMF were diagnosed by screening family members. Pseudo-dominant and true dominant inheritances were detected in two families respectively, while the rest of the patients exhibited autosomal recessive mode of inheritance.

**CONCLUSION:** Screening the family members of newly diagnosed FMF patients provides the opportunity to reveal undiagnosed new cases and to understand the mode of inheritance.

NALP3 inflammasome functional polymorphisms and gout susceptibility.

Miao ZM(1), Zhao SH, Yan SL, Li CG, Wang YG, Meng DM, Zhou L, Mi QS.

Author information:

(1)Department of Medicine, the Affiliated Hospital of Qingdao Medical College, Qingdao University, Qingdao, P.R. China. miaozm@qdumh.qd.sd.cn

Gout is the most common autoinflammatory arthritis characterized by elevated serum urate and recurrent attacks of intra-articular crystal deposition of monosodium urate (MSU). Although the pathogenesis of gout is still unclear, accumulated studies indicate that genetic factors trigger gout development, including some susceptibility genes that control the production and clearance of urate and lead to hyperuricemia. However, the epidemiological evidence suggests that only less than 10% of hyperuricemia patients develop gout, indicating that other genes unrelated to the urate metabolism may also contribute to the diseases susceptibility. Accumulated evidences have implied that MSU crystal-induced inflammation is a paradigm of innate immunity and that NALP3 inflammasome, an innate immune complex containing NALP3, ASC and CARD-8, is involved in gout development. Recent studies suggest that NALP3 and CARD-8 functional mutations contribute to the development of autoinflammatory diseases including hereditary periodic fever syndrome, arthritis as well as hypertension susceptibility. Taking into account these genetic findings, here we would like to propose a novel hypothesis that functional mutations in NALP3 inflammasome may make NALP3 inflammasome as attractive susceptibility candidates and genetic markers for gout. Further clinical genetic studies need to be performed to confirm the role of NALP3 inflammasome in the etiology of gout.

We used a candidate gene approach to identify a set of SNPs, located in a predicted regulatory region on chromosome 1q44 downstream of NLRP3 (previously known as CIAS1 and NALP3) that are associated with Crohn's disease. The associations were consistently replicated in four sample sets from individuals of European descent. In the combined analysis of all samples (710 father-mother-child trios, 239 cases and 107 controls), these SNPs were strongly associated with risk of Crohn's disease ( $P(\text{combined}) = 3.49 \times 10^{-9}$ ), odds ratio = 1.78, confidence interval = 1.47-2.16 for rs10733113), reaching a level consistent with the stringent significance thresholds imposed by whole-genome association studies. In addition, we observed significant associations between SNPs in the associated regions and NLRP3 expression and IL-1 $\beta$  production. Mutations in NLRP3 are known to be responsible for three rare autoinflammatory disorders. These results suggest that the NLRP3 region is also implicated in the susceptibility of more common inflammatory diseases such as Crohn's disease.

Conjunctival impression cytology and tear-film changes in patients with familial Mediterranean fever.

Karalezli A(1), Borazan M, Yilmaz S, Kiyici H, Akova YA.

Author information:

(1)Department of Ophthalmology, Rheumatology and Pathology, Baskent University School of Medicine, Ankara, Turkey. akaralezli@yahoo.com

Comment in

Acta Ophthalmol. 2010 Mar;88(2):e5; author reply e6.

**PURPOSE:** To evaluate the ocular surface changes and tear-film functions in patients with familial Mediterranean fever (FMF).

**METHODS:** This prospective case-control clinical study examined 35 patients with FMF (group 1) and 35 controls (group 2). All patients underwent a full ophthalmological examination. Ocular surface changes were evaluated by determining cell content of surface conjunctival epithelium using conjunctival impression cytology and tear-film functions using Schirmer-I, break-up time (BUT), corneal fluorescein and Rose Bengal tests. Subjective ocular complaints were scored with a four-point scale. Between-group results were compared.

**RESULTS:** In group 1, impression cytology revealed grade 0 changes in 15 eyes, grade 1 changes in 11 eyes and grade 2 changes in nine eyes in group 1; in group 2, it revealed grade 0 changes in 27 eyes, grade 1 changes in five eyes and grade 2 changes in three eyes ( $p = 0.013$ ). Mean goblet cell density was  $765 \pm 45$  cells/mm<sup>2</sup> in group 1 and  $1730 \pm 100$  cells/mm<sup>2</sup> in group 2 ( $P < 0.001$ ). Mean results on the Schirmer-I test results were  $17.36 \pm 3.18$  mm in group 1 and  $19.60 \pm 4.17$  mm in group 2 ( $p = 0.364$ ). Mean BUT was  $8.20 \pm 1.60$  seconds in group 1 and  $9.93 \pm 2.33$  seconds in group 2 ( $p = 0.001$ ). Mean corneal fluorescein and Rose Bengal staining scores were  $3.26 \pm 1.67$  and  $0.96 \pm 0.71$  in group 1 and  $1.37 \pm 0.34$  and  $0.40 \pm 0.49$  in group 2 ( $p = 0.037$ ,  $p = 0.005$ ). The presence of subjective ocular complaints was more frequent in group 1 than in

group 2.

CONCLUSION: Despite normal tear production, the ocular surface and tear-film functions of FMF patients differ from those of healthy individuals. These changes may be related to the chronic inflammatory nature of FMF.

Familial Mediterranean Fever: a review for clinical management.

Fonnesu C(1), Cerquaglia C, Giovinale M, Curigliano V, Verrecchia E, de Socio G, La Regina M, Gasbarrini G, Manna R.

Author information:

(1)Department of Internal Medicine, Periodic Fevers Research Centre, Catholic University, Largo F.Vito 1, 00168 Rome, Italy.

Familial Mediterranean Fever (FMF) is a hereditary autosomal recessive, autoinflammatory disorder characterized by recurrent, self-limiting episodes of short duration (mean 24-72 h) of fever and serositis. FMF is the most frequent periodic febrile syndrome among the autoinflammatory syndromes (AS), a heterogeneous group of recently identified diseases clinically characterized by recurrent febrile attacks, in the absence of autoantibodies and antigen-specific T lymphocytes. In FMF, periodic attacks show inter- and intra-individual variability in terms of frequency and severity. Usually, they are triggered by apparently innocuous stimuli and may be preceded by a prodromal period. The Mediterranean Fever gene (MEFV) responsible gene maps on chromosome 16 (16p13) encoding the pyrin-marenostrin protein. The precise pathologic mechanism is still to be definitively elucidated; however a new macromolecular complex, called inflammasome, seems to play a major role in the control of inflammation and it might be involved in the pathogenesis of FMF. The most severe long-term complication is type AA amyloidosis, principally affecting the kidney and the cause of chronic renal failure. Two types of risk factors, genetic and non-genetic, have been identified for this complication. Currently, the only effective treatment of Familial Mediterranean Fever is the colchicine. New drugs

in a few colchicine resistant patients have been tried, but additional studies on larger series are necessary to draw definitive conclusions.

The human skin is constantly exposed to microbial pathogens but infections only rarely occur. Innate cutaneous immunity is a primary system for protection against infection, and antimicrobial peptides (AMPs) expressed in skin are essential defence molecules. The AMPs include molecules such as the defensins that were first characterized for their antimicrobial properties as well as other peptides and proteins first known for their activity as chemokines, enzymes, enzyme inhibitors and neuropeptides. Cathelicidins are unique AMPs that act as defensive and signalling molecules. Two different pathways are involved in this function: cathelicidins have direct antimicrobial activity and they also initiate a host of cellular responses in cytokine release, inflammation and angiogenesis. Several skin diseases are associated with cathelicidin dysfunction. In atopic eczema, for example, cathelicidin expression is suppressed, whereas in rosacea cathelicidin peptides are abnormally processed to forms that induce cutaneous inflammation and a vascular response. In psoriasis cathelicidin peptide converts self-DNA to a potent stimulus in an autoinflammatory cascade. Current studies have unexpectedly identified vitamin D3 as a major factor for the regulation of cathelicidin expression. This finding may provide new strategies in the management of infectious and inflammatory diseases of the skin by targeting control of the expression and function of cathelicidin and other AMPs.

Anakinra suppresses familial Mediterranean fever crises in a colchicine-resistant patient.

Mitroulis I(1), Papadopoulos VP, Konstantinidis T, Ritis K.

Author information:

(1)First Division of Internal Medicine, Democritus University of Thrace, Alexandroupolis, Greece.

We describe a 34-year-old male patient suffering from familial Mediterranean fever and experiencing an increase in both the frequency and severity of disease attacks, suggesting resistance to chronic treatment with colchicine. Since no alternative treatment is established, anakinra, an interleukin-1 receptor antagonist, was administered, not daily, as it has been previously reported, but only during crises, with successful outcome.

NOD1 expression in the eye and functional contribution to IL-1beta-dependent ocular inflammation in mice.

Rosenzweig HL(1), Galster KT, Planck SR, Rosenbaum JT.

Author information:

(1)Casey Eye Institute, Oregon Health & Science University, Portland, Oregon 97239, USA. rosenzwh@ohsu.edu

**PURPOSE:** NOD1 plays an important role in host defense and recognizes the minimal component of bacterial cell walls, meso-diaminopimelic acid (iE-DAP).

Polymorphisms in NOD1 are associated with autoinflammatory diseases characterized by uveitis such as Crohn's disease and sarcoidosis. NOD1 is homologous to NOD2, which is responsible for an autosomal dominant form of uveitis. Nonetheless, the role of NOD1 in intraocular inflammation has not been explored. The induction of uveitis by iE-DAP in mice and the potential contribution of interleukin (IL)-1beta were investigated.

**METHODS:** BALB/c mice or mice deficient in caspase-1 or IL-1R1 and their congenic controls were injected intravitreally with iE-DAP or saline. The time course, dose response, and contribution of IL-1beta to ocular inflammation were quantified by intravital video microscopy, histology, and immunohistochemistry.

NOD1 and IL-1beta were measured in eye tissue by immunoblotting and ELISA.

**RESULTS:** NOD1 protein is expressed in the eye and promotes ocular inflammation in a dose- and time-dependent fashion. The authors previously defined the role of IL-1beta in NOD2 uveitis and tested whether NOD1 and NOD2 used similar mechanisms. Treatment with iE-DAP significantly increased IL-1beta, which was caspase-1 dependent. However, in contrast to NOD2, caspase-1 and IL-1R1 were essential mediators of iE-DAP-induced uveitis, suggesting that NOD1 and NOD2 induce ocular inflammation by distinct mechanisms involving IL-1beta.

**CONCLUSIONS:** These findings demonstrate that NOD1 is expressed within the eye and that its activation results in uveitis in an IL-1beta-dependent mechanism.

Characterizing the differences between NOD1 and NOD2 responses may provide insight into the pathogenesis of uveitis.

The analysis of interleukin-1 receptor antagonist and interleukin-1beta gene polymorphisms in Turkish FMF patients: do they predispose to secondary amyloidosis?

Balci-Peynircioğlu B(1), Taşkiran ZE, Türel B, Arici M, Bakkaloğlu A, Ozen S, Yilmaz E.

Author information:

**OBJECTIVE:** Amyloid development in familial Mediterranean fever (FMF) patients is associated with acute phase response and the acute phase reactant serum amyloid A which is induced by IL-1Beta. Its concentration can increase to more than 1000 fold during inflammation. In view of the inflammatory nature of FMF disease we have investigated whether IL-1Beta and IL-1 receptor antagonist gene polymorphisms may be involved in amyloid development in FMF patients.

**METHODS:** Ninety-nine FMF patients without amyloidosis; 54 FMF patients with amyloidosis and 60 healthy controls samples were genotyped for IL-1Beta-511 (C/T) and IL-1Beta+3953 (C/T) polymorphisms using PCR-RFLP and for IL-1Ra VNTR polymorphism using PCR.

**RESULTS:** The allele and genotype frequencies of IL-1Beta-511 (C/T), IL-1Beta+3953 (C/T) and IL-1Ra VNTR polymorphisms in FMF patients with and without amyloidosis were all compared with those in controls. There were no significant differences between FMF patients with and without amyloidosis and healthy control samples for these polymorphisms (all P-values are >0.05). These polymorphisms were not associated with M694V mutation in FMF patients with and without amyloidosis.

**CONCLUSION:** IL-1Beta-511 (C/T), IL-1Beta+3953 (C/T) and IL-1Ra VNTR polymorphisms are not associated with the development of amyloid in FMF patients.

MEFV gene 3'-UTR Alu repeat polymorphisms in patients with familial Mediterranean fever.

Ustek D(1), Ekmekçi C, Oku B, Coşan F, Cakiris A, Abaci N, Celik S, Kamali S, Hatemi G, Kasapçopur O, Ozdoğan H, Gül A.

Author information:

(1)Department of Genetics, Institute for Experimental Medicine, Istanbul Faculty of Medicine, Istanbul, Turkey.

**OBJECTIVE:** Familial Mediterranean fever (FMF), an autosomal recessively inherited autoinflammatory disorder, is caused by missense mutations in the pyrin-encoding MEFV gene. The MEFV mutations can be detected in the majority of FMF patients, but there is an important proportion of patients with the FMF phenotype who carry a single or no coding region mutation. This study aimed to investigate the promoter region and 3'-UTR polymorphisms of the MEFV gene in a group of FMF patients with no coding region mutations, to identify variations with a possible role in the regulation of MEFV expression.

**METHODS:** The study group consisted of 289 patients with FMF and 103 ethnically-matched healthy individuals of Turkish origin. All individuals were first genotyped for the five most commonly observed mutations (M694V, M680I, V726A, E148Q and M694I). Then, the coding regions of the MEFV gene in patients carrying none of the 5 mutations were amplified and screened using single-stranded conformation polymorphism and DNA sequencing. After the exclusion of patients with mutations in exons, the promoter and 3'-UTR regions of the MEFV gene were investigated in the remainder. For the haplotype analysis, all study groups were genotyped for two of the 3'-UTR single nucleotide polymorphisms (SNP).

**RESULTS:** Genotyping for five mutations revealed 186 patients (64.4%) with two mutations, 61 patients (21.1%) with one mutation, and 42 patients (14.5%) with no mutation. The carrier rate for healthy controls was found to be 10%. After screening all 10 exons in the patients with none of the 5 mutations, we identified 36 patients (12.5%) who had no coding region mutations. Analysis of the 3'-UTR region in these patients showed two Alu repeats (AluSx and AluSq), which were located in the 3'-UTR of the reference mRNA sequence. Sequencing of the 3'-UTR of the MEFV gene showed several SNPs that were clustered in 2 haplotypes. When we genotyped all study groups for two of the 3'-UTR SNPs (rs2741918 and rs450021), we observed a significant increase in the frequency of

heterozygotes for the 3'-UTR haplotypes in the FMF patients with no coding region polymorphisms compared to the healthy controls (75% versus 48.5%,  $p=0.006$ ,  $OR=3.2$ , 95% CI 1.4-7.4).

**CONCLUSION:** This study showed a group of 3'-UTR polymorphisms in the MEFV gene that are clustered in two haplotypes. In addition, a genetic association was observed between 3'-UTR polymorphisms and the FMF patients with no coding region mutations. These findings may suggest a role for 3'-UTR sequences in the regulation of MEFV expression.

IL-17A enhances vitamin D3-induced expression of cathelicidin antimicrobial peptide in human keratinocytes.

Author information:

(1)Department of Dermatology and Allergology, Ludwig-Maximilians-University, Munich, Germany.

Cathelicidin is strongly expressed in lesional skin in psoriasis and may play an important role as both an antimicrobial peptide and as an autoinflammatory mediator in this chronic skin disease. The mechanism of increased cathelicidin in psoriatic keratinocytes is not known, but recent observations have found that psoriasis has abundant Th17 cells that produce IL-17A and IL-22. We found that human keratinocytes stimulated with supernatants from T cells isolated from lesional psoriatic skin increased expression of cathelicidin when stimulated in the presence of 1,25-dihydroxyvitamin D(3) (1,25D(3)). This increase was signaled through the IL-17RA. In vitro, IL-17A, but not IL-22, enhanced cathelicidin mRNA and peptide expression in keratinocytes dependent on the presence of 1,25D(3). At the same time, coincubation with 1,25D(3) blocked induction of human beta-defensin 2 (HBD2), IL-6, and IL-8, which are other target genes of IL-17A. Act1, an adaptor associated with IL-17RA and essential for IL-17A signaling, mediated cathelicidin induction, as its suppression by small interfering RNA

inhibited HBD2 and cathelicidin. Both, 1,25D(3) and IL-17A signaled cathelicidin induction through MEK-ERK. These results suggest that increased IL-17A in psoriatic skin increases cathelicidin through a vitamin D(3)-, Act1-, and MEK-ERK-dependent mechanism. Therapy targeting this cathelicidin-regulating system might be beneficial in patients suffering from psoriasis.

Recurrent pericarditis as the initial manifestation of Familial Mediterranean fever.

Okutur K(1), Seber S, Oztekin E, Bes C, Borlu F.

Author information:

(1)Sisli Etfal Research and Training Hospital Department of Internal Medicine, Istanbul, Turkey. keremokutur007@yahoo.com

**BACKGROUND:** Familial Mediterranean fever is an autosomal recessive disease largely restricted to certain ethnic groups and presenting with recurrent febrile serositis attacks. Peritonitis, pleuritis, and synovitis are common manifestations; however, the pericardium is rarely affected.

**CASE REPORT:** In this case report, we describe a 25-year-old Turkish woman who presented with recurrent pericarditis of no obvious cause, which eventually responded to colchicine therapy. Using gene mutation analysis to detect the MEFV gene, the patient's condition was finally diagnosed as Familial Mediterranean fever.

**CONCLUSIONS:** Familial Mediterranean fever should be considered in patients with idiopathic recurrent pericarditis unresponsive to nonsteroidal anti-inflammatory medications and corticosteroids. Mutation analyses should be done.

S100A12 is a novel molecular marker differentiating systemic-onset juvenile idiopathic arthritis from other causes of fever of unknown origin.

Author information:

(1)University Hospital Muenster, Muenster, Germany.

OBJECTIVE: Fever of unknown origin (FUO) in children presents a diagnostic

challenge. The differential diagnosis includes systemic-onset juvenile idiopathic arthritis (JIA), an autoinflammatory syndrome associated with activation of phagocytic cells that, at presentation, is difficult to differentiate from severe systemic infections. The aim of this study was to investigate whether serum concentrations of the phagocytic proinflammatory protein S100A12 may help in deciding whether to treat patients with FUO with antibiotics or immunosuppressive agents.

**METHODS:** Serum samples were obtained from 45 healthy control subjects and from 240 patients (60 with systemic-onset JIA, 17 with familial Mediterranean fever [FMF], 18 with neonatal-onset multisystem inflammatory disease [NOMID], 17 with Muckle-Wells syndrome [MWS], 40 with acute lymphoblastic leukemia [ALL], 5 with acute myeloblastic leukemia [AML], and 83 with systemic infections). All samples were collected at the time of presentation, before the initiation of any treatment, and concentrations of S100A12 were determined by enzyme-linked immunosorbent assay.

**RESULTS:** The mean  $\pm$  95% confidence interval serum levels of S100A12 were as follows: in patients with JIA, 7,190  $\pm$  2,690 ng/ml; in patients with FMF, 6,720  $\pm$  4,960 ng/ml; in patients with NOMID, 720  $\pm$  450 ng/ml; in patients with MWS, 150  $\pm$  60 ng/ml; in patients with infections, 470  $\pm$  160 ng/ml; in patients with ALL, 130  $\pm$  80 ng/ml; in patients with AML, 45  $\pm$  60 ng/ml; in healthy control subjects, 50  $\pm$  10 ng/ml. The sensitivity and specificity of S100A12 to distinguish between systemic-onset JIA and infections were 66% and 94%, respectively.

**CONCLUSION:** S100A12, a marker of granulocyte activation, is highly overexpressed in patients with systemic-onset JIA or FMF, which may point to as-yet unknown common inflammatory mechanisms in these diseases. The measurement of S100A12 serum levels may provide a valuable diagnostic tool in the evaluation of FUO.

Familial Mediterranean fever (FMF) is an autosomal recessive disease characterized by self-limited attacks of fever and polyserositis. Articular involvement in early-onset FMF is a common finding characterized by non-erosive, generally asymmetric monoarthritis in large joints. Protracted FMF arthritis was reported in 2.6% of Turkish patients. An 8-year-old female who has a history of FMF for 5 years applied to our hospital with complaints of persistent swelling and pain of her left knee for 8 months. The patient had been tried to be managed with non-steroidal anti-inflammatory drugs as well as intra-articular steroids and colchicine. However, arthritis and acute phase response persisted. With sulphasalazine, complete recovery was achieved. It is our belief that sulphasalazine can be a choice of medical treatment in protracted FMF arthritis.

ozel@medicine.ankara.edu.tr

Familial Mediterranean fever (FMF) is an autosomal recessive disease that is the most common of a rare group of disorders collectively termed familial hereditary periodic fever syndromes, also known as autoinflammatory syndromes. FMF is predominantly affecting people of Mediterranean descent and clinically characterized by intermittent attacks of fever with peritonitis and abdominal pain, pleuritis, arthritis, or erysipelas-like rashes. Amyloidosis due to chronic

inflammation progressing to renal failure is one of the most serious potential complications of this disease. Patients with inflammatory diseases, such as systemic lupus erythematosus and rheumatoid arthritis, and conditions with chronic subclinical inflammation, like obesity and diabetes mellitus, are now considered to have an increased risk of atherosclerotic cardiovascular complications. FMF is also an inflammatory disease, and it is accepted that even during attack-free periods significant inflammatory reaction continues. However, whether this inflammatory process causes premature atherosclerosis is not known due to a lack of data. Different studies have investigated the association between the fibrinolytic and inflammatory process parameters. PAI-1 is paracrine secretion of pro- and antiinflammatory cytokines, thereby playing a possible role in the adiposity-related inflammation and atherosclerosis. The patients with IRS have higher values of fibrinogen, factor VII, VIII, Von Willebrand factor and Plasminogen Activator Inhibitor (PAI) compared to control subjects. So that we aimed in this study to investigate whether FMF patients with/without amyloidosis and with M694V homozygote mutation, have increased risk for atherosclerotic cardiovascular complications and to determine the strength of association between MEFV gene-mutation types. To our knowledge, this is the first case control and cross-sectional study in the pediatric age groups.

(1)6th Medical Department with Nephrology and Dialysis, Wilhelminenspital, 1160 Vienna, Montleartstrasse 37, Austria. Christian.moser.md@aon.at

Familial Mediterranean fever (FMF) is an autosomal recessive disease characterized by recurrent episodes of fever and inflammation. The most severe

complication of FMF is the development of AA amyloidosis, which can be life threatening. The only current effective treatment for FMF is colchicine. Regular prophylactic treatment with colchicine at a dose of 1-2 mg daily prevents or substantially reduces the clinical manifestations of FMF in at least 90% of cases. However, approximately 10% of patients are reported to be resistant or non-responsive to colchicine and in these cases there is no consensus as to which second line agents should be used. We describe the first case, to our knowledge, of a patient with FMF and end-stage renal failure due to AA amyloidosis, successfully treated with IL-1 receptor blockade. Our data suggest that the IL-1 receptor antagonist Anakinra (Kineret; r-metHuIL-1 ra) may represent a safe and effective therapy for the treatment of colchicine-resistant FMF, in patients requiring renal replacement therapy, with dialysis or transplantation.

Nutcracker syndrome in a child with familial Mediterranean fever (FMF) disease: renal ultrastructural features.

Ozcan A(1), Gonul II, Sakallioglu O, Oztas E.

Author information:

(1)Department of Pathology, Gulhane Military Medical Academy, Etlik, Ankara, 06018, Turkey. aozcan06018@yahoo.com

Renal nutcracker syndrome is an uncommon clinical condition caused by compression of the left renal vein. It is usually accompanied by hematuria and/or orthostatic proteinuria. To date, the pathogenic mechanism of proteinuria and its ultrastructural features have not been clearly identified. Here, we present the glomerular ultrastructural features of nutcracker syndrome and our attempt to analyze the relationship between proteinuria and ultrastructural features. Two months prior to admission, a 11-year-old girl with familial Mediterranean fever who was treated with colchicine was found to have proteinuria. Accompanying hematuria was not identified, and laboratory findings were otherwise normal. Doppler ultrasonography and computerized tomography angiography revealed an

entrapment of the left renal vein. A kidney biopsy was performed due to the persistent proteinuria. Light microscopy revealed segmental, minimal increases in the mesangial cells and matrix. No amyloid deposition was present. Neither immunofluorescence nor electron microscopy showed immunoglobulin deposition. Increased thickness of the glomerular basement membrane due to the unequivocal radiolucent widening of the lamina rara interna was the most striking ultrastructural finding. At high magnification, there were no amyloid fibrils. It has been proposed that hemodynamic alterations and structural changes in glomerular basement membrane glycosaminoglycans may play a role in the pathogenesis of proteinuria. Radiolucent expansion of the lamina rara interna of the glomerular basement membrane in the presenting case would seem to support these data.

**OBJECTIVE:** Tumor necrosis factor receptor 1-associated periodic syndrome (TRAPS) is an autosomal dominantly inherited autoinflammatory disorder resulting from mutations in the TNFRSF1A gene, which encodes the p55 receptor for tumor necrosis factor alpha. We recently identified the R92Q mutation encoded by exon 4 in six patients with multiple sclerosis (MS) who reported at least two symptoms suggestive of TRAPS. The current study presents the characteristics of a larger cohort of MS patients carrying this mutation.

**METHODS:** Clinical and laboratory parameters, including human leukocyte antigen (HLA)-DR15 status, were evaluated, and genetic testing was performed. Whenever possible, family members were also invited for interview and mutation analysis.

**RESULTS:** Twenty TNFRSF1A R92Q carriers had MS according to the McDonald criteria, and 1 had clinically isolated syndrome. The majority of patients had typical onset and features of MS. Nine patients carried an HLA-DR15 haplotype. All individuals showed TRAPS-compatible symptoms, which consisted mainly of myalgias, arthralgias, headache, severe fatigue, and skin rashes; were milder than usually described; and appeared mainly in adulthood. Most patients experienced severe side effects during immunomodulatory therapy for MS. Seventeen family members carried the identical mutation, and 15 of them reported symptoms suggestive of TRAPS.

**CONCLUSION:** In most cases with multiple sclerosis (MS) and coexisting tumor necrosis factor receptor 1-associated periodic syndrome (TRAPS), features of MS were quite typical, whereas TRAPS presented mostly without the fever episodes observed in childhood. The penetrance of the R92Q mutation in affected family members was higher than reported. We recommend careful observation of MS patients with coexisting TRAPS with regard to unexpected side effects of immunomodulatory therapies.

Autoinflammatory diseases.

Touitou I(1), Koné-Paut I.

Author information:

(1)CHU Montpellier, Unité médicale des maladies autoinflammatoires, Hôpital A de Villeneuve, Montpellier, France. isabelle.touitou@igh.cnrs.fr

Autoinflammatory diseases (AIDs) are illnesses caused by primary dysfunction of the innate immune system. Proteins that are mutated in AIDs mediate the regulation of NFkappaB activation, cell apoptosis, and IL-1beta secretion through cross-regulated and sometimes common signaling pathways. AIDs include a broad number of monogenic [e.g., familial Mediterranean fever (FMF), cryopyrin-associated periodic syndrome (CAPS), mevalonate kinase deficiency (MKD), tumor necrosis factor (TNF)-receptor-associated periodic syndrome (TRAPS)] and multifactorial (e.g., Behçet's syndrome) disorders. These conditions are characterized by recurrent attacks of fever, abdominal pain, arthritis, and cutaneous signs; these symptoms sometimes overlap, obscuring diagnosis. Distinguishing signs and the use of specific functional tests where available (e.g., in MKD) are helpful. However, some patients remain hard to manage despite the advent of new genetic tests and/or due to lack of effective treatment.

Behçet's syndrome.

Yurdakul S(1), Yazici H.

Author information:

(1)Department of Medicine, Division of Rheumatology, Cerrahpasa Medical Faculty, University of Istanbul, Istanbul, Turkey. profsyurdakul@yahoo.com

Recent epidemiological work suggests that genetic background overrides environmental factors in the pathogenesis of Behçet's syndrome (BS). There are at

least two clusters of disease expression. The first is the cluster of superficial vein thrombosis, deep vein thrombosis and dural sinus thrombi; the second cluster is that of acne, arthritis and enthesitis. The association of antibodies to anti-Saccharomyces cerevisiae antibodies and the presence of inflammatory bowel disease is perhaps another such cluster. The presence of such clusters suggests that there might be more than one disease mechanism operative in this complex disorder. There is a recent trend to classify BS with the autoinflammatory disorders. However, practically all autoinflammatory conditions are recurrent fever syndromes of children, and are genetically linked to well-defined loci; none of this is true for BS. Recent guidelines from the European League Against Rheumatism are quite useful for the management of the disease in organ systems other than the vascular, neurological and gastrointestinal systems, because of the lack of controlled studies related to these latter pathologies.

Author information:

(1)Department of Pediatrics, Graduate School of Medical Sciences, Kyushu University, Fukuoka, Japan. yamaken@pediatr.med.kyushu-u.ac.jp

We investigated a possible association between Kawasaki disease (KD), a systemic vasculitis of unknown etiology, or its coronary artery lesions (CAL) and MEFV gene variants including E148Q, the most common and mild mutation in the MEFV gene for familial Mediterranean fever or vasculitis-related disorders. The study population comprised a total of 138 Japanese patients with KD, including 45 patients with CAL and 93 patients without CAL and 170 normal controls. Sequence variations for the MEFV gene were detected by direct sequencing, followed by the TaqMan SNP genotyping assay. The genotype and allele frequencies of MEFV gene variants (E148Q, L110P, R202Q, P369S, R408Q) were compared between KD patients with and without CAL or between KD patients with CAL and controls. E148Q

heterozygotes and homozygotes were observed in 37.1 and 5.5% of healthy controls, 33.3 and 5.1% of KD patients, and 37.8 and 4.4% of KD patients with CAL. No significant differences were observed in the genotype and allele frequencies of other MEFV gene variants (L110P, R202Q, P369S, R408Q) between KD patients with and without CAL or between KD patients with CAL and controls. No associations were detected between the MEFV gene variants and the development of KD or CAL formation in KD.

Tumor markers in familial Mediterranean fever and their correlation with the frequency of attacks.

Balaban YH(1), Simsek H, Yilmaz R, Sarer-Yurekli BP, Shorbagi A, Tatar G.

Author information:

(1)Department of Internal Medicine, Division of Gastroenterology, Hacettepe University, Ankara, Turkey. ybalaban@superonline.com

**OBJECTIVE:** Serum levels of tumor markers can be elevated in several benign diseases affecting the serosal surfaces. Familial Mediterranean fever (FMF) is a genetic disease characterized by acute attacks of fever and inflammation of the serosal membranes. The aim of this study was to examine the levels of tumor markers in FMF patients and their correlation with the frequency of attacks.

**METHODS:** Serum levels of CA 125, CA 19-9, CA 15-3, CA 72-4, CEA, and AFP were measured by ELISA in 36 patients with a definitive diagnosis of FMF (21 males, 15 females, mean age 36.4+/-10.3 yrs) and in 19 healthy controls.

**RESULTS:** Serum levels of all tumor markers were normal in the controls. In FMF patients serum levels of CA 125, CA 19.9, CA 15.3, CEA and AFP were within normal ranges, whereas CA 72.4 was significantly higher than in the controls ( $p=0.001$ ). Half of the FMF patients showed increased levels of CA 72.4; the mean level was lower in those in complete remission. However, no statistically significant correlation was found between FMF attacks and acute phase reactant levels.

**CONCLUSION:** With the exception of Ca 72.4, serum levels of tumor markers are not affected by changes in inflammatory cytokines levels during FMF attacks.

tigmag@sci.am

Similar behavior of lymphoid cells, their nuclei and nucleoli in periodic disease and leukemia attest to nonspecific reaction of the immune system to these diseases, but the intensity of this reaction and mechanisms of the population recovery are different. DNA hyperreplication plays an important role in this process: in periodic disease it is realized via gene amplification, which manifests by the formation of H2c nuclei and increase in the number of nucleoli, while in leukemia bone marrow lymphoblasts double the DNA content during S phase, mature during G2 phase, and then divide. We called this mechanism "reserve lymphopoiesis" by analogy with reserve erythropoiesis discovered previously by us.

Relation between microalbuminuria and gene mutations in familial Mediterranean fever.

Ergüven M(1), Emeksiz C, Deveci M, Özlü SG.

Author information:

(1)Department of Pediatrics, Ministry of Health Göztepe Training Hospital, Istanbul, Turkey.

We aimed to investigate the urinary microalbumin level, which is a sensitive marker of glomerular function for establishing probable renal involvement in early stages of the disease in patients with familial Mediterranean fever (FMF), and to determine the relation between gene mutations of these cases and urinary microalbumin levels. Fifty patients with FMF who were admitted to our department and had been followed up in the pediatric rheumatology outpatient clinic for five years were included in the study. Diagnosis was based on Tel-Hashomer criteria. Gene mutations (M694V, V726A, M680I) and acute phase reactants were determined as supportive findings. Routine renal function tests with 24 hour urinary microalbumin levels and urinary microalbumin/creatinine ratios were evaluated. There was a statistically significant difference between the study and control groups in terms of microalbumin/creatinine ratios, whereas no difference was observed with respect to the other parameters. Comparison of subgroups (gene mutations) in terms of all parameters (age, age at diagnosis, duration of delay in treatment, glomerular filtration rate, tubular reabsorption of phosphorus, and microalbumin/creatinine ratios) showed no difference. We suggest measurement of urinary microalbumin levels at regular intervals in order to establish renal injury early and decrease related complications.

The hyperimmunoglobulinemia D and periodic fever syndrome (HIDS), one of the autoinflammatory syndromes, is caused by mutations in the gene coding for mevalonate kinase (MVK). We conducted the current study to assess the genetic, laboratory, and clinical features as well as the complications and course of disease in patients with genetically confirmed HIDS. In addition, we studied the quality of life and course of life in a selection of patients. Follow-up data were obtained by a questionnaire sent to all physicians of patients in the International HIDS Database. In addition, we assessed the course of life and quality of life in Dutch patients aged >16 years using validated quality of life instruments. Data were obtained from 103 patients from 18 different countries. The median age of first attack was 6 months (range, 0-120 mo), with a median period of 9.9 years from onset of disease to diagnosis. The most frequent symptoms that accompanied attacks of fever were lymphadenopathy, abdominal pain, arthralgia, diarrhea, vomiting, skin lesions, and aphthous ulcers. Amyloidosis was a severe but infrequent complication (2.9%). The median serum IgD level was 400 U/mL. IgD levels were normal in 22% of patients. The 4 most prevalent mutations (V377I, I268T, H20P/N, P167L) accounted for 71.5% of mutations found. The frequency of attacks decreased with the patient's increasing age, although 50% of patients over the age of 20 years still had 6 or more attacks per year. Many drugs have been tried in HIDS. Some patients responded to high-dose prednisone (24.4% response). Anakinra and etanercept can also be effective (33.3% response). Quality of life was determined in a subgroup of patients (n = 28). Social functioning, general health perception, and vitality were significantly lower in patients with HIDS than in controls, as were autonomy and social

development. In addition, HIDS had an adverse impact on educational achievements and employment status. In conclusion, HIDS is an early-onset disease that is accompanied by an array of inflammatory symptoms. Although the frequency of attacks decreases during the patient's life, many patients continue to have frequent attacks. HIDS impairs several aspects of quality of life.

MEFV mutations in systemic onset juvenile idiopathic arthritis.

Ayaz NA(1), Ozen S, Bilginer Y, Ergüven M, Taşkıran E, Yilmaz E, Beşbaş N, Topaloğlu R, Bakkaloğlu A.

Author information:

(1)Pediatric Nephrology and Rheumatology Unit, Hacettepe University Faculty of Medicine, Ankara, Turkey.

**OBJECTIVES:** Autoinflammatory diseases constitute a large spectrum of monogenic diseases like FMF or cryopyrin-associated periodic syndromes (CAPS) and complex genetic trait diseases such as systemic onset juvenile idiopathic arthritis (SoJIA). An increased rate of MEFV mutations has been shown among patients with PAN and HSP, in populations where FMF is frequent. The aim of the study is to search for MEFV mutations in our patients with SoJIA and see whether these mutations had an effect on disease course or complications.

**METHODS:** Thirty-five children with the diagnosis of SoJIA were screened for 12 MEFV mutations. The control data were obtained from a previous study of our centre determining the carrier frequency in Turkish population.

**RESULTS:** Two patients were homozygous and three patients were heterozygous for the M694V mutation. One patient was a compound heterozygote for the M680I/V726A mutations. Heterozygous V726A mutation was found in one patient. The overall mutation frequency of patients was 14.28%. This figure had been compared with the previously published rate of disease-causing mutations in this country, which is 5%. Disease-causing mutations were found to be significantly more frequent in the SoJIA patients than the population ( $P < 0.01$ ). Among these, M694V was the leading

mutation with a frequency of 10% in SoJIA. Six patients carrying MEFV mutations were among the most resistant cases requiring biological therapy.

CONCLUSION: SoJIA patients had a significantly higher frequency of MEFV mutations but clinical studies with large number of patients are needed to confirm the association of MEFV mutations with SoJIA and its course.

3638. J Periodontal Res. 2009 Jun;44(3):354-61. doi: 10.1111/j.1600-0765.2008.01115.x. Epub 2008 Oct 7.

Periodontal disease in patients with familial Mediterranean fever: from inflammation to amyloidosis.

Cengiz MI(1), Bagci H, Cengiz S, Yigit S, Cengiz K.

Author information:

(1)Department of Periodontology, Ondokuz Mayıs University, Samsun, Turkey.  
dtinanc@mynet.com

BACKGROUND AND OBJECTIVE: Familial Mediterranean fever stimulates a very intense acute-phase reactants response and if left untreated eventually leads to amyloidosis. The aim of this study was to determine the prevalence of periodontal disease among patients with familial Mediterranean fever in the Black Sea region in Turkey and to evaluate whether periodontitis is related to amyloidosis in patients with familial Mediterranean fever.

MATERIAL AND METHODS: One-hundred and thirty three patients with familial Mediterranean fever and 50 healthy subjects were included in this study. Periodontal health and disease were evaluated using the gingival index, papillary bleeding index, plaque index and periodontal disease index. The concentrations of serum acute-phase reactants were measured at baseline and at 4-6 wk after completion of the nonsurgical periodontal therapy. Genetic testing for familial Mediterranean fever was performed using the familial Mediterranean fever StripAssay. Kidney biopsy was carried out on all proteinuric patients.

RESULTS: The prevalence of moderate to severe periodontitis in familial Mediterranean fever patients with amyloidosis (80.6%) was significantly greater ( $p < 0.01$ ) than in familial Mediterranean fever patients without amyloidosis

(38%) and in controls (20%). Serum levels of acute-phase reactants in familial Mediterranean fever patients were reduced significantly following nonsurgical periodontal therapy ( $p < 0.01$ ).

**CONCLUSION:** Periodontal therapy seems to reduce the serum levels of acute-phase reactants in patients with familial Mediterranean fever. Therefore, treating periodontitis might help to alleviate the disease burden in patients with familial Mediterranean fever.

Genetic testing in clinical practice.

Lamberts SW(1), Uitterlinden AG.

Author information:

(1)Department of Internal Medicine, Erasmus Medical Center, Rotterdam, The Netherlands. s.w.j.lamberts@erasmusmc.nl

In the practice of internal medicine, the value of genetic testing in common (mono)genetic diseases such as familial hemochromatosis, hypercholesterolemia, Mediterranean fever, and thrombophilia is limited. The genotype insufficiently predicts the phenotype because of the powerful effects of other modifying genes, environmental influences, and lifestyle factors. Many common diseases, including diabetes mellitus, osteoporosis, and cardiovascular disease, have strong genetic influences but are called complex genetic traits. The underlying genetic factors are currently investigated using new molecular tools such as genome-wide association studies, analyzing up to 500,000 markers in huge numbers of patients. Many new (often unexpected) markers have been identified, and in many instances their functional significance is unknown. Genomic profiles play a rapidly growing role in the field of pharmacogenomics. A number of recently identified pharmacogenomic biomarkers are helpful to predict drug-related toxic effects.

Development of interferon induced sarcoidosis in a patient with familial mediterranean fever.

Oz GS(1), Emri S, Apras Bilgen S.

Author information:

(1)Division of General Internal Medicine, Department of Internal Medicine, Faculty of Medicine, Hacettepe University, Ankara, Turkey.

A 42-year-old male patient, who had been on colchicine therapy for familial mediterranean fever admitted with dyspnea on exertion. He had a history of interferon-alpha (IFN-alpha) administration. The chest X-ray showed diffuse distribution of reticulonodular opacities in both lungs. A computerized tomography scan of the lungs revealed mediastinal and bilateral hilar lymphadenopathies, translucent densities, consolidations, reticular opacities and subpleural milimetric cystic spaces. Pulmonary-function studies demonstrated defects in diffusing and vital capacity. Histopathological evaluation was compatible with granulomatous lymphadenitis. The patient was diagnosed as having pulmonary sarcoidosis. He reflects the characteristics of IFN-induced sarcoidosis, but the duration between the cessation of IFN therapy and the development of symptoms is 42 months, which is longer than usually expected. In this case, history of IFN-alpha administration led us to suspect sarcoidosis because of a possible association between IFN therapy and the development of sarcoidosis.

Measurement of formamidopyrimidines in DNA.

Jaruga P(1), Kirkali G, Dizdaroglu M.

Author information:

(1)Chemical Science and Technology Laboratory, National Institute of Standards and Technology, Gaithersburg, MD 20899, USA.

Formamidopyrimidines, 4,6-diamino-5-formamidopyrimidine (FapyAde) and 2,6-diamino-4-hydroxy-5-formamidopyrimidine (FapyGua), are among major lesions in DNA generated by hydroxyl radical attack, UV radiation, or photosensitization in vitro and in vivo. FapyAde and FapyGua exist in living cells at detectable background levels and are formed by exposure of cells to DNA-damaging agents. Numerous prokaryotic and eukaryotic DNA glycosylases exist for the repair of formamidopyrimidines by base excision repair pathways in cells, indicating their biological significance. Moreover, they are premutagenic lesions, albeit to different extents, revealing a possible role in disease processes. Methodologies using gas chromatography/mass spectrometry (GC/MS) with capillary columns have been developed to accurately measure FapyAde and FapyGua in DNA in vitro and in vivo. Stable isotope-labeled analogues of these compounds have been synthesized and are commercially available to be used as internal standards for accurate quantification. GC/MS with isotope dilution provides excellent sensitivity and selectivity for positive identification and accurate quantification, and has widely been applied in the past to the measurement of formamidopyrimidines under numerous experimental conditions. This paper reports on the details of this GC/MS methodology.

Platelet activation in patients with Familial Mediterranean Fever.

Coban E(1), Adanir H.

Author information:

(1)Department of Internal Medicine, Akdeniz University Faculty of Medicine, Antalya, Turkey. ecoban@akdeniz.edu.tr

Increased platelet activation and aggregation are central processes in the pathophysiology of atherosclerosis. Increased platelet activity is associated

with increased platelet volume. Mean platelet volume (MPV), a determinant of platelet function, is a newly emerging risk factor for atherothrombosis. Familial Mediterranean Fever (FMF) is an autosomal recessive disease characterized by recurrent inflammatory febrile attacks of serosal and synovial membranes. Recently few studies have shown that FMF is associated with increased atherosclerosis risk. The present study was designed to evaluate levels of MPV in FMF patients compared with healthy subjects. We selected 35 FMF patients and 35 healthy control subjects matched for age, gender, and body mass index. Metabolic parameters and MPV levels were measured in all groups. Metabolic parameters were not different among the study groups ( $p > 0.05$ ). The levels of MPV were significantly higher in the FMF group than in the control group ( $8.6 \pm 0.9$  fl vs  $7.8 \pm 0.5$  fl,  $p = 0.001$ ). The MPV levels were negatively correlated with duration of colchicine treatment ( $r = -0.40$ ,  $p = 0.017$ ). Also MPV levels showed positive correlation with delay of diagnosis ( $r = 0.58$ ,  $p = 0.001$ ). In conclusion, our results suggest that patients with FMF tend to have an increased platelet activation. Increased platelet activity could contribute to increasing the atherosclerotic risk in FMF patients.

Multiple sclerosis (MS) is the most common demyelinating disease caused by an autoimmune inflammatory process in the central nervous system (CNS) and is associated with aberrant immune response to myelin selfantigens. Coexistence of MS with other autoimmune disorders, including connective tissue disorders including systemic lupus erythematosus, rheumatoid arthritis, Sjögren's syndrome

and scleroderma have been reported previously. In the present article we report the coexistence of MS, familial mediterranean fever and ankylosing spondylitis in a patient and review the clinical presentation, neurologic findings, cerebrospinal fluid and radiologic characteristics and treatment options. We further discuss the immunopathogenetic mechanisms for a possible association between MS and autoimmune disorders.

**OBJECTIVE:** To investigate the prevalence of MEFV gene mutations in Turkish patients with Henoch-Schönlein purpura (HSP) but with no symptoms of familial Mediterranean fever (FMF). In addition, we assessed the clinical and laboratory

characteristics of HSP patients with and without MEFV mutations.

**METHODS:** Eighty pediatric patients with HSP (44 boys and 36 girls) were enrolled. Blood for mutation analysis was obtained either at the time of the diagnosis of HSP or during followup visits in previously diagnosed patients. No patient had the diagnosis of FMF in their history and in the followup period. Exon 10 of the MEFV gene was screened, together with p.E148Q mutation analysis.

**RESULTS:** Twenty-seven (34%) patients were found to be heterozygous for one of the screened MEFV mutations; p.M694V in 16, p.M680I in 5, p.V726A in 3, and p.E148Q in 3 patients. Patients with MEFV mutations were younger than those without mutations and they had edema and arthritis more frequently. Also, the frequencies of elevated erythrocyte sedimentation rate and C-reactive protein values were found to be significantly higher in patients who had MEFV mutations.

**CONCLUSION:** Alterations in the MEFV gene are important susceptibility factors for the development of HSP and also affect the clinical presentation of it.

Indications and results of videocapillaroscopy in clinical practice.

Gallucci F(1), Russo R, Buono R, Acampora R, Madrid E, Uomo G.

Author information:

(1)Department of Internal Medicine, Cardarelli Hospital, Naples, Italy.

Nailfold videocapillaroscopy (NVC) is one of the best diagnostic non-invasive imaging techniques to evaluate microcirculation in vivo and is increasingly employed in the field of rheumatology. Indeed, at present, the most important utility of NVC is in the identification of microvascular involvement in many rheumatic diseases, particularly in systemic sclerosis. More recently, this technique has been shown to be applicable to the study of many other extra-rheumatic diseases, such as arterial hypertension, diabetes mellitus, acromegaly, hyperthyroidism, cardiac syndrome X, primary biliary cirrhosis, Crohn's disease, psoriasis, familial Mediterranean fever. This article sets down the methodology of examination and normal pattern of capillary vessels and reviews the applications of NVC in clinical practice and its results in rheumatic

and non-rheumatic diseases.

B cell cytopenia in two brothers with hyper-IgD and periodic fever syndrome.

Sornsakrin M(1), Wenner K, Ganschow R.

Author information:

(1)Department of Pediatrics, Division of Pediatric Immunology, University Medical Center Hamburg-Eppendorf, Hamburg, Germany.

We report on two brothers with hyperimmunoglobulinemia D (patient 1: serum immunoglobulin D [IgD] concentration initially 61 IU/ml, later on 340 IU/ml; patient 2: serum IgD concentration 144 IU/ml; normal <100 IU/ml, 97th centile) and periodic fever syndrome (HIDS). Both are compound heterozygous for the mevalonate kinase (MVK) mutations V377I and I268T. They developed significant B cell cytopenia (7%, 129/microl and 11%, 132/microl, respectively; normal ranges 12-22%, 300-500/microl) with hypogammaglobulinemia (IgG 5.48 g/l and IgG 5.22 g/l, respectively; normal range IgG 6-13 g/l). Furthermore, the clinical spectrum shows an interesting atypical autoinflammatory symptomatology. The therapy consisted of prednisone, azathioprine, and intravenous immunoglobulins (IVIG), which results in reduced incidence and severity of febrile attacks. CONCLUSION: The pathogenesis and clinical presentation of HIDS is still not fully understood and show a great variability. To our knowledge, severe B cell cytopenia in children with HIDS has not been reported before. Furthermore, the therapy of febrile episodes is still performed on an individual basis in affected patients.

We evaluated the effect of attack frequency, homozygosity for the M694V mutation

and colchicine treatment on growth in children with familial Mediterranean fever (FMF). Prepubertal patients with FMF (19 M, 14 F) were evaluated retrospectively for height SDS, weight SDS and body mass index (BMI) before and after 46.2 +/- 39.8 months of colchicine therapy. Pretreatment attack frequency and acute phase markers at diagnosis were also recorded. While acute phase markers were not correlated to anthropometric variables, attack rate was negatively, albeit insignificantly, correlated to height and weight SDS. Height SDS did not change, while BMI showed a slight but significant increase during colchicine therapy (16.2 +/- 2.6 to 17.3 +/- 3.1 kg/m<sup>2</sup>, p = 0.035). Homozygosity for M694V did not affect time from the onset of symptoms to diagnosis, anthropometric variables and acute phase markers. In conclusion, pre-treatment attack rate and anthropometric development correlated negatively. Colchicine therapy improved BMI slightly, but significantly. Homozygosity for M694V had no effect on anthropometric development.

Familial Mediterranean fever gene as a possible modifier of Sweet syndrome with chronic myelogenous leukemia.

Miyoshi T(1), Yamashita K, Ohno T, Izumi T, Takaori-Kondo A, Sasada M, Uchiyama T.

Author information:

(1)Department of Hematology and Oncology, Graduate School of Medicine, Kyoto University, Kyoto, Japan.

Sweet syndrome is a multisystem inflammatory disorder characterized by acute fever, as well as painful erythematous plaques infiltrated with mature neutrophils in the absence of vasculitis. The pathogenesis of the disease has not yet been clarified, although several proinflammatory cytokines have been reported to be involved in the disease process. We describe here a patient clinically diagnosed with Sweet syndrome with chronic myelogenous leukemia. The mutational analysis of the patient revealed a compound heterozygous E148Q/R202Q mutation in exon 2 of MEFV gene, which is a causative gene for familial Mediterranean fever.

This is the first report to describe MEFV gene mutations in Sweet syndrome. Our results suggest that Sweet syndrome may be mediated through similar inflammatory mechanisms to those of familial Mediterranean fever.

In familial mediterranean fever (FMF), fertility is normal in treated patients. There is no abnormality of spermatogenesis under usual therapeutic doses of colchicine. The risk of early abortion is increased if inflammatory attacks occur during the pregnancy. It is recommended to continue colchicine treatment during the conception and the pregnancy. Careful follow-up must be organized, even more in patients with renal amyloidosis. Breast-feeding is allowed under colchicine with no risk for the baby. There is no indication for systematic amniocentesis in FMF patients treated with colchicine.

**INTRODUCTION:** Few cases of patients with both Familial Mediterranean Fever (FMF) and Multiple Sclerosis (MS) have been reported, mainly from Turkey. Central nervous system manifestations are rare in FMF.

**CASE REPORT:** We report the case of a 37-year-old right-handed man with FMF diagnosed at 17 the age of years and successfully treated with colchicine. The patient was born in Algeria and lived in France since he was four years old. He had a brother who had multiple sclerosis. When the patient was 23 years old, he experienced diplopia and leg numbness that resolved spontaneously without treatment. Ten years later, new neurological events appeared every six months and were treated with corticoid-steroids. The diagnosis of MS was made. In 2006, he was hospitalized for new explorations in order to search for neuro-Behçet's disease, because of the development of a canker sore. There was no argument for

neuro-Behçet's disease.

**DISCUSSION:** Neurological complications of FMF are rare. It is important to rule out a neuro-Behçet disease in a FMF patient with neurological disorders. Previous studies and case reports on the association between FMF and MS have failed to draw a clear conclusion as to whether this is a true association or a simple coincidence. In our patient's clinical situation, we found no argument for changing the treatment of MS and FMF.

Erratum in

Proc Natl Acad Sci U S A. 2008 Dec 9;105(49):19561. Rutschmann, Sophie [added].

A recessive phenotype called spin (spontaneous inflammation) was induced by N-ethyl-N-nitrosourea (ENU) mutagenesis in C57BL/6J mice. Homozygotes display chronic inflammatory lesions affecting the feet, salivary glands and lungs, and antichromatin antibodies. They are immunocompetent and show enhanced resistance to infection by *Listeria monocytogenes*. TLR-induced TNF and IL-1 production are normal in macrophages derived from spin mice. The autoinflammatory phenotype of spin mice is fully suppressed by compound homozygosity for *Myd88*(poc), *Irak4*(otiose), and *Il1r1*-null mutations, but not *Ticam1*(Lps2), *Stat1*(m1Btlr), or *Tnf*-null mutations. Both autoimmune and autoinflammatory phenotypes are suppressed when spin homozygotes are derived into a germ-free environment. The

spin phenotype was ascribed to a viable hypomorphic allele of Ptpn6, which encodes the tyrosine phosphatase SHP1, mutated in mice with the classical motheaten alleles me and me-v. Inflammation and autoimmunity caused by SHP1 deficiency are thus conditional. The SHP1-deficient phenotype is driven by microbes, which activate TLR signaling pathways to elicit IL-1 production. IL-1 signaling via MyD88 elicits inflammatory disease.

crispian.scully@eastman.ucl.ac.uk

Recurrent oral ulceration that clinically resembles recurrent aphthous stomatitis but presents atypically, including commencement after adolescence, with fever, with a strong family history, or failing to resolve with age, has been termed aphthous-like ulceration (ALU). It may be seen in some immunodeficiency states, chronic viral infections, rheumatologic disorders, skin diseases, and the periodic syndromes. The periodic syndromes, considered to be the prototypic autoinflammatory diseases, present with recurrent short attacks of myalgia, arthralgia, rashes, abdominal pain, lymphadenopathy, and fever. Several of the syndromes can result in amyloidosis. Genetic studies have enhanced the clinical characterization of these conditions and elucidation of their molecular etiopathogenesis. This paper describes 2 patients with periodic syndromes presenting with ALU and reviews the present understanding of the syndromes.

3657. Ann Rheum Dis. 2009 Feb;68(2):246-8. doi: 10.1136/ard.2008.092031. Epub 2008 Sep 18.

Disease severity in children and adolescents with familial Mediterranean fever: a comparative study to explore environmental effects on a monogenic disease.

Ozen S(1), Aktay N, Lainka E, Duzova A, Bakkaloglu A, Kallinich T.

Author information:

(1)Department of Paediatrics, Hacettepe University, Faculty of Medicine, 06100 Ankara, Turkey. sezaozen@hacettepe.edu.tr

**BACKGROUND:** Worldwide, familial Mediterranean fever (FMF) is the most common autoinflammatory disease. It has been suggested that environmental factors affect the phenotype as some patients do not develop the complication of secondary amyloidosis.

**OBJECTIVE:** To analyse whether disease severity in Turkish children with FMF, living in Turkey and Germany is different.

**PATIENTS AND METHODS:** A total of 55 Turkish children living in Turkey were compared with 45 Turkish children born and raised in Germany. Mean age among the group from Turkey and Germany was 42.2 and 44.29 months, respectively. M694V was the leading mutation in both groups. The severity scores were compared with two scoring systems, modified according to published paediatric data for dosage.

**RESULTS:** There was no significant difference between the mean C-reactive protein and erythrocyte sedimentation rate levels of the two groups. According to the modified Sheba Center score, 78.2% of patients from the group living in Turkey had a severe course compared with 34.1% from the group living in Germany. The modified score of Pras et al also showed more severe disease in the patients from Turkey. The difference between the two groups for both scoring systems were significant (both  $p < 0.05$ ).

**CONCLUSIONS:** We believe the modified scores that we introduce can be widely used for children. Our results suggest that the environment affects the phenotype of a monogenic disease of the innate inflammatory pathway.

Appendectomy in familial Mediterranean fever: clinical, genetic and pathological findings.

Lidar M(1), Doron A, Kedem R, Yosepovich A, Langevitz P, Livneh A.

Author information:

(1)Heller Institute of Medical Research, Sheba Medical Center, Tel-Hashomer, Israel. merav.lidar@sheba.health.gov.il

**BACKGROUND:** Abdominal attacks of familial Mediterranean fever (FMF) may simulate acute appendicitis and bring about considerable uncertainty. The similar presentation of the two clinical entities often leads to an unnecessary appendectomy.

**METHODS:** 182 consecutive FMF patients were retrospectively reviewed for this study. Clinical and genetic data was compared between those who had undergone an appendectomy (n=71) and those who had not (n=111).

**RESULTS:** The frequency of appendectomy found in FMF was far above the reported rate in the general population (40% vs. 12-25%). The rate of non-inflamed appendectomies was extremely high (80% vs. 20%) and remained constant over time. Tertiary hospitals and improved therapeutic and diagnostic measures that have evolved over the years did not reduce misdiagnosis of acute appendicitis in FMF.

Severe phenotype and homozygosity for M694V were identified as risk factors for appendectomy in FMF. A change from the regular diffuse involvement to right lower quadrant abdominal pain was found to be the best predictor of inflamed appendix in FMF patients undergoing appendectomy for suspected acute appendicitis.

**CONCLUSION:** Reliance on clinical parameters should improve diagnostic accuracy of acute appendicitis in the FMF patient population.

The frequency of sacroiliitis in familial Mediterranean fever and the role of HLA-B27 and MEFV mutations in the development of sacroiliitis.

Kaşıfoğlu T(1), Çalışır C, Cansu DU, Korkmaz C.

Author information:

(1)Division of Rheumatology, Department of Internal Medicine, Eskişehir Osmangazi University, Eskişehir, Turkey.

The objective of this study was to investigate the frequency of sacroiliitis in familial Mediterranean fever (FMF) patients and the role of HLA-B27 and MEFV mutations in the development of sacroiliitis. The study group consisted of 256 FMF patients (male 128, female 128, mean age 27.2 +/- 6.3 years). After evaluation of the medical records, 70 patients (27.4%) were determined to have one or more of musculoskeletal manifestations. Sacroiliitis was determined in 18 (32.7%) FMF patients. The frequency of sacroiliitis among all FMF patients was found to be 7%. HLA-B27 was 47% and 6.3% in FMF patients with and without sacroiliitis, respectively. The frequency of M694V mutations in FMF patients with sacroiliitis was 93.7%. Sacroiliitis may be seen more frequently in FMF patients than expected. HLA-B27 positivity and/or M694V mutation may play a role in the development of sacroiliitis and the severity of seronegative spondyloarthropathy.

Familial Mediterranean fever (FMF) is the most common form of autoinflammatory syndromes and is characterized by recurrent inflammatory attacks of fever and serositis. Amyloidosis is the most common renal complication of FMF. In addition to amyloidosis, many renal lesions have been anecdotally reported in patients

with FMF and other hereditary periodic fevers. We report a Turkish child with FMF presenting with hematuria during attacks, in whom kidney biopsy documented the presence of mesangial IgA deposits and the absence of amyloidosis. Kidney biopsy should be performed in patients showing microscopic or gross hematuria during attacks of familial Mediterranean fever in order to gain additional epidemiological data about specific features of renal involvement and to allow adequate treatment.

Expression of ASC in renal tissues of familial mediterranean fever patients with amyloidosis: postulating a role for ASC in AA type amyloid deposition.

Balci-Peynircioglu B(1), Waite AL, Schaner P, Taskiran ZE, Richards N, Orhan D, Gucer S, Ozen S, Gumucio D, Yilmaz E.

Author information:

(1)Hacettepe University, Tip Fakultesi, Tibbi Biyoloji AD, Rektorluk Binasi, A Kapisi, 4. Kat, 06100 Sıhhiye, Ankara, Turkey.

Familial Mediterranean fever (FMF) is characterized by recurrent attacks of fever and serositis; in some cases, ensuing amyloidosis results in kidney damage. Treatment with colchicine reduces the frequency and severity of FMF attacks and prevents amyloidosis, although the mechanisms behind these effects are unknown. Pyrin, the protein product of the MEFV gene, interacts with ASC, a key molecule in apoptotic and inflammatory processes. ASC forms intracellular speck-like aggregates that presage cell death. Here we show that cell death after ASC speck formation is much slower in nonmyeloid cells than in myeloid cells. Additionally, we demonstrate that colchicine prevents speck formation and show that specks can survive in the extracellular space after cell death. Because we also found that ASC is expressed in renal glomeruli of patients with FMF but not in those of control patients, we posit that high local ASC expression may result in speck formation and that specks from dying cells may persist in the extracellular space where they have the potential (perhaps in association with pyrin) to nucleate

amyloid. The fact that speck formation requires an intact microtubule network as shown here could potentially account for the ability of prophylactic colchicine to prevent or reverse amyloidosis in patients with FMF.

Increased asymmetric dimethylarginine levels in young men with familial Mediterranean fever (FMF): is it early evidence of interaction between inflammation and endothelial dysfunction in FMF?

Terekeci HM(1), Oktenli C, Ozgurtas T, Nalbant S, Top C, Celik S, Tapan S, Kucukardali Y, Sanisoglu YS, Solmazgul E, Sahan B, Sayan O.

Author information:

(1)Division of Internal Medicine, GATA Haydarpasa Training Hospital, Istanbul, Turkey. mhterekeci@yahoo.com.tr

**OBJECTIVE:** Unlike in many other chronic inflammatory rheumatic diseases, studies investigating endothelial dysfunction and atherosclerosis in familial Mediterranean fever (FMF) are limited, and the results are controversial. Asymmetric dimethylarginine (ADMA) is considered an indicator for endothelial dysfunction and a sensitive marker for cardiovascular risk. There have been no reports on serum ADMA levels in patients with FMF.

**METHODS:** We aimed (1) to determine serum ADMA concentrations in 38 young male patients with FMF and 23 age- and body mass index-matched healthy volunteers; (2) to evaluate its correlations with MEFV mutations, C-reactive protein (CRP) levels, and lipid profile; and (3) to compare effects of colchicine on circulating ADMA concentrations.

**RESULTS:** In patients with FMF, ADMA and CRP levels were higher than in healthy controls. The mean levels of ADMA and CRP were higher during acute attacks than in attack-free periods. Patients taking colchicine had lower serum ADMA levels than non-colchicine users. There was a positive strong correlation between ADMA and CRP in patients with FMF. Stepwise linear regression analysis in patients with FMF revealed that age and CRP levels were independently associated with serum ADMA levels.

CONCLUSION: Our data imply that higher serum ADMA levels in FMF may indicate inflammation-related "endothelial dysfunction." It seems likely that regular use of colchicine is effective in preventing the development of and reversing not only amyloidosis but also endothelial dysfunction in patients with FMF.

Skin toxicity caused by EGFR antagonists-an autoinflammatory condition triggered by deregulated IL-1 signaling?

Rodeck U(1).

Author information:

(1)Department of Dermatology, Cutaneous Biology and Kimmel Cancer Center, Thomas Jefferson University, Philadelphia, Pennsylvania, USA. ulrich.rodeck@mail.tju.edu

Acneiform skin eruptions associated with sterile inflammation frequently accompany pharmacological inhibition of signaling through the epidermal growth factor receptor (EGFR) in cancer patients. Here we discuss possible pathogenic mechanisms for this phenomenon linked to control of inflammatory mediators by EGFR blockade in keratinocytes of the outer root sheath of the hair follicle. This discussion is focused on the putative role of EGFR activation in restraining interleukin (IL)-1-dependent inflammatory networks at the hair follicle.

Elevated systemic antibodies towards commensal gut microbiota in autoinflammatory condition.

Manukyan GP(1), Ghazaryan KA, Ktsoyan ZA, Khachatryan ZA, Arakelova KA, Kelly D, Grant G, Aminov RI.

Author information:

(1)Institute of Molecular Biology, National Academy of Sciences, Yerevan, Armenia.

**BACKGROUND:** Familial Mediterranean fever (FMF) is an autoinflammatory condition, which is characterized by acute, self-limiting episodes of fever and serositis and chronic subclinical inflammation in remission. Here we investigated the consequence of this condition on the level of systemic antibodies directed towards common intestinal bacteria.

**METHODOLOGY/PRINCIPAL FINDINGS:** The level of systemic antibodies towards the antigens of *Bacteroides*, *Parabacteroides*, *Escherichia*, *Enterococcus* and *Lactobacillus* was measured by ELISA in FMF patients at various stages of the disease and in healthy controls. The difference between remission and attack was not significant. IgG antibodies against the antigens of *Bacteroides*, *Parabacteroides*, *Escherichia* and *Enterococcus* were significantly increased in FMF compared to control while IgA levels were not significantly affected. Western blot analyses demonstrated the IgG reactivity against multiple antigens of commensal bacteria in FMF. Serological expression cloning was performed to identify these antigens. No single dominant antigen was identified; the response was generalized and directed against a variety of proteins from *Bacteroides*, *Parabacteroides*, *Escherichia*, and other gut commensals.

**CONCLUSIONS/SIGNIFICANCE:** This autoinflammatory syndrome is characterized by the increased systemic reactivity against commensal gut microbiota. This is probably the consequence of hypersensitivity of the inflammasome in FMF that triggers the inflammation and contributes to the excessive translocation of bacteria and bacterial antigens through the gut barrier.

Familial Mediterranean fever during pregnancy: an independent risk factor for

preterm delivery.

Ofir D(1), Levy A, Wiznitzer A, Mazor M, Sheiner E.

Author information:

(1)Departments of Obstetrics and Gynecology, Faculty of Health Sciences, Soroka University Medical Center, Ben Gurion University of the Negev, Be'er-Sheva, Israel.

**OBJECTIVE:** To investigate pregnancy outcome of patients with Familial Mediterranean fever (FMF).

**STUDY DESIGN:** A population-based study comparing all pregnancies of women with and without FMF between the years 1988 and 2006 was conducted. Stratified analyses, using the Mantel-Haenszel procedure and multiple logistic regression models, were performed to control for confounders.

**RESULTS:** During the study period there were 175,572 deliveries, of which 239 occurred in patients with FMF. Using a multivariable analysis, the following conditions were significantly associated with FMF: preterm delivery (PTD, <37 weeks) (odds ratio (OR)=1.5; 95% confidence interval (CI) 1.1-2.2), fertility treatments (OR=2.5; 95% CI 1.4-4.4), recurrent abortions (OR=2.2; 95% CI 1.5-3.2), labor induction (OR=1.9; 95% CI 1.5-2.5) and malpresentations (OR=1.8; 95% CI 1.2-2.8). Patients with FMF were more likely to deliver by cesarean delivery (CD) as compared to the comparison group (18.0% vs. 12.8%;  $P=0.017$ ). However, while controlling for possible confounders such as malpresentations, labor dystocia and failed induction, using multivariable analysis with CD as the outcome variable, FMF was not found as an independent risk factor for CD (adjusted OR=1.2; 95% CI 0.8-1.8,  $P=0.388$ ). No significant differences were noted between the groups regarding perinatal outcomes such as low Apgar scores (<7) at 1 and 5 min (2.4% vs. 4.3%,  $P=0.153$  and 0.4% vs. 0.6%,  $P=0.692$ ; respectively), congenital malformations (5.2% vs. 4.9%,  $P=0.838$ ), or perinatal mortality (0.8% vs. 1.4%,  $P=0.445$ ). Stratified analysis, using the Mantel-Haenszel technique, was used to assess the association between FMF and PTD while controlling for possible confounders such as iatrogenic labor induction, fertility treatments, recurrent abortions and placental abruption. None of those variables explained the higher incidence of PTD in the group of patients with FMF.

**CONCLUSION:** Familial Mediterranean fever is an independent risk factor for preterm delivery. Nevertheless, perinatal outcome is comparable to the general population.

B cells are required for Aire-deficient mice to develop multi-organ autoinflammation: A therapeutic approach for APECED patients.

Gavanescu I(1), Benoist C, Mathis D.

Author information:

(1)Research Division, Joslin Diabetes Center, Department of Medicine, Brigham and Women's Hospital, Harvard Medical School, Boston, MA 02215, USA.

Autoimmune regulator (Aire)-deficient mice and humans have circulating autoantibodies against a multitude of organs and multiorgan autoinflammatory infiltrates. It is not known to what extent autoantibodies or their source, B lymphocytes, are required for disease onset or progression. We show in this research that B cells must be present for Aire-deficient mice to develop fulminant infiltrates. We found no evidence that autoantibodies were directly pathogenic; rather, B cells appeared to play a critical early role in T cell priming or expansion. A therapeutic reagent directed against B cells, Rituximab, induced remission of the autoimmune disease in Aire-deficient mice, raising the hope of applying it to human patients with autoimmune-polyendocrinopathy-candidiasis-ectodermal dystrophy (APECED).

Fevers, genes, and innate immunity.

Ryan JG(1), Kastner DL.

Author information:

The characterization of patients with recurrent inflammatory syndromes into distinct clinical phenotypes provided early clues to the mode of inheritance of these conditions and facilitated the subsequent identification of causative gene mutations. The prototype autoinflammatory syndrome, familial Mediterranean fever, is characterized by self-limiting episodes of localized inflammation. Hallmarks of the classical autoimmune response are largely absent. The use of positional cloning techniques led to the identification of the causative gene, MEFV, and its product pyrin. This previously unrecognized protein plays an important role in modulating the innate immune response. Cryopyrin, the protein encoded by CIAS1, is mutated in a spectrum of autoinflammatory conditions, the cryopyrinopathies. In response to a wide range of potential pathogens, it forms a macromolecular complex termed the "inflammasome," resulting in caspase-1 activation and subsequent release of the active proinflammatory cytokine interleukin-1beta (IL-1beta). The role of an established biochemical pathway in regulating inflammation was uncovered by the discovery that the hyperimmunoglobulin D with periodic fever syndrome (HIDS) results from mutations in MVK, which encodes an enzyme in the isoprenoid pathway. The discovery that mutations in the gene encoding tumor necrosis factor (TNF) receptor 1 (TNFR1) cause a proinflammatory phenotype was unanticipated, as it seemed more likely that such mutations would instead have resulted in an immunodeficiency pattern. This review describes the clinical phenotypes of autoinflammatory syndromes, the underlying gene mutations, and current concepts regarding their pathophysiology.

Predominant role of host genetics in controlling the composition of gut microbiota.

Khachatryan ZA(1), Ktsoyan ZA, Manukyan GP, Kelly D, Ghazaryan KA, Aminov RI.

Author information:

(1)Laboratory of Molecular Genetics, Institute of Molecular Biology of Armenian National Academy of Sciences, Yerevan, Armenia.

**BACKGROUND:** The human gastrointestinal tract is inhabited by a very diverse symbiotic microbiota, the composition of which depends on host genetics and the environment. Several studies suggested that the host genetics may influence the composition of gut microbiota but no genes involved in host control were proposed. We investigated the effects of the wild type and mutated alleles of the gene, which encodes the protein called pyrin, one of the regulators of innate immunity, on the composition of gut commensal bacteria. Mutations in MEFV lead to the autoinflammatory disorder, familial Mediterranean fever (FMF, MIM249100), which is characterized by recurrent self-resolving attacks of fever and polyserositis, with no clinical signs of disease in remission.

**METHODOLOGY/PRINCIPAL FINDINGS:** A total of 19 FMF patients and eight healthy individuals were genotyped for mutations in the MEFV gene and gut bacterial diversity was assessed by sequencing 16S rRNA gene libraries and FISH analysis. These analyses demonstrated significant changes in bacterial community structure in FMF characterized by depletion of total numbers of bacteria, loss of diversity, and major shifts in bacterial populations within the Bacteroidetes, Firmicutes and Proteobacteria phyla in attack. In remission with no clinical signs of disease, bacterial diversity values were comparable with control but still, the bacterial composition was substantially deviant from the norm. Discriminant function analyses of gut bacterial diversity revealed highly specific, well-separated and distinct grouping, which depended on the allele carrier status of the host.

**CONCLUSIONS/SIGNIFICANCE:** This is the first report that clearly establishes the link between the host genotype and the corresponding shifts in the gut microbiota (the latter confirmed by two independent techniques). It suggests that the host genetics is a key factor in host-microbe interaction determining a specific profile of commensal microbiota in the human gut.

Blau syndrome (BS) is a rare familial disease transmitted as an autosomal dominant trait, characterized by arthritis, uveitis, skin rash and granulomatous inflammation. Until now BS has been observed in 136 persons belonging to 28 families as well as in 4 sporadic cases. The gene responsible for BS has recently been identified in the nucleotide-binding domain (NBD) of caspase recruitment domain (CARD15/NOD2), also involved in the pathogenesis of Crohn's disease. In addition to three missense mutations (R334Q, R334W and L469F) previously identified, a new CARD 15 mutation (E383K) has recently been described in a family followed by us for the past 25 years. The characteristics of this family which, to our knowledge, is the only one affected with BS in Italy, are the object of this manuscript. Both the proband and her daughter were originally affected with a papulonodular skin eruption and then with mild arthritis of the hands and feet. The proband, but not the daughter, complained of severe chronic bilateral uveitis, followed by glaucoma and, a few years later, by cataracts. Histological examination of skin biopsies from both subjects and a joint biopsy (daughter only), showed non-caseating granulomas with multinucleated giant cells which, at electron microscopy, revealed "comma-shaped bodies" in epithelioid cells, thought to be a marker for BS. The disease is presently well controlled with low doses of prednisone for the mother and non-steroidal anti-inflammatory drugs (NSAIDs) plus low doses of prednisone, when necessary, for the daughter. As

in Crohn's disease, CARD15/NOD2 mutation is believed to be responsible for the granulomatous autoinflammatory reactions probably triggered by microorganisms in BS.

Left ventricular diastolic function evaluated with tissue Doppler imaging in children with familial Mediterranean fever.

Baysal T(1), Peru H, Oran B, Sahin TK, Koksall Y, Karaaslan S.

Author information:

(1)Department of Pediatric Cardiology, Meram Medical Faculty, Selcuk University, Meram, Konya, Turkey. tbaysal2@yahoo.com

The aim of this study was to assess the left ventricular diastolic function using conventional echocardiography and tissue Doppler imaging in children with familial Mediterranean fever. This study included 29 (13 males and 16 females) patients and 30 healthy subjects as controls. Body mass index was calculated and arterial blood pressure was monitored. After an overnight fast, venous blood samples were taken and serum amyloid A protein, C-reactive protein, serum-fasting glucose, total cholesterol, triglycerides, high-density lipoprotein cholesterol, very low density lipoprotein cholesterol, and serum low-density lipoprotein cholesterol levels were measured. A complete 2-dimensional, M-mode, pulse wave Doppler, and pulse wave tissue Doppler echocardiographic examination was performed. There were no significant differences between the groups regarding age, body mass index values, systolic and diastolic blood pressures, heart rates, serum-fasting glucose, total cholesterol, triglycerides, high-density lipoprotein cholesterol, very low density lipoprotein cholesterol, and serum low-density lipoprotein cholesterol. Serum levels of inflammatory markers were higher in patients' group (C-reactive protein and serum amyloid A protein levels were 10.84 mg/dl, 22.32 mg/l in patients' group, respectively, and 4.11 mg/dl, 3.65 mg/l, respectively, in the healthy controls.) Peak mitral A wave, E and A wave ratio differed significantly in both groups. There were statistically significant

differences regarding parameters observed by tissue Doppler imaging such as E'm, A'm, E'm, and A'm ratio between patients' group and controls. Tissue Doppler imaging provided additional information on left ventricular diastolic function. While systolic functions were in normal range, some of the diastolic function parameters were impaired in patients with familial Mediterranean fever during childhood.

The heat shock protein [Hsp] family guides several steps during protein synthesis, are abundant in prokaryotic and eukaryotic cells, and are highly conserved during evolution. The Hsp60 family is involved in assembly and transport of proteins, and is expressed at very high levels during autoimmunity or autoinflammatory phenomena. Here, the pathophysiological role of the wild type [WT] and the point mutated K(409)A recombinant Hsp65 of *M. leprae* in an animal model of Systemic Lupus Erythematosus [SLE] was evaluated in vivo using the genetically homogeneous [NZBxNZW]F(1) mice. Anti-DNA and anti-Hsp65 antibodies responsiveness was individually measured during the animal's life span, and the mean survival time [MST] was determined. The treatment with WT abbreviates the MST in 46%, when compared to non-treated mice [ $p < 0.001$ ]. An increase in the IgG2a/IgG1 anti-DNA antibodies ratio was also observed in animals injected with the WT Hsp65. Incubation of BALB/c macrophages with F(1) serum from WT treated mice resulted in acute cell necrosis; treatment of these cells with serum from K(409)A treated mice did not cause any toxic effect. Moreover, the involvement of WT correlates with age and is dose-dependent. Our data suggest that Hsp65 may be a central molecule intervening in the progression of the SLE, and that the point mutated K(409)A recombinant immunogenic molecule, that counteracts the

deleterious effect of WT, may act mitigating and delaying the development of SLE in treated mice. This study gives new insights into the general biological role of Hsp and the significant impact of environmental factors during the pathogenesis of this autoimmune process.

Recurrent pericarditis: infectious or autoimmune?

Brucato A(1), Maestroni S, Cumetti D, Thiella G, Alari G, Brambilla G, Imazio M, Doria A, Palmieri G, Adler Y.

Author information:

(1)Department of Internal Medicine, Ospedali Riuniti di Bergamo, Bergamo, Italy.  
albrucato@ospedaliriuniti.bergamo.it

The etiology and pathogenesis of idiopathic recurrent acute pericarditis (IRAP) remain controversial standing like a bridge that crosses infectious, autoimmune and autoinflammatory pathways. Anything may cause acute pericarditis; Echo-virus, and Coxsackie are the most frequently involved viruses, Mycobacterium tuberculosis and Coxiella burnetii the most common bacteria, but in 85% of cases it remains "idiopathic". Recurrences occur in up to 20-50% of patients. An immuno-mediated pathogenesis is suggested by the presence of pro-inflammatory cytokines in pericardial fluid, the presence of antinuclear autoantibodies (ANA) in sera of the patients, the occurrence of new autoimmune diagnoses and the good response to anti-inflammatory or immunosuppressive therapy. Nonsteroidal anti-inflammatory drugs (NSAIDs) must be used at recommended dosages, till the resolution of symptoms and normalization of C-reactive protein and erythrocyte sedimentation rate. Corticosteroids should be used rarely, at low doses, with an extremely low tapering and with osteoporosis prevention. Colchicine leads to a clinically important and statistically significant benefit, reducing recurrences by 50%. The long term outcome of IRAP is good, without evidence of constriction even after a very long follow-up.

Osteopoikilosis (OPK) is a rare benign sclerosing disease of the skeleton and inherited as an autosomal dominant trait. OPK is associated with inflammatory rheumatic disorders, such as rheumatoid arthritis, scleroderma, reactive arthritis and familial Mediterranean fever (FMF). We report a rare case of OPK coexistent with ankylosing spondylitis and FMF. The patient presented multiple sclerotic lesions within and around the sacroiliac joints and a series of radiological diagnostic challenges.

The population genetics of familial mediterranean fever: a meta-analysis study.

Papadopoulos VP(1), Giaglis S, Mitroulis I, Ritis K.

Author information:

(1)First Department of Internal Medicine, Democritus University of Thrace, Alexandroupolis, Greece. vaspapmd@otenet.gr

Our aim was to construct a Familial Mediterranean Fever (FMF) cumulative database and to propose a MEFV based phylogenetic tree. Data were collected from published studies. A meta-analysis based on 16,756 chromosomes from FMF patients and normal individuals from 14 affected populations was performed. Arlequin 2.0 and Phylip 3.2 software were used for population genetics analysis and phylogenetic tree construction. We have shown that MEFV mutations are distributed non-uniformly along the Mediterranean Sea area. The most frequent mutations detected in FMF patients are M694V (39.6%), V726A (13.9%), M680I (11.4%), E148Q (3.4%), and M694I (2.9%), while 28.8% of chromosomes carry unidentified or no mutations, especially in Western Europeans. The mean overall carrier rate is 0.186 with peak values in Arabs, Armenians, Jews, and Turks. Only V726A obeys the Hardy-Weinberg law in FMF patients implying that this mutation is the most ancient. Jews present the most intense genetic isolation and drift; thus they might have nested de novo mutations and accelerated evolution. Besides Jews, three population groups might follow distinct evolutionary lines (Asia Minor, Eastern European, and Western European). In conclusion, the MEFV mutation pattern is non-uniform regarding distribution, phenotypic expression, neutrality and population genetics characteristics. Jews are the candidate population for founder effects in MEFV.

Tumor necrosis factor receptor-associated periodic syndrome (TRAPS) or familial Hibernian fever: presentation in a four-day-old infant.

Savage T(1), Loftus BG, Tormey V, McDermott MF, Moylett E.

Author information:

(1)Academic Department of Paediatrics, National University of Ireland, Galway, Ireland.

Tumor necrosis factor receptor-associated periodic syndrome (TRAPS) is one of a number of well described hereditary periodic febrile syndromes. We report a case in an infant, with a strong family history of this disorder, who presented on day-of-life 4 with high fever, irritability, diarrhea, lethargy, and raised acute

phase reactants. An extensive work-up, including a full sepsis evaluation, proved negative. Symptoms resolved spontaneously. Representation with similar symptoms at 7 months of age prompted successful diagnosis after full evaluation. Subsequent genetic mutation analysis has proven positive for the T50M mutation in exon 2 of the TNFRSF1A gene. To our knowledge, this is the youngest reported age of presentation of this rare autoinflammatory disorder which should be considered even at such a young age.

HMG-CoA reductase inhibition induces IL-1beta release through Rac1/PI3K/PKB-dependent caspase-1 activation.

Kuijk LM(1), Beekman JM, Koster J, Waterham HR, Frenkel J, Coffey PJ.

Author information:

(1)Department of General Pediatrics, University Medical Centre, Utrecht, The Netherlands.

Mevalonate kinase deficiency (MKD) is an autoinflammatory disorder characterized by recurring fever episodes and results from disturbed isoprenoid biosynthesis.

Lipopolysaccharide-stimulated peripheral blood mononuclear cells from MKD patients secrete high levels of interleukin-1beta (IL-1beta) because of the presence of hyperactive caspase-1, and this has been proposed to be the primary cause of recurring inflammation. Here we show that inhibition of HMG-CoA reductase by simvastatin treatment, mimicking MKD, results in increased IL-1beta secretion in a Rac1/PI3K-dependent manner. Simvastatin treatment was found to activate protein kinase B (PKB)/c-akt, a primary effector of PI3K, and ectopic expression of constitutively active PKB was sufficient to induce IL-1beta release. The small GTPase Rac1 was activated by simvastatin, and this was required for both PKB activation and IL-1beta secretion. IL-1beta release is mediated by caspase-1, and simvastatin treatment resulted in increased caspase-1 activity in a Rac1/PI3K-dependent manner. These data suggest that, in MKD, dysregulated isoprenoid biosynthesis activates Rac1/PI3K/PKB, resulting in caspase-1 activation with increased IL-1beta release. Importantly, inhibition of Rac1 in peripheral blood mononuclear cells isolated from MKD patients resulted in a dramatic reduction in IL-1beta release. These data suggest that pharmacologic inhibition of Rac1 could provide a novel therapeutic strategy for treatment of MKD.

A new era for innate immunity.

Montero Vega MT(1).

Author information:

(1)Servicio de Bioquímica-Investigación, Hospital Ramón y Cajal, Madrid, Spain.  
teresa.montero@hrc.es

In recent years our concept of the non-specific nature of innate immunity has changed following the identification of a network of germline-encoded receptors that recognise with substantial specificity molecular motifs of microorganisms and many other cues produced during tissue injury. Stimulation of these innate sensors by their specific ligands triggers signalling pathways that result in the activation of innate effector mechanisms as well as the priming of naive

lymphocytes for the type of response that must be induced. These events culminate in the generation of an immune response appropriately adapted to the damage that has occurred. These new insights into innate immunity herald an entirely new era in the understanding of the molecular events that initiate and drive a host-protective response, changing many concepts about susceptibility to infections and providing greater insight into the underlying inflammatory pathology of other diseases. Targeted manipulation of innate immunity has enormous potential for the development of new vaccines and innovative therapies for the treatment of diseases such as infections, cancer, allergy, autoimmunity and autoinflammatory diseases. This article provides an overview of current trends in the field of innate immunity and its role in the control of infection and disease.

**OBJECTIVE:** To investigate systolic and diastolic ventricular functions, aortic elastic properties and the presence of pericardial effusion in familial Mediterranean fever (FMF) patients.

**METHODS:** A case-controlled, cross-sectional study was performed on 44 FMF patients and 27 controls. Subjects with hypertension, diabetes mellitus and hyperlipidemia were excluded. Left and right ventricular functions were measured

using echocardiography including two-dimensional, M-mode, and conventional Doppler as well as pulsed wave tissue Doppler imaging (TDI). Aortic elasticity was analyzed using M-mode tracing guided by the two-dimensional echocardiography. Statistical analysis was performed using Mann Whitney U, Spearman rho correlation and Fisher's exact tests.

RESULTS: Age, sex, body mass index, smoking status and lipids were comparable in patients and controls ( $p>0.05$ ). None of the subjects had pericarditis and/or pericardial effusion. Aortic wall properties were similar between groups ( $p>0.05$ ). The TDI parameters of mitral lateral annulus revealed significantly lower Em/Am ratios in patients compared to controls [1.77 (0.6-3.4) vs. 1.79 (0.9-4.8),  $p=0.02$ ]. Mitral flow propagation velocity was significantly lower in patients than healthy subjects [63 (39-100) vs. 74 (40-94) cm/s,  $p=0.008$ ]. Tricuspid annular plane systolic excursion (TAPSE) was significantly reduced in FMF group than in controls [2 (1.3-2.5) vs. 2.5 (1.7-3.2) cm;  $p<0.001$ ]. Eight of the patients and one control had impaired TAPSE ( $<2$  cm;  $p=0.025$ ). There was no difference regarding right ventricular diastolic dysfunction (RVDD) as assessed by using standard Doppler echocardiography ( $p>0.05$ ). However, pronounced RVDD was observed in FMF patients documented by TDI ( $Em/Am<1$ ; 19 patients vs. 0 controls,  $p<0.001$ ).

CONCLUSION: Subclinical myocardial involvement is present in a cohort of relatively young FMF patients who were also free of classical cardiovascular risk factors. Pericardium and aorta seem to be spared during attack free periods of FMF.

**BACKGROUND:** Amyloid A (AA) amyloidosis can complicate chronic inflammatory diseases, chronic infections and recurrent periodic fever syndromes. Its treatment is challenging, given its heterogeneous spectrum of etiologies.

**OBJECTIVE:** To review the available literature regarding treatment options for AA amyloidosis, particularly focusing on eprodisate, a newly developed inhibitor of fibrillogenesis.

**METHODS:** A PubMed search was performed without any date limits, mainly using the search terms 'amyloidosis', 'colchicine', 'eprodisate', '1,3-propanedisulfonate', 'NC-503', 'Fibrillex' and 'TNF-blockers'.

**RESULTS/CONCLUSION:** Antibiotics and colchicine are effective in preventing and treating infection-related and familial Mediterranean fever-related AA amyloidosis, respectively. Recently, TNF-alpha blockers have emerged as effective agents in inflammatory AA amyloidosis. Eprodisate binds to the glycosaminoglycan binding site on amyloid fibrils, thus targeting amyloid fibril polymerization and tissue deposition. Eprodisate has possible applicability to other types of amyloidosis; the results of a recent randomized trial showed that it may slow the progression of AA amyloidosis-related renal disease but confirmatory studies are necessary.

Comment in

Nat Clin Pract Rheumatol. 2009 Jan;5(1):14-5.

**OBJECTIVE:** Familial cold autoinflammatory syndrome (FCAS) is caused by mutations in the CIAS1 gene, leading to excessive secretion of interleukin-1beta (IL-1beta), which is associated with cold-induced fevers, joint pain, and systemic inflammation. This pilot study was conducted to assess the safety and efficacy of rilonacept (IL-1 Trap), a long-acting IL-1 receptor fusion protein, in patients with FCAS.

**METHODS:** Five patients with FCAS were studied in an open-label trial. All patients received an initial loading dose of 300 mg of rilonacept by subcutaneous injection, were evaluated 6 and 10 days later for clinical efficacy, and remained off treatment until a clinical flare occurred. At the time of flare, patients were again treated with 300 mg of rilonacept and then given maintenance doses of 100 mg/week. Patients whose FCAS was not completely controlled were allowed a dosage increase to 160 mg/week and then further to 320 mg/week during an inpatient dosage-escalation phase. Safety, disease activity measures (daily diary reports of rash, joint pain and/or swelling, and fevers), health quality measures (Short Form 36 health survey questionnaire), and serum markers of inflammation (erythrocyte sedimentation rate [ESR], high-sensitivity C-reactive protein [hsCRP], serum amyloid A [SAA], and IL-6) were determined at 3, 6, 9, 12, and 24 months after initiation of rilonacept and were compared with baseline values.

**RESULTS:** In all patients, clinical symptoms typically induced by cold (rash, fever, and joint pain/swelling) improved within days of rilonacept administration. Markers of inflammation (ESR, hsCRP, and SAA) showed statistically significant reductions ( $P < 0.01$ ,  $P < 0.001$ , and  $P < 0.001$ , respectively) at doses of 100 mg. Dosage escalation to 160 mg and 320 mg resulted in subjectively better control of the rash and joint pain. Furthermore, levels of the acute-phase reactants ESR, hsCRP, and SAA were lower at the higher doses; the difference was statistically significant only for the ESR. All patients continued taking the study drug. The drug was well-tolerated. Weight gain in 2 patients was noted. No study drug-related serious adverse events were seen.

**CONCLUSION:** In this study, we present 2-year safety and efficacy data on rilonacept treatment in 5 patients with FCAS. The dramatic improvement in clinical and laboratory measures of inflammation, the sustained response, and the good tolerability suggest that this drug may be a promising therapeutic option in patients with FCAS, and the data led to the design of a phase III study in this patient population.

Comment in

Nat Clin Pract Rheumatol. 2009 Jan;5(1):14-5.

**OBJECTIVE:** To assess the efficacy and safety of rilonacept (Interleukin-1 [IL-1] Trap), a long-acting and potent inhibitor of IL-1, in patients with cryopyrin-associated periodic syndromes (CAPS), including familial cold autoinflammatory syndrome (FCAS) and Muckle-Wells syndrome (MWS).

**METHODS:** Forty-seven adult patients with CAPS, as defined by mutations in the causative NLRP3 (CIAS1) gene and pathognomonic symptoms, were enrolled in 2 consecutive phase III studies. Study 1 involved a 6-week randomized double-blind comparison of weekly subcutaneous injections of rilonacept (160 mg) versus placebo. Study 2 consisted of 9 weeks of single-blind treatment with rilonacept (part A), followed by a 9-week, randomized, double-blind, placebo-controlled withdrawal procedure (part B). Primary efficacy was evaluated using a validated composite key symptom score.

**RESULTS:** Forty-four patients completed both studies. In study 1, rilonacept therapy reduced the group mean composite symptom score by 84%, compared with 13% with placebo therapy (primary end point;  $P < 0.0001$  versus placebo). Rilonacept also significantly improved all other efficacy end points in study 1 (numbers of multisymptom and single-symptom disease flare days, single-symptom scores, physician's and patient's global assessments of disease activity, limitations in daily activities, and C-reactive protein and serum amyloid A [SAA] levels). In study 2 part B, rilonacept was superior to placebo for maintaining the

improvements seen with rilonacept therapy, as shown by all efficacy parameters (primary end point;  $P < 0.0001$  versus placebo). Rilonacept was generally well tolerated; the most common adverse events were injection site reactions.

CONCLUSION: Treatment with weekly rilonacept provided marked and lasting improvement in the clinical signs and symptoms of CAPS, and normalized the levels of SAA from those associated with risk of developing amyloidosis. Rilonacept exhibited a generally favorable safety and tolerability profile.

Cryopyrinopathies: update on pathogenesis and treatment.

Neven B(1), Prieur AM, Quartier dit Maire P.

Author information:

(1)Hôpital Necker-Enfants-Malades, Paris, France. benedicte.neven@nck.aphp.fr

Cryopyrinopathies are a group of rare autoinflammatory diseases that includes familial cold autoinflammatory syndrome, Muckle-Wells syndrome and chronic infantile neurologic cutaneous articular syndrome (also termed neonatal-onset multisystemic inflammatory disease). These syndromes were initially considered to be distinct disease entities despite some clinical similarities; however, mutations of the same gene have since been found in all three cryopyrinopathies. These diseases, therefore, are not separate but represent a continuum of subphenotypes. The gene in question, CIAS1 (now renamed NLRP3) encodes NALP3 (also known as cryopyrin). NALP3 is an important mediator of inflammation and interleukin 1 $\beta$  processing. New therapies based on biologic agents that specifically target interleukin 1 $\beta$  are currently being developed. These new agents have provided very encouraging results for patients with these long-lasting inflammatory conditions--which used to be considered refractory to treatment. The development of therapeutic options for these cryopyrinopathies illustrates effective translation of basic science to clinical practice and the convergence of human genetics and targeted therapies.

**BACKGROUND:** Familial Mediterranean fever (FMF) is an autosomal recessive disorder, caused by mutations in MEFV gene that encodes pyrin protein. In this study, we analyzed the most common five mutations in MEFV gene of 202 patients who were diagnosed formerly as FMF according to Tel-Hashomer criteria. The results of genetical analysis, clinical symptoms, and demographical aspects of those patients were evaluated retrospectively.

**METHODS AND RESULTS:** Between the dates of February 2005 and March 2007, we analyzed five common MEFV gene mutations, which were M680I, M694V, M694I, V726A, and E148Q, in 202 patients by the PCR-ELISA method in our medical genetics laboratory. The most frequent mutation detected in our patients was M694V, and other mutations according to frequency were E148Q, M680I, V726A, and M694I. The detected mutations were homozygous in 45 of the patients (22.2%), heterozygous in 103 (51%), compound heterozygous in 52 (25.8%), and in 2 patients (1%) complex alleles were defined. The most common symptom was abdominal pain (80.4%) and other symptoms, respectively, were fever (57.8%), arthralgia (36.7%), chest pain (4.5%), and skin rash (2%). Amyloidosis was present in seven patients, and five of them had M694V mutation (homozygous), one of them had E148Q (heterozygous) mutation, and the other one had M694V/M694I mutation.

**CONCLUSION:** In our patients, we defined 21 different genotypes of MEFV gene and the most common mutation was M694V. The most common symptoms were abdominal pain and fever. We detected significant correlation between the M694V, E148Q, and V726A mutations and clinical findings.

Author information:

(1)Service de Pédiatrie 1 Unité d'Immunologie Clinique, CHU Ibn Rochd, Casablanca, Morocco.

A 12-year-old daughter of consanguineous Moroccan parents was diagnosed with cyclic neutropenia, based on a combination of recurrent gingivostomatitis, a fluctuating neutrophil count, and several episodes of severe neutropenia. No ELA2 gene mutations were found. At age 19 years she presented with edema of the limbs, proteinuria and renal failure. Renal amyloidosis AA was diagnosed by biopsy. Gene mutations associated with family Mediterranean fever (FMF) were sought, and a homozygous mutation (M694V) was found in the MFEV gene. This is the novel finding of FMF that masqueraded as cyclic neutropenia.

[Familial Mediterranean fever. Rare manifestation without fever and with inconspicuous family case history].

[Article in German]

Vogel Y(1), Büchner NJ, Haverkamp T, Henning BF.

Author information:

(1)Marienhospital Herne, Ruhr-Universität Bochum, Medizinische Klinik I, Bochum.

**HISTORY AND ADMISSION FINDINGS:** A 33-year-old man of Turkish descent had suffered from recurrent diffuse abdominal pain and shoulder pain since 13 years.

Repeatedly performed investigations in the past had produced numerous diagnoses. The symptoms had been recurring quarterly to weekly, lasted three days on average and resolved spontaneously. He never had fever and the family history was unremarkable.

**DIAGNOSIS, TREATMENT, AND COURSE:** Blood tests demonstrated increased parameters for systemic inflammation and mild normochromic normocytic anemia. In addition to splenomegaly the abdominal computed tomography revealed signs of sacroiliitis. There was no arthritis of the shoulder radiologically. Despite lack of familial history and fever genetic analysis of the Mediterranean fever gene (MEFV) revealed two heterozygous mutations in this MEFV gene for M694 and V726A. The patient was treated with colchicine and has now remained free of symptoms for meanwhile 10 months. There had been no comparable symptom-free period during the last 10 years.

**CONCLUSION:** Sometimes the name "Familial Mediterranean Fever" (FMF) is misleading because this disease may, although rarely, occur without both, fever and familial history. Because of the increasing number of immigrants FMF should be considered in the initial differential diagnosis of patients of Mediterranean origin presenting with abdominal pain. Genetic analysis of the MEFV-gene as well as a therapeutic trial with colchicine, may help to detect FMF.

Tibbiye Cad, 34668 Kadikoy, Istanbul, Turkey. mhterekeci@yahoo.com.tr

The aim of this study is to investigate the tissue Doppler echocardiographic (TDE) characteristics of acute familial Mediterranean fever (FMF) attack on young Turkish males. Thirty-four young males with FMF were investigated utilizing echocardiography both before and after FMF attacks. Echocardiographic findings were assessed by two cardiologist utilizing Vingmed system V echocardiography machine and a 2.5 MHz probe by two-dimensional and color Doppler examination, as well as tissue Doppler parameters. The incidence of pericardial effusion was found to be 23.3% during acute FMF attack. There was no significant difference between the patients in attack-free period and attack period with respect to TDE measurements. TDE measurements did not differ between the patients with and without pericardial effusion. There was no correlation between pericardial effusion and disease duration, family history, and physical findings. In conclusion, our results suggest preserved systolic and diastolic ventricular functions in attack period. Pericardial effusion is not associated with impaired TDE parameters.

m.e.vangijn@umcutrecht.nl

Familial mediterranean fever (FMF) is a hereditary autoinflammatory autosomal recessive disease caused by mutations in the MEFV gene. Despite the identification of many disease associated MEFV mutations, often the clinical

diagnosis cannot be genetically confirmed. The currently used diagnostic sequencing techniques only allow the detection of point mutations, small deletions or duplications. The question as to whether larger genetic alterations are also involved in the pathophysiology of FMF remains to be answered. To address this question, we used multiplex ligation-dependent probe amplification (MLPA) on a total of 216 patients with FMF symptoms. This careful analysis revealed that not a single deletion/duplication could be detected in this large cohort of patients. This result suggests that single or multiexon MEFV gene copy number changes do not contribute substantially, if at all, to the MEFV mutation spectrum.

Protracted febrile myalgia mimicking polyarteritis nodosa.

Bircan Z(1), Usluer H.

Author information:

(1)Department of Pediatric Nephrology, Kocaeli University Faculty of Medicine, Kocaeli, Turkey. zbircan@superonline.com

An insidious onset of unexplained fever, weight loss, skin lesions, abdominal pain, and musculoskeletal pain should suggest the diagnosis of polyarteritis nodosa (PAN). However, familial Mediterranean fever (FMF) with protracted febrile myalgia (PFM) should be kept in mind in the differential diagnosis. In this report, 6 cases of PFM mimicking PAN are described. Patients presented with severe muscle and abdominal pain lasting longer than 4 weeks. Their common medical history included recurrent febrile abdominal pain or arthritis. Physical examination revealed hypertension together with severe muscle tenderness. Laboratory examination revealed high acute phase reactants, negative p-ANCA, normal creatine kinase, and complement levels. Duplex abdominal ultrasonography was normal. Four of 6 patients were hospitalized with initial diagnoses of PAN. Renal and mesenteric angiography performed in 1 patient was normal. Steroid therapy controlled all the severe symptoms including hypertension in all of the cases. FMF with PFM is important in the differential diagnosis of patients with

suspected vasculitis especially when myalgia is present. Hypertension may be present as a result of sympathetic discharge because of severe myalgia. Because PFM rapidly responds to a short course of corticosteroids, a rapid diagnosis of PFM in FMF patients can reduce unnecessary workup and decrease the time patients have to suffer.

Defects in actin dynamics lead to an autoinflammatory condition through the upregulation of CXCL5.

Verdoni AM(1), Smith RS, Ikeda A, Ikeda S.

Author information:

(1)Department of Medical Genetics, University of Wisconsin-Madison, Madison, Wisconsin, United States of America.

**BACKGROUND:** Destrin (DSTN) is a member of the ADF/cofilin family of proteins and is an important regulator of actin dynamics. The primary function of destrin is to depolymerize filamentous actin into its monomeric form and promote filament severing. While progress has been made in understanding the biochemical functions of the ADF/cofilin proteins, the study of an animal model for cells deficient for DSTN provides an opportunity to investigate the physiological processes regulated by proper actin dynamics in vivo. A spontaneous mouse mutant, corneal disease 1(corn1), is deficient for DSTN, which causes epithelial hyperproliferation and neovascularization in the cornea. Dstn(corn1) mice exhibit an actin dynamics defect in the cornea as evidenced by the formation of actin stress fibers in the epithelial cells. Previously, we observed a significant infiltration of leukocytes into the cornea of Dstn(corn1) mice as well as the upregulation of proinflammatory molecules. In this study, we sought to characterize this inflammatory condition and explore the physiological mechanism through which a loss of Dstn function leads to inflammation.

**METHODOLOGY/PRINCIPAL FINDINGS:** Through immunofluorescent analyses, we observed a significant recruitment of neutrophils and macrophages to the Dstn(corn1) cornea, demonstrating that the innate immune system is spontaneously activated in this

mutant. The inflammatory chemokine, CXCL5, was ectopically expressed in the corneal epithelial cells of Dstn(corn1) mice, and targeting of the receptor for this chemokine inhibited neutrophil recruitment. An inflammatory reaction was not observed in the cornea of allelic mutant strain, Dstn(corn1-2J), which has a milder defect in actin dynamics in the corneal epithelial cells.

CONCLUSIONS/SIGNIFICANCE: This study shows that severe defects in actin dynamics lead to an autoinflammatory condition that is mediated by the expression of CXC chemokines.

Serositis is a common clinical manifestation of systemic lupus erythematosus (SLE), as well as being the hallmark of familial Mediterranean fever (FMF), the most prevalent monogenic disease in the Jewish population. We have treated four patients who suffered from both SLE and FMF since 2001 in our clinic, which also serves as the national center for FMF. Our cases illustrate both similarities and dissimilarities between the clinical manifestations of these two diseases, an aspect which should be borne in mind, especially in the young female patients. In general, it seems that co-occurrence of FMF moderates the presentation of lupus.

(1)Infectious Diseases & Clinical Microbiology Department, Ankara Research & Training Hospital, Ankara, Turkey. drzeliha@hotmail.com

Colchicine is widely used, primarily for the treatment of gouty arthritis and familial Mediterranean fever. Colchicine intoxication is a rare but potentially life-threatening event. Herein, we reported a 26-year-old woman who presented to the emergency department after ingesting 27.5 mg of colchicine in a suicide attempt. She exhibited signs typical of colchicine-poisoning and developed infectious complications but with subsequent complete recovery. This paper discusses the role of colchicine poisoning in increasing susceptibility to infections. This aspect is usually under-appreciated in the clinical picture of colchicine overdose.

Chronic infantile neurological cutaneous and articular (CINCA) syndrome is an autoinflammatory disease, defined by the triad of urticarial rash, neurological manifestations, and arthropathy, accompanied by recurrent fevers and systemic inflammation. Increasing neurological deficits result from aseptic meningitis. Sensorineural hearing loss and progressive loss of vision caused by keratoconjunctivitis or papilloedema may emerge. An autosomal-dominant inheritance is suspected although sporadic cases are reported frequently. Sixty per cent of CINCA patients carry mutations in the cold-induced autoinflammatory syndrome (CIAS1) gene. We report the favourable response of a 23-year-old CINCA patient without CIAS1 mutations to treatment with the recombinant interleukin-1 (IL-1) receptor antagonist anakinra.

The spectrum of monogenic autoinflammatory syndromes: understanding disease mechanisms and use of targeted therapies.

Glaser RL(1), Goldbach-Mansky R.

Author information:

(1)National Institute of Arthritis and Musculoskeletal and Skin Diseases, National Institutes of Health Building 10, Room 6N-216A, 10 Center Drive, Bethesda, MD 20892, USA.

Monogenic autoinflammatory diseases encompass a distinct and growing clinical entity of multisystem inflammatory diseases with known genetic defects in the innate immune system. The diseases present clinically with episodes of seemingly unprovoked inflammation (fever, rashes, and elevation of acute phase reactants). Understanding the genetics has led to discovery of new molecules involved in recognizing exogenous and endogenous danger signals, and the inflammatory response to these stimuli. These advances have furthered understanding of innate inflammatory pathways and spurred collaborative research in rheumatology and infectious diseases. The pivotal roles of interleukin (IL)-1beta in cryopyrin-associated periodic syndromes, tumor necrosis factor (TNF) in TNF receptor-associated periodic syndrome, and links to inflammatory cytokine dysregulation in other monogenic autoinflammatory diseases have resulted in effective therapies targeting proinflammatory cytokines IL-1beta and TNF and uncovered other new potential targets for anti-inflammatory therapies.

Author information:

(1)Department of Internal Medicine, Gülhane Askeri Tip Akademisi Romatoloji Bilim Dalı, Etlik, Ankara, 06010, Turkey. muhcinar@hotmail.com

In this study, our aim was to investigate the prevalence of Mediterranean fever (MEFV) gene mutations in patients with ankylosing spondylitis (AS) and assessing their clinical significance. Ninety-five consecutive patients (12 women, 83 men) with active AS were included to the study. All patient's relevant clinical data were recorded at the beginning and patient assessment measures were performed. The frequency of the eight most common MEFV mutations: M694V, V726A, E148Q, M680I, M694I, P369S, F479L, and the R761H were determined. Genetic analysis was carried out by the NanoChip Molecular Genetics Workstation. NSAIDs were given to patients for treatment. The rate of MEFV mutations and their clinical significance were assessed. With regard to the MEFV mutation analysis, 30.5% of AS patients were found to have at least one mutation. The response rate to the NSAIDs ( $P=0.825$ ) or frequency of patients having active disease ( $P=0.066$ ) after the treatment, were not found different between the patients those have MEFV mutations and the patients those were non-carriers. Furthermore, no clinical and laboratory difference between MEFV mutation carriers and non-carriers were found. We think that although prevalence of MEFV mutations is significantly high in AS patients without clinical features of familial Mediterranean fever, its influence to the prognosis is less likely. Further investigations are needed to define the impact of MEFV mutations on the disease course of ankylosing spondylitis.

Intramuscular gold for the treatment of seronegative spondyloarthropathy associated with familial Mediterranean fever.

Demirag MD(1), Ozturk MA, Goker B, Haznedaroglu S.

Author information:

(1)Department of Internal Medicine, Section of Rheumatology, Gazi University, School of Medicine, Demetgöl Mah. 6. sokak No:15/16, Yenimahalle, 06200, Ankara, Turkey. mehmetderyademirag@yahoo.com

Articular attack is a common feature of familial Mediterranean fever (FMF). FMF arthritis commonly resolves without any sequale within a few weeks. However,

approximately 10% of the patients develop protracted arthritis persisting for months to years. Treatment with colchicine may not be effective and nonsteroidal antiinflammatory drugs or second line agents may be needed for the management of protracted arthritis. In this paper, we describe a 22-year-old patient with FMF who was complicated with protracted arthritis in the knee and shoulder joints and bilateral sacroiliitis. He was successfully treated by intramuscular gold 50 mg weekly. However, gold treatment was discontinued 8 months later because of the development of asymptomatic proteinuria. In conclusion, FMF should be considered in the evaluation of peripheral oligoarthritis, particularly in patients with Mediterranean origin. Intramuscular gold might be an effective agent. However, care should be taken regarding the development of proteinuria.

The etiology and pathogenesis of certain types of disease remain controversial and stand like a bridge that crosses infectious, autoimmune and autoinflammatory pathways. Infection, for example, may initiate a disease, although it is the genetic regulation in the host, the interplay between virus or bacteria persistence and autoimmunity that produces the later phases of disease, the antigenic determinants responsible for inducing autoimmune disease, and the pathogenetic effector mechanisms. Infections agents cause pericarditis, but in 85% of cases it is "idiopathic". It has also been shown that persistent *Chlamydia pneumoniae*, *Porphyromonas gingivalis*, and *Helicobacter pylori* infections cause host immunity and promote atherogenesis. A number of infectious agents have been suggested as potential triggers for primary biliary cirrhosis. Infections and vaccinations have also been linked to the pathogenesis of fibromyalgia syndrome, a common, chronic syndrome of widespread pain. Many factors are also responsible

for fever of unknown origin such as: infections, autoimmunity disease, etc. However, it is difficult to determine a direct correlation between the infections agents in such a large group of diseases. The aim of this review is to analyze some of the controversies about the role of infections in autoimmune diseases.

The autoinflammatory syndromes are a group of disorders characterized by recurrent episodes of seemingly unprovoked inflammation without significant levels of autoantibodies and antigen specific T cells. Although a direct association between defective innate immune responses to bacterial components and these diseases has not been formally established, much ongoing research is aimed towards confirmation of that hypothesis. This article will review recent advances in the study of a subset of NOD-like receptors (NLRs), which control the activation of caspase-1 through the assembly of a large protein complex called inflammasome. Moreover, we will review recent progresses in understanding of a range of autoinflammatory conditions in humans.

The Fifth International Congress on Familial Mediterranean Fever and Systemic Autoinflammatory Diseases (Rome, Italy, 4-8 April, 2008) reviewed developments in the field of innate immunity and discussed their relevance to the pathogenesis of associated diseases. The meeting gathered over 300 participants from 32 countries. New modes of inheritance of autoinflammatory diseases, animal models, novel related genes and the remarkable efficacy of IL-1beta blockage in most of these diseases were emphasized.

Therapy insight: the changing spectrum of rheumatic disease in HIV infection.

Maganti RM(1), Reveille JD, Williams FM.

Author information:

(1)University of Texas Health Science Center at Houston, TX 77030, USA.

HIV infection and AIDS have protean and multisystem manifestations throughout the various stages of infection. Progression from HIV infection to AIDS is associated with a gradual loss of immunocompetence and the occurrence of opportunistic infections and malignancies; it is also associated with immune dysregulation and persistent, prolonged immune activation that leads to autoimmune phenomena such as vasculitis and serological abnormalities. In people who are infected with HIV, the recognition of autoinflammatory disorders, their differentiation from infections or lymphoproliferative malignancies and their treatment using potentially immunosuppressive drugs is a challenging clinical scenario. The spectrum of rheumatologic diseases reported in HIV-infected individuals has

changed dramatically since the introduction of highly active antiretroviral therapy in 1995. Complications such as metabolic abnormalities, osteoporosis, and immune restoration inflammatory syndrome have emerged.

chaej@exchange.nih.gov

Familial Mediterranean fever (FMF) is an autoinflammatory disease caused by mutations in MEFV, which encodes a 781-amino acid protein denoted pyrin. We have previously shown that pyrin regulates caspase-1 activation and IL-1beta production through interaction of its N-terminal PYD motif with the ASC adapter protein, and also modulates IL-1beta production by interaction of its C-terminal B30.2 domain with the catalytic domains of caspase-1. We now asked whether pyrin might itself be a caspase-1 substrate, and found that pyrin is cleaved by caspase-1 at Asp330, a site remote from the B30.2 domain. Pyrin variants harboring FMF-associated B30.2 mutations were cleaved more efficiently than wild-type pyrin. The N-terminal cleaved fragment interacted with the p65 subunit of NF-kappaB and with IkappaB-alpha through its 15-aa bZIP basic domain and adjacent sequences, respectively, and translocated to the nucleus. The interaction of the N-terminal fragment with p65 enhanced entrance of p65 into the nucleus. The interaction of N-terminal pyrin with IkappaB-alpha induced calpain-mediated degradation of IkappaB-alpha, thus potentiating NF-kappaB activation. Absolute and relative quantities of cleaved pyrin and IkappaB-alpha degradation products were substantially increased in leukocytes from FMF patients

compared with healthy controls. Our data support a new pyrin/caspase-1 pathway for NF-kappaB activation.

Autoinflammatory genes and susceptibility to psoriatic juvenile idiopathic arthritis.

Day TG(1), Ramanan AV, Hinks A, Lamb R, Packham J, Wise C, Punaro M, Donn RP.

Author information:

(1)University of Manchester, Manchester, UK.

**OBJECTIVE:** To investigate the association of NLRP3, NOD2, MEFV, and PSTPIP1, genes that cause 4 of the autoinflammatory hereditary periodic fever syndromes (HPFS), with juvenile idiopathic arthritis (JIA).

**METHODS:** Fifty-one single-nucleotide polymorphisms (SNPs) across the 4 loci were investigated using MassArray genotyping in 950 Caucasian patients with JIA living in the UK and 728 ethnically matched healthy controls.

**RESULTS:** Prior to Bonferroni correction for multiple testing, significant genotype associations between 6 SNPs in MEFV and JIA were observed and, in subgroup analysis, associations between 12 SNPs across all 4 loci and the subgroup of patients with psoriatic JIA were found. After Bonferroni correction for multiple testing, 2 genotype associations remained significant in the subgroup of patients with psoriatic JIA (MEFV SNP rs224204 [corrected P = 0.025] and NLRP3 SNP rs3806265 [corrected P = 0.04]).

**CONCLUSION:** These findings support the use of monogenic loci as candidates for investigating the genetic component of complex disease and provide preliminary evidence of association between SNPs in autoinflammatory genes and psoriatic JIA. Our findings raise the interesting possibility of a shared disease mechanism between the HPFS and psoriatic JIA, potentially involving abnormal production of interleukin-1beta.

The pathogenesis of chronic joint inflammation remains unclear, although the involvement of pathogen recognition receptors has been suggested recently. In the present article, we describe the role of two members of the NACHT-LRR (NLR) family, Nod1 (nucleotide-binding oligomerization domain) and Nod2 in a model of acute joint inflammation induced by intraarticular injection of *Streptococcus pyogenes* cell wall fragments. Here, we show that Nod2 deficiency resulted in

reduced joint inflammation and protection against early cartilage damage. In contrast, Nod1 gene-deficient mice developed enhanced joint inflammation with concomitant elevated levels of proinflammatory cytokines and cartilage damage, consistent with a model in which Nod1 controls the inflammatory reaction. To explore whether the different function of Nod1 and Nod2 occurs also in humans, we exposed peripheral blood mononuclear cells (PBMCs) carrying either Nod1ins/del or Nod2fs mutation with SCW fragments in vitro. Production of both TNFalpha and IL-1beta was clearly impaired in PBMCs carrying the Nod2fs compared with PBMCs isolated from healthy controls. In line with results in Nod1 gene-deficient mice, PBMCs from individuals bearing a newly described Nod1 mutation produced enhanced levels of proinflammatory cytokines after 24-h stimulation with SCW fragments. These data indicate that the NLR family members Nod1 and Nod2 have different functions in controlling inflammation, and that intracellular Nod1-Nod2 interactions may determine the severity of arthritis in this experimental model. Whether a distorted balance between the function of Nod1 and/or Nod2 is involved in the pathogenesis of human autoinflammatory or autoimmune disease, such as rheumatoid arthritis, remains to be elucidated.

The vitamin D pathway: a new target for control of the skin's immune response?

Schauber J(1), Gallo RL.

Author information:

(1)Department of Dermatology and Allergology, Ludwig-Maximilians-University, Munich, Germany. juergen.schauber@med.uni-muenchen.de

The surface of our skin is constantly challenged by a wide variety of microbial pathogens, still cutaneous infections are relatively rare. Within cutaneous innate immunity the production of antimicrobial peptides (AMPs) is a primary system for protection against infection. Many AMPs can be found on the skin, and these include molecules that were discovered for their antimicrobial properties,

and other peptides and proteins first known for activity as chemokines, enzymes, enzyme inhibitors and neuropeptides. Cathelicidins were among the first families of AMPs discovered on the skin. They are now known to have two distinct functions; they have direct antimicrobial activity and will initiate a host cellular response resulting in cytokine release, inflammation and angiogenesis. Dysfunction of cathelicidin is relevant in the pathogenesis of several cutaneous diseases including atopic dermatitis where cathelicidin induction is suppressed, rosacea, where cathelicidin peptides are abnormally processed to forms that induce cutaneous inflammation and a vascular response, and psoriasis, where a cathelicidin peptide can convert self-DNA to a potent stimulus of an autoinflammatory cascade. Recent work has unexpectedly identified vitamin D3 as a major factor involved in the regulation of cathelicidin expression. Therapies targeting the vitamin D3 pathway and thereby cathelicidin may provide new treatment modalities in the management of infectious and inflammatory skin diseases.

Chronic infantile neurologic cutaneous articular (CINCA) syndrome is a serious chronic systemic inflammatory disease that presents at a young age and that is characterized by skin, joint, and central nervous system disease. Skin symptoms are the first to appear, in the form of a longstanding nonpruritic urticarial rash, with exacerbations coinciding with episodes of fever, arthritis, and enlarged lymph nodes. The findings of biopsy of skin lesions are extremely variable but characterized by perivascular neutrophilic infiltrate. With the discovery of mutations in the CIAS1 gene, which encodes a protein known as cryopyrin, this entity has been classified as one of the cryopyrin-associated autoinflammatory diseases, along with familial cold urticaria and Muckle-Wells syndrome. This discovery has also made available new therapeutic options. We present the case of a boy diagnosed with CINCA syndrome who presented with an outbreak of painful skin lesions and fever. These lesions were thought to be an exacerbation of underlying lesions during an episode of fever.

Decreased bone mineral density in adult familial Mediterranean fever patients: a pilot study.

Suyani E(1), Ozturk MA, Deger SM, Demirag MD, Goker B, Haznedaroglu S.

Author information:

(1)Department of Internal Medicine, Faculty of Medicine, Gazi University, Ankara, Turkey. elifsuyani@hotmail.com

We investigated the association between familial Mediterranean fever (FMF) and osteoporosis (OP) in adult patients. Thirty-five attack-free FMF patients (28 females, 7 males; mean age 36.9 +/- 5.7 years) were individually matched to control subjects on the basis of age (within 2 years) and sex. All patients were taking regular colchicine. Subjects having any condition that can cause decreased bone mineral density (BMD) were excluded from the study. BMD was measured at the spine and femur by dual X-ray absorptiometry (DXA). Data was given as the median (IQR). T scores of the spine were -0.700 (-1.097 to -0.262) and -0.450 (-0.830 to 0.112) in FMF patients and healthy controls, respectively ( $p > 0.05$ ). T scores of the femur neck were -0.900 (-1.480 to -0.570) and -0.430 (-1.472 to 0.247) in FMF patients and healthy controls, respectively ( $p > 0.05$ ). Total femur T scores were significantly lower in FMF patients than healthy controls (-0.780 [-1.222 to -0.085] vs. -0.100 [-0.765 to 0.537], respectively,  $p = 0.021$ ). Total femur T scores were significantly decreased in adult patients with FMF. Ongoing subclinical inflammation may be associated with decreased bone mineral content in those patients.

Author information:

(1)Rheumatology Department, Reina Sofia Hospital, Avenida Menendez Pidal s/n, 14004 Cordoba, Spain. peperosa@teleline.es

Familial Mediterranean fever (FMF), a recessively inherited autoinflammatory disorder, is the prototype of a group of disorders termed systemic autoinflammatory diseases. Such diseases are characterized by seemingly unprovoked episodes of inflammation without evidence of high-titer autoantibodies or antigen-specific T cell. Repeated bouts of inflammation may lead to systemic AA protein deposition, making FMF a potentially fatal disease. Pyrin, the protein mutated in FMF, regulates caspase-1 activation and consequently IL-1beta production. Although colchicine is the standard prophylactic therapy for attacks and amyloid deposition, some patients fail to respond or cannot tolerate its side effects. Anticytokine therapies have shown promise in the treatment of autoinflammatory disorders in children. We report on the use of the recombinant interleukin 1 receptor antagonist anakinra in one child with therapy-resistant FMF. The patient experienced immediate, sustained resolution of symptoms and laboratory markers of inflammation, and also, possibly, a reduced long-term risk of AA amyloidosis.

Central nervous system involvement in pediatric rheumatic diseases: current concepts in treatment.

Duzova A(1), Bakkaloglu A.

Author information:

(1)Department of Pediatrics, Pediatric Nephrology and Rheumatology Unit, Hacettepe University Faculty of Medicine, Ankara, Turkey.

Central nervous system (CNS) manifestations are not rare in pediatric rheumatic diseases. They may be a relatively common feature of the disease, as in systemic lupus erythematosus (SLE) and Behçet's disease. Direct CNS involvement of a systemic rheumatic disease, primary CNS vasculitis, indirect involvement secondary to hypertension, hypoxia and metabolic changes, and drug associated adverse events may all result in CNS involvement. We have reviewed the CNS manifestations of SLE, Behçet's disease, Henoch-Schönlein purpura, polyarteritis nodosa, juvenile idiopathic arthritis, juvenile ankylosing spondylitis, familial Mediterranean fever, scleroderma, sarcoidosis, Wegener's granulomatosis, Takayasu's arteritis, CINCA syndrome, Kawasaki disease, and primary CNS vasculitis; and adverse CNS effects of anti-rheumatic drugs in pediatric patients. The manifestations are diverse; ranging from headache, seizures, chorea, changes in personality, depression, memory and concentration problems, cognitive impairment, cerebrovascular accidents to coma, and death. The value of cerebrospinal fluid (CSF) examination (pleocytosis, high level of protein), auto-antibodies in serum and CSF, electroencephalography, neuroimaging with computerized tomography, magnetic resonance imaging, SPECT, PET, and angiography depends on the disease. Brain biopsy is gold standard for the diagnosis of CNS vasculitis, however it may be inconclusive in 25% of cases. A thorough knowledge of the rheumatic diseases and therapy-related adverse events is mandatory for the management of a patient with rheumatic disease and CNS involvement. Severe CNS involvement is associated with poor prognosis, and high mortality rate. High dose steroid and cyclophosphamide (oral or intravenous) are first choice drugs in the treatment; plasmapheresis, IVIG, thalidomide, and intrathecal treatment may be valuable in treatment-resistant, and serious cases.

Interferon-alpha as a treatment modality for colchicine- resistant familial Mediterranean fever.

Tweezer-Zaks N(1), Rabinovich E, Lidar M, Livneh A.

Author information:

(1)Heller Institute of Medical Research, Sheba Medical Center, Tel-Hashomer, affiliated with Sackler Faculty of Medicine, Tel-Aviv University, Tel-Aviv, Israel.

**OBJECTIVE:** Previous reports on interferon-alpha (IFN-alpha) were conflicting with respect to its efficacy in familial Mediterranean fever (FMF) refractory to colchicine treatment. We investigated the effect of IFN-alpha in patients with colchicine-resistant FMF.

**METHODS:** In a prospective, patient self-controlled, open-label study evaluating the safety and efficacy of IFN-alpha in patients with FMF with a severe phenotype, refractory to intensified (oral plus intravenous) colchicine therapy, we advised patients to subcutaneously inject IFN-alpha, 3 million international units, at the onset of the FMF attack. Attacks not treated with IFN-alpha of the same patients and in the same sites served as control attacks. Features of each attack were recorded in a questionnaire, eventually used to compare between IFN-alpha-treated and non-treated attacks.

**RESULTS:** Ten patients with a total of 80 attacks were recruited. Compared to 22 untreated attacks, a > 20% and > 50% reduction in the duration of the attacks was noted in 100% and 90% of the 58 IFN-alpha-treated attacks, respectively ( $p < 0.001$  for both). The severity (degree of pain) of the IFN-alpha-treated attacks was attenuated by > 20% and > 50% in 88% and 49% of these attacks, respectively ( $p < 0.001$  for both). The most common drug-related adverse events were chills and fatigue.

**CONCLUSION:** Early intervention with IFN-alpha injections was associated with reduced attack length and/or severity in a substantial number of bouts, with an acceptable cost of adverse events.

A diagnostic score for molecular analysis of hereditary autoinflammatory syndromes with periodic fever in children.

Gattorno M(1), Sormani MP, D'Osualdo A, Pelagatti MA, Caroli F, Federici S,

Cecconi M, Solari N, Meini A, Zulian F, Obici L, Breda L, Martino S, Tommasini A, Bossi G, Govers A, Touitou I, Woo P, Frenkel J, Koné-Paut I, Baldi M, Ceccherini I, Martini A.

Author information:

(1)Giannina Gaslini Institute, Genoa, Italy.

**OBJECTIVE:** To identify a set of clinical parameters that can predict the probability of carrying mutations in one of the genes associated with hereditary autoinflammatory syndromes.

**METHODS:** A total of 228 consecutive patients with a clinical history of periodic fever were screened for mutations in the MVK, TNFRSF1A, and MEFV genes, and detailed clinical information was collected. A diagnostic score was formulated based on univariate and multivariate analyses in genetically positive and negative patients (training set). The diagnostic score was validated in an independent set of 77 patients (validation set).

**RESULTS:** Young age at onset (odds ratio [OR] 0.94,  $P = 0.003$ ), positive family history of periodic fever (OR 4.1,  $P = 0.039$ ), thoracic pain (OR 4.6,  $P = 0.05$ ), abdominal pain (OR 33.1,  $P < 0.001$ ), diarrhea (OR 3.3,  $P = 0.028$ ), and oral aphthosis (OR 0.2,  $P = 0.007$ ) were found to be independently correlated with a positive genetic test result. These variables were combined in a linear score whose ability to predict a positive result on genetic testing was validated in an independent data set. In this latter set, the diagnostic score revealed high sensitivity (82%) and specificity (72%) for discriminating patients who were genetically positive from those who were negative. In patients with a high probability of having a positive result on genetic testing, a regression tree analysis provided the most reasonable order in which the genes should be screened.

**CONCLUSION:** The proposed approach in patients with periodic fever will increase the probability of obtaining positive results on genetic testing, with good specificity and sensitivity. Our results further help to optimize the molecular analysis by suggesting the order in which the genes should be screened.

Recurrent pleurisy as sole manifestation of familial Mediterranean fever. An 18-year-old woman of Turkish descent visited our outpatient department with a 12-year history of recurrent self-limiting febrile attacks accompanied by chest pain. At first the symptoms were attributed to recurrent lower airway infections. However, the persistent nature of the attacks combined with her ethnic background and the spontaneous recovery from the short paroxysmal episodes, led to the consideration of familial Mediterranean fever (FMF). After undergoing treatment with colchicine the patient was free of symptoms. Later it became clear that her 28-year-old brother had the same clinical manifestations of FMF. He was also successfully treated with colchicine. The often long interval from disease onset to correct diagnosis reflects the unfamiliarity of physicians with this disease and the frequency with which it is confused with other syndromes. In patients with paroxysmal febrile attacks and chest pain, especially if they originate from the eastern Mediterranean area, FMF should be considered and colchicine be prescribed to relieve symptoms and prevent amyloidosis.

Unusual Gilbert's syndrome genotype in a Greek patient suffering from both Gilbert's syndrome and familial mediterranean fever. A case report.

Kalotychou V(1), Kanta A, Rombos Y, Konstantopoulos K.

Author information:

(1)First Department of Internal Medicine, University of Athens School of

Medicine, Laikon University Hospital, Athens, Greece. vkalotyc@med.uoa.gr

Gilbert's syndrome is a genetically controlled non-hemolytic unconjugated hyperbilirubinemia, caused by reduced activity of UDP-glucuroniltransferase 1, an enzyme critical in bilirubin metabolism. Several molecular configurations may be implicated in a Gilbert's phenotype. Familial mediterranean fever (FMF) is an inherited acute relapsing inflammatory disorder, affecting Mediterranean and Middle East populations. The molecular basis of the disorder concerns the MEFV gene coding for a protein named pyrin; several point mutations of MEFV gene have been associated with the disease. The authors present an unusual patient co-affected by both Gilbert's syndrome and FMF who carried a peculiar Gilbert's genotype. The coexistence of these two genetic conditions seems to be rare but interesting as the potentially overlapping clinical symptoms may rise interesting diagnostic problems.

Hyperimmunoglobulinemia D and periodic fever syndrome; treatment with etanercept and follow-up.

Topaloglu R(1), Ayaz NA, Waterham HR, Yüce A, Gumruk F, Sanal O.

Author information:

(1)Pediatric Nephrology and Rheumatology Unit, Faculty of Medicine, Hacettepe University, 06100, Sıhhiye, Ankara, Turkey. rtopalog@hacettepe.edu.tr

The hyperimmunoglobulinemia D and periodic fever syndrome (HIDS) is an autoinflammatory syndrome. It is caused by the mutations of the mevalonate kinase gene. There is no consensus for specific therapy of HIDS, but there are some case reports and studies in regards to its treatment with drugs like colchicine, steroids, nonsteroid anti-inflammatory drugs, simvastatin, anakinra, thalidomide, and etanercept. We are reporting a case evaluated for the complaints of abdominal pain and febrile episodes with massive hepatomegaly, not common finding on physical examination, its treatment with etanercept, and long-term follow-up.

Evaluation of intima media thickness of the common and internal carotid arteries with inflammatory markers in familial Mediterranean fever as possible predictors for atherosclerosis.

Bilginer Y(1), Ozaltin F, Basaran C, Duzova A, Besbas N, Topaloglu R, Ozen S, Bakkaloglu A.

Author information:

(1)Department of Pediatric Nephrology and Rheumatology, Hacettepe University Faculty of Medicine, 06100 Sıhhiye, Ankara, Turkey.

The aim of the present study was to determine whether intima-media thickness (IMT) of the common (CCA) and internal carotid arteries (ICA) was increased due to chronic inflammation occurring in familial Mediterranean fever (FMF) patients compared to healthy controls. Erythrocyte sedimentation rate (ESR), serum C-reactive protein (CRP), serum amyloid A protein (SAA), lipid profile and homocysteine levels were examined in 70 FMF patients [median age 14 years (range 4-24)] in an attack free period and in 50 healthy controls [median age 14 years (range 4-18)]. All the patients were homozygous or compound heterozygous for MEFV mutations. IMT of both CCA and ICA was evaluated with a high resolution B-mode ultrasonography. ESR, CRP, fibrinogen and SAA levels were significantly higher in FMF patients as compared to healthy controls ( $P < 0.05$ ). Intima media thickness of the common carotid artery was found to be significantly higher in FMF patients when compared to those in healthy controls [0.37 mm (0.26-0.61) vs. 0.28 mm (0.21-0.35),  $P < 0.001$ ]. The median ICA-IMT was significantly increased in the patients when compared to those in the controls [0.25 mm (0.18-0.44) vs. 0.22 mm (0.10-0.26),  $P < 0.001$ ]. A positive correlation between CCA-IMT and SAA levels ( $r = 0.24$ ,  $P = 0.04$ ) was found while ICA-IMT positively correlated with ESR ( $r = 0.31$ ,  $P = 0.008$ ) and fibrinogen levels ( $r = 0.30$ ,  $P = 0.012$ ). Intima media thickness, an early predictor of atherosclerosis, may be associated with subclinical inflammation in children with FMF. Further studies will enlighten

whether these patients will be predisposed more to coronary artery disease.

Coexistence of familial Mediterranean fever and psoriasis in a patient with seronegative spondyloarthropathy.

Bodur H(1), Seçkin U, Eser F, Ergül G, Seçkin S.

Author information:

(1)Department of Physical Medicine and Rehabilitation, Ankara Numune Education and Research Hospital, Ankara, Turkey. haticebodur@gmail.com

Familial Mediterranean fever (FMF) is a self-limited disease characterized by fever and polyserositis attacks. Arthritis caused by synovitis is either in acute monoarthritis or chronic mono-oligoarthritis form, usually affecting the lower extremities. Another potential but rare form of involvement is spondyloarthropathy (SSpA). Psoriatic arthritis (PsA) is inflammatory arthropathy of peripheral joints, spine and entheses areas. Some PsA cases are classified as psoriatic spondyloarthropathy. A 43-year-old male patient with concomitant FMF and psoriasis presenting with bilateral sacroiliitis, chronic hip and knee arthritis has been presented along with follow-up findings and treatment options used.

Prevalence of known mutations in the familial Mediterranean fever gene (MEFV) in various carrier screening populations.

Mikula M(1), Buller A, Sun W, Strom CM.

Author information:

(1)Quest Diagnostics Nichols Institute, San Juan Capistrano, California 92690, USA. mario.x.mikula@questdiagnostics.com

**PURPOSE:** To determine the carrier frequency of familial Mediterranean fever (FMF) mutations of individuals in three different US testing populations: Cystic fibrosis, Factor V Leiden, and Ashkenazi Jews.

**METHODS:** DNA samples from 1234 anonymous samples were screened for 12 FMF mutations using a laboratory-developed test.

**RESULTS:** Genotyping revealed carrier frequencies of 1:16, 1:46, and 1:8, respectively.

**CONCLUSION:** MEFV mutation frequency seems to correlate positively with Mediterranean influence of the tested population and the high overall carrier rate for MEFV mutations in the Factor V Leiden testing population (1:46) suggests that the disease may be under-diagnosed in the US population or that the mutant alleles have a low penetrance.

Macular involvement in secondary systemic amyloidosis.

Altiparmak UE(1), Koklu B, Unlu N, Yagci R, Bayrak R, Gul Yilmaz Cinar F, Duman S.

Author information:

(1)Department of Ophthalmology, Ankara Training and Research Hospital, Ankara - Turkey. ealtiparmak@hotmail.com

**PURPOSE:** A patient with subretinal and preretinal hemorrhage after secondary systemic amyloidosis due to familial Mediterranean fever is presented.

**METHODS:** Case presentation.

**RESULTS:** A 30-year-old woman with secondary systemic amyloidosis secondary to familial Mediterranean fever presented with painless visual loss in the right eye. The examination demonstrated multiple subretinal and preretinal hemorrhages,

massive deposits which may represent amyloid material at the left macular region.

After 6 months, the hemorrhages disappeared, but deposits persisted.

CONCLUSIONS: The macular deposition and hemorrhage is an uncommon manifestation of secondary systemic amyloidosis secondary to familial Mediterranean fever.

Further evidence is necessary to understand the nature of these deposits and their relevance to secondary systemic amyloidosis and/or familial Mediterranean fever.

New insights into autoimmune liver diseases.

Kumagi T(1), Alswat K, Hirschfield GM, Heathcote J.

Author information:

(1)Toronto Western Hospital, University Health Network, University of Toronto, Toronto, Ontario, Canada.

Autoinflammatory liver disease represents an important aspect of global hepatological practice. The three principal disease divisions recognized are autoimmune hepatitis, primary sclerosing cholangitis and primary biliary cirrhosis. Largely, but not exclusively, these diseases are considered to be autoimmune in origin. Increased recognition of outlier and overlap syndromes, changes in presentation and natural history, as well as the increased awareness of IgG4-associated sclerosing cholangitis, all highlight the limitations of the classic terminology. New insights continue to improve the care given to patients, and have arisen from carefully conducted clinical studies, therapeutic trials, as well as genetic and laboratory investigations. The challenges remain to treat patients before liver injury becomes permanent and to prevent the development of organ failure.

The genetics of generalized vitiligo.

Spritz RA(1).

Author information:

(1)Human Medical Genetics Program, University of Colorado Denver, Anschutz Medical Campus, Aurora, CO 80045, USA. Richard.Spritz@uchsc.edu

Generalized vitiligo is an acquired disorder in which patches of depigmented skin, overlying hair and oral mucosa result from progressive autoimmune loss of melanocytes from the involved areas. Perhaps the most common pigmentary disorder, vitiligo results from a complex interaction of environmental, genetic and immunologic factors that ultimately contribute to melanocyte destruction, resulting in the characteristic depigmented lesions. In the past few years, studies of the genetic epidemiology of generalized vitiligo have led to the recognition that vitiligo is part of a broader, genetically determined, autoimmune and autoinflammatory diathesis. Attempts to identify genes involved in vitiligo susceptibility have involved gene expression studies, allelic association studies of candidate genes and genome-wide linkage analyses to discover new genes, and these studies have begun to shed light on the mechanisms of vitiligo pathogenesis. It is anticipated that the discovery of biological pathways of vitiligo pathogenesis will provide novel therapeutic and prophylactic targets for future approaches to the treatment and prevention of vitiligo and its associated autoimmune diseases.

**OBJECTIVES:** Despite the well-defined genetics of FMF, limited information is available regarding the regulation of inflammation by cytokines.

**DESIGN AND METHODS:** The levels of systemic cytokines and other markers of inflammation in FMF patients and control were measured by ELISA and Cytometric Bead Array (CBA).

**RESULTS:** In FMF attack the levels of IL-6, IL-10, IL-17, TGF-beta, CRP, and sIL-2R were significantly different from the norm and FMF remission.

**CONCLUSIONS:** Inflammation in FMF involves Treg and Th17 lineages.

Antimicrobial peptides and the skin immune defense system.

Schauber J(1), Gallo RL.

Author information:

(1)Department of Dermatology and Allergology, Ludwig-Maximilians-University, Munich, Germany.

Republished in

J Allergy Clin Immunol. 2009 Sep;124(3 Suppl 2):R13-8.

Our skin is constantly challenged by microbes but is rarely infected. Cutaneous production of antimicrobial peptides (AMPs) is a primary system for protection, and expression of some AMPs further increases in response to microbial invasion. Cathelicidins are unique AMPs that protect the skin through 2 distinct pathways: (1) direct antimicrobial activity and (2) initiation of a host response resulting in cytokine release, inflammation, angiogenesis, and reepithelialization.

Cathelicidin dysfunction emerges as a central factor in the pathogenesis of several cutaneous diseases, including atopic dermatitis, in which cathelicidin is suppressed; rosacea, in which cathelicidin peptides are abnormally processed to forms that induce inflammation; and psoriasis, in which cathelicidin peptide converts self-DNA to a potent stimulus in an autoinflammatory cascade. Recent work identified vitamin D3 as a major factor involved in the regulation of cathelicidin. Therapies targeting control of cathelicidin and other AMPs might provide new approaches in the management of infectious and inflammatory skin diseases.

**OBJECTIVE:** To evaluate the efficacy and safety of treatment with the interleukin-1 receptor antagonist anakinra in patients with tumor necrosis factor receptor-associated periodic syndrome (TRAPS) requiring high cumulative doses of steroids.

**METHODS:** Four children (mean age 9.1 years [range 4-13 years]) and 1 adult (age 33 years) with TRAPS were enrolled in the study. The 3 children with cysteine mutations (C52Y, C55Y, C43R) had prolonged and frequent attacks of fever. One child with the R92Q mutation and the adult patient with the C43R mutation displayed a more chronic disease course, with fluctuating, nearly continuous symptoms and persistent elevation of acute-phase reactant levels (including serum amyloid A [SAA]). All patients were treated with anakinra (1.5 mg/kg/day).

**RESULTS:** All of the patients had a prompt response to anakinra, with disappearance of symptoms and normalization of acute-phase reactant levels,

including SAA. In all pediatric patients, anakinra was withdrawn after 15 days of treatment. After a few days (mean 5.6 days [range 3-8]) a disease relapse occurred, which dramatically responded to reintroduction of anakinra. During the following period of observation (mean 11.4 months [range 4-20 months]), the patients did not experience episodes of fever or other disease-related clinical manifestations. Levels of acute-phase reactants remained in the normal range. No major adverse reactions or severe infections were observed.

CONCLUSION: Continuous treatment with anakinra effectively controlled both the clinical and laboratory manifestations in patients with TRAPS and prevented disease relapses.

The familial periodic fevers are Known as autoinflammatory syndromes. It is important in clinical practice to recognize these uncommon illnesses characterized by recurrent bouts of unspecific systemic symptoms associated to elevation of acute phase reactants without autoantibodies or underlying infection. The clinical suspicion supported on the molecular diagnosis represents a new perspective in relation to treatment and prognosis of these patients.

Infervers (Internet Fevers; <http://fmf.igh.cnrs.fr/ISSAID/infervers>), a website dedicated to mutations responsible for hereditary autoinflammatory diseases, was created in 2002 and has continued to evolve. This new version includes eight genes; six were already present: MEFV, MVK, TNFRSF1A, NLRP3, NOD2, PSTPIP1, and two are new, LPIN2 and NLRP7. Currently, Infervers contains over 540 sequence variants. Several new database functions were recently instituted. The website now accepts confidential data and complex alleles. For each gene, a newly created menu offers: 1) a tabular list of the variants that can be sorted by several parameters; 2) a gene graph providing a schematic representation of the variants along the gene; 3) statistical analysis of the data according to the phenotype, alteration type, and location of the mutation in the gene; 4) the cDNA and gDNA sequences of each gene, showing the nucleotide changes along the sequence, with a color-based code highlighting the gene domains, the first ATG, and the termination codon; and 5) a "download" menu making all tables and figures available for the users, which, except for the gene graphs, are all automatically generated and updated upon submission of the variants. Finally, the entire database was curated to comply with the HUGO Gene Nomenclature Committee (HGNC) and HGVS nomenclature guidelines, and wherever necessary, an informative note was provided. Infervers has already proven useful for the scientific community with a mean number of visits per month of 200 in 2002 and 800 in 2007, and its new design will lead to a more comprehensive comparative analysis and interpretation of auto-inflammatory sequence variants.

Author information:

(1)Pediatric Rheumatology Unit, Pediatrics Department, University of São Paulo, Av. Dr. Enéas de Carvalho Aguiar, 647, 05403-900, São Paulo, SP, Brazil.

TRAPS is the most common of the autosomal dominant periodic fever syndromes. It is caused by mutations in the TNFRSF1A gene, which encodes for the type 1 TNF-receptor (TNFR1). We describe here a Brazilian patient with TRAPS associated to a novel TNFRSF1A de novo mutation and the response to anti-TNF therapy. The patient is a 9-year-old girl with recurrent fevers since the age of 3 years, usually lasting 3 to 7 days, and recurring every other week. These episodes are associated with mild abdominal pain, nausea, vomiting and generalized myalgia. Recurrent conjunctivitis and erysipela-like skin lesions in the lower limbs also occur. Laboratory studies show persistent normocytic normochromic anemia, thrombocytosis, elevated erythrocyte sedimentation rate and C-reactive protein. IgD levels are normal. Mutational screening of TNFRSF1A revealed the association of a novel C30F mutation with the common R92Q low-penetrance mutation. The R92Q mutation is seen in 5% of the general population and is associated with an atypical inflammatory phenotype. The patient had a very good response to etanercept, with cessation of fever and normalization of inflammatory markers. Our report expands the spectrum of TNFRSF1A mutations associated with TRAPS, adding further evidence for possible additive effects of a low-penetration R92Q and cysteine residue mutations, and confirms etanercept as an efficacious treatment alternative.

An unusual association between familial mediterranean fever and IgM nephropathy.

Peru H(1), Elmaci AM, Akin F, Akcoren Z, Orhan D.

Author information:

(1)Department of Pediatric Nephrology, Faculty of Meram Medicine, Selcuk University, Konya, Turkey. harunperu@gmail.com

OBJECTIVE: To report a case with the diagnosis of IgM nephropathy and familial Mediterranean fever (FMF).

CLINICAL PRESENTATION AND INTERVENTION: A 9-year-old boy was admitted to our hospital with recurrent abdominal pain since the age of 4 years. Laboratory investigations revealed a sedimentation rate of 88 mm/h, C-reactive protein: 83.2 mg/l (0-10 mg/l), white blood cell count: 12,700/mm(3), fibrinogen: 622 mg/dl (200-400 mg/dl) and serum amyloid A: 186 mg/l (0-5.8 mg/l). Urinalysis revealed +2 proteinuria. A 24-hour urinary protein excretion was 12 mg/m(2)/h. M694V homozygous mutation was identified in exon 10. Percutaneous renal biopsy showed mesangial cell proliferation and increased mesangial matrix in the glomeruli, without amyloid accumulation. Immunofluorescence study showed IgM (+1) and C1q (+1) deposits. Treatment with 1 mg/day colchicine was started. Six weeks later, proteinuria had disappeared and the patient was asymptomatic.

CONCLUSION: This case illustrates the unusual association of FMF with non-amyloid glomerulopathy. Glomerular diseases such as IgM nephropathy may be seen as a manifestation of FMF.

Familial Mediterranean Fever in Armenian population.

Sarkisian T(1), Ajrapetian H, Beglarian A, Shahsuvarian G, Egiazarian A.

Author information:

(1)Center of Medical Genetics and Primary Health Care Yerevan.

Familial Mediterranean Fever (FMF) is an inherited, recessively transmitted inflammatory condition usually occurred in populations from Mediterranean descent (Armenian, Arab, Jewish, Greek, Turkish and Italian populations). Identification of MEFV gene mutations has been of tremendous help for early diagnosis of most cases. The frequency of FMF is different. The prevalence of heterozygous carriers of one of the mutations of MEFV gene is as high as 1 in 5 healthy individuals in Armenia. Genetic testing of this rare Mendelian disorder (MIM no 249100) is efficient for early and prenatal diagnosis of the disease, especially for atypic cases, for carrier screening and pregnancy planning since certain mutations have

been shown to have significant correlation with renal amyloidosis (RA), the most severe possible manifestation of FMF. Also genetic testing is very important for colchicine therapy correction. Twelve MEFV mutations are identified in 7000 Armenian FMF patients. Investigation of MEFV mutations in FMF patients (heterozygotes, homozygotes and compound heterozygotes) in comparison with healthy individuals has revealed the most frequent mutations and genotypes, and the information was received about the heterozygous carriers and genotype-phenotype correlation. In heterozygote carriers the most prevalent and severe cases are caused by the presence of a single M694V mutation. Our results could confirm that the MEFV gene analysis provides the first objective diagnostic criterion for FMF (characterisation of the two MEFV mutated alleles in more than 90% of the patients). Molecular testing is also used to screen the MEFV gene for mutations in patients with a clinical suspicion of FMF. We also demonstrated the unfavourable prognostic value of the M694V homozygous genotype, and provided the first molecular evidence for incomplete penetrance and pseudo-dominant transmission of the disease. Overall, these data, which confirm the involvement of the MEFV gene in the development of FMF, should be essential in clinical practice, leading to new ways of management and treatment of FMF patients.

[What's new in autoinflammatory diseases?].

[Article in French]

Stankovic K(1), Grateau G.

Author information:

(1)Service de médecine interne, centre de référence des amyloses d'origine inflammatoire et de la fièvre méditerranéenne familiale, hôpital Tenon, Assistance publique-Hôpitaux de Paris (AP-HP), faculté de médecine, université de Paris-Paris cedex 20, France.

PURPOSE: The concept of auto-inflammation was initially coined to define the

group of mendelian disorders characterized by recurrent inflammatory symptoms. The core of this group mainly consists of hereditary recurrent fevers, which has been lately enlarged to other inflammatory mendelian disorders as well as to some sporadic diseases with a genetic component relevant to innate immunity.

CURRENT KNOWLEDGE AND KEY POINTS: Cryopyrin, the product of the CIAS1/PYPPAF1/NALP3/NLRP gene, whose mutations underline some mendelian syndromes (Mückle-Wells and chronic infantile neurological cutaneous and articular (CINCA), familial cold urticaria) can now be considered as a major factor of the regulation of interleukin-1 production within the multiprotein complex called inflammasome. This discovery has lit up our view of innate immunity.

FUTURE PROSPECTS AND PROJECTS: The contribution of the innate immunity mechanisms in inflammatory disorders have led to a new look to the current nosology of this vast group of diseases and to suggest a classification with two poles. The first would be defined by the predominance of auto-inflammation, whereas in the second one auto-immunity predominates.

The autoinflammatory diseases should be considered in the differential diagnosis of recurrent fever in childhood. These diseases are characterized by inflammatory episodes without an evident cause. Some of these diseases, like the Familial Mediterranean Fever, have a genetic origin and need a chronic treatment to avoid severe complications on the long term. PFAPA syndrome is the most frequent cause of recurrent fever and is diagnosed based on unspecific criteria. The treatment is still controversial. One dose of Prednisone is able to interrupt the flare and

tonsillectomy may induce a remission in the majority of the cases.

Familial Mediterranean fever (FMF) is an autosomal recessive disease affecting predominantly populations surrounding the Mediterranean basin. It is the most prevalent hereditary periodic fever syndrome characterized mainly by recurrent and short attacks of fever and serositis (pleuritis, arthritis, peritonitis).

Unilateral polymorphonuclear exudative pleuritis associated with fever has been reported as the solitary manifestation of the first FMF attack, in < 10% of patients. This case study describes a 30-year-old Greek man with recurrent episodes of lymphocytic exudative pleuritis associated with fever. After a thorough workup (clinical criteria and molecular genetic testing identifying homozygosity polymorphisms of the FMF gene), the diagnosis of FMF was established. Treatment with colchicine, 2 mg/d, eliminated FMF attacks. To our knowledge, this is the first well-documented case report of a patient with FMF presenting with a lymphocytic exudative pleural effusion.

# Circulating adrenomedullin levels in ankylosing spondylitis and Familial Mediterranean Fever.

Ureten K(1), Ozbek M, Oztürk MA, Dogru I, Dogru A, Yürekli M, Karakurt F, Onat AM.

Author information:

(1)Department of Rheumatology, Saglik Bakanligi Ankara Egitim ve Arastirma Hastanesi, Ankara, Turkey.

**INTRODUCTION:** Adrenomedullin (AM) is a 52-amino acid peptide with vasorelaxant properties. Apart from its roles on vascular tonus, AM can also contribute to inflammatory events. Plasma AM levels were elevated in connective tissue diseases and vasculitic disorders. Ankylosing spondylitis (AS) is a chronic inflammatory disease of the spine initiating in the sacroiliac joints. Familial Mediterranean Fever (FMF) is a hereditary disorder characterized by self-limiting acute attacks of fever and the presence of sustained subclinical inflammation in the attack-free periods. In this study, we investigated plasma AM levels in patients with AS and patients with FMF.

**METHODS:** Twenty AS patients with active disease manifestations (mean age: 41.6 $\pm$ 10.9 years, female/male: 7/13), 28 FMF patients with acute attack (mean age: 27.4 $\pm$ 10.7 years, female/male: 17/11), and 26 healthy controls (mean age: 39.9 $\pm$ 5.5 years, female/male: 16/10) were enrolled in this study. AM levels were also measured in 11 FMF patients 2 months after the cessation of their attacks. AM levels of those 11 patients during their FMF attacks and attack-free periods were also compared.

**RESULTS:** Median plasma AM levels were 23.86 (17.24-40.09) pmol/mL, 27.33 (17.24-38.52) pmol/mL, and 26.11 (17.05-37.42) pmol/mL in AS patients, FMF patients with acute attack, and healthy controls, respectively ( $p>0.05$ ). AM levels were also similar in the attack-free periods of FMF patients [26.35 (24.35-34.14) pmol/mL]. There was no correlation between plasma AM levels and C-reactive protein, or between plasma AM levels and erythrocyte sedimentation rate.

**CONCLUSIONS:** AM does not seem to have any role in the pathogenesis of AS and FMF. Previous reports of elevated levels of AM in connective tissue disorders and vasculitic diseases are probably disease specific, and AM does not seem to be a common component of inflammatory rheumatic disorders.

jjaroste@clinic.ub.es

Hereditary systemic autoinflammatory diseases result from a genetically-based dysregulated inflammatory process, and are clinically characterized by recurrent or persistent systemic inflammatory episodes, which typically occur in the absence of infectious, neoplastic or autoimmune etiology. Elucidation of their molecular basis has enabled the use of genetic analyses to achieve an accurate and definitive diagnosis, and to establish a tailored treatment. The present review is the second and last part of an updated and comprehensive overview of hereditary systemic autoinflammatory diseases, and will introduce persistent, non-periodic autoinflammatory diseases, such as: a) the group of cryopyrin-associated periodic syndromes (CAPS), which includes familial cold-induced autoinflammatory syndrome (FCAS), Muckle-Wells syndrome, and CINCA-NOMID syndrome; b) the group of pediatric systemic granulomatosis, which includes both Blau syndrome and early-onset sarcoidosis, and c) the pyogenic sterile arthritis, pyoderma gangrenosum and acne (PAPA) syndrome.

Familial Mediterranean Fever (FMF) is an autosomal recessive genetic disorder characterised by recurrent and self-limited abdominal pain, synovitis and pleuritis. MEFV gene mutations are responsible for the disease and its protein product, pyrin or marenostrin, plays an essential role in the regulation of the inflammatory reactions. MEFV gene contains 10 exons and most of the mutations have been found on the last exon. Up to date, 152 mutations and polymorphisms have been reported in where V726A, M694V, M694I, M680I and E148Q are the most common mutations. In this study, MEFV allele frequencies of 136 individuals (60 from Pediatrics, 76 from Internal Medicine) have been evaluated, and compared with each other. Asymptomatic individuals with FMF family history (4 from Pediatrics, 6 from Internal Medicine) were excluded from the analysis. The prominent mutations indicated in the Pediatrics group are V726A, M694V and M680I (G/C) and with the allele frequency of 0.06, 0.05 and 0.04 respectively while they were E148Q, M694V, M680I (G/C) in the Internal Medicine group with the allele frequency of 0.12, 0.08 and 0.04. The E148Q mutation is significantly overrepresented in the adult referrals ( $P = 0.02$ ). Mutation on both alleles was observed in only 12% of cases. Overall mutation frequency was low, seen in 26.2% (66/252). However, when only diagnosed patients were analyzed it is 72.7% (16/22). It is also interesting that 63% of individuals are female that there may be sex influence on FMF phenotype.

(1)Division of Rheumatology, David Geffen Medical School at UCLA, Los Angeles, CA 90095, USA.

To review clinical manifestations and genetic features of the autoinflammatory diseases, a group of rare, genetically defined diseases which have been newly grouped into a coherent whole. We performed a literature review using the keywords 'periodic fever syndrome', 'autoinflammatory disease' and 'therapy'. All relevant original and review articles in English were reviewed. A case report of each autoinflammatory disease was excerpted from the literature and presented. This review summarizes the clinical manifestations, genetic analysis and therapy of FMF, TNF-alpha receptor-associated periodic fever syndrome, hyperimmunoglobulinaemia D periodic fever syndrome and cryopyrin-associated periodic fever syndrome. These diseases have periodic fever, are hereditary and recurrent, with elevated acute-phase reactants. Differentiating features of these disorders are tabulated. Autoinflammatory diseases have some communalities in their presentation although they represent a relatively diverse group of genetically associated diseases.

A rare cause of ascites: Familial Mediterranean fever.

Bektaş M(1), Soykan I, Gören D, Altan M, Korkut E, Cetinkaya H, Ozden A.

Author information:

(1)Department of Gastroenterology, Ankara University, School of Medicine, Ankara, Turkey. mbektas70@hotmail.com

Familial Mediterranean fever is an autosomal recessive disorder characterized by sporadic, paroxysmal attacks of fever and serosal inflammation. In Familial Mediterranean fever, peritoneal effusion during abdominal attacks is usually mild, is not detected by clinical evaluation, and disappears during clinical

remission. Chronic ascites has rarely been described in patients with Familial Mediterranean fever. Genetic analysis is highly specific and sensitive for diagnosis of Familial Mediterranean fever. All of the four cases discussed in our study had no benign or malignant pathology that could explain the ascites. They had suffered from repetitive periods of fever and ascites since childhood. Genetic analysis of these four cases revealed that one was M694V/M694V homozygote, one was M694V/? heterozygote, and the other two were M694V/V726A compound heterozygote. Ascites regressed with colchicine therapy. Since Familial Mediterranean fever is common our country, it should be kept in mind in the differential diagnosis in patients with ascites of unknown etiology.

Author information:

(1)Department of Cardiology, Gazi University School of Medicine, Beşevler 06500, Ankara, Turkey. yusuftavil@gmail.com

**INTRODUCTION:** To evaluate aortic wall stiffness and its relation between the aortic stiffness and the left ventricular function in patients with Familial Mediterranean Fever (FMF).

**METHODS:** The study population was composed of 31 patients with FMF in attack-free period (12 men, 19 women; mean age: 36+/-7 years) and 27 healthy subjects (10 men, 17 women; mean age: 34+/-7 years) who had volunteered to participate. Aortic stiffness indices, aortic strain and distensibility, were calculated from the aortic diameters measured by echocardiography and blood pressure obtained by sphygmomanometry.

**RESULTS:** There were significant differences between the control and the patient group in aortic strain (mean (SD), 7.23+/-2.14 versus 4.91+/-1.66%, p=0.01) and distensibility (4.02+/-1.42 versus 2.84+/-1.46, 10(-6)cm(2)dyn(-1), p=0.001).

Although there was no correlation between the aortic stiffness parameters and the left ventricular function parameters, there were significant negative correlations between the disease duration and aortic strain index ( $r=-0.29$ ,  $p<0.001$ ), and between the disease duration and distensibility ( $r=-0.32$ ,  $p<0.001$ ).

CONCLUSION: Aortic stiffness measurements were found abnormal in patients with FMF. We have also demonstrated that there were significant correlations between aortic stiffness parameters and disease duration.

The Schnitzler syndrome: chronic urticaria and monoclonal gammopathy--an autoinflammatory syndrome?

[Article in English, German]

Eiling E(1), Schröder JO, Gross WL, Kreiselmaier I, Mrowietz U, Schwarz T.

Author information:

(1)Department of Dermatology, Venereology and Allergy, University Hospital Schleswig-Holstein, Campus Kiel, Germany.

Schnitzler syndrome describes the simultaneous occurrence of monoclonal gammopathy and chronic urticaria with at least two additional minor symptoms (arthralgia, bone pain, fever of uncertain origin, hepato- or splenomegaly, lymphadenopathy, increased erythrocyte sedimentation rate, leukocytosis/thrombocytosis or increased bone density). Schnitzler syndrome is not wellknown and very likely under-recognized. Comprehensive diagnostic examinations are necessary to rule out other diseases, especially those of hematologic origin. Close interdisciplinary collaboration is mandatory. The etiology of Schnitzler syndrome is unclear, but the rapid response to the interleukin-1 receptor inhibitor anakinra underlines the pivotal role which the proinflammatory cytokine interleukin-1 may play in the pathophysiology of this potentially autoinflammatory disorder.

Diagnosis and management of autoinflammatory diseases in childhood.

Gattorno M(1), Federici S, Pelagatti MA, Caorsi R, Brisca G, Malattia C, Martini A.

Author information:

(1)2nd Division of Pediatrics, G. Gaslini Scientific Institute, Largo G. Gaslini 5, 16147, Genova, Italy. marcogattorno@ospedale-gaslini.ge.it

**INTRODUCTION:** Autoinflammatory diseases are a group monogenic inflammatory conditions characterized by an early onset during childhood.

**DISCUSSION:** Under the term "periodic fevers" are gathered some monogenic diseases (familial Mediterranean fever, mevalonate kinase deficiency, and tumor necrosis factor receptor-associated syndrome) characterized by periodic or recurrent episodes of systemic inflammation causing fever often associated with rash, serositis (peritonitis, pleuritis), lymphadenopathy, arthritis, and other clinical manifestations. Systemic reactive (AA) amyloidosis may be a severe long-term complication. Cryopyrinopathies are a group of conditions associated to mutations of the gene Cryopyrin that are responsible for a spectrum of diseases (familial cold autoinflammatory syndrome, Muckle-Wells syndrome, and chronic infantile neurological cutaneous and articular syndrome) characterized by a chronic or recurrent systemic inflammation variably associated with a number of clinical features, such as urticarial-like rash, arthritis, sensorineural deafness, and central nervous system and bone involvement. Other disorders are dominated by the presence of sterile pyogen abscesses prevalently affecting the skin, joints, and bones (pyogenic disorders). These include pyogenic sterile arthritis, pyoderma gangrenosum, and acne syndrome, and Majeed syndrome. Finally, some diseases, such as Blau's syndrome, are characterized by the appearance of typical noncaseating granulomatous inflammation affecting the joints, skin, and uveal tract (granulomatous disorders). In the present review, we will focus on the clinical presentation of these disorders in childhood and report on the available therapeutic strategies.

Familial Mediterranean fever in northwest of Iran (Ardabil): the first global report from Iran.

Salehzadeh F(1), Emami D, Zolfegari AA, Yazdanbod A, Habibzadeh S, Bashardost B, Barak M, Feizi I, Azimi H, Jastan M, Khalafi J.

Author information:

(1)Department of Pediatrics, Ardabil University of Medical Science (ARUMS), Ardabil, Iran.

Familial Mediterranean fever (FMF), which is the prototype of the hereditary periodic fever syndromes, is common in the countries around the Mediterranean Sea. Considering its geographical position in the northwest of Iran, with its population of Turkish origin and its vicinity to the Mediterranean Sea, the incidence of FMF should be high in Ardabil. The goal of this study was to introduce FMF as a disease with significant outbreak in this area. Based on the Tel-Hashomer criteria, patients suffering from FMF were collected from private clinics together with the medical records of adult and pediatric rheumatology clinics. Of 112 total patients determined, 74 were studied. All of the patients were interviewed and completed a questionnaire. Familial Mediterranean fever was common among children under 18 years (76%), and it was more common in males than females (M/F 1.17). Abdominal pain was the most common complaint (74%) and abdominal pain and fever (95% and 84%, respectively) were the main clinical symptoms. The average duration of pain was 12-72 hours and the average recovery (attack-free period) was from one week to one month (63.5%). The majority of the patients had hospital admission for diagnostic work-up (85%) and some (32%) had undergone surgical operation erroneously; 92% of the patients had taken medications with incorrect diagnosis; and 20% had positive familial history of FMF. Fifty percent of the patients' parents were first-degree relatives and in 59.5% delay in diagnosis was more than three years. It seems that FMF is more common in the Northwest of Iran than previously thought, although physicians are not familiar with it. The common age for manifestation of this disease is under

18 years and its presentation after the age of 40 years is very rare.

3750. *Pediatr Int.* 2008 Apr;50(2):208-12. doi: 10.1111/j.1442-200X.2008.02554.x.

Genotype-phenotype correlation in children with familial Mediterranean fever in a Turkish population.

Duşunsel R(1), Dursun I, Gündüz Z, Poyrazoğlu MH, Gürgöze MK, Dunder M.

Author information:

(1)Department of Pediatric Nephrology and Rheumatology, Erciyes University Faculty of Medicine, Kayseri, Turkey.

**BACKGROUND:** The aim of the present study was not only to review clinical and demographic features of child-onset familial Mediterranean fever (FMF) patients but also to investigate whether there is a phenotype-genotype correlation in the same patient population.

**METHODS:** The medical records of 102 patients with FMF were retrospectively reviewed. Patients were classified into three groups according to mutations: group 1, Met694Val-Met694Val (homozygote); group 2, Met694Val-other; and group 3, other-other. These groups were compared with regard to gender, age of onset, age of diagnosis, time interval between disease onset and diagnosis, fever, abdominal pain, arthritis, chest pain, erysipelas-like erythema, edema, amyloidosis, number of attacks per year before and after treatment, consanguinity, severity score, response of colchicines treatment, and family history of FMF and amyloidosis.

**RESULTS:** The presence of M694V homozygote was found to be associated with amyloidosis. Homozygosity for M694V was found in 46 patients (45%).

**CONCLUSIONS:** M694V homozygosity is associated with phenotype II and amyloidosis compared to other common genotypes in patients with FMF. Despite current knowledge on FMF, prospective clinical studies with large numbers of patients and different ethnic groups will help us to clarify this considerable disease.

Autoinflammatory diseases: mimics of autoimmunity or part of its spectrum? Case presentation.

Kiss MH(1), Magalhães CS.

Author information:

(1)Rheumatology Ph.D, University of São Paulo Medical School, São Paulo, Brazil.  
mhbkiss@terra.com.br

**INTRODUCTION:** Autoinflammatory diseases are very rare diseases presenting within a wide clinical spectrum. Recognition of the main clinical features are challenging due to overlapping or mimicking with autoimmune diseases.

**DISCUSSION:** A case series is reviewed to illustrate typical and atypical features and the difficulties of these diagnoses in the low prevalence areas--a typical unrecognized case of familial Mediterranean fever (FMF) in a youngster, an atypical adult case with overlapping of FMF with Behçet disease, and an early presentation of FMF in infant presenting with inflammatory colitis, as well as the overlapping features within the cryopirin diseases spectrum in an 8-year-old boy who presented with systemic onset arthritis.

**CONCLUSION:** These cases may represent examples of a very puzzling relationship among disorders of innate and adaptive immune systems and inflammation.

3752. Clin Rheumatol. 2008 Sep;27(9):1135-9. doi: 10.1007/s10067-008-0879-z. Epub 2008 Mar 20.

Is there an association between familial Mediterranean fever and celiac disease?

Kuloğlu Z(1), Ozçakar ZB, Kirsaclioğlu C, Yüksel S, Kansu A, Girgin N, Ekim M, Yalçinkaya F.

Author information:

(1)Pediatric Gastroenterology, Ankara University School of Medicine, Ankara, Turkey. zarifekuloglu@yahoo.com

Familial Mediterranean fever (FMF) and celiac disease (CD) shares some clinical features such as abdominal pain, diarrhea, arthralgia, and arthritis. Furthermore, both diseases are related to several inflammatory disorders. Based on these analogies, we have investigated whether there is any relationship between CD and FMF. The study had two groups. Group I: 50 children with FMF were questioned and examined for the evidence of CD, serum immunoglobulin A (IgA) levels, antigliadin antibodies (AGA) IgA, AGA IgG, and anti-endomysial antibodies (EMA) IgA were tested, and intestinal biopsy was performed when necessary. Group II: 17 children with CD were evaluated for the presence of clinical and laboratory features of FMF and mutation analysis for MEFV gene was performed to all of them. Six predominant mutations (p.M694V, p.M680I, p.M694I, p.V726A, p.K695R, p.E148Q) in the MEFV gene were studied. The results were as follows-group I: three patients had diarrhea, six had abdominal pain, one had positive AGA IgA, six had AGA IgG, and one had EMA IgA. Intestinal biopsy was performed in one patient who was normal, so none of the patients with FMF were diagnosed as CD and group II: none of the patients with CD had complaints consistent with FMF. Four of the 17 patients (23.5%) were found to carry MEFV mutations. Three of them had heterozygous p.E148Q mutation and one of them had heterozygous p.M680I mutation. None of the FMF patients had CD. MEFV mutation frequency in patients with CD was similar to the normal population in Turkey. Our study did not reveal any association between CD and FMF.

[Article in Croatian]

Harjacek M(1).

Author information:

(1)Klinika za dječje bolesti Zagreb, Klaićeva 16, 10000 Zagreb.

Progress in the field of pediatric rheumatology has been extraordinary; subspecialty is accepted as essential, vital, indispensable and distinct from adult rheumatology. It is clear that arthritis in children is more heterogeneous than RA. Although there are similarities between the inflammatory arthritides occurring in adults and children, RA and JIA appear to be distinct phenotypically with exception for the older child with RF-positive polyarticular arthritis. Progress in molecular biology has enabled us to diagnose those children earlier, and treat them more efficaciously with variety of drugs and biologic agents. In recent years a new group of hereditary autoinflammatory disorders has emerged. These rare syndromes are characterized by recurrent episodes of seemingly unprovoked, intermittent inflammation. In the near future we will be able to distinguish various subtypes of autoimmune/autoinflammatory diseases earlier in the course, have a better understanding of the biomarkers and other prognostic factors, and most importantly treat them earlier with extended set of various new exciting drugs and biological therapy.

Autoinflammatory diseases: clinical and genetic advances.

Farasat S(1), Aksentijevich I, Toro JR.

Author information:

(1)Genetic Epidemiology Branch, Division of Cancer Epidemiology and Genetics, National Cancer Institute, 6120 Executive Blvd, Executive Plaza South, Room 7012, Rockville, MD, USA.

We conducted a literature review to investigate the recent advances in genetics, molecular biology, clinical manifestations, and therapy of 7 inherited diseases that are characterized by seemingly unprovoked inflammation. These autoinflammatory diseases include familial Mediterranean fever; tumor necrosis factor receptor-associated periodic syndrome; hyperimmunoglobulinemia D with periodic fever syndrome; pyogenic arthritis, pyoderma gangrenosum, and acne syndrome; and the 3 cryopyrinopathies: neonatal-onset multisystem inflammatory

disease/chronic infantile neurologic cutaneous and arthropathy syndrome, familial cold autoinflammatory syndrome, and Muckle-Wells syndrome. Recent identification of the susceptibility genes for autoinflammatory diseases has broadened the clinical spectrum as well as the molecular basis of these diseases. The cryopyrinopathies represent a continuum of diseases associated with mutations in the cold-induced autoinflammatory syndrome 1 (CIAS1) gene that encodes cryopyrin. Cryopyrin and pyrin (protein mutated in familial Mediterranean fever) belong to the family of PYRIN domain-containing proteins. Pyogenic arthritis, pyoderma gangrenosum, and acne syndrome is associated with mutations in the gene that encodes for CD2-binding protein 1 (CD2BP1), which binds pyrin. Recent studies have shown that activation of the interleukin 1beta pathway is a common mechanism in the pathogenesis of autoinflammatory diseases, further unifying these diseases. Recent advances in genetics and molecular biology have advanced our understanding of the pathogenesis of autoinflammatory diseases. Understanding autoinflammatory diseases will further our knowledge of cutaneous as well as systemic inflammation. Anakinra, a recombinant human interleukin 1 receptor antagonist, is a promising new biologic agent for the treatment of cryopyrinopathies as well other autoinflammatory diseases, such as tumor necrosis factor receptor-associated periodic syndrome and hyperimmunoglobulinemia D with periodic fever syndrome.

Tumoral necrosis factor receptor-associated periodic syndrome (TRAPS) is an

autosomal dominantly inherited disease belonging to the hereditary periodic fever syndromes, which are the main subgroup among systemic autoinflammatory diseases. TRAPS is characterized by prolonged and recurrent inflammatory attacks associated with fever and an acute phase reaction. Articular, cutaneous, ocular and abdominal symptoms may also be present. We describe the case of a 4-year-old boy with recurrent inflammatory episodes, fever and cutaneous symptoms who was diagnosed with TRAPS. We review the clinical and laboratory findings, genetic diagnosis, and treatment approach in this disease.

A 24-year-old Japanese woman had been suffering from a periodic fever since 10 months of age. She developed deformities in her fingers, with severe atrophy of

subcutaneous adipose tissue, myositis, and frostbitten hands. She showed elevated C-reactive protein, creatine kinase, and gamma-globulin. She was also positive for antinuclear, anti-DNA, anti-SS-B, and anti-U1RNP antibodies. Her myositis was similar to amyopathic dermatomyositis rather than juvenile dermatomyositis. Although consanguineous marriage of her parents and early onset of disease suggested her disease as a hereditary disorder with periodic fever, her clinical feature and laboratory tests were unlike any known periodic fever syndromes. Her disease was regarded as a unique type of periodic-fever-syndrome-like disorder with autoimmune abnormalities.

Amyloidosis is a systemic disorder characterized by the extracellular tissue deposition of insoluble, toxic aggregates in bundles of beta-sheet fibrillar proteins. These deposits are typically identified on the bases of their apple-green birefringence under a polarized light microscope after staining with Congo red, and by the presence of rigid, nonbranching fibrils 8 to 10 nm in diameter on electron microscopy. The type of amyloid fibril unit can be further defined by immunohistology or by immunoelectron microscopy. It has been described at least 25 different human protein precursors of amyloid fibrils, which will describe its corresponding amyloid disease. The most common types of amyloidosis are AL (primary) and AA (secondary) types; the former, is the most frequent and is due to deposition of proteins derived from immunoglobulin light chain fragments, occurring alone or in association with multiple myeloma. The later (AA), is caused by deposition of fibrils composed of fragments of the acute phase

reactant serum amyloid A (SAA) and complicates chronic diseases with ongoing or recurring inflammation, namely; rheumatoid arthritis (RA), juvenile chronic polyarthritis, ankylosing spondylitis, familial periodic fever syndromes (Familial Mediterranean Fever), chronic infections and furthermore, some neoplasms (mainly renal cell carcinoma and Hodgkin's disease). Despite its less frequent association, some benign neoplasms can subsequently complicate to AA amyloidosis, therefore, an early diagnose and successful treatment may lead indeed, to regression of the amyloid disease. Herein, we present two cases of AA amyloidosis, both of them caused by 2 different benign neoplasms: 1. A 34 year-old woman, after chronic oral contraceptive use, developed an hepatic adenoma (fig. 1) which finally lead to AA amyloidosis with primary kidney presentation (pure nephrotic syndrome) (table 1). Post-surgical complications yield to acute renal failure from which unfortunately could not be recovered. After being on hemodialysis therapy during 10 months she received a first renal allograft without any complication. 2. A 20 year old woman, was diagnosed of AA amyloidosis after a renal biopsy (fig. 2) because of nephrotic syndrome (table 1). Further investigation lead to the finding of a hialyne-vascular type Castleman's disease located in the retroperitoneum (fig. 2). Despite surgical resection and medical treatment (colchicine) she developed progressive renal failure requiring initialization of hemodialysis therapy. After 6 years being on hemodialysis, she received a first renal allograft which is currently functioning after one year of follow- up. Although other chronic inflammatory diseases complicate more frequently to AA amyloidosis, benign tumors have to be taken into account as a potential ethiological cause for secondary amyloidosis.

Mutations in pyrin cause the autoinflammatory disorder familial Mediterranean fever (FMF), a syndrome characterized by sporadic and unpredictable attacks of fever and localized severe pain. Currently, it is not clear how attacks are triggered, nor why they spontaneously resolve after 2 or 3 days. In fact, the cellular function of the pyrin protein and the molecular underpinnings of its malfunction in FMF have so far eluded clear definition. The identification of pyrin-interacting proteins has the potential to increase our understanding of the cellular networks in which pyrin functions. Previous reports have established that pyrin interacts with the apoptotic protein ASC, the cytoskeletal adaptor protein PSTPIP1, the inflammatory caspase, Caspase-1 and certain forms of the cytosolic anchoring protein 14-3-3. Here, we report that pyrin also interacts with Siva, a pro-apoptotic protein first identified for its interaction with the cytosolic tail of CD27, a TNF family receptor. The interaction between pyrin and Siva involves the C-terminal B30.2/rfp/SRPY domain of pyrin and exon 1 of Siva. We show that Siva and pyrin are indeed co-expressed in human neutrophils, monocytes, and synovial cells. Furthermore, using a novel protein/protein interaction assay, we demonstrate that pyrin can recruit Siva to ASC specks, establishing a potential platform for intersection of ASC and Siva function. Finally, we show that pyrin modulates the apoptotic response to oxidative stress mediated by Siva. Thus, the Siva-pyrin interaction may be a potential target for future therapeutic strategies.

BACKGROUND: Familial Mediterranean fever (FMF) is an autosomal recessive disease

characterized by recurrent attacks of fever with serosal inflammation. FMF gene (MEFV) mutations have been identified primarily in patients from Mediterranean populations. Although several clinical cases have been reported in Japan, there have been few reports to date on mutation analysis. We studied FMF patients and their relatives to examine the clinical and genetic features of this disease in the Japanese population.

**METHODS:** Twelve Japanese FMF patients who met the Tel Hashomer criteria and a total of 17 relatives from 5 of 10 families underwent molecular genetic studies to detect MEFV mutations. The characteristics of these Japanese FMF patients and geno-phenotypical correlations were examined.

**RESULTS:** Almost all of our patients had been suffering for a long time from fever of unknown origin and one patient also had systemic amyloidosis. In our 12 FMF patients, we detected the substitutions E84K, L110P, E148Q, R761H and M694I. We also newly diagnosed 2 relatives as having FMF based on clinical symptoms and the existence of FMF mutations. One patient was homozygous for E148Q, the patient with systemic amyloidosis was a homozygote for M694I and 4 patients from 3 families were compound heterozygotes for E148Q and M694I. Three patients in one family were compound heterozygotes for E148Q, L110P and M694I. There were 3 patients who were heterozygous for E84K, L110P-E148Q or M694I and had no other nucleotide changes in the exons of MEFV. On the other hand, 2 relatives who had never experienced symptoms of FMF were homozygous for L110P-E148Q as well as compound heterozygous for E148Q/E148Q-R761H. E148Q and M694I were the most frequently detected substitutions in our study.

**CONCLUSIONS:** MEFV mutations occur in Japanese FMF patients though FMF is rare in Japan. The identification of MEFV mutations could be a reliable diagnostic test for FMF. The results of genetic analyses on 14 Japanese FMF patients in this study revealed that E148Q and M694I are frequent alleles.

The future of the IL-1 receptor antagonist anakinra: from rheumatoid arthritis to adult-onset Still's disease and systemic-onset juvenile idiopathic arthritis.

Kalliolas GD(1), Liossis SN.

Author information:

(1)Hospital for Special Surgery, Arthritis and Tissue Degeneration Program,  
Department of Medicine, New York, NY 10021, USA.

**BACKGROUND:** IL-1 receptor antagonist (IL-1Ra) is a naturally occurring IL-1RI-binding molecule that blocks the biologic effects of the proinflammatory cytokine IL-1. A recombinant form of human IL-1Ra, anakinra (Kineret), has been approved for use in rheumatology initially to manage rheumatoid arthritis (RA) patients that are refractory to more conventional forms of treatment.

**OBJECTIVE:** This review summarizes the experience with anakinra in the treatment of patients with rheumatic diseases emphasizing its beneficial effects in novel applications.

**METHODS:** English-language trials of anakinra were searched using MEDLINE and abstracts from rheumatology scientific meetings.

**RESULTS/CONCLUSIONS:** In the treatment of patients with RA anakinra is effective but inferior to TNF-alpha blocking agents. Over the last few years it has become increasingly evident that anakinra is highly effective and safe in patients with systemic-onset juvenile idiopathic arthritis, adult-onset Still's disease, hereditary autoinflammatory syndromes, Schnitzler's syndrome and recently in gouty attacks.

Familial Mediterranean fever (FMF) is a heterogeneous disorder; at present, it is diagnosed using only genetic methods. In the current study, we performed molecular analysis in two families presenting with FMF. In the first family, we report two brothers with a common genotype (M694V/V726A) but with different clinical presentation. In the second family, we identified the M694V and K695R mutations in a presymptomatic carrier.

Comment in

Arthritis Rheum. 2008 Dec;58(12):3970; author reply 3970-1.

Muckle-Wells syndrome (MWS) is a dominantly inherited autoinflammatory syndrome. Patients with MWS have a mutation in *CIAS1*, the gene encoding cryopyrin, a component of the inflammasome that regulates the processing of interleukin-1beta (IL-1beta). In this report we describe an 8-year-old Japanese girl with MWS who had symptoms of periodic fever, urticarial rash, conjunctivitis, arthropathy, and sensory deafness. Laboratory analysis of the patient's serum showed abnormally high concentrations of C-reactive protein, serum amyloid A, and IL-1beta, and she had a heterozygous mutation in the *CIAS1* gene, with C-to-T transversion at nucleotide position 778, encoding an arginine-to-tryptophan mutation at position 260 (R260W). Mononuclear cells (MNCs) isolated from the patient secreted large amounts of IL-1beta, without stimulation, and were highly sensitive to muramyl dipeptide and lipopolysaccharide. After treatment with anakinra, laboratory results normalized, and clinical symptoms, including sensory deafness, disappeared, while MNCs appeared to remain activated. Thus, our case suggests that anakinra possibly affects the cryopyrin inflammasome and markedly improves the clinical and laboratory manifestations of MWS.

Familial Mediterranean fever (FMF) is characterized by recurrent fever,

serositis, and arthritis. Due to the abundance of mutations and clinical heterogeneity of the disease, different screening methods have been developed. In this study, we aimed to compare our findings of mutations determined by polymerase chain reaction-restriction fragment length polymorphism (PCR-RFLP) with reverse hybridization (RH) methods. In 152 of 263 patients (57.79%) different mutations were determined with RH. Allelic frequencies were E148Q 6.84%, M680I(G/C) 3.61%, M694V 20.91%, V726A 7.03%, P369S 1.33%, F479L 0.19%, M680I(G/A) 0.76%, M694I 0.57%, K695R 0.57%, A744S 0.38%, R731H 0.38%, and del1692 0%. Frequent mutations were also confirmed by PCR-RFLP. There were no conflicting results between the two methods. Four of these genotypes were homozygous for a single mutation, 15 were heterozygous for two mutations, 8 were heterozygous for a single mutation, 1 was heterozygous for three mutations, and 1 was homozygous for one mutation and heterozygous for another mutation. It has been reported that analytical sensitivity of RH is 97%. We did not find a discrepancy between the two methods. In 21 patients, we detected additional mutations with RH. This finding was regarded as an advantage of RH, and we concluded that this assay is a useful method for detection of first stage FMF mutation screening.

Colchicine for the prevention of recurrent pericarditis.

Markel G(1), Imazio M, Brucato A, Adler Y.

Author information:

(1)Sheba Cancer Research Center, Sheba Medical Center, Tel Hashomer, Israel.

The most troublesome complication of acute pericarditis is recurrent episodes of pericardial inflammation, which occur in 15-32% of cases. It was recently found that viral infection has a major role, but in many cases the cause is unknown. The optimal method for prevention has not been fully established; accepted modalities include non-steroidal anti-inflammatory drugs, corticosteroids, immunosuppressive agents, and pericardiectomy. Based on the proven efficacy of colchicine in familial Mediterranean fever, several small and large-scale international clinical trials have shown the beneficial effect of colchicine therapy in preventing recurrent pericarditis. Indeed, colchicine-treated patients consistently display significantly fewer recurrences, longer symptom-free periods, and even when attacks occur they are weaker and shorter in nature. It was also found that pretreatment with corticosteroids substantially attenuates the efficacy of colchicine, as evidenced by significantly more recurrence episodes and longer therapy periods. Colchicine is a safe and effective modality for the treatment and prevention of recurrent pericarditis, especially as an adjunct to other modalities, since it provides a sustained benefit superior to all current modalities. The safety profile seems superior to other drugs such as corticosteroids and immunosuppressive drugs.

Author information:

(1)Department of Internal Medicine, Gazi University Faculty of Medicine, Ankara, Turkey.

Familial Mediterranean Fever (FMF) is an autosomal recessive disease characterized by periodic attacks of fever and polyserositis. The effects of the MEFV genotype differences on clinical picture and inflammatory activity have not been well documented. The aim of this study was to investigate levels of conventional inflammation markers, procalcitonin, interleukin levels, TNF-alpha, and C5a levels in patients with FMF who had different MEFV genotypes and compare them with those of healthy subjects. The study consisted of 41 patients with FMF (F/M: 23/18), and 31 healthy subjects (F/M: 18/13). Tests were performed during the attack-free period. White-blood cell count, CRP and IL-8 levels were higher in patients with FMF than in healthy subjects ( $p < 0.05$ ) and also higher in M680I carriers than in the patients with M694V allele carriers. However, ESR, fibrinogen, procalcitonin, IL-6, C5a, TNF-alpha, and IgD levels were not significantly different between patients and healthy subjects ( $p > 0.05$ ). Arthralgia or arthritis was significantly higher in M694V carriers than in non-M694V carriers ( $p < 0.05$ ). It is concluded that the clinical features and inflammatory-cytokine activities were higher in patients with FMF during the attack-free period than in healthy subjects, and the different genotype might be related to different clinical pictures.

[New aspects of the pathogenesis of gout. Danger signals, autoinflammation and beyond].

[Article in German]

Lamprecht P(1), Till A, Kabelitz D.

Author information:

(1)Poliklinik für Rheumatologie, Universität zu Lübeck, Vaskulitzszentrum - Universitätsklinikum Schleswig-Holstein (UKSH) und Rheumaklinik Bad Bramstedt, Lübeck, Deutschland. peter.lamprecht@rheuma.uni-luebeck.de

Gout is caused by monosodium urate (MSU) crystal-induced inflammation of the joints and periarticular tissues. MSU crystals activate the NOD-like receptor (NLR) NALP3, which functions as a pattern recognition receptor (PRR). Activated NALP3 mediates interleukin-1 $\beta$  (IL-1 $\beta$ ) generation from its inactive pro-form, resulting in the activation of further cells and an IL-8-mediated neutrophil influx into the joint. Based on these new findings on the pathophysiology of gout, an open pilot study has recently demonstrated successful treatment of gout with the soluble IL-1R antagonist anakinra in 10 patients. The physiological role of MSU crystals might be that of a danger signal in peripheral tissues, where they stimulate dendritic cell maturation. The role of PRRs such as the NLR is underlined by NALP3 mutations causing hereditary autoinflammatory syndromes and NOD2 polymorphisms as genetic risk factors for Crohn's disease. In addition to the recognition of danger-associated molecular patterns (e.g. MSU), PRRs confer autoantigen recognition and activation of the innate and adaptive immune system in autoimmune diseases. Detection of RNA and DNA-containing immune complexes by toll-like receptors inducing B-cell activation in systemic lupus erythematosus and of proteinase 3 by the protease-activated receptor-2 inducing dendritic cell maturation in Wegener's granulomatosis have recently been reported.

The development of small molecules to modulate caspase activity offers a novel therapeutic strategy in the treatment of apoptosis-related and inflammatory diseases. Caspases are key mediators of apoptosis and inflammation; deregulation of their activation or expression can lead to the development of conditions such

as neurodegenerative and autoinflammatory disorders. This review details the different caspase-associated disorders while focusing on caspase-1 inhibition as a potential therapeutic strategy. Problems facing the development of effective and safe caspase therapeutics will also be addressed.

Author information:

(1)Armenicum Research Centre, CJSC Armenicum, Yerevan, Republic of Armenia.  
tigdav@excite.com

Familial Mediterranean fever (FMF) is a relapsing autoinflammatory disorder, caused by various mutations in the MEFV gene, which encodes a protein called pyrin, expressed in neutrophils and activated monocytes. Induction of monocyte endotoxin tolerance is observed in FMF patients during attack, whereas monocytes from patients in the attack-free period failed to induce lipopolysaccharide tolerance and exhibited heightened sensitivity to bacterial endotoxin. In this study, we demonstrated that impaired lipopolysaccharide tolerance induction in attack-free FMF patients correlates with both increased lipopolysaccharide-induced proinflammatory cytokine synthesis polarization and a different time-course pattern of lipopolysaccharide-induced changes on monocytic surface expression of CD14 and CD11b coreceptors. We found that this pattern is characterized either by delayed turnover of CD14 or increased surface retention of CD11b receptors on monocytes during stimulation with lipopolysaccharide. In addition, enhancement of lipopolysaccharide-induced apoptosis of neutrophils was observed in FMF patients, and was confirmed based on the fact that neutrophils from FMF patients previously unexposed to *Salmonella enteritidis* exhibited heightened susceptibility to the lipopolysaccharide of this pathogen similar to

that of patients infected with this species.

**OBJECTIVE:** To investigate endotoxin-induced tolerance, intracellular cytokine synthesis polarization and monocyte apoptosis during Familial Mediterranean Fever (FMF).

**METHODS:** Lipopolysaccharide (LPS)-induced tolerance, intracellular cytokine synthesis and monocyte apoptosis were determined in FMF patients by flow cytometry using whole blood cell culture technique.

**RESULTS:** Endotoxin homo- and cross-tolerance, detected as the percentage of TNF-alpha synthesizing monocytes, developed in whole blood preparations of patients in attack period, but not during remission. The induction of anti-inflammatory cytokine synthesis polarization and enhancement of iodine-lithium-alpha-dextrin- and LPS-induced monocyte apoptosis was observed in FMF patients during the attack, whereas monocytes from patients in remission period exhibited proinflammatory cytokine polarization and resistance to the repeated LPS-induced apoptosis. Colchicine induced anti-inflammatory cytokine synthesis and caused down-modulation of monocyte apoptosis, whereas cytokines did not alter LPS-induced monocyte apoptosis.

**CONCLUSION:** The self-limited nature of attacks during FMF may represent periods of inflammation resolution compensatory to continued sub-clinical inflammation during the remission.

The spectrum of autoinflammatory diseases: recent bench to bedside observations.

Ryan JG(1), Goldbach-Mansky R.

Author information:

(1)Genetics and Genomics Branch, Office of the Clinical Director, National Institute of Arthritis and Musculoskeletal and Skin Diseases, National Institutes of Health, Bethesda, Maryland 20892, USA.

**PURPOSE OF REVIEW:** The autoinflammatory diseases are a group of conditions that include the hereditary fever syndromes, and result from upregulated innate immune responses. The discovery of the genetic basis for these conditions led to the description of novel intracellular receptors for infectious and noninfectious danger signals. This article focuses on recent progress in our understanding of autoinflammatory syndromes, and how insights into these conditions have triggered the exploration of the role of innate immunity in common rheumatologic diseases.

**RECENT FINDINGS:** New models for the pathogenesis of several autoinflammatory syndromes have been proposed, including the role of pyrin and cryopyrin in regulating inflammation. Robust evidence has emerged that IL-1beta oversecretion is pivotal in cryopyrin-associated periodic syndromes, and that IL-1 inhibition ameliorates the clinical features of these syndromes. Monosodium urate crystals stimulate IL-1beta secretion via cryopyrin, which led to the addition of gout to the spectrum of autoinflammatory diseases.

**SUMMARY:** Advances in our understanding of the autoinflammatory diseases have led to renewed interest in the innate immune system, and its role in the pathogenesis of more common rheumatic diseases.

The last ten years of research in the field of innate immunity have been incredibly fertile: the transmembrane Toll-like receptors (TLRs) were discovered as guardians protecting the host against microbial attacks and the emerging pathways characterized in detail. More recently, cytoplasmic sensors were identified, which are capable of detecting not only microbial, but also self molecules. Importantly, while such receptors trigger crucial host responses to microbial insult, over-activity of some of them has been linked to autoinflammatory disorders, hence demonstrating the importance of tightly regulating their actions over time and space. Here, we provide an overview of recent findings covering this area of innate and inflammatory responses that originate from the cytoplasm.

Familial Mediterranean fever (FMF) is an autosomal recessive disease characterized by recurrent inflammatory attacks of serosal membranes. Several studies have focused on the differences between frequency of the mutations and their phenotypical manifestations. The aim of this study was to evaluate whether or not this phenotypical variation is associated with the existence of particular mutations. Twelve MEFV (Mediterranean fever) gene mutations were investigated in 119 patients suffering from FMF. Heterozygote M694V (21/119), heterozygote E148Q (21/119), homozygote M694V (17/119) and heterozygote V726A (12/119) mutations were the most common mutations. Patients were grouped according to the presence of the M694V mutation: group I was M694V/M694V, group II was M694V/others, and group III was other/other. Mean severity scores for the groups were 13.94 +/- 4.10, 10.79 +/- 3.01 and 8.31 +/- 2.26, respectively. There were statistically significant differences between the mean severity scores of groups I and II ( $p = 0.029$ ), groups I and III ( $p < 0.0001$ ), and groups II and III ( $p < 0.0001$ ). Diagnosis of amyloidosis was established in four (23%) patients of group I, and three (8%) patients of group II, but in none of the patients in group III. There was also a statistically significant difference between groups I and III ( $p = 0.046$ ), but not between groups II and III ( $p = 0.083$ ) and groups I and II ( $p = 0.317$ ) in terms of amyloidosis development. In conclusion, we found a higher disease severity score and higher prevalence of amyloidosis in FMF patients who were M694V mutation carriers. Many ethnic groups live in Anatolia and more ethnic origin-based studies are needed to determine the real effect of these mutations on disease severity and amyloidosis.

Patients with systemic amyloidosis often have symptoms related to impaired gastrointestinal motility due to delayed gastric emptying, which results from autonomic nerve or smooth muscle infiltration with amyloid. There is no current report about gastric delaying secondary to amyloidosis due to familial Mediterranean fever. In this report, we have described a renal transplant recipient with delayed gastric emptying secondary to amyloidosis due to familial Mediterranean fever, which improved with erythromycin treatment.

Dendritic cells and cytokines in human inflammatory and autoimmune diseases.

Blanco P(1), Palucka AK, Pascual V, Banchereau J.

Author information:

(1)CHU Bordeaux, 33076 Bordeaux, France. patrick.blanco@chu-bordeaux.fr

Dendritic cells (DCs) produce cytokines and are susceptible to cytokine-mediated activation. Thus, interaction of resting immature DCs with TLR ligands, for example nucleic acids, or with microbes leads to a cascade of pro-inflammatory cytokines and skewing of T cell responses. Conversely, several cytokines are able to trigger DC activation (maturation) via autocrine, for example TNF and plasmacytoid DCs, and paracrine, for example type I IFN and myeloid DCs, pathways. By controlling DC activation, cytokines regulate immune homeostasis and the balance between tolerance and immunity. The increased production and/or bioavailability of cytokines and associated alterations in DC homeostasis have been implicated in various human inflammatory and autoimmune diseases. Targeting these cytokines with biological agents as already is the case with TNF and IL-1 represents a success of immunology and the coming years will expand the range of cytokines as therapeutic targets in autoinflammatory and autoimmune pathology.

**BACKGROUND:** The susceptibility gene for familial cold autoinflammatory syndrome (FCAS) has been mapped to chromosome 1q44 and a point mutation determined to be present in all affected members of a large Canadian kindred. Anakinra (Kineret)

is known to block IL-1 receptor and in the few patients with FCAS in whom it has been used, it has been shown to provide relief for this lifelong disability.

OBJECTIVE: To demonstrate the efficacy and safety of anakinra (Kineret) in FCAS.

METHODS: Eight affected family members aged 29 to 77 years received anakinra 100 mg subcutaneously daily for 4 weeks preceded and followed by a 2-week control period.

RESULTS: The treatment was rapidly effective paralleled by the immediate fall of the C-reactive protein and serum amyloid A protein. The only significant side effect was an injection-site reaction in 50%, which declined in the follow-up period. The effect was sustained in all who continued to use the treatment at 4 and 16 months of follow-up.

CONCLUSION: This is the first treatment of FCAS that is completely effective while it is used.

NALP proteins, also known as NLRPs, belong to the CATERPILLER protein family involved, like Toll-like receptors, in the recognition of microbial molecules and the subsequent activation of inflammatory and immune responses. Current advances in the function of NALPs support the recently proposed model of a disease continuum bridging autoimmune and autoinflammatory disorders. Among these diseases, hereditary periodic fevers (HPFs) are Mendelian disorders associated with sequence variations in very few genes; these variations are mostly missense mutations whose deleterious effect, which is particularly difficult to assess, is

often questionable. The growing number of identified sporadic cases of periodic fever syndrome, together with the lack of discriminatory clinical criteria, has greatly hampered the identification of new disease-causing genes, a step that is, however, essential for appropriate management of these disorders. Using a candidate gene approach, we identified nonambiguous mutations in NALP12 (i.e., nonsense and splice site) in two families with periodic fever syndromes. As shown by means of functional studies, these two NALP12 mutations have a deleterious effect on NF-kappaB signaling. Overall, these data identify a group of HPFs defined by molecular defects in NALP12, opening up new ways to manage these disorders. The identification of these first NALP12 mutations in patients with autoinflammatory disorder also clearly demonstrates the crucial role of NALP12 in inflammatory signaling pathways, thereby assigning a precise function to this particular member of an emerging family of proteins whose putative biological properties are currently inferred essentially through in vitro means.

Familial Mediterranean fever gene and protection against asthma.

Rabinovitch E(1), Harats D, Yaron P, Luvish T, Lidar M, Kedem R, Shaish A, Ben-Dov I, Livneh A.

Author information:

(1)Heller Institute of Medical Research, Sheba Medical Center, Tel-Hashomer, Israel.

**BACKGROUND:** Asthma is an inflammatory airway disease caused by interaction between susceptibility genes and diverse environmental factors. In Israel, asthma seems to be familial and more severe in patients of Iraqi Jewish descent. On the other hand, asthma is less frequent in individuals with familial Mediterranean fever, an autoinflammatory disease prevalent in the Iraqi Jewish community and linked to mutations in the familial Mediterranean fever gene, designated MEFV.

**OBJECTIVES:** To explore a possible role for mutated MEFV in the reduced

susceptibility to asthma and to determine its expression in Israeli subjects of Iraqi origins.

**METHODS:** Using a case-control approach, we studied the presence of the 3 most common MEFV mutations (M694V, V726A, and E148Q) in DNA samples from 75 patients with asthma and 45 asymptomatic first-degree relatives, all of Iraqi Jewish origin. The severity of asthma was evaluated using a published severity score.

**RESULTS:** Eleven patients with asthma and 14 of their relatives carried 1 or 2 mutations in the MEFV gene, a carrier rate significantly lower in patients with asthma than in their first-degree relatives and in ethnically matched healthy individuals ( $P < .03$  and  $P < .003$ , respectively). Carriers of MEFV mutations had less severe disease, compared with noncarriers ( $P < .002$ ).

**CONCLUSION:** These findings suggest that MEFV mutations may have a protective effect in the pathogenesis of asthma.

Familial Mediterranean fever (FMF) can present cutaneous symptoms. In the reported case, infiltrating perineal and scrotal inflammation were attributed to FMF and treated by systemic medication with colchicine. The poor outcome of this conservative approach and pathognomonic axillary dermatological findings allowed the diagnosis of acne inversa to be made. Knowledge of this clinical picture possibly including genital manifestations is crucial, as early excision of all affected regions is the therapy of choice that enables healing.

Drugs antagonizing tumor necrosis factor (TNF) alpha have been increasingly and successfully used in the treatment of psoriasis vulgaris and psoriatic arthritis. We report a patient with TNF receptor 1-associated periodic syndrome (TRAPS) who received TNF-alpha antagonist etanercept. A month later, the patient developed for the first time generalized psoriasis vulgaris. This paradoxical phenomenon has been reported sporadically in patients receiving TNF-alpha antagonists for other inflammatory diseases. The cause of psoriasis induced by TNF-alpha antagonists is still obscure.

Analysis of vascular endothelial growth factor gene 936 C/T polymorphism in patients with familial Mediterranean fever.

Gunesacar R(1), Erken E, Ozer HT, Bozkurt B, Dinkci S, Deveci D.

Author information:

(1)Department of Rheumatology-Immunology, Faculty of Medicine, Cukurova University, Adana, Turkey. gamgul@cu.edu.tr

Vascular endothelial growth factor (VEGF) is a cytokine that promotes endothelial cell proliferation, leucocyte chemotaxis and expression of adhesion molecules and is a major mediator of vascular permeability. It has been demonstrated that VEGF directly activates neutrophils and it could promote acute recruitment of leucocytes. It is known that neutrophils are the major cell population involved in acute inflammation in familial Mediterranean fever (FMF) and the role of VEGF in these cells may be crucial. The aim of this study was to investigate whether the 936 C/T functional polymorphism of the VEGF gene is associated with susceptibility to FMF and its relationship with the main clinical features of the disease. Polymerase chain reaction-restriction fragment length polymorphism technique was used to determine 936 C/T polymorphism within the VEGF gene in 75 patients with FMF and 122 non-related healthy controls. Genotype and allele frequencies of the VEGF 936 C/T polymorphism between patients with FMF and healthy control groups were not significantly different (OR = 0.74, 95% CI =

0.40-1.37,  $P = 0.335$  for CT genotype; OR = 1.11, 95% CI = 0.67-1.83,  $P = 0.700$ , for T allele). Although VEGF 936 TT genotype was found to be more frequent in patients with FMF than in healthy controls (6.7% vs. 1.6%, respectively), the difference was not significant (OR = 4.28, 95% CI = 0.81-22.67,  $P = 0.108$ ). No associations were found between the studied polymorphism and either the clinical features such as arthritis, abdominal pain, pleuritis, myalgia, arthralgia and erysipelas-like erythema of the disease or the four common studied exon 10 mutations (M694V, M680I, V726A, M694I) of the Mediterranean fever gene. Present results suggest that VEGF gene 936 C/T polymorphism does not seem to be associated with susceptibility to FMF and its clinical manifestations.

A 14-year-old girl was diagnosed with familial Mediterranean fever (FMF) with homozygous for M694V mutation of the MEFV gene and was started on colchicine therapy 4 years before admission to our hospital. She was uncompliant to therapy and was admitted to a local hospital with complaining of fever, malaise, abdominal pain and arthralgia lasting for 2 months. Multiple hypoechogenic mass lesions were detected on liver and kidneys with ultrasonography (US) and diagnosed to be hematomas by laparoscopic examination. She was referred to our hospital because of development of convulsions. On physical examination her blood pressure was 140/90 mmHg and body temperature was 39 degrees C. She was pale and extremely cachectic, with atrophic muscles of the extremities. She had diffuse abdominal tenderness and hepatosplenomegaly. Laboratory investigations revealed a hemoglobin of 9.8 g/dl, white blood cell count 9,900/mm<sup>3</sup>, platelets 213,000/mm<sup>3</sup>,

erythrocyte sedimentation rate (ESR) 112 mm/h, C- reactive protein (CRP) 78 mg/L (normal < 2 mg/L) and fibrinogen 500 mg/dl. Electrolytes, renal and hepatic functions and urinalysis were normal. Examinations of peripheral blood smear and bone marrow aspiration were normal. X-rays of bones and chest showed no pathological finding. Protrombine, partial thromboplastine and bleeding times were normal. Bacterial cultures of blood, urine and stool grew no organisms. Serological tests for hepatitis B and C, cytomegalovirus, salmonella and brucella were negative.

**OBJECTIVES:** To study the clinical outcome, treatment response, T-cell subsets and functional consequences of a novel tumour necrosis factor (TNF) receptor type 1 (TNFRSF1A) mutation affecting the receptor cleavage site.

**METHODS:** Patients with symptoms suggestive of tumour necrosis factor receptor-associated periodic syndrome (TRAPS) and 22 healthy controls (HC) were screened for mutations in the TNFRSF1A gene. Soluble TNFRSF1A and inflammatory cytokines were measured by ELISAs. TNFRSF1A shedding was examined by stimulation of peripheral blood mononuclear cells (PBMCs) with phorbol 12-myristate 13-acetate followed by flow cytometric analysis (FACS). Apoptosis of PBMCs was studied by stimulation with TNFalpha in the presence of cycloheximide and annexin

V staining. T cell phenotypes were monitored by FACS.

RESULTS: TNFRSF1A sequencing disclosed a novel V173D/p.Val202Asp substitution encoded by exon 6 in one family, the c.194-14G>A splice variant in another and the R92Q/p.Arg121Gln substitution in two families. Cardiovascular complications (lethal heart attack and peripheral arterial thrombosis) developed in two V173D patients. Subsequent etanercept treatment of the V173D carriers was highly effective over an 18-month follow-up period. Serum TNFRSF1A levels did not differ between TRAPS patients and HC, while TNFRSF1A cleavage from monocytes was significantly reduced in V173D and R92Q patients. TNFalpha-induced apoptosis of PBMCs and T-cell senescence were comparable between V173D patients and HC.

CONCLUSIONS: The TNFRSF1A V173D cleavage site mutation may be associated with an increased risk for cardiovascular complications and shows a strong response to etanercept. T-cell senescence does not seem to have a pathogenetic role in affected patients.

Author information:

(1)Institute of Nephrology and Hypertension, Sheba Medical Center, Tel-Hashomer, Israel.

Glomerulonephritis, particularly IgA nephropathy (IgAN), seems to be more common in familial Mediterranean fever (FMF), an inherited disease caused by mutations in the MEiterranean FeVer gene (MEFV). The present study is aimed to determine, in populations not suffering from FMF, whether carriage of MEFV mutations may modify or precipitate IgAN and other forms of primary glomerulonephritis (PGN).

Forty patients with biopsy proven IgAN and 40 with PGN were surveyed for the presence of the three most common MEFV mutations (M694V, V726A and E148Q), using

polymerase chain reaction amplification and restriction enzyme analysis. The rate of MEFV mutations in the patients was related to the expected carrier rate in the general population of the same ethnic extraction. The effect of mutation carriage on the disease course was determined in the IgAN patient group. The frequency of MEFV mutations in IgAN or PGN was comparable to that found in ethnically adjusted general population ( $p = 0.1$  and  $0.5$ , respectively). Carriage of mutated MEFV was not associated with the course and severity of the disease or findings in kidney biopsy and urine analysis. In a population, mostly of Jewish extraction, MEFV mutations do not seem to predispose to the development of IgAN and other forms of PGN or affect the phenotype.

Author information:

(1)Department of Internal Medicine, Medical School, University of Crete, Heraklion, Crete, Greece.

Familial Mediterranean Fever (FMF) is an autosomal, recessively inherited disease, characterized by recurrent and short attacks of fever with serosal inflammation that are caused by mutations in MEFV gene that encodes pyrin protein. To date, more than 70 disease-associated mutations have been identified, almost all of them representing missense nucleotide changes. FMF is very common among patients with Mediterranean ancestry, although the exact prevalence is not yet known, Greeks are considered to be at 'intermediate risk'. In the present study, we studied FMF patients in natives of Crete, a population sharing a common genetic and cultural background. The spectrum of MEFV gene mutations in 71 patients as well as 158 healthy controls was studied by performing a molecular analysis focused on the 12 most frequent FMF-associated mutations. We found that

59 of 71 (83.1%) FMF patients had at least one MEFV mutation, five patients were homozygotes and 54 heterozygotes for FMF-associated mutations. No mutations were detected in 12 patients (16.9%). As in high-risk populations, common MEFV mutations were found in Cretan FMF patients, with the M694V being the most penetrant. M694V and M694I mutations were associated with severe phenotypes, with many patients presenting with uncommon clinical manifestations such as erysipelas-like erythema or renal disturbances. Of interest, 20 (37%) of our heterozygous FMF patients presented with a severe phenotype. Population genetics analysis showed an FMF carrier frequency in healthy Cretan population of approximately 6% (1:17) and places Cretans closer to the Western rather than Eastern populations of the Mediterranean basin. Finally, we constructed a three-dimensional model showing the interaction of the PRYSPRY domain of pyrin with caspase-1 onto which we mapped MEFV mutations, classified according to disease severity. In this model, the 'flexible loops' of caspase-1 appear to have no access to some positions that have been previously associated with mild disease, suggesting that alternative pathogenic pathways leading to FMF need to be explored.

New CIAS1 mutation and anakinra efficacy in overlapping of Muckle-Wells and familial cold autoinflammatory syndromes.

Maksimovic L(1), Stirnemann J, Caux F, Ravet N, Rouaghe S, Cuisset L, Letellier E, Grateau G, Morin AS, Fain O.

Author information:

(1)Service de Médecine Interne, Hôpital Jean Verdier, Assistance Publique-Hôpitaux de Paris, Université Paris 13, Paris, France.

**OBJECTIVES:** Muckle-Wells syndrome (MWS) and familial cold autoinflammatory syndrome (FCAS) are rare periodic fevers associated with CIAS1 mutations. A third entity, the chronic infantile neurological, cutaneous, articular (CINCA) syndrome was also recently associated with mutation in the same gene. A phenotypic and

genotypic continuum seems to exist from the most benign (FCAS) to the most severe forms (CINCA). Although a CIAS1 mutation can be associated with two different phenotypes.

**METHODS:** We report a family of three patients exhibiting the MWS and FCAS phenotypes. These phenotypes were associated with a novel missense mutation in CIAS1.

**RESULTS:** Anakinra controlled inflammatory flares in the three patients.

**CONCLUSIONS:** FCAS, MWS and CINCA could be different phenotype expressions of the same disease.

Exposition to chickenpox of two children with autoinflammatory syndromes under treatment with anakinra.

Rigante D(1), Ansuini V, Berrettini A, Bersani G, Stabile A.

Author information:

(1)Department of Pediatric Sciences, Center of Periodic Fevers, Università Cattolica Sacro Cuore, Rome, Italy. drigante@gmail.com

We report two children with autoinflammatory syndromes treated with anakinra who came in contact with the varicella-zoster virus after being exposed accidentally to infected children: both cases were managed prophylactically with specific antichickenpox intravenous immunoglobulins and anakinra temporary suspension; neither adverse events nor complications related to the natural course of chickenpox were experienced by the two patients. The risk of developing infectious events should be closely monitored, because of the absence of data concerning long-term safety of biological agents in the pediatric age, and prevention strategies should be highly encouraged before they are started.

Primer: inflammasomes and interleukin 1beta in inflammatory disorders.

Church LD(1), Cook GP, McDermott MF.

Author information:

(1)Leeds Institute of Molecular Medicine, St James's University Hospital, Leeds, UK.

Inflammasomes are large, multimeric protein complexes that link the sensing of microbial products and metabolic stress to the proteolytic processing of prointerleukin (pro-IL)-1beta to its active form. NALP1 and NALP2 are founding members of the Nod-like receptor family. Other Nod-like receptors, including NALP3 and NOD2, which are associated with inflammatory disorders, have also been described. The NALP1 and NALP3 inflammasomes are located in the cytoplasm and can, therefore, detect intracellular infection through recognition of microbial pathogen-associated molecular patterns. The inflammasome pathways cooperate with Toll-like receptor pathways to mediate a rapid and appropriate response to pathogens and genotoxic stress. Mutations in both pyrin and NALP3 components of inflammasomes are associated with innate-immune-mediated diseases (familial Mediterranean fever and the 'cryopyrinopathies'), and aberrant IL-1beta processing has been reported in several autoinflammatory conditions, including Muckle-Wells syndrome, chronic infantile neurologic, cutaneous and articular syndrome/neonatal onset multisystem inflammatory disease, and gout. The effectiveness of IL-1beta blockade in treating many of these conditions has transformed the understanding and management of these disorders and also highlighted the role of aberrant IL-1beta signaling in other conditions, such as adult-onset Still's disease and systemic juvenile idiopathic arthritis.

Comment in

Arthritis Rheum. 2008 Jul;58(7):2213-4; author reply 2214-5.

**OBJECTIVE:** Tumor necrosis factor receptor-associated periodic syndrome (TRAPS) is an autosomal-dominant autoinflammatory condition caused by mutations in the TNFRSF1A gene. The cellular mechanisms by which mutations in this gene trigger inflammation are currently unclear. Because NF-kappaB is the major intracellular signaling component inducing secretion of proinflammatory cytokines, we sought to determine whether differences in the clinical phenotype of patients with TRAPS may be attributable to variable effects of TNFRSF1A mutations on TNFRI expression, localization, or NF-kappaB activity.

**METHODS:** Peripheral blood mononuclear cells were obtained from patients (following informed consent), and cellular nuclear and cytosolic fractions were generated by subcellular fractionation. Localization of IkappaBalpha and NF-kappaB was determined by Western blotting of the resultant fractions. NF-kappaB subunit activity was determined by enzyme-linked immunosorbent assay analysis and confirmed by electrophoretic mobility shift assay. Subcellular localization of TNFRI was determined by immunofluorescence confocal microscopy or by immunoblotting following affinity isolation of plasma membrane by subcellular fractionation.

**RESULTS:** Cells from patients with the fully penetrant C73R mutation had marked activation of the proinflammatory p65 subunit of NF-kappaB. In contrast, cells from patients with the low-penetrant R92Q mutation displayed high levels of DNA binding by the p50 subunit, an interaction previously linked to repression of inflammation. Interestingly, although cells from patients with the C73R mutation have no TNFRI shedding defect, there was nonetheless an unusually high concentration of functional TNFRI at the plasma membrane.

**CONCLUSION:** High levels of TNFRI at the cell surface in patients with the C73R mutation hypersensitizes cells to stimulation by TNF, leading to increased NF-kappaB p65 subunit activation and an exaggerated proinflammatory response.

An overview of familial Mediterranean fever with emphasis on pyrin and colchicine.

Dbouk HA(1), Uthman IW.

Author information:

(1)Department of Biology, Faculty of Arts and Sciences, American University of Beirut, Beirut, Lebanon.

Familial Mediterranean fever (FMF) is the earliest known autoinflammatory disease, characterized by symptoms such as arthritis, peritonitis, pleuritis, erysipelas-like erythema, and most importantly amyloidosis. This disease is very common in populations of the Mediterranean area, and due to its high carrier frequency and occurrence rate in these populations, it has been the focus of much research work. Such research has allowed greater insights into the genetics of FMF, leading to the discovery of the responsible gene in 1997 and the determination of mutations and their effect on the phenotype of patients, as well as the interactions and roles of the pyrin protein, which seems to have various roles in regulation of innate immunity, inflammation, and apoptosis. Colchicine has been used as preventive treatment since 1972, and recent studies have allowed the determination of its mode of action.

ATP binding by monarch-1/NLRP12 is critical for its inhibitory function.

Ye Z(1), Lich JD, Moore CB, Duncan JA, Williams KL, Ting JP.

Author information:

(1)Department of Microbiology and Immunology, University of North Carolina, CB7295, 450 West St., Chapel Hill, NC 27599, USA.

The recently discovered nucleotide binding domain-leucine rich repeat (NLR) gene family is conserved from plants to mammals, and several members are associated with human autoinflammatory or immunodeficiency disorders. This family is defined by a central nucleotide binding domain that contains the highly conserved Walker A and Walker B motifs. Although the nucleotide binding domain is a defining feature of this family, it has not been extensively studied in its purified form. In this report, we show that purified Monarch-1/NLRP12, an NLR protein that negatively regulates NF-kappaB signaling, specifically binds ATP and exhibits ATP hydrolysis activity. Intact Walker A/B motifs are required for this activity. These motifs are also required for Monarch-1 to undergo self-oligomerization, Toll-like receptor- or CD40L-activated association with NF-kappaB-inducing kinase (NIK) and interleukin-1 receptor-associated kinase 1 (IRAK-1), degradation of NIK, and inhibition of IRAK-1 phosphorylation. The stable expression of a Walker A/B mutant in THP-1 monocytes results in increased production of proinflammatory cytokines and chemokines to an extent comparable to that in cells in which Monarch-1 is silenced via short hairpin RNA. The results of this study are consistent with a model wherein ATP binding regulates the anti-inflammatory activity of Monarch-1.

Author information:

(1)Institute of Rheumatology, Tokyo Women's Medical University School of Medicine, Tokyo, Japan.

We report on three Japanese patients (two families) with familial Mediterranean fever (FMF), a rare disease in the Far East. Two of the patients (siblings with definite FMF) were heterozygous for both E148Q and M694I, and the remaining patient (with probable FMF and no family history of the disease) was heterozygous for both P369S and R408Q. Although the M694I mutation is less common among Mediterranean populations, it was present in 22 (76%) of 29 Japanese patients with FMF (previously reported cases). We therefore investigated the allele frequency of M694I in the healthy Japanese population, as well as other FMF-causing mutations in exon 10 (M680I, M694V, and V726A) and polymorphisms (E148Q, P369S, and R408Q) of the Mediterranean fever gene (MEFV). The allele frequencies of disease-causing mutations, even M694I, were  $<0.001$ . While those of E148Q, P369S, and R408Q were 0.23, 0.057, and 0.054, respectively. Because of the low allele frequencies of disease-causing mutations, FMF is an extremely rare disease among Japanese individuals. However, FMF is an important component of hereditary autoinflammatory syndrome, and a diagnosis of FMF is crucial for the choice of treatment, because of the benefit of colchicine therapy.

Acne inversa complicated by squamous cell carcinoma in association with diffuse malignant peritoneal mesothelioma arising in the absence of predisposing factors: a case report.

Barresi V(1), Vitarelli E, Barresi G.

Author information:

(1)Dipartimento di Patologia Umana, Policlinico Universitario G. Martino, University of Messina, Italy. [valeriabarresi@hotmail.com](mailto:valeriabarresi@hotmail.com)

Diffuse malignant peritoneal mesothelioma (DMPM) is a relatively rare neoplasm. Risk factors associated with its development include asbestos exposure, chronic irritation or inflammation of the peritoneum, abdominal radiotherapy, familial Mediterranean fever and simian virus 40. A familial segregation of this neoplasia has been reported in small villages of the Cappadocian region of Turkey, and it has been postulated that hereditary factors may predispose to mesothelioma, even

with exposure to small amounts of asbestos. We report a case of DMPM, which apparently occurred in the absence of predisposing factors in a patient with a clinical history characterized by recurrent pre-sacral acne inversa of long duration. The association of this chronic inflammatory disease with DMPM has never been reported. The genetic locus for acne inversa has recently been identified within the 1p21.1-1q25.3 chromosomal region. Interestingly, frequent losses in chromosomal region 1p.21-22 have been found in mesothelioma as well. It is thus tempting to speculate that genetic mutations involving chromosome 1p.21-22 may account for the development of both diseases.

**OBJECTIVE:** To characterise and investigate the functional consequences of a novel TNFRSF1A splice site mutation causing tumour necrosis factor receptor associated periodic syndrome (TRAPS) in a 16-year-old male patient and his mother.

**METHODS:** Mutational DNA screening was performed in the patient and his mother. Western blotting was used to analyse protein expression levels of TNFR1. A multiplex bead immunoassay was used to quantify serum levels of range of cytokines, and an ELISA-based transcription factor assay to measure nuclear factor (NF)-kappaB transactivation. Serum levels of soluble TNFR1 (sTNFR1) were measured by ELISA and fluorescence-activated cell sorting (FACS) analysis used to measure monocyte TNFR1 cell surface expression.

**RESULTS:** A novel mutation, c.472+1G>A (C158delinsYERSSPEAKPSPHPRG), involving a splice site in intron 4 of TNFRSF1A, was found in the proband and affected mother

leading to a 45 nucleotide insertion of intronic DNA into the mRNA, resulting in an in-frame insertion of 15 amino acids in the mature TNFR1 protein and a deletion of a cysteine residue C129 (158) in cysteine rich domain (CRD)3. The patients had reduced serum sTNFR1 and surface expression levels of TNFR1, with marked increases in pro- and anti-inflammatory cytokine. Their peripheral blood mononuclear cells (PBMC) had increased basal NF-kappaB activation compared with healthy controls and also had increased p50 nuclear expression following tumour necrosis factor (TNF) stimulation compared with PBMC from healthy controls, as well as T50M (T79M) and C88R (C117R) patients with TRAPS and patients with rheumatoid arthritis (RA).

CONCLUSION: A novel, TRAPS causing, TNFRSF1A splice site mutation is associated with decreased sTNFR1 levels, cell surface and whole cell extract expression and increased NF-kappaB transcription factor activation.

We describe in this paper the phenotype-genotype analysis of a Brazilian cohort of patients with cryopyrin-associated periodic syndromes (CAPS). Patient 1 presented with an urticarial rash and recurrent fever exacerbated by cold weather, arthritis, and anterior uveitis, thus, receiving a clinical diagnosis of familial cold autoinflammatory syndrome. CIAS1 sequencing identified the T436I mutation, previously associated to a clinical phenotype of chronic infantile neurological cutaneous and articular/neonatal onset multisystem inflammatory disease. Patient 2 developed a papular exanthema with daily fever shortly after birth, frontal bossing, patellae enlargement, and cognitive and motor impairments. Sequencing identified the exceedingly rare G755R CIAS1 mutation in

exon 4. Patient 3 developed skin rash and articular symptoms 6 h after birth, followed by aseptic meningitis. He was found to have the novel C148Y missense mutation in CIAS1. This report expands the spectrum of CIAS1 mutations associated to clinical disease, suggests that the same mutation can be associated with different clinical syndromes, and supports the evidence that CAPS patients should always be screened for mutations outside exon 3.

Retraction in

Dig Dis Sci. 2009 Dec;54(12):2772.

**BACKGROUND:** Familial Mediterranean fever (FMF) is also called recurrent polyserositis. The salient features of this disease include brief recurrent episodes of peritonitis, pleuritis, and arthritis, which are usually associated with fever. Colchicine is highly effective in the treatment of FMF and in preventing the development of recurrent attacks and amyloidosis, and it is essential to make the correct diagnosis and institute daily therapy with colchicine (0.5-0.6 mg bid). Colchicine is used to treat a variety of conditions but it is known to have gastrointestinal (GI) side effects. In this study, effects of colchicines on the gastrointestinal tract were evaluated in patients with FMF treated with colchicine.

**METHODS:** Biopsies were reviewed from 43 patients attending Ain Shams University Hospital (Egypt) who were diagnosed with FMF and treated with colchicine. One-hundred and twelve GI biopsies, obtained over a 14-year period, were

reviewed. This included biopsies from stomach body (38), stomach antrum (50), and colon (24). In addition, gastric biopsies were reviewed from 17 control patients who did not have FMF and were not on colchicine.

RESULTS: Three patients known to have FMF and on colchicine therapy showed typical histological features of colchicine (metaphase mitoses, epithelial pseudoproliferation, mucin depletion, and frequent apoptosis). These features were seen only in gastric antral biopsies and not in colonic biopsies. None of the control group showed the characteristic morphological features of colchicine toxicity.

CONCLUSION: This is the first report of histological changes seen in the stomach following colchicine therapy. In contrast with previous reports, we did not find any definitive change in the large intestine. Our data show that gastric changes can be encountered in symptomatic patients who have recently had colchicine. If these findings are seen histologically, they merit correlation with the clinical impression and should not be interpreted as toxicity in isolation.

The triad of fever, rash, and arthritis in a hospitalized child suggests an inflammatory, infectious, or postinfectious process in most cases; however, malignancy must be considered. The most common causes in this age group are inflammatory conditions, including Kawasaki disease, Henoch-Schönlein Purpura, serum sickness-like reaction, and juvenile idiopathic arthritis. Other rarer inflammatory processes can present with this triad of symptoms such as Cryopyrin-related diseases (autoinflammatory disorders), urticarial vasculitis, and systemic lupus erythematosus. We will discuss the differential diagnosis and inpatient management of fever, rash, and arthritis in a young child, focusing on inflammatory conditions. The important features which can help distinguish these conditions include the nature of the rash, associated signs or symptoms, time course of the eruption, and characteristic laboratory and/or histologic findings.

Cryopyrin-associated periodic syndrome (CAPS) is a spectrum of systemic autoinflammatory disorders in which the majority of patients have mutations in the cold-induced autoinflammatory syndrome (CIAS)1 gene. Despite having indistinguishable clinical features, some patients lack CIAS1 mutations by conventional nucleotide sequencing. We recently reported a CAPS patient with mosaicism of mutant CIAS1, and raised the possibility that CIAS1 mutations were

overlooked in "mutation-negative" patients, due to a low frequency of mosaicism. To determine whether there were latent mutant cells in "mutation-negative" patients, we sought to identify mutation-associated biologic phenotypes of patients' monocytes. We found that lipopolysaccharide selectively induced necrosis-like cell death in monocytes bearing CIAS1 mutations. Monocyte death correlated with CIAS1 up-regulation, was dependent on cathepsin B, and was independent of caspase-1. Cell death was intrinsic to CIAS1-mutated monocytes, was not mediated by the inflammatory milieu, and was independent of disease severity or anti-IL-1 therapy. By collecting dying monocytes after lipopolysaccharide treatment, we succeeded in enriching CIAS1-mutant monocytes and identifying low-level CIAS1-mosaicism in 3 of 4 "mutation-negative" CAPS patients. Our findings reveal a novel effect of CIAS1 mutations in promoting necrosis-like cell death, and demonstrate that CIAS1 mosaicism plays an important role in mutation-negative CAPS patients.

MEFV mutations in patients with familial Mediterranean fever in the Black Sea region of Turkey: Samsun experience [corrected].

Yigit S(1), Bagci H, Ozkaya O, Ozdamar K, Cengiz K, Akpolat T.

Author information:

(1)Department of Medical Biology, Ondokuz Mayis University, Samsun, Turkey.

Erratum in

J Rheumatol. 2008 Feb;35(2):367.

**OBJECTIVE:** To investigate MEFV mutations among patients with familial Mediterranean fever (FMF), their relatives, and healthy controls in the Black Sea region of Turkey; to compare 3 different MEFV mutation analysis methods; to evaluate the role of MEFV mutations in the diagnosis of FMF; and to investigate the role of M694V in the development of amyloidosis.

**METHODS:** In total, 890 subjects (625 patients, 165 relatives, 100 healthy controls) were included in this prospective study. MEFV mutations were studied

with the amplification refractory mutation system (ARMS; n = 335), polymerase chain reaction-restriction fragment length polymorphism (PCR-RFLP; n = 335), and reverse hybridization assay (FMF StripAssay; n = 693).

RESULTS: All methods were used in 79 patients. The ratio of false negativity was about 2% using ARMS compared to PCR-RFLP. The FMF StripAssay was used to investigate 9 more mutations and detected 17 mutations in 14 patients. The M694V/M694V genotype was more common in patients with amyloidosis (37%) compared to patients without amyloidosis (18%) ( $p = 0.009$ ). The frequency of MEFV carriers was 27%. The frequency of individuals having 2 mutations among asymptomatic relatives of FMF patients was 6%.

CONCLUSION: The FMF StripAssay is a reliable and time-saving method. In spite of detection of new mutations and developments in MEFV assay technology, there were patients in whom no mutation was detected. Our data, combined with previous studies, show that patients having M694V/M694V carry a risk for amyloidosis.

The metastasis associated protein S100A4: a potential novel link to inflammation and consequent aggressive behaviour of rheumatoid arthritis synovial fibroblasts.

Oslejsková L(1), Grigorian M, Gay S, Neidhart M, Senolt L.

Author information:

(1)Institute of Rheumatology, 1st Medical Faculty, Charles University, Prague, Czech Republic.

The metastasis-associated protein S100A4 belongs to the large family of S100 calcium-binding proteins that appear to play regulatory roles in diverse biological activities. Moreover, a prognostic role of S100A4 has been suggested for patients with several types of cancer. Cancer promoting properties for S100A4 have been demonstrated, particularly through its regulation of cell motility, proliferation and apoptosis, as well as by stimulation of angiogenesis and remodelling of the extracellular matrix. Increased expression of S100A4 mRNA has been detected in proliferating synovial fibroblasts in rheumatoid arthritis. Furthermore, strong upregulation of the S100A4 protein in rheumatoid arthritis synovial tissue compared with osteoarthritis and control tissues has been demonstrated recently, especially at sites of joint invasion. Several immune and vascular cells were also identified to be producing S100A4 within the synovium. The local upregulation of S100A4 was accompanied by high plasma and synovial fluid concentrations of the S100A4 protein existing in the bioactive oligomeric form in patients with rheumatoid arthritis. Consistent with data from cancer studies, the extracellular S100A4 oligomer appears to be involved in regulation of several matrix-degrading enzymes and modulation of the transcriptional activation function of the tumour suppressor protein p53 in rheumatoid arthritis synovial fibroblasts. Taken together, one can speculate that increased S100A4 protein in circulation and locally at sites of inflammation, particularly at sites of joint destruction, might be linked to the process of aggressive fibroblast behaviour contributing to the pathogenesis of chronic autoinflammatory diseases such as rheumatoid arthritis.

Elevated CD16 expression by monocytes from patients with tumor necrosis factor receptor-associated periodic syndrome.

Todd I(1), Radford PM, Ziegler-Heitbrock L, Ghaemmaghami AM, Powell RJ, Tighe PJ.

Author information:

(1)Division of Immunology, University of Nottingham, Queen's Medical Centre, Nottingham, UK. ian.todd@nottingham.ac.uk

**OBJECTIVE:** Tumor necrosis factor receptor-associated periodic syndrome (TRAPS) is an inherited autosomal-dominant autoinflammatory condition caused by mutations in the ectodomain of the 55-kd tumor necrosis factor (TNF) receptor superfamily 1A.

Proinflammatory blood monocytes with the phenotype CD14<sup>+</sup>,CD16<sup>+</sup>,HLA-DR<sup>++</sup> are a major source of TNF, and the number of such monocytes is increased during infection and inflammation. The aim of this study was to investigate whether the expression of circulating CD16<sup>+</sup> monocytes is affected in patients with TRAPS.

**METHODS:** Peripheral blood obtained from patients with TRAPS and healthy control subjects was stained with monoclonal antibodies to detect CD14<sup>++</sup>,CD16<sup>-</sup> monocytes and CD14<sup>+</sup>,CD16<sup>+</sup> monocytes, using flow cytometry. Lipopolysaccharide-induced TNF production was measured by intracellular cytokine staining. Activation-induced shedding of CD16 was investigated by treating blood samples with phorbol myristate acetate.

**RESULTS:** The level of CD16 expression by CD14<sup>+</sup>,CD16<sup>+</sup> monocytes, but not their

absolute number, was significantly elevated in patients with TRAPS, even though the patients were not experiencing clinically overt episodes of autoinflammation at the time of sampling. These findings are similar to those for the C-reactive protein levels and erythrocyte sedimentation rates in the same patients. The enhanced level of CD16 expression by monocytes from patients with TRAPS was not attributable to a defect in activation-induced shedding of CD16. The CD14<sup>+</sup>,CD16<sup>+</sup> monocytes were the predominant source of TNF in both patients and healthy control subjects.

**CONCLUSION:** The level of CD16 expression by monocytes was elevated in patients with TRAPS, as a feature of the underlying constitutive inflammation status.

(1)Cancer Research UK London Research Institute, Clare Hall Laboratories, South Mimms, Hertfordshire EN6 3LD, UK.

Comment in

Cell. 2007 Nov 30;131(5):836-8.

Trex1 is the major 3' DNA exonuclease in mammalian cells, and mutations in the human TREX1 gene can cause Aicardi-Goutières syndrome, characterized by perturbed immunity. Similarly, Trex1(-/-) mice have an autoinflammatory phenotype; however, the mechanism of Trex1-deficient disease is unknown. We report that Trex1, ordinarily associated with the endoplasmic reticulum (ER), relocalizes to the S phase nucleus after gamma irradiation or hydroxyurea treatment. Notably, Trex1-deficient cells show defective G1/S transition and chronic ATM-dependent checkpoint activation, even in the absence of exogenous stress, correlating with persistent single-stranded DNA molecules produced in S phase, which accumulate in the ER. Our data indicate that Trex1 acts on a single-stranded DNA polynucleotide

species generated from processing of aberrant replication intermediates to attenuate DNA damage checkpoint signaling and prevent pathological immune activation.

Prevalence of the MEFV gene mutations in childhood polyarteritis nodosa.

Yalçinkaya F(1), Ozçakar ZB, Kasapçopur O, Oztürk A, Akar N, Bakkaloğlu A, Arisoy N, Ekim M, Ozen S.

Author information:

(1)Ankara University School of Medicine, Division of Pediatric Nephrology, Ankara, Turkey. yalcinkaya@tr.net

**OBJECTIVES:** To test the hypothesis that alterations in the Mediterranean fever (MEFV) gene are a susceptibility factor for the development of polyarteritis nodosa (PAN) we investigated the prevalence of MEFV mutations in patients with PAN without any symptoms of familial Mediterranean fever (FMF).

**STUDY DESIGN:** Pediatric patients with PAN (n = 29) were enrolled in this study. Six predominant mutations (p.M694V, p.M680I, p.M694I, p.V726A, p.K695R, p.E148Q) in the MEFV gene were studied.

**RESULTS:** Fifteen MEFV mutations were identified in 58 chromosomes. Eleven of the 29 patients (38%) were found to carry MEFV mutations. Three (10.3%) of them had homozygous p.M694V mutation, and one of the patients (3.4%) had compound heterozygous mutation (p.V726A/p.E148Q).

**CONCLUSIONS:** Our study confirms that alterations in the MEFV gene are important susceptibility factors for the development of PAN. We believe that mutations in MEFV gene provide a basis for the development of PAN both by forming a proinflammatory state and by possibly giving exaggerated response to streptococcal infections.

Regulatory T cells and toll-like receptors: regulating the regulators.

Sutmuller R(1), Garritsen A, Adema GJ.

Author information:

Roger.Sutmuller@organon.com

Regulatory T cells (Treg) play a crucial role in maintaining control of leucocytes. Several studies have shown that in vivo Treg depletion results in autoimmune syndromes like thyroiditis, gastritis, diabetes mellitus and colitis, but at the same time, may also result in improved anti-tumour vaccination. Although Treg are recognised to maintain peripheral tolerance in healthy individuals, recent research has shown that Treg also suppress immune responses during infections to prevent tissue damage. How the Treg themselves are regulated is still under investigation. Their suppressive activity must be regulated in order to allow for the effective elimination of pathogens. Until recently, this control of Treg function was found to be through modulation via cytokines or by stimulation via co-stimulatory molecules on antigen-presenting cells. It is now demonstrated, however, that the presence of pathogens can be communicated to Treg directly through toll-like receptors (TLRs). Up until now, Treg have been reported to respond to ligands for TLR2, 4, 5 and 8, and different TLRs can have alternative effects on Treg resulting in more suppression or, in contrast, abrogation of suppression. As TLRs can also recognise endogenous proteins, such as heat shock proteins, it is tempting to speculate on the role of these proteins in modulating Treg function during chronic inflammation. In this review, we will discuss the implications of TLR engagement on Treg and any consequences this may have for chronic autoinflammatory diseases like rheumatoid arthritis (RA).

Deletion of a single mevalonate kinase (Mvk) allele yields a murine model of hyper-IgD syndrome.

Hager EJ(1), Tse HM, Piganelli JD, Gupta M, Baetscher M, Tse TE, Pappu AS, Steiner RD, Hoffmann GF, Gibson KM.

Author information:

(1)Division of Medical Genetics, Children's Hospital of Pittsburgh, University of Pittsburgh School of Medicine, Rangos Research Building, Room 2113, 3460 Fifth Ave., Pittsburgh, PA 15213, USA.

In the current study our objective was to develop a murine model of human hyper-IgD syndrome (HIDS) and severe mevalonic aciduria (MA), autoinflammatory disorders associated with mevalonate kinase deficiency (MKD). Deletion of one Mvk allele (Mvk (+/-)) yielded viable mice with significantly reduced liver Mvk enzyme activity; multiple matings failed to produce Mvk (-/-) mice. Cholesterol levels in tissues and blood, and isoprene end-products (ubiquinone, dolichol) in tissues were normal in Mvk (+/-) mice; conversely, mevalonate concentrations were increased in spleen, heart, and kidney yet normal in brain and liver. While the trend was for higher IgA levels in Mvk (+/-) sera, IgD levels were significantly increased (9-12-fold) in comparison to Mvk (+/+) littermates, in both young (<15 weeks) and older (>15 weeks) mice. Mvk (+/-) animals manifested increased serum TNF-alpha as compared to wild-type littermates, but due to wide variation in levels between individual Mvk (+/-) mice the difference in means was not statistically significant. Mvk (+/-) mice represent the first animal model of HIDS, and should prove useful for examining pathophysiology associated with this disorder.

Common MEFV mutation analysis in Iranian Azeri Turkish patients with familial Mediterranean fever.

Esmaeili M(1), Bonyadi M, Rafeey M, Sakha K, Somi MH.

Author information:

(1)Molecular-Genetic Lab, Animal Biology Department, Faculty of Natural Sciences, University of Tabriz, Tabriz, Iran.

**OBJECTIVES:** To identify the frequency and distribution of familial Mediterranean fever (FMF) gene (MEFV) mutations among Azeri Turkish patients from northwestern Iran.

**METHODS:** One hundred ninety unrelated patients were referred by specialists to the Molecular-Medical Genetic Center of Tabriz. A clinical diagnosis of FMF was made according to published criteria. Mutation screening of the MEFV gene was performed for the 5 most commonly known mutations, namely M694V, V726A, M680I, M694I, and E148Q, by using amplification refractory mutation system for the first 4 and by polymerase chain reaction restriction-digestion testing for E148Q. These methods may also be used as a screening tool within affected families.

**RESULTS:** Of the unrelated patients investigated, 120 (63%) had 1 or 2 mutations. Of those with mutations, 41 were homozygous, 37 were compound heterozygous, and 42 had only 1 identifiable mutation. Of the studied alleles, the most frequent mutation was M694V (28%), followed by V726A (9%), E148Q (7%), M680I (7%), and M694I (1%) mutations.

**CONCLUSIONS:** Our results indicate that the common Mediterranean mutations are frequent in the Azeri Turkish FMF patients but with some differences in the frequency of individual mutations. The high frequency of E148Q in Azeri Turks compared with Mediterranean ethnic groups is rather interesting. The results open the way for further investigations on patients diagnosed as having FMF and in whom no mutations or only 1 mutated allele were found.

(1)Heller Institute of Medical Research, Sheba Medical Center, Tel-Hashomer,

Israel.

Familial Mediterranean fever (FMF) is a febrile disease characterized by acute, spontaneously resolving episodes of fever and pain caused by serosal inflammation and associated with mutations in the FMF gene, MEFV. Prophylaxis is maintained with colchicine. To our knowledge, no study has yet shown an association between FMF and cirrhosis of the liver. We conducted the current study to describe cryptogenic cirrhosis in FMF and to examine the possible relationship between the 2 entities. Patients with chronic liver disease were retrospectively identified through a computer search of a registry of 6000 patients with FMF followed in the clinics of the National Center for FMF. Data pertaining to FMF phenotype and genotype and characteristics of the liver disease were abstracted from patients' charts. Cryptogenic cause of cirrhosis was determined by exclusion of known causes of liver disease. Nine patients with cryptogenic cirrhosis were identified, comprising 0.15% of the FMF patient population, a rate significantly higher than the rate of 0.015% of cirrhosis of all types expected in the total population of Israel ( $p < 0.000$ ). Most patients had typical FMF, with a normal severity score distribution. The mean daily dose of colchicine was  $1.4 \pm 0.4$  mg, not different from the usual dose. All 7 patients who underwent mutation analysis had 2 mutations. Five of them were homozygous for M694V. Child-Pugh classification was determined in 6 patients at the time of cirrhosis diagnosis, and was classified as A in 4 of them. These findings suggest that MEFV may serve as a modifier gene in cryptogenic cirrhosis. Genetic analysis in patients with cryptogenic cirrhosis unrelated to FMF, particularly patients of a Mediterranean origin, may be warranted in future studies.

A very frequent mutation and remarkable association of R761H with M694V mutations in Turkish familial Mediterranean fever patients.

Demirkaya E(1), Tunca Y, Gok F, Ozen S, Gul D.

Author information:

(1)Department of Pediatrics, Gülhane Military Medical Academy, Etlik, Ankara,

Familial Mediterranean fever (FMF) is an autosomal-recessive disease. It is characterized by recurring fever, abdominal pain, and serositis. The Mediterranean fever (MEFV) gene is localized on 16p13.3 and more than 35 mutations have been described to date. There are some differences in the gene mutations of FMF in the various ethnic groups. The aim of this study is to determine the frequency of the mutations which has been reported comparatively rare, to define the most effective mutation set, and to select the most suitable DNA analysis system for Turkish FMF patients. Mutations in 330 Turkish FMF patients with typical phenotypes from various regions of Turkey were evaluated for the research purposes. These patients were analyzed for six MEFV gene mutations by the NanoChip Molecular Genetics Workstation. The most frequent mutation was M694V, identified in 50.00% of the alleles examined; M680I followed with 14.10% and V726A--9.70%. Consequently, we determined that R761H (n = 23; 3.48%) was the most frequent rare mutations in Turkish FMF patients. Frequency of the rare mutations were R761H (3.48%), E148Q (1.36%), and M694I (1.21%). All of these mutations were in the compound heterozygote state. Our study showed that R761H mutations were higher than it has been reported in literature until now and were mainly associated with M694V. We suggest that mutation R761H should be included in the mutation scanning analysis researches or considered if the patient has M694V/? mutation especially in Turkish FMF patients. Larger serial studies need to be done to investigate the rate and coexistence of these mutations.

**OBJECTIVES:** To present an analysis of patients with protracted febrile myalgia (PFM), a rarely reported manifestation of familial Mediterranean fever (FMF), and propose clinical criteria for working diagnosis.

**METHODS:** A multicenter retrospective cohort study of children with PFM was performed. Clinical and laboratory data were obtained by medical record review.

**RESULTS:** The study group included 15 patients with PFM. PFM occurred as the presenting sign of FMF in 33%. FMF was diagnosed clinically in all and by genetic analysis in 93%. M694V allelic involvement was noted in 93% of the patients. PFM occurred at a mean age of 9 +/- 3.4 years and was characterized by severe generalized muscle pain in all patients and fever in 71%. Mean duration up to diagnosis was 15.5 +/- 6 days. Mean erythrocyte sedimentation rate was 104 +/- 26 mm/h; mean C-reactive protein was 15.4 +/- 6.3 mg%. Creatine kinase was normal. Treatment included corticosteroids (4 patients) and nonsteroidal anti-inflammatory drugs (NSAIDs) (9 patients) with a symptomatic relief achieved at a mean of 7.7 +/- 4.3 days and 5 +/- 3.8 days, respectively ( $p = 0.14$ ) (mean severity score 3 and 2.2, respectively,  $p = 0.075$ ). Symptomatic relief in 2 untreated patients was achieved at a mean of 45.5 days.

**CONCLUSION:** Based on our data, we propose criteria for working diagnosis including: severe disabling myalgia of at least 5 days in a young patient with FMF, associated with fever, elevated levels of inflammatory markers and presence of at least one M694V mutation.

Clin Exp Rheumatol. 2008 Jul-Aug;26(4 Suppl 50):S128-9; author reply S129.

**OBJECTIVE:** Familial Mediterranean Fever (FMF) and TNF-Receptor Associated Periodic Syndrome (TRAPS) are two inheritable inflammatory disorders. They share some clinical manifestations but their treatments are different. We present here the case of an overlap syndrome of FMF and TRAPS in a patient carrying a mutation in both the MEFV and TNFRSF1A genes.

**CASE REPORT:** A 20-year-old woman of Mediterranean origin had suffered since childhood from attacks of fever and arthritis, with skin and ophthalmic manifestations. The initial diagnosis was FMF. The symptoms responded poorly to colchicine but regressed with steroids. Genetic analysis revealed a homozygous M694V mutation in MEFV and a heterozygous R92Q mutation in TNFRSF1A. We discuss the complexity of this combined FMF-TRAPS phenotype.

**CONCLUSION:** This case shows that mutations in MEFV and TNFRSF1A can occur together in a single patient, a condition that may modify its response to treatment. It would be interesting to evaluate the role of the R92Q mutation in TNFRSF1A in patients of Mediterranean origin with FMF unresponsive to colchicine.

mesutonat@yahoo.com

**OBJECTIVE:** Familial Mediterranean fever (FMF) is the most common auto-inflammatory syndrome with exaggerated acute phase and inflammatory response. After revealing the MEFV gene mutation with the finally disturbed end product pyrin, some of the mechanisms were explained. However it is still unknown what triggers or ends these periodical attacks. Moreover, the treatment of up to 30% of the patients, that are resistant to colchicine is still a problem. In this study we investigated the role of serotonin in colchicine-resistant FMF patients.

**METHODS:** Twenty-four FMF patients (male/female: 15/9) and 32 age- and sex-matched healthy controls (male/female: 17/15) were included into the study. Patients were subdivided into two groups. Thirteen had FMF attacks despite regular colchicine (colchicine-resistant group), other 11 had disease under control with colchicine for at least 6-months. Sampling was done both during the attack and ten days after its cessation. Plasma and platelet serotonin levels and acute phase reactants were studied in patients and controls.

**RESULTS:** Colchicine-resistant patients had plasma serotonin (5-HT) levels of  $7.85 \pm 1.0$  nmol/l during acute attacks which significantly reduced to the levels of  $6.3 \pm 0.6$  nmol/l ( $p < 0.001$ ), after 10 days of acute attacks and these levels were significantly lower than those of attack-free patients' and controls' ( $10.7 \pm 0.2$  nmol/l and  $10.1 \pm 0.3$  nmol/l, respectively). Platelet 5-HT level was  $6.4 \pm 0.3$  nmol/10(9) platelets during acute attack, and this level was increased to  $9.8 \pm 0.5$  nmol/10(9) platelets on the 2(nd) sampling, 10 days after the cessation of the acute attack ( $p < 0.001$ ). They were both significantly higher than those of attack-free FMF patients ( $5.9 \pm 0.1$  nmol/10(9) platelets) and healthy controls ( $5.7 \pm 0.3$  nmol/10(9) platelets). There was a negative correlation between plasma and platelet 5-HT levels ( $r = -0.77$ ,  $p < 0.001$ ).

**CONCLUSION:** Changes in plasma and platelet 5-HT levels may be related to the disturbances in 5-HT transport mechanisms or may also be attributed to the potential role of serotonin in the inflammatory cascade. Last but not least, serotonin may have a role in the pathogenesis of FMF.

Author information:

(1)Servicio de Medicina Interna, Hospital Universitario La Paz, Madrid, Spain.  
mirestmun@gmail.com

Familial mediterranean fever (FMF) is a disease whose importance in recent years is reappearing thanks to the advances in molecular genetics. The diagnosis is established by symptoms, presence of inflammatory episodes of fever and serositis, family background and genetic study. Identification of the most prevalent mutations of the MEFV gene may confirm atypical or incomplete forms of FMS that are difficult to recognize based on the classical major and minor criteria. Knowledge of this more extensive clinical spectrum makes it possible to have a new diagnostic and therapeutic perspective based on the treatment of colchicine and secondary prevention of AA amyloidosis.

Periodic fever syndromes: a diagnostic challenge for the allergist.

Lierl M(1).

Author information:

(1)Cincinnati Children's Hospital Medical Center - Allergy and Immunology,  
Cincinnati, OH 41017, USA.

The objective was to present a case of periodic fever with aphthous stomatitis, pharyngitis and cervical adenitis (PFAPA), summarize the medical literature on PFAPA, review the differential diagnosis and suggest a diagnostic approach to periodic fevers in children. A PubMed search was conducted for all case reports and series of patients with PFAPA. The references of these papers yielded further case reports. Review articles or large case series were used for sources of information regarding the other periodic fever and autoinflammatory syndromes. All cases reported as PFAPA were included in the review, even though a few of the cases may not have been accurately diagnosed. The periodic fever and autoinflammatory syndromes of childhood are a group of diseases that cause repeated febrile illnesses with various associated symptoms. Except for PFAPA, each of these diseases is caused by a known genetic mutation. Effective treatment options and long-term prognosis varies among these syndromes. Children with periodic fever or autoinflammatory syndromes sometimes present to an Allergy/Immunology clinic for immunologic evaluation. It is important for the Allergy/Immunology specialist to be familiar with the clinical presentation, diagnostic approach and treatment of these conditions.

Regulation of IL-17 production in human lymphocytes.

Chen Z(1), O'Shea JJ.

Author information:

(1)Molecular Immunology and Inflammation Branch, National Institutes of Arthritis, and Musculoskeletal and Skin Diseases, National Institutes of Health, Bethesda, MD, USA. zchen@utu.fi

The discovery of a new lineage of helper T cells that selectively produces interleukin (IL)-17 has provided exciting new insights into immunoregulation, host defense and the pathogenesis of autoimmune diseases. Although the factors that promote murine Th17 differentiation have been intensively examined, there has been much less information on the regulation of this cytokine in human T cells. IL-17 is readily produced by human memory T cells, which we now know exhibit distinct patterns of chemokine receptor expression and may differentiate in response to selective pathogens. Recently it has been shown that IL-1, IL-6 and IL-23 are important in driving human Th17 differentiation. However, TGFbeta-1 which is important for the differentiation of murine Th17 cells and inducible regulatory T cells (iTregs), is reportedly not required and even inhibits for human Th17 differentiation. In addition, human Th17 cells also produce other proinflammatory cytokines. Further characterization of the transcription regulation of human IL-17 expression, and the epigenetic regulation of human IL17 locus should improve our understanding the lineage commitment of human Th17 cells. Targeting the production and action of this cytokine is also likely to be beneficial therapeutically for autoinflammatory and autoimmune diseases.

Regulation of interferon-gamma during innate and adaptive immune responses.

Schoenborn JR(1), Wilson CB.

Author information:

(1)Molecular and Cellular Biology Graduate Program, University of Washington, Seattle, Washington, USA.

Interferon-gamma (IFN-gamma) is crucial for immunity against intracellular pathogens and for tumor control. However, aberrant IFN-gamma expression has been

associated with a number of autoinflammatory and autoimmune diseases. This cytokine is produced predominantly by natural killer (NK) and natural killer T (NKT) cells as part of the innate immune response, and by Th1 CD4 and CD8 cytotoxic T lymphocyte (CTL) effector T cells once antigen-specific immunity develops. Herein, we briefly review the functions of IFN-gamma, the cells that produce it, the cell extrinsic signals that induce its production and influence the differentiation of naïve T cells into IFN-gamma-producing effector T cells, and the signaling pathways and transcription factors that facilitate, induce, or repress production of this cytokine. We then review and discuss recent insights regarding the molecular regulation of IFN-gamma, focusing on work that has led to the identification and characterization of distal regulatory elements and epigenetic modifications with the IFN-gamma locus (*Ifng*) that govern its expression. The epigenetic modifications and three-dimensional structure of the *Ifng* locus in naïve CD4 T cells, and the modifications they undergo as these cells differentiate into effector T cells, suggest a model whereby the chromatin architecture of *Ifng* is poised to facilitate either rapid opening or silencing during Th1 or Th2 differentiation, respectively.

Transport proteins PotD and Crr of *Escherichia coli*, novel fusion partners for heterologous protein expression.

Han KY(1), Seo HS, Song JA, Ahn KY, Park JS, Lee J.

Author information:

(1)Department of Chemical and Biological Engineering, Korea University, Anam-Dong 5-1, Sungbuk-Ku, Seoul 136-713, South Korea.

The *Escherichia coli* proteome response to the stressor GdnHCl was analyzed through 2-dimensional gel electrophoresis (2-DE). We identified PotD (spermidine/putrescine-binding periplasmic protein) and Crr [glucose-specific phosphotransferase (PTS) enzyme IIA component] as a stress-responsive protein. Even under a stress situation where the total number of soluble proteins decreased by about 10%, 3.5- and 2.2-fold increase was observed in the synthesis

of PotD and Crr, respectively. As fusion partners, PotD and Crr dramatically increased the solubility of many aggregation-prone heterologous proteins [e.g. human minipro-insulin (mp-INS), human epidermal growth factor (EGF), human prepro-ghrelin (ppGRN), human interleukin-2(hIL-2), human activation induced cytidine deaminase (AID), human glutamate decarboxylase (GAD(448-585)), *Pseudomonas putida* cutinase (CUT), human ferritin light chain (hFTN-L), human granulocyte colony-stimulating factor (G-CSF), and cold autoinflammatory syndrome1 protein (NALP3) Nacht domain (NACHT)] in the *E. coli* cytoplasm. Presumably PotD and Crr were very effective in shielding interactive surfaces of heterologous proteins associated with non-specific protein-protein interactions leading to the formation of inclusion bodies most likely due to intrinsic high folding efficiency, chaperone-like activity, or a combination of both factors. Both the stress-induced proteins were well suited for the production of a biologically active fusion mutant of *P. putida* cutinase that can be expected to be of biotechnological and commercial interest.

Cytokines affect nearly every biological process; these include embryonic development, disease pathogenesis, non-specific response to infection, specific response to antigen, changes in cognitive functions and progression of the degenerative processes of aging. In addition, cytokines are part of stem cell differentiation, vaccine efficacy and allograft rejection. This short insight focuses on the milestones in cytokine biology and how the various and often contradictory activities of these small, non-structural proteins affected the fields of inflammation and immunology. Multiple biological properties or pleiotropism is the hallmark of a cytokine. Today, the term "cytokine" encompasses interferons, the interleukins, the chemokine family, mesenchymal growth factors, the tumor necrosis factor family and adipokines. As of this writing, 33 cytokines are called interleukins, but many are part of families of related but distinct gene products. There are certainly over 100 separate genes coding for cytokine-like activities, many with overlapping functions and many still unexplored. Also discussed in this overview are the failures and successes of cytokines as therapeutic targets. A recent advance in the field has been that of differential cytokine production, which can be used to classify human disease as being "autoimmune" or "autoinflammatory" thus impacting on therapeutic interventions.

Familial Mediterranean fever (FMF) is a hereditary syndrome characterized by recurrent episodes of fever and serositis. In this report, we describe a Japanese patient with FMF and Sjögren's syndrome, in whom acute elevations of transaminase occurred. The histological findings from the liver biopsy specimens demonstrated a nonspecific hepatitis, with liver cell necrosis and interlobular inflammatory cell invasion, without the presence of interface hepatitis or bile duct injury. This case underscores the possibility that MEFV mutations contribute to hepatic inflammation, as seen in this case, by way of an alteration of the pyrin function.

**BACKGROUND:** Nailfold video-capillaroscopy (VCP) is nowadays worldwide considered as one of the best diagnostic noninvasive imaging technique able to study microcirculation in vivo.

**AIM:** To review the applications of VCP in the clinical practice and its results in rheumatic and non-rheumatic diseases.

**METHODS:** Review of literature

**RESULTS:** The possibility of managing the imaging, by means of dedicated software able to characterize quantitative and qualitative data, represents another relevant property of VCP. This technique is very useful at the identification of microvascular involvement in many rheumatic diseases, particularly in systemic sclerosis and related disorders. At the same time, VCP has been showed valuable in many other extra-rheumatic diseases. The authors review the applications of VCP in the clinical practice and its results in rheumatic and non-rheumatic

diseases.

jjaroste@clinic.ub.es

**OBJECTIVE:** Blau syndrome and early-onset sarcoidosis are NOD2 gene-associated chronic autoinflammatory diseases characterized by skin rash, arthritis, and/or eye involvement, with noncaseating granulomata as their pathologic hallmark. This study was undertaken to describe the expanded clinical phenotype, treatment outcomes, and NOD2 gene mutation analysis in a Spanish cohort with pediatric granulomatous arthritis, a chronic disease resembling Blau syndrome/early-onset sarcoidosis.

**METHODS:** Clinical, laboratory, and treatment data on the 12 patients in the cohort were obtained through direct interviews. NOD2 gene analysis was performed in a central laboratory, by bidirectional sequencing. Cytokine levels were measured using the human Flex-Set cytokine bead array.

**RESULTS:** The classic Blau syndrome/early-onset sarcoidosis triad of skin rash, arthritis, and recurrent uveitis was identified in 5 patients (41.7%), whereas 7 patients (58.3%) presented with fewer than 3 of the classic features. Novel atypical manifestations such as persistent fever and myocardopathy were also observed. NOD2 analysis revealed 1 heterozygous mutation in each patient, and familial studies confirmed its full penetrance. Of the 12 cases, 58.3% were sporadic, due to de novo mutations. Four different missense mutations on exon 4 were detected. Two of them (R334W and R334Q) were recurrent mutations and were found in 77.8% of the Spanish families, whereas the other 2 (C495Y and R587C)

were novel. In the patient who received anakinra treatment, all clinical inflammatory symptoms improved and plasma cytokine levels normalized.  
CONCLUSION: These findings indicate that the expanding clinical heterogeneity of the disease (that is, the presentation of incomplete forms of the classic triad and atypical manifestations) and the high prevalence of sporadic cases should alert clinicians to the possible genetic basis of the condition and support the inclusion of DNA analysis as a diagnostic test. The positive response to anakinra observed in 1 patient suggests a new potential therapeutic approach that merits further investigation, and suggests that the pathogenesis of pediatric granulomatous arthritis may involve interleukin-1-mediated events.

**OBJECTIVE:** To address whether or not the rarity of amyloidosis in Greek patients with rheumatoid arthritis (RA) is related to specific alleles of single nucleotide polymorphisms (SNPs) in the 5'-flanking region and the exon 3 of the SAA1 gene.

**METHODS:** The genotypes of the -13T/C SNP in the 5'-flanking region of the SAA1 gene and the two SNPs within exon 3 of SAA1 (2995C/T and 3010C/T polymorphisms) were determined in 88 Greek patients with RA, 14 patients with familial Mediterranean fever (FMF) and 110 healthy controls. Linkage disequilibrium and haplotype frequencies involving -13T/C, 2995C/T and 3010C/T in these populations were tested and estimated, respectively.

**RESULTS:** The genotypic distribution and allelic frequencies were similar in all groups tested. SNPs 2995 and 3010 were in linkage disequilibrium for all study populations ( $p < 0.05$ ), whereas SNP -13 was not in linkage disequilibrium with either 2995 or 3010 ( $p > \text{or} = 0.05$ ). Two major haplotypes presented in all patients with RA and FMF and controls: -13C; 2995T; 3010C (-13C; alpha) and -13C; 2995C; 3010T (-13C; beta). The -13T allele was linked with the gamma haplotype in Greek patients with RA and controls. The frequency of the -13T allele was found to be very rare in all groups tested.

**CONCLUSIONS:** In conclusion, the rarity of the putative amyloidogenic -13T allele in Greek populations may be related to low prevalence of AA amyloidosis development in Greek RA patients.

Oxidative DNA damage in polymorphonuclear leukocytes of patients with familial Mediterranean fever.

Kirkali G(1), Tunca M, Genc S, Jaruga P, Dizdaroglu M.

Author information:

(1)Chemical Science and Technology Laboratory, National Institute of Standards and Technology, Gaithersburg, MD 20899, USA. gkirkali@gmail.com

Familial Mediterranean fever (FMF) is an autosomal recessively inherited disorder characterized by recurrent, inflammatory self-limited episodes of fever and other symptoms. This disease is caused by more than 25 mutations in the gene MEFV. During fever attacks, there is a substantial influx of polymorphonuclear leukocytes into the affected tissues. Attack-free periods are accompanied by the up-regulation of neutrophil and monocyte phagocytic activity and oxidative burst. These facts led us to hypothesize that oxidative damage by free radicals to DNA may accumulate in FMF patients. To test this hypothesis, we investigated oxidative DNA damage in polymorphonuclear leukocytes of FMF patients during the attack-free period in comparison with FMF-free control individuals. DNA was isolated from polymorphonuclear leukocytes of 17 FMF patients and 10 control individuals. DNA samples were analyzed by liquid chromatography/mass spectrometry and gas chromatography/mass spectrometry to measure the levels of various typical oxidatively induced products of DNA. We show, for the first time, that FMF patients accumulate statistically significant levels of these lesions in their DNA when compared to FMF-free control individuals. This work suggests that the persistent oxidative stress with excess production of free radicals in FMF patients may lead to accumulation of oxidative DNA damage. Defective DNA repair may also contribute to this phenomenon, perhaps due to mutations in the MEFV gene. The accumulation of mutagenic and cytotoxic DNA lesions may contribute to increased mutations and apoptosis in FMF patients, thus to worsening of the disease and well-being of the patients. Future research should deal with

prevention of oxidative DNA damage and apoptosis in FMF patients, and also the elucidation of a possible role of DNA repair in this disease.

The molecular mechanism by which mutations in the cytoskeleton-organizing protein PSTPIP1 cause the autoinflammatory PAPA syndrome is still elusive. Here, we demonstrate that PSTPIP1 requires the familial Mediterranean fever protein pyrin to assemble the ASC pyroptosome, a molecular platform that recruits and activates caspase-1. We provide evidence that pyrin is a cytosolic receptor for PSTPIP1. Pyrin exists as a homotrimer in an autoinhibited state due to intramolecular interactions between its pyrin domain (PYD) and B-box. Ligation by PSTPIP1, which is also a homotrimer, activates pyrin by unmasking its PYD, thereby allowing it to interact with ASC and facilitate ASC oligomerization into an active ASC pyroptosome. Because of their high binding affinity to pyrin's B-box, PAPA-associated PSTPIP1 mutants were found to be more effective than WT PSTPIP1 in inducing pyrin activation. Therefore, constitutive ligation and activation of pyrin by mutant PSTPIP1 proteins explain the autoinflammatory phenotype seen in PAPA syndrome.

Relationship between periodontal findings and specific polymorphisms of interleukin-1alpha and -1beta in Turkish patients with Behçet's disease.

Akman A(1), Ekinci NC, Kacaroglu H, Yavuzer U, Alpsoy E, Yegin O.

Author information:

Genetic factors predispose individuals to Behçet's disease (BD) and periodontal disease. IL-1 has been implicated in the pathogenesis of both BD and periodontal disease. The relationship between periodontitis and pathogenesis of BD has not yet been determined. Since IL-1 has been implicated in the pathogenesis of both BD and periodontal disease, we aimed to investigate the possible relation of the periodontal scores and SNPs of IL-1alpha-889C/T, IL-1beta-511C/T, and IL-1beta+3962T/C with BD compared to healthy controls (HC) and recurrent aphtous stomatitis (RAS). A total of 155 Turkish individuals were enrolled in this study. The periodontal status of all subjects was evaluated according to the WHO community periodontal index of treatment needs. For genotyping, CTS-PCR-SSP was employed. IL-1alpha-889C allele was significantly higher in BD patients ( $p = 0.03$ ) and RAS ( $p = 0.02$ ) compared to HC. The frequency of IL-1beta+3962T allele was significantly higher in RAS patients compared to HC ( $p = 0.015$ ). Male gender ( $p = 0.04$ ), age ( $p = 0.02$ ) and carrying IL-1beta-511T allele ( $p = 0.01$ ) were found to be a significant risk factors for higher periodontal scores in Turkish population. We can speculate that susceptibility to the development of periodontal disease could be influenced by IL-1 SNPs. Periodontitis-induced autoinflammatory response also may play a role in the development/severity of BD and RAS via IL-1 gene alteration.

Familial Mediterranean fever (FMF), the most frequent of the periodic fever syndromes, is an autosomal recessive disease, predominantly affecting people of Mediterranean descent. The disease is caused by mutations in the MEFV gene, encoding the pyrin protein thought to be associated with the interleukin-1 related inflammation cascade. The condition manifests as attacks of serositis, commonly involving the abdomen, chest or joints, typically accompanied by fever and elevated acute phase reactants. Attacks subside spontaneously within one to three days, without residue. Continuous treatment with colchicine, at a daily dose of 1 to 2 mg, reduces attack frequency, duration and intensity in the majority of patients, and also prevents the development of secondary amyloidosis, the most dreaded complication of the disease. In this communication we review the current state of the art in the diagnosis and care of FMF patients, starting with the presentation of a typical case.

Hereditary recurrent fevers are rare genetic diseases characterized by apparently spontaneous attacks of inflammation. They include familial Mediterranean fever (FMF); tumor necrosis factor (TNF) receptor periodic syndrome (TRAPS); hyperimmunoglobulinemia D syndrome (HIDS); and hereditary periodic fevers related to mutations in the CIAS1 (cold induced autoinflammatory syndrome 1) gene, such as Muckle-Wells syndrome, familial cold urticaria, and CINCA/NOMID (chronic infantile neurological cutaneous and articular/neonatal-onset multisystemic inflammatory disease). Musculoskeletal manifestations are common. They may occur as features of the acute inflammatory attacks or persist for longer periods. Among them, the most common include arthritis of the large and medium-sized joints in FMF and CINCA, arthralgia in HIDS, and myalgia or pseudo-fasciitis in TRAPS. The outcome is usually favorable, although joint destruction may develop in CINCA or at the hip in FMF. The recurrent bouts of fever and accompanying clinical manifestations suggest the diagnosis, which can be confirmed by genetic testing. Among differential diagnoses, infection should be considered routinely. The treatment of the inflammatory attacks is nonspecific. New pathophysiological insights have led to the development of promising maintenance treatments designed to reduce the number and severity of the inflammatory attacks and to diminish the risk of secondary amyloidosis.

Cutting edge: Modulation of intestinal autoimmunity and IL-2 signaling by sphingosine kinase 2 independent of sphingosine 1-phosphate.

Author information:

(1)Inflammation, Autoimmunity, and Transplantation Research, Roche Palo Alto, Palo Alto, CA 94304, USA.

Sphingosine kinase (Sphk) phosphorylates sphingosine into sphingosine-1-phosphate (S1P), but its recently identified isoform Sphk2 has been suggested to have

distinct subcellular localization and substrate specificity. We demonstrate here that, surprisingly, Sphk2(-/-) CD4(+) T cells exhibit a hyperactivated phenotype with significantly enhanced proliferation and cytokine secretion in response to IL-2 as well as reduced sensitivity to regulatory T cell-mediated suppression in vitro, apparently independent of effects upon S1P. Such findings appear to reflect a requirement for Sphk2 to suppress IL-2 signaling because, in Sphk2(-/-) CD4(+) T cells, IL-2 induced abnormally accentuated STAT5 phosphorylation and small interfering RNA knockdown of STAT5 abrogated their hyperactive phenotype. This pathway physiologically modulates autoinflammatory responses, because Sphk2(-/-) T cells induced more rapid and robust inflammatory bowel disease in scid recipients. Thus, Sphk2 regulates IL-2 pathways in T cells, and the modulation of Sphk2 activity may be of therapeutic utility in inflammatory and/or infectious diseases.

yshinar@sheba.health.gov.il

**OBJECTIVES:** To determine the spectrum of mutations in the Mediterranean fever gene (MEFV) of Iranian Jews with familial Mediterranean fever (FMF) and to analyse their clinical manifestations.

**METHODS:** FMF patients with both parents of Iranian-Jewish (IJ) extraction or with one IJ parent (IJ-other, 10 of each) were characterized for clinical manifestations, and the B30.2 (PRYSPRY) domain of their MEFV was sequenced for mutations.

**RESULTS:** Only one rare mutation, R653H, and one new mutation, G632S were present in the IJ group (in 2/10 patients), whereas the new, and common mutations were present in the IJ-other patients (8/10 patients). The new mutation was traced

thrice to an IJ ancestor, and although carried asymptotically by family members, it was over-represented in the patients (3/28 unrelated IJ alleles) compared non-affected IJ subjects (1/126 alleles,  $P = 0.03$ ) or with non-Jewish Iranians (0/108 alleles,  $P = 0.001$ ). The mutation was associated with a distinct phenotype regarding sites involved in the attack ( $P = 0.001$ ), mild severity, sole expression of febrile episodes ( $P = 0.01$ ) and a male bias ( $P = 0.01$ ). In two 3D PRYSPRY models the G632S mutation was localized to a surface loop and close to a putative binding site.

CONCLUSIONS: Iranian Jews with FMF have a unique spectrum of mutations including a newly described mutation with a non-typical phenotype.

Human autoinflammatory diseases (except for PFAPA) are a heterogeneous group of genetically determined diseases characterized by seemingly unprovoked inflammation in the absence of autoimmune or infective causes (Table 2). The last decade has witnessed tremendous advances in the understanding of these disorders. These advances have allowed therapeutic interventions resulting in improvement in the short-term and long-term morbidity of all of these diseases. Future research into the molecular mechanisms underlying these inflammatory diseases should lead to a better understanding of inflammatory diseases in general and, it is hoped, to better and more targeted therapies.

Deaths from intravenous colchicine resulting from a compounding pharmacy error--Oregon and Washington, 2007.

Centers for Disease Control and Prevention (CDC).

Colchicine for injection has been available in the United States since the 1950s. Although not approved by the Food and Drug Administration (FDA), intravenous (IV) colchicine has been an accepted treatment for acute gout symptoms. Several additional IV uses have been studied, including treatment of familial Mediterranean fever, pericarditis, primary biliary cirrhosis, amyloidosis, and

Behçet's syndrome. More recently, outpatient use of IV administration for chronic back pain has been advocated by alternative medicine providers but is not an accepted practice. Colchicine has well-known toxicities that limit its safe therapeutic use. IV doses that exceed the standard single-use therapeutic dose of 2--4 mg per episode of gout have resulted in life-threatening toxicity. In March 2007, two persons from Washington and Oregon died after receiving IV colchicine for back pain from an alternative medicine clinic in Oregon. This report describes the investigation, which determined that a measuring error by a Texas compounding pharmacy resulted in a fatal colchicine concentration that was eight times greater than the recognized standard level. A subsequent review of medical records revealed that a third death from colchicine toxicity in a patient treated at the Oregon clinic also occurred in March and likely was associated with the same compounding error. These deaths highlight the potential risk from use of IV colchicine for back pain and the possibly fatal consequences of measuring errors in compounding pharmacy products.

Cryopyrin-associated periodic syndromes and autoinflammation.

Shinkai K(1), McCalmont TH, Leslie KS.

Author information:

(1)Department of Dermatology, University of California, San Francisco, CA, USA.

Autoinflammatory syndromes are a distinct class of inherited diseases of cytokine dysregulation with important cutaneous features. Several disorders, including familial cold autoinflammatory syndrome (FCAS), Muckle-Wells syndrome and neonatal onset multisystem inflammatory disorder (NOMID), are associated with mutations in a common gene, CIAS-1. These disorders are now believed to represent related conditions along a spectrum of disease severity, in which FCAS is the mildest and NOMID is the most severe phenotype. Patients typically present with lifelong atypical urticaria with systemic symptoms, with potential for developing end-organ damage due to chronic inflammation. Advances in the understanding of the genetic basis of these syndromes have also revealed cytokine signalling

molecules that are critical to normal regulation of inflammatory pathways. The dramatic response of these syndromes to anakinra, an interleukin (IL)-1 antagonist, highlights the important role of IL-1 cytokine signalling in the pathogenesis of this rare but fascinating class of diseases.

The evaluation of carotid intima-media thickness in children with familial Mediterranean fever.

Peru H(1), Altun B, Doğan M, Kara F, Elmaci AM, Oran B.

Author information:

(1)Department of Pediatric Nephrology, Meram Medical Faculty, Selcuk University, 42080 Konya, Turkey. peruharun@yahoo.com

The aim is to investigate whether pediatric familial Mediterranean fever (FMF) patients have an increased risk of premature atherosclerosis and to determine the possible strength of association between atherosclerosis and Mediterranean fever (MEFV) gene mutation gene type. Demographic characteristics and MEFV mutations were defined in 49 children diagnosed with FMF (26 female, 23 male; mean age, 10.71 +/- 3.69 years). Twenty-six age-, sex-, and body-mass-index-matched healthy children constituted the control group. We evaluated the blood counts and acute-phase proteins during attack-free periods. Mean C-reactive protein (CRP), serum amyloid-A (SAA), homocysteine (Hcy), lipoprotein-a (Lp-a), and common carotid artery intima-media thickness (CCA-IMT) were 10.75 +/- 15.29 vs 4.03 +/- 1.20, 23.22 +/- 41.94 vs 3.53 +/- 1.04, 10.36 +/- 3.36 vs 8.64 +/- 3.15, 20.84 +/- 23.89 vs 8.56 +/- 7.48, and 0.038 +/- 0.007 vs 0.032 +/- 0.004, respectively, and significantly higher than the mean values of control group ( $p < 0.05$ ). However, no correlation was found between CCA-IMT and CRP, SAA, Hcy, and Lp-a. Twenty-nine patients had M694V mutation, and 13 patients had other mutations. There was no correlation between CCA-IMT and MEFV mutation subgroups. In conclusion, because of the nature of the disease, FMF patients should be considered to have an increased risk of early vascular alteration and atherosclerosis. For this reason, CCA-IMT measurement can be recommended as a

noninvasive and early diagnostic method.

The realisation that the production of inflammatory cytokines in inflammatory rheumatic diseases may be induced by non-infectious endogenous signals has encouraged researchers to explore mechanisms of innate immunity and their contribution to the pathogenesis of these diseases. The nucleotide-binding and oligomerisation domain (NOD)-like receptors (NLRs) sense pathogens, products of damaged cells or endogenous metabolites and could potentially be involved in the initiation, amplification and progression of the inflammatory response in rheumatic diseases. NLRs are involved in the regulation of innate immune

responses with some of them promoting the activation of inflammatory caspases within multiprotein complexes, called inflammasomes. A typical inflammasome consists of a sensor, an NLR protein, an adaptor protein such as ASC (for apoptosis-associated speck-like protein containing a caspase recruitment domain (CARD)) and an effector protein that is a caspase that activates pro-inflammatory cytokines such as interleukin (IL)1 $\beta$  and IL18. Recent data suggest a role of the inflammasome in the pathogenesis of autoinflammatory as well as inflammatory rheumatic diseases such as juvenile chronic arthritis, adult onset Still disease, rheumatoid arthritis and gout. Modulation of these pathways may be a potential therapeutic target for inflammatory rheumatic diseases.

Familial Mediterranean fever (FMF) is the most common of a rare group of disorders collectively termed familial hereditary periodic fever syndromes, also known as autoinflammatory syndromes. FMF is clinically characterized by intermittent bouts of fever with peritonitis and abdominal pain, pleuritis, arthritis, or erysipelas-like rashes. Amyloidosis due to chronic inflammation progressing to renal failure is one of the most serious potential complications of this disease. Individuals with FMF have identifiable genetic defects in the Mediterranean fever (MEFV) gene, which codes for the protein pyrin. Pyrin normally blunts neutrophil-mediated inflammation, likely via interleukin-1 (IL-1) downregulation, but is defective in FMF. Potential treatments include colchicine, with case reports of benefits with catecholamine blockade (prazosin), tumor necrosis factor (TNF) antagonism (etanercept, thalidomide), and IL-1 receptor blockade (anakinra).

The notion of autoinflammatory diseases delineates a heterogenous group of genetic pathologies characterized by spontaneous periodic systemic inflammation in the absence of infectious or autoimmune causes. The general hypothesis is that the innate immune response in these patients is wrongly tuned, being either too

sensitive to minor stimuli or turned off too late. Clinical pictures of these disorders are characterized by high spiking fever associated with involvement of musculo-skeletal system, tegumentary apparatus and serosas. Although inflammatory syndromes are considered rare, they may represent a model in order to unravel some aspects of the innate immune system and of the inflammatory cascade.

The therapeutic approach to JIA is sometimes very troublesome and progression to erosive polyarthritis may occur in all JIA categories. Only Methotrexate has shown efficacy and safety in a large controlled trial. Nevertheless, in many cases, drug resistance or intolerance has led to try other therapeutic options, with still debatable results. Therefore, there has been space, in the last few years, for new therapies as the TNF-inhibitors. This therapeutic approach has shown a dramatic clinical benefit in active polyarticular refractory JIA: the rate and rapidity of response have exceeded those of all other studied DMARDs. Preliminary data show that they are efficacious also for other pediatric rheumatic disease (spondyloarthropathies, autoimmune uveitis, dermatomyositis, Kawasaki syndrome and some autoinflammatory diseases). TNF-inhibitors in JIA have demonstrated a favourable benefit-to-risk profile. However, as their use has increased worldwide, some unusual, usually not serious, adverse events have emerged. Severe infections, including TB, and deaths have been reported. Long-lasting active disease, systemic disease, concurrent and previous immunosuppressive therapies, all contribute to risk of infection and other

serious AEs. Given the evidence that TNF has a primary role in the pathogenesis of JIA, particularly in joint destruction, neutralizing this cytokine early, within the window of opportunity, could halt or delay progression of joint damage and debilitating consequences of the disease. Thus, for JIA patients whose disease is not quickly controlled with MTX, TNF blockers may be considered as first-line treatment, although long-term safety data still need to be established.

Comment on

Mol Pharmacol. 2007 Dec;72(6):1447-56.

P2X receptors (P2XR) function as ATP-gated nonselective ion channels permeable to Na<sup>+</sup>, K<sup>+</sup>, and Ca<sup>2+</sup>, and they are expressed in a wide range of excitable, epithelial/endothelial, and immune effector cell types. The channels are trimeric complexes composed of protein subunits encoded by seven different P2XR genes expressed in mammalian and other vertebrate genomes. Current genetic, biochemical, and/or physiological evidence indicates that the extended family of functional P2X receptors includes six homomeric channels composed of P2X1, P2X2, P2X3, P2X4, P2X5, or P2X7 subunits and six heteromeric channels that involve subunit pairings of P2X1/P2X2, P2X1/P2X4, P2X1/P2X5, P2X2/P2X3, P2X2/P2X6, or P2X4/P2X6. Thus, all P2XR subtypes--with the salient exception of P2X7R--have previously been implicated in the assembly of heteromeric ATP-gated ion channels that can comprise unique pharmacological targets in different tissues. The assumed "go-it alone" function of the P2X7R has important implications because

agents that target this particular receptor have been proposed as useful therapeutics in various autoinflammatory diseases or amelioration of inflammatory pain. However, this assumption and the interpretations based on it now require reevaluation in light of a new report in this issue of *Molecular Pharmacology* (p. 1447) that provides convincing biochemical and electrophysiological evidence for the existence of P2X4/P2X7 heteromeric receptors.

Regulatory T cells in the prevention of mucosal inflammatory diseases: patrolling the border.

Lan RY(1), Mackay IR, Gershwin ME.

Author information:

(1)Division of Rheumatology, Allergy and Clinical Immunology, Genome and Biomedical Sciences Facility, University of California at Davis, 451 E. Health Sciences Drive, Suite 6510, Davis, CA 95616, USA.

Regulatory T (Treg) cells are important contributors to the maintenance of immune tolerance in the periphery, and deficiency of Tregs is associated with various immunopathic diseases. Murine models of autoimmune and autoinflammatory disorders have helped to elucidate how Tregs are involved in these diseases. A feature in common between human and mice that lack one or another of the key Treg subsets is the occurrence of mucosal inflammation. The relatively fragile mucosal surface represents a complex system that is normally well equipped to ward off harmful pathogens yet at the same time is inhibitory to destructive inflammatory responses to biologically needed (probiotic) microorganisms, or other common environmental antigens e.g. nutrients. We here discuss the importance of Tregs in maintaining tolerance at mucosal surfaces and the outcomes of deficiency of Treg function. The intestinal tract and its inflammatory diseases provide the "point of departure" for discussion, but similar considerations could apply to other mucosal linings exposed to the environment such as other members of the digestive system. However, the lungs, bile ducts, urogenital tract and other mucosal surfaces are susceptible to poorly understood inflammatory states that possibly

depend on dysfunction of Treg cells. Finally there are now potential therapies predicated on reconstitution of effective function of Treg cells.

From inflammasomes to fevers, crystals and hypertension: how basic research explains inflammatory diseases.

McDermott MF(1), Tschopp J.

Author information:

(1)Leeds Institute of Molecular Medicine, St James's University Hospital, Leeds LS9 7TF, UK.

Pattern-recognition receptors, such as Toll-like receptors and NOD-like receptors (NLRs), are able through the recognition of pathogen-associated molecular patterns and danger-associated molecular patterns to sense microbe-dependent and microbe-independent danger and thereby initiate innate immune responses. In some autoinflammatory conditions, abnormalities in NLR signaling pathways are involved in pathogenesis, as exemplified by NOD2 mutations associated with Crohn's

disease. Some other NLRs are components of the inflammasome, a caspase-1- and prointerleukin-1 $\beta$ -activating complex. Clinical and experimental studies are beginning to reveal the central role of the inflammasome in innate immunity. Here, we focus on monogenic hereditary inflammatory diseases, such as Muckle-Wells syndrome, which are associated with mutations in proteins that modulate the activity of the inflammasome, and on some multifactorial disorders, such as Type 2 diabetes and hypertension.

d.g.mcgonagle@leeds.ac.uk

The nucleotide-binding domain, leucine-rich repeat containing family (NLR) network has provided pivotal genetic and molecular insights into diseases that were hitherto regarded as autoimmune. The NLR-related disorders include rare monogenic autoinflammatory diseases collectively termed cryopyrin-associated periodic syndromes, Crohn's disease which is a common polygenic disease and also an association at the mechanistic level with gout and pseudogout. Unlike the classical autoimmune diseases where disease immunopathogenesis is played out primarily in the primary and secondary lymphoid organs, the immunopathogenesis of the NLR-related disorders is played out in the tissues where inflammation arises. As the genetic mutations or molecular cascades associated with the NLR-related disorders have a widespread cellular distribution, it has been somewhat enigmatic why these disorders attack certain territories, but not others. This implies that tissue-specific factors in the target organs themselves contribute to disease expression. Such examples include the high abundance of NOD2 expressing cells in the part of the gut most typically afflicted by Crohn's disease and the

preferential deposition of crystals in the joints to where inflammation localises in gout and pseudogout. The NLR network is associated principally with increases in TNF or IL-1 production, both of which are key players in innate immunity. Therefore, the NLR network identifies at the genetic and molecular level a robust paradigm for innate immune activation against self. This tissue-specific-factor-associated inflammation is the diametric opposite of classical autoimmunity. Of note, the MHC class-I-associated diseases including psoriasis (HLA-Cw6) and ankylosing spondylitis (HLA-B27) show striking clinical overlaps with Crohn's disease and also some rare monogenic diseases. Thus, the NLR innate immune pathway allows the full spectrum of inflammation against self to be viewed along an immunological disease continuum with autoantibody-associated disease at one end, innate immune diseases at the other and MHC class-I-related disorders as an intermediate.

Diagnostic value of serum immunoglobulinaemia D level in patients with a clinical suspicion of hyper IgD syndrome.

Ammouri W(1), Cuisset L, Rouaghe S, Rolland MO, Delpech M, Grateau G, Ravet N.

Author information:

(1)Department of Internal Medicine, Tenon Hospital, Paris, France.

**OBJECTIVE:** The hyperimmunoglobulinaemia D and periodic fever syndrome (HIDS) was originally defined by the presence of a high serum level of immunoglobulin D associated with recurrent fever. Since the discovery of the mevalonate kinase gene (MVK) gene encoding the mevalonate kinase enzyme, most patients with a clinical diagnostic of HIDS are now found to have a mevalonate kinase deficiency based on metabolic and genetic data. We aimed to assess the value of a high IgD serum level for the diagnosis of HIDS in a cohort of patients with a phenotype of recurrent fever, and to characterize patients with a high IgD serum level without mevalonate kinase mutation.

**METHODS:** Main clinical and biological data of 50 patients who presented with clinical signs compatible with HIDS have been prospectively registered on a

standard form. Clinical data have been analysed according the IgD serum level and the presence of MVK mutation.

**RESULTS:** The metabolic and genetic data establishing the diagnosis of HIDS correlated in all cases. In this series of 50 patients, the sensitivity of a high IgD value for the diagnosis of HIDS is 0.79. In five patients with MVK mutation, IgD levels were found to be in the normal range. Likelihood ratios indicate that IgD measurement is not relevant for the diagnostic of HIDS. Most patients with a high serum IgD level and no MVK mutation have no definite diagnosis.

**CONCLUSION:** The clinical relevance of the IgD measurement for the diagnosis of MKD in our population appears as poor, as reflected by likelihood ratios which are both close to 1.

**OBJECTIVES:** To examine the association of the -173 single-nucleotide G/C polymorphism of the macrophage migration inhibitory factor gene (MIF) and serum macrophage migration inhibitory factor (MIF) concentrations in a group of Italian patients with hereditary periodic fevers (HPF), tested during a symptom-free phase of their disease.

**METHODS:** Genomic DNA for MIF and serum MIF were evaluated in 22 patients with HPF and compared with healthy controls of the same ethnic group. The MIF-173G/C polymorphism was genotyped using polymerase chain reaction (PCR) and visualized by ethidium bromide staining. Serum MIF levels were measured by enzyme-linked immunosorbent assay (ELISA).

**RESULTS:** MIF-173\*C allele frequency and MIF serum concentrations were

significantly higher in patients with HPF than in controls, with no statistically significant difference between familial Mediterranean fever (FMF) and hyperimmunoglobulinaemia D/periodic fever syndrome (HIDS) and no correlation with specific MIF genotypes.

CONCLUSIONS: The MIF-173\*C allele was found more frequently in patients with HPF than in controls and MIF serum concentrations were considerably elevated in attack-free phases, suggesting a persistent state of subclinical cytokine activation with MIF involvement in the autoinflammatory cascade.

jean-michel.dayer@hcuge.ch

The assessment of systemic inflammation by means of laboratory tests often complements the results of medical examination. Traditionally, the erythrocyte sedimentation rate and leukocytosis with left shift are diagnostic markers for inflammatory and infectious diseases. The levels of acute-phase proteins--especially C-reactive protein--are used to assess both the presence of inflammation and any response to treatment. The determination of C-reactive protein levels may be advised in three types of pathological situation: infection, acute or chronic inflammation, and evaluation of metabolic risk. Procalcitonin is useful as a marker of sepsis and severe infection. The concentration of serum amyloid A predicts the chances of survival of patients with secondary (AA) amyloidosis. Ferritin and its glycosylated form are of interest in the study of specific diseases such as adult-onset Still's disease. Markers of cartilage and bone turnover are complementary to these markers of inflammation. Although cytokine serum levels are transiently crucial to the generation of inflammation, their usefulness in the clinic is still under

investigation. Serum concentrations of cytokine inhibitors or soluble cytokine receptors, as well as the clinical response of patients to treatment with cytokine antagonists, might generate important information for monitoring autoinflammatory diseases.

Autoinflammatory bone disorders.

Ferguson PJ(1), El-Shanti HI.

Author information:

(1)Department of Pediatrics, University of Iowa, Iowa City, Iowa 52242, USA.

polly-ferguson@uiowa.edu

**PURPOSE OF REVIEW:** This review provides an update on clinical, genetic, and immunologic aspects of the autoinflammatory bone disorders.

**RECENT FINDINGS:** Chronic noninfectious inflammation of the bone is a clinical feature of both chronic recurrent multifocal osteomyelitis and (to a lesser degree) cherubism. The genes responsible for Majeed syndrome (LPIN2), murine chronic multifocal osteomyelitis (pstpip2), and cherubism (SH3BP2 and possibly PTPN11) have been identified. Murine models of both chronic recurrent multifocal osteomyelitis and cherubism have demonstrated that the bone inflammation is mediated by hematopoietically derived cells and can occur in the absence of a functioning adaptive immune system. As the immunologic defects become better defined, the cells of the myeloid lineage are emerging as the primary players.

**SUMMARY:** Chronic multifocal osteomyelitis and cherubism are hereditary chronic inflammatory disorders in which bone is the primary inflammatory target. Recent genetic and immunologic discoveries demonstrate involvement of the innate immune system, which places these entities in the category of autoinflammatory disorders.

Adjuvant chemotherapy with 5-fluorouracil in a patient with colorectal cancer and Familial Mediterranean Fever.

Purim O(1), Sulkes A, Brenner B.

Author information:

(1)Institute of Oncology, Davidoff Cancer Center, Rabin Medical Center, Petah Tiqwa and Sackler Faculty of Medicine, Tel Aviv University, Tel Aviv, Israel.

Colorectal cancer is a common malignancy often requiring adjuvant chemotherapy. Familial Mediterranean Fever is a chronic hereditary disease which is relatively prevalent in the Middle East and is associated with recurrent episodes of serosal, synovial or cutaneous inflammations. The aim of this paper was to describe a patient with Familial Mediterranean Fever who received fluorouracil-based adjuvant chemotherapy for colorectal cancer. A 56-year-old man with Familial Mediterranean Fever and amyloidosis was referred for evaluation and treatment following surgery for colorectal cancer. In light of his relatively young age, good general state of health and apparently well-controlled Familial Mediterranean Fever, he was treated with chemotherapy consisting of four cycles of 5-fluorouracil and leucovorin. The patient's clinical course during chemotherapy was unremarkable except for one minor attack of Familial Mediterranean Fever. The patient's follow-up was notable for periodic fluctuations in serum carcinoembryonic antigen levels, up to 4-fold of normal. The Familial Mediterranean Fever remained stable. Although our patient showed a good tolerability of treatment, the administration of chemotherapy to patients with Familial Mediterranean Fever raises several concerns. These include a potential deterioration in the Familial Mediterranean Fever status owing to chemotherapy-induced stress, the potential effect of Familial Mediterranean Fever or its treatment on the tolerability of chemotherapy and an overlapping toxicity of the drugs used to treat the two diseases. An increase in serum carcinoembryonic antigen in this setting may be related to the underlying pathophysiologic mechanism of Familial Mediterranean Fever but does not necessarily indicate disease recurrence. Clinicians should be aware of these issues considering the recent worldwide increase in colorectal cancer.

Autoinflammatory syndromes with a dermatological perspective.

Kanazawa N(1), Furukawa F.

Author information:

(1)Department of Dermatology, Wakayama Medical University, Wakayama, Japan.  
nkanazaw@wakayama-med.ac.jp

The term autoinflammatory syndromes describes a distinct group of systemic inflammatory diseases apparently different from infectious, autoimmune, allergic and immunodeficient ones. Originally, it was almost synonymous with clinically defined hereditary periodic fever syndromes, including familial Mediterranean fever, hyper immunoglobulin D syndrome with periodic fever and tumor necrosis factor receptor-associated periodic syndrome. Similar but distinct periodic fever syndromes accompanied by urticarial rash, familial cold autoinflammatory syndrome, Muckle-Wells syndrome and chronic infantile neurological cutaneous articular syndrome, have all been reportedly associated with CIAS1 mutations and are collectively called cryopyrin-associated periodic syndromes. Consequently, the concept of autoinflammatory syndromes has been spread to contain other systemic inflammatory diseases: rare hereditary diseases with or without periodic fevers, such as pyogenic sterile arthritis, pyoderma gangrenosum and acne syndrome, Blau syndrome and chronic recurrent multifocal osteomyelitis, and the more common collagen disease-like diseases, such as Behcet's disease, Crohn's disease, sarcoidosis and psoriatic arthritis. These diseases are all caused by or associated with mutations of genes regulating innate immunity and have common clinical features accompanied with activation of neutrophils and/or monocytes/macrophages. In this review, major autoinflammatory syndromes are summarized and the pathophysiology of related skin disorders is discussed in association with dysregulated innate immune signaling.

J Pediatr. 2008 Aug;153(2):298.

**OBJECTIVE:** We carried out a prospective, randomized, controlled trial to clarify the effect of tonsillectomy on the clinical course of periodic fever, aphthous stomatitis, pharyngitis, and adenitis (PFAPA) syndrome.

**STUDY DESIGN:** Twenty-six consecutive children (mean age 4.1 years) with at least 5 PFAPA attacks were recruited from 3 tertiary care pediatric hospitals during 1999-2003 and randomly allocated to tonsillectomy or follow-up alone. They were all followed up with symptom diaries for 12 months. Tonsillectomy was allowed after 6 months in the control group if the attacks recurred.

**RESULTS:** Six months after randomization all 14 children in the tonsillectomy group and 6/12 children in the control group (50%) were free of symptoms (difference 50%, 95% confidence interval 23% to 75%,  $P < .001$ ). Tonsillectomy was performed on 5/6 of the patients in the control group who still had symptoms after 6 months. The remaining unoperated child in the control group had recurrences of the fever episodes throughout the follow-up, but the symptoms became less severe, and the parents did not choose tonsillectomy.

**CONCLUSION:** Tonsillectomy appeared to be effective for treating PFAPA syndrome. The fever episodes ceased without any intervention in half of the control subjects. We conclude that although the mechanisms behind this syndrome are unknown, tonsillectomy can be offered as an effective intervention for children with PFAPA.

virginie.petrilli@unil.ch

IL-1beta is a cytokine with major roles in inflammation and innate immune responses. IL-1beta is produced as an inactive proform that must be cleaved within the cell to generate biologically active IL-1beta. The enzyme caspase-1 catalyzes the reaction. Recent work showed that caspase-1 must be activated by a complex known as the inflammasome. The inflammasome comprises NALP, which is an intracellular receptor involved in innate immunity, and an ASC adapter that ensures caspase-1 recruitment to the receptor. The most extensively described inflammasome to date is formed by the NALP3 receptor within monocytes. Mutations involving the NALP3 gene cause hereditary periodic fever syndromes in humans. Increased inflammasome activity responsible for uncontrolled IL-1beta production occurs in these syndromes. Inhibition of the IL-1beta pathway by IL-1 receptor antagonist (anakinra) is a highly effective treatment for inherited periodic fever syndromes. A major role for inflammasome activity in the development of gout attacks was established recently. Urate monosodium crystals are specifically detected via the NALP3 inflammasome, which results in marked IL-1beta overproduction and initiation of an inflammatory response. This finding opens up new possibilities for the management of gouty attacks.

Familial Mediterranean Fever in Lebanon: founder effects for different MEFV mutations.

Jalkh N(1), Génin E, Chouery E, Delague V, Medlej-Hashim M, Idrac CA, Mégarbané A, Serre JL.

Author information:

(1)Unité de Génétique Médicale, Faculté de médecine, Université Saint-Joseph, Beirut, Lebanon.

Haplotype analysis of 376 Familial Mediterranean Fever (FMF) patients and 100 controls from Lebanon was performed using 4 microsatellite loci to study founder effects for the five most frequent mutations within the MEFV gene (M694V, M694I, V726A, M680I and E148Q). Each of these mutations was associated with a particular haplotype that was less frequent among controls, confirming that they have probably arisen from unique mutation events and that the carrier chromosomes derived from a common ancestor. The estimated ages of the most recent common ancestor for each of the 5 mutations, using the ESTIAGE program, were 7000, 8500, 15000, 23000 and 30000 years for M694V, M694I, V726A, M680I and E148Q,

respectively. Varying the mutation rate at one of the markers led to younger age estimates, but the mutation E148Q remained the oldest one. Comparison of haplotype distributions among the different Lebanese religious groups confirmed that Muslim sub-populations (Shiites and Sunnites) as well as Christian ones, including Armenians who were formerly settled in the South-Eastern part of Asia Minor (Cilicia), are all derived from an ancient common ancestral population in which most of the MEFV mutations were already present with their respective associated haplotypes.

We describe a 19-year-old male patient with a previous diagnosis of familial Mediterranean fever (FMF), nephrotic syndrome and secondary amyloidosis, who presented with anemia and leukopenia. The bone marrow assessments showed dysplastic precursors including vacuolated myeloid and erythroid precursors and increased proportion of immature cells up to 19%. The patient received erythropoietin and G-CSF for myelodysplastic syndrome (MDS). No response was observed. During his evaluations copper deficiency was detected. One month after oral copper replacement, the peripheral blood counts and bone marrow findings became completely normalized. An evaluation to identify the cause of copper deficiency, revealed intestinal amyloidosis. Based on our experience we recommend serum copper determination in the diagnostic workup of MDS in patients with comorbidities.

Which statin should be used together with colchicine? Clinical experience in three patients with nephrotic syndrome due to AA type amyloidosis.

Sahin G(1), Korkmaz C, Yalcin AU.

Author information:

(1)Division of Nephrology, Eskisehir Osmangazi University Medical Faculty, Eskisehir, Turkey.

Colchicine and statins are well known drugs that cause myopathy and neuropathy. Co-administration of certain drugs with statins may increase myotoxic effect, causing myopathy and varying degrees of rhabdomyolysis. Therefore, it is very

crucial to know which statin should be used during a combination therapy including colchicine and other drugs. We present three cases with AA amyloidosis secondary to familial Mediterranean fever, who developed neuromyopathy while receiving the combination of colchicine and statin. We also briefly discussed the different metabolic pathways of statins and colchicine when used together.

A new family of hereditary immunologic disorders known as the autoinflammatory diseases involves dysregulation of the innate immune system. Elucidation of the genetic basis of these disorders has resulted in improved understanding of the disease pathophysiology of systemic and tissue inflammation, and has also revealed novel nonpathologic innate immune mechanisms. These advances have also resulted in direct improvement in diagnosis and therapy for autoinflammatory disorders such as the cryopyrinopathies and familial Mediterranean fever and have implications for more common inflammatory diseases.

The rate of pyrin mutations in critically ill patients with systemic inflammatory response syndrome and sepsis: a pilot study.

Koc B(1), Oktenli C, Bulucu F, Karadurmus N, Sanisoglu SY, Gul D.

Author information:

(1)Department of Internal Medicine, Gülhane Military Medical Academy, Ankara, Turkey. bkoc@gata.edu.tr

**OBJECTIVE:** The role of individual genetic differences in susceptibility to systemic inflammatory response syndrome (SIRS) and sepsis is generally unrecognized or underestimated. We investigated the rate of pyrin mutations in critically ill patients with SIRS and sepsis, and compared whether carriers for pyrin mutations are associated with respect to the frequency of and certain features of sepsis and SIRS.

**METHODS:** We tested M694V, M680I, V726A, R761H, and M694I mutations in critically ill patients.

**RESULTS:** Twenty-four of 80 (30%) critically ill patients were found to carry some pyrin mutations; none had a history compatible with familial Mediterranean fever. We also found a high frequency of carriers in patients having pneumonia (30.3%), urinary tract infection (29.4%), and acute pancreatitis (30.8%). When we compared our results with the pyrin mutation carrier rate of a healthy Turkish population (10%), the rate of pyrin mutations in all patients ( $p < 0.001$ ), and patients with urinary tract infection ( $p < 0.001$ ), acute pancreatitis ( $p < 0.001$ ), and pneumonia ( $p < 0.001$ ) were found to be significantly high. The white blood cell count, erythrocyte sedimentation rate, lactic dehydrogenase, and rate of fever and pulse were significantly higher, whereas systolic and diastolic blood pressure and albumin levels were significantly lower in patients with pyrin mutation compared to those without the mutation.

**CONCLUSION:** Our results showed that critically ill patients with SIRS and sepsis have increased prevalence of pyrin mutations, and patients with SIRS and sepsis carrying the pyrin mutation seem to be highly susceptible for a severe disease course.

Systemic autoinflammatory diseases are an heterogeneous group of systemic disorders clinically characterized by recurrent or persistent inflammatory episodes, which occur in the absence of infectious, neoplastic or autoimmune etiology. During the past years, genetic defects affecting different proteins involved in the regulation of inflammatory processes have been identified in these diseases. These advances offer new genetic tools to clinicians, in order to achieve an accurate and definitive diagnostic, and to establish a tailored treatment. Present review is an updated and comprehensive overview on hereditary systemic autoinflammatory diseases, and it has been organized in 2 separate and independent parts. The first of them will introduce the group of hereditary periodic fever syndromes, which includes familial Mediterranean fever, hyperimmunoglobulinemia D with periodic fever syndrome (HIDS), and tumour necrosis factor receptor-associated periodic syndrome (TRAPS).

Can a Multi-Dimensional Health Assessment Questionnaire (MDHAQ) and Routine Assessment of Patient Index Data (RAPID) scores be informative in patients with all rheumatic diseases?

Pincus T(1), Sokka T.

Author information:

(1)NYU-Hospital for Joint Diseases, 301 East 17 Street, New York, NY 10003, USA.  
tedpincus@gmail.com

A multidimensional health assessment questionnaire (MDHAQ) is useful in standard care of patients with all rheumatic diseases in a busy clinical setting. The MDHAQ was adapted from the classical health assessment questionnaire (HAQ) for feasibility in standard clinical care, with reduction of the number of activities from 20 to 10, visual analog scales (VAS) as 21 circles rather than 10 cm lines, availability of all core data set patient self-report measures and scoring templates on the front side, and a review of systems symptom checklist and review of recent medical history on the reverse side of a single page. Scoring templates are also available for routine assessment of patient index data (RAPID) scores, based on a composite of the three patient reported outcome (PRO) measures from the core data set included on the HAQ and MDHAQ, physical function pain, and patient estimate of global status. Flow sheets illustrating use of the MDHAQ in standard clinical care of patients with various rheumatic diseases, including psoriatic arthritis, systemic lupus erythematosus, ankylosing spondylitis, gout, scleroderma, vasculitis, fibromyalgia, inflammatory bowel disease arthritis, Behcet's syndrome, and familial Mediterranean fever, are presented to illustrate use of this simple questionnaire to add to clinical decisions and document patient courses and outcomes in standard clinical care of patients with all rheumatic diseases.

Compound heterozygosity for three common MEFV mutations in a highly consanguineous family with familial Mediterranean fever.

Seidel H(1), Steinlein OK.

Author information:

(1)Institute of Human Genetics, University Hospital, Ludwig-Maximilians-University, Munich, Germany.

Consanguinity is not the only factor influencing the occurrence of autosomal recessive disorders such as familial Mediterranean fever (FMF). The extended, multiple consanguineous Turkish pedigree presented here demonstrates that the

population frequency of certain mutations (so-called "ancient" mutations) can be at least equally important. In high-risk populations different combinations of mutations can occur within the same family, increasing not only the intrafamilial clinical variability, but also causing considerable recurrence risks even in marriages with unrelated spouses.

Successful treatment with infliximab and low-dose methotrexate in a Japanese patient with familial Mediterranean fever.

Nakamura A(1), Matsuda M, Tazawa K, Shimojima Y, Ikeda S.

Author information:

(1)Department of Rheumatology and Collagen Disease, Shinshu University School of Medicine, Matsumoto.

We report a Japanese patient with familial Mediterranean fever (FMF) who was successfully treated with the anti-tumor necrosis factor (TNF)-alpha monoclonal antibody, infliximab, and low-dose methotrexate. This patient was diagnosed as having FMF based on periodic fever with polyarthralgia typical of this disease and heterozygous mutations in the MEFV gene. Conventional treatment, such as colchicine and reserpine, failed to sufficiently control the FMF attacks. After starting infliximab (3 mg/kg) and low-dose methotrexate (6 mg/week), the frequency of the FMF attacks dramatically decreased and the clinical effect has remained unchanged for longer than 1 year. Combination therapy with infliximab and low-dose methotrexate may be a potent therapeutic option for FMF patients, particularly when conventional treatment is ineffective or cannot be employed because of adverse events.

**BACKGROUND:** Patients with inflammatory rheumatic diseases have an increased risk of developing atherosclerosis. However, the question of whether patients with familial Mediterranean fever (FMF) are at risk of atherosclerosis and related diseases remains controversial.

**OBJECTIVE:** We aimed to use transthoracic Doppler echocardiography to investigate coronary flow reserve (CFR) and left ventricular (LV) diastolic function in patients with FMF.

**METHODS:** CFR and LV diastolic function were studied in 33 patients with FMF (16 men, 17 women; mean age, 36.7+/-12.0 years) and 35 healthy volunteers (20 men, 15 women; mean age, 36.8+/-5.2 years). Coronary diastolic peak flow velocities (DPFV) were measured at baseline and after dipyridamole infusion. LV diastolic function was assessed by standard and tissue Doppler imaging.

**RESULTS:** CFR was significantly lower in the FMF group than in the control group (2.27+/-0.38 versus 3.02+/-0.50,  $P<0.0001$ ). Significant between-group differences were found regarding LV diastolic function mitral E/A ratio, mitral E-wave deceleration time, and lateral A(m). Serum high sensitivity C-reactive protein (hsCRP) levels were significantly higher in the patients with FMF, and hsCRP values independently correlated with CFR.

**CONCLUSIONS:** Coronary microvascular function and LV diastolic function are impaired in patients with FMF. The severity of these impairments is correlated with hsCRP. Impaired CFR may be an early manifestation of cardiac involvement in patients with FMF.

TNF receptor-associated periodic syndrome (TRAPS) is a dominantly inherited disease caused by missense mutations in the TNF receptor 1 (TNFR1) gene. Patients suffer from periodic bouts of severe abdominal pain, localised inflammation, migratory rashes, and fever. More than 40 individual mutations have been identified, all of which occur in the extracellular domain of TNFR1. In the present review we discuss new findings describing aberrant trafficking and function of TNFR1 harbouring TRAPS mutations, challenging the hypothesis that TRAPS pathology is driven by defective receptor shedding, and we suggest that TNFR1 might acquire novel functions in the endoplasmic reticulum, distinct from its role as a cell surface receptor. We also describe the clinical manifestations of TRAPS, current treatment regimens, and the widening array of patient mutations.

Late-onset tumor necrosis factor receptor-associated periodic syndrome in multiple sclerosis patients carrying the TNFRSF1A R92Q mutation.

Kümpfel T(1), Hoffmann LA, Rübsamen H, Pöllmann W, Feneberg W, Hohlfeld R, Lohse P.

Author information:

(1)Institute of Clinical Neuroimmunology-Grosshadern, Ludwig-Maximilian-University of Munich, Marchioninistrasse 15, D-81377 Munich,

**OBJECTIVE:** Tumor necrosis factor receptor-associated periodic syndrome (TRAPS) is an autosomal-dominantly inherited autoinflammatory disorder caused by mutations in the TNFRSF1A gene. It is characterized by episodes of autoinflammation usually associated with fever, abdominal pain, myalgia, exanthema, arthralgia/arthritis, and ocular involvement. We undertook this study to investigate the prevalence of TRAPS in patients with multiple sclerosis (MS) who reported, in addition to their neurologic symptoms, at least 2 other symptoms compatible with TRAPS.

**METHODS:** Twenty-five unrelated MS patients were prospectively screened for TNFRSF1A mutations. In addition, blood samples from 365 unrelated MS patients and 407 unrelated Caucasian controls were analyzed to determine the R92Q carrier frequency.

**RESULTS:** Six of 25 adult MS patients (24%) with symptoms suggestive of TRAPS were found to carry the identical arginine-to-glutamine substitution at amino acid position 92 (R92Q or p.Arg121Gln) encoded by exon 4 of the TNFRSF1A gene. All R92Q heterozygotes had similar symptoms, including arthralgias/arthritis, myalgias, urticarial rash, and severe fatigue, which began before the onset of MS. In 5 of the 6 patients, we could identify family members who had TRAPS symptoms and had inherited the identical mutation. The R92Q exchange was also detected in 17 of 365 unselected MS patients (4.66%) and in 12 of 407 controls (2.95%) ( $P = 0.112$ ). Three patients were heterozygous carriers of MEFV variants, in 1 patient in combination with the R92Q mutation.

**CONCLUSION:** Autoinflammatory syndromes and especially late-onset TRAPS should be considered in MS patients who report symptoms such as arthralgias/arthritis, myalgias, urticarial rash, and severe fatigue.

Mutant tumor necrosis factor receptor associated with tumor necrosis factor receptor-associated periodic syndrome is altered antigenically and is retained within patients' leukocytes.

Todd I(1), Radford PM, Daffa N, Bainbridge SE, Powell RJ, Tighe PJ.

Author information:

(1)Division of Immunology, Queen's Medical Center, University of Nottingham, Derby Road, Nottingham, UK. [ian.todd@nottingham.ac.uk](mailto:ian.todd@nottingham.ac.uk)

**OBJECTIVE:** To investigate the effect of mutations in tumor necrosis factor receptor superfamily member 1A (TNFRSF1A) in TNFR-associated periodic syndrome (TRAPS) on the binding of anti-TNFRSF1A monoclonal antibodies (mAb), and to investigate the subcellular distribution of mutant versus wild-type (WT) TNFRSF1A in patients with TRAPS.

**METHODS:** HEK 293 cells transfected with WT and/or mutant TNFRSF1A were used to investigate the interaction of anti-TNFRSF1A mAb with the WT and mutant proteins. Monoclonal antibodies that differentially bound to C33Y TNFRSF1A were used to investigate the distribution of WT and mutant TNFRSF1A in TRAPS patients with the C33Y mutation.

**RESULTS:** We identified a mAb whose binding to TNFRSF1A was completely abolished by the C33Y or C52F TRAPS-associated mutations, whereas other mutations (T50M, C88Y, R92Q) had lesser effects on the binding of this mAb. A different mAb was found to bind efficiently to all of the mutant forms of TNFRSF1A examined as well as to the WT receptor. Exploitation of the differential binding properties of these mAb indicated that mutant (as distinct from WT) TNFRSF1A showed abnormal intracellular retention in the neutrophils of TRAPS patients with the C33Y mutation, with little if any expression of mutant TNFRSF1A on the cell surface or as soluble receptor in plasma.

**CONCLUSION:** TRAPS-associated mutant TNFRSF1A has an antigenically altered structure and shows abnormal retention in the leukocytes of patients with TRAPS, which is consistent with previous findings from in vitro and transgenic model systems. This is consistent with a misfolded protein response contributing to the pathophysiology of TRAPS.

Comment in

Arthritis Rheum. 2008 Jun;58(6):1885; author reply 1885-6.

**OBJECTIVE:** To investigate whether the MEFV gene, which is involved in the regulation of the inflammatory response and has been associated with familial Mediterranean fever (FMF) and intermittent hydrarthrosis, is implicated in the pathogenesis of palindromic rheumatism (PR) and to examine its clinical presentation and its evolution in a Spanish cohort of PR patients.

**METHODS:** Family histories, demographic clinical data, and laboratory characteristics of 75 patients diagnosed as having PR were collected from medical records and personal interviews. The healthy control group included 325 blood bank donors. The FMF control group was made up of 84 Spanish FMF patients. Genomic DNA was isolated, and MEFV gene mutation analysis was performed by polymerase chain reaction amplification and sequence analysis.

**RESULTS:** Sixty-five unrelated PR patients were finally included in the study. MEFV gene mutation analysis identified 8 of these 65 patients (12.3%) as carriers of at least 1 mutated MEFV allele. Patients with MEFV mutations had higher mean age and age at disease onset, but lower mean serum levels of anti-citrullinated protein antibodies (ACPAs). No other significant differences were observed between patients with and those without mutations. The frequency of MEFV mutations in ACPA-negative PR patients was 22.2%, compared with 5.3% in ACPA-positive PR patients ( $P = 0.058$ ).

**CONCLUSION:** This study shows a previously unreported high prevalence of mutations of the MEFV gene in patients with ACPA-negative PR. This supports the hypothesis that it might be a susceptibility gene. Our findings also support the hypothesis that the MEFV gene might participate in the pathogenesis of other undifferentiated relapsing inflammatory rheumatic disorders.

Familial mediterranean Fever and renal disease.

El-Shanti HI(1).

Author information:

(1)University of Iowa Hospitals and Clinics, Department of Pediatrics, Division of Medical Genetics, USA.

Familial Mediterranean Fever (FMF) is a genetic disorder frequently diagnosed among the Arabs. It is also prevalent among Jews, Armenians and Turks. The clinical picture consists of febrile and painful attacks such as joint or chest pain that differ in quality across patients and even within the same patient. The gene responsible for FMF, MEFV, has been cloned and mutations were identified within its coding sequence. It encodes a protein that is expected to be a down regulator of inflammation. The major renal involvement in FMF is the occurrence of amyloidosis that primarily affects the kidneys causing proteinuria and ending

in death from renal failure. It can be treated by dialysis and renal transplantation, but can be prevented by a daily regimen of colchicine. Other renal manifestations of FMF are discussed.

The detailed assessment of left and right ventricular functions by tissue Doppler imaging in patients with familial Mediterranean fever.

Tavil Y(1), Ureten K, Oztürk MA, Sen N, Kaya MG, Cemri M, Cengel A.

Author information:

(1)Department of Cardiology, Gazi University School of Medicine, Beşevler, Ankara, Turkey. yusuftavil@gmail.com

In the contrary to other rheumatologic disorders, there have been limited numbers of studies investigating the cardiac involvement in patients with familial Mediterranean fever (FMF), although the disease may carry a potential for cardiovascular disorders because of sustained inflammation during its course. In the present study, we used high usefulness tissue Doppler echocardiography for detailed analysis of cardiac changes in FMF patients. The study population included 30 patients with FMF (11 men, 19 women; mean age, 35 +/- 7 years, mean disease duration, 15.4 +/- 7.6 years) and 30 healthy subjects as controls (12 men, 18 women; mean age, 33 +/- 7 years). The diagnosis of FMF was established according to the Tell-Hashomer criteria. Left and right ventricular functions were measured using echocardiography comprising standard two-dimensional, M-mode, and conventional Doppler as well as tissue Doppler imaging. The conventional echocardiographic parameters were similar apart from left ventricular relaxation time was longer (107 +/- 25 vs 85 +/- 10 ms,  $p < 0.001$ , respectively) in patients with FMF. According to the tissue Doppler measurements, while systolic velocities of both ventricles were not different, diastolic filling velocities of left ventricle including  $E'(m)$  (12.6 +/- 3.4 vs 14.7 +/- 3.3 cm/s,  $p = 0.04$ ),  $A'(m)$  (10.1 +/- 2.6 vs 8.6 +/- 2.0 cm/s,  $p = 0.015$ ), and  $E'(m)/A'(m)$  (1.24 +/- 0.4 vs 1.71 +/- 0.5 cm/s,  $p = 0.012$ ) values were statistically different between the groups. Left ventricular myocardial performance indices and

right ventricular diastolic functions were found similar between two groups. In addition, there were no significant correlations between the disease duration, clinical features, and echocardiographic parameters. In conclusion, we have demonstrated that although systolic functions were comparable in the patients and controls, left ventricular diastolic function indices were impaired in FMF patients by using tissue Doppler analysis.

The anesthetic management of children with neonatal-onset multi-system inflammatory disease.

Lauro CF(1), Goldbach-Mansky R, Schmidt M, Quezado ZM.

Author information:

(1)Department of Anesthesia and Surgical Services, National Institutes of Health Clinical Center, National Institutes of Health, Bethesda, MD 20892-1512, USA.

**BACKGROUND:** Neonatal-onset multi-system inflammatory disease (NOMID), a rare autosomal dominantly inherited disease, belongs to a growing spectrum of autoinflammatory diseases, is characterized by urticarial rash, arthropathy, and chronic aseptic meningitis, and is associated with mutations in the cold-induced autoinflammatory gene, CIAS1, the gene that encodes the protein, cryopyrin. As little is known about the anesthetic considerations of the disease, we sought to identify the main features and respective anesthetic and perioperative implications of NOMID.

**METHODS:** We examined perianesthetic records of children with NOMID who were anesthetized for invasive diagnostic and therapeutic interventions between 2003 and 2006. In addition, we conducted an extensive literature review of the genetic, clinical, and biochemical abnormalities of the disease.

**RESULTS:** Seventeen children with NOMID (median age 8 yr, range 9 mo to 11 yr) were anesthetized for diagnostic and therapeutic procedures. All patients had neurological involvement, including increased intracranial pressure, chronic aseptic meningitis, and developmental delay; 7 had bony overgrowth, 15 ocular, and 14 otological manifestations of NOMID. Despite the complexity of the disease,

the perioperative course was uncomplicated, and no serious adverse events were observed.

**CONCLUSIONS:** This study is the first to investigate the anesthetic implications of NOMID, an autoinflammatory disease associated with arthropathy, recurrent fevers, urticarial rash, and chronic aseptic meningitis. While for the pediatric anesthesiologist, the presence of fever and aseptic meningitis might make the conduct of anesthetics for elective procedures less desirable, our findings suggest that without evidence of active infection, even in the presence of fever and chronic aseptic meningitis, general and regional anesthesia may be conducted in patients with NOMID without untoward complications.

Secondary amyloidosis due to FMF.

Yonem O(1), Bayraktar Y.

Author information:

(1)Department of Gastroenterology, Hacettepe University Faculty of Medicine, Ankara, Turkey.

Familial Mediterranean fever (FMF) is an ethnically restricted disease with an autosomal recessive inheritance characterized by recurrent attacks of fever, painful manifestations in the abdomen, chest and joints. The disease affects mainly non-Ashkenazi Jews, Armenians, Turks Arabs and other people of Mediterranean origin. The disease may present at any age, more than 80% of patients being symptomatic by the age of 20. Although the inflammatory attacks that characterize the disease may sometimes be debilitating, secondary (AA) amyloidosis remains the most serious manifestation of FMF causing considerable morbidity due mostly to nephropathic amyloidosis. The largest series of secondary amyloidosis in FMF have been reported from Turkey. The pathophysiological steps in progressing a patient from FMF to amyloidosis are not definitely known. Daily treatment with colchicine can prevent both the attacks and amyloid deposition but no effective alternative treatment exists for colchicine resistant cases.

Meanwhile more population based epidemiological and genetic data should be gathered by worldwide collaborative studies to elucidate the link between FMF and amyloidosis and to develop alternative therapies.

Pyrin levels in human monocytes and monocyte-derived macrophages regulate IL-1beta processing and release.

Seshadri S(1), Duncan MD, Hart JM, Gavrilin MA, Wewers MD.

Author information:

(1)Davis Heart and Lung Research Institute, Ohio State University, Columbus, OH 43210, USA.

Macrophages and their precursors, monocytes, are key cells involved in the innate immune response. Although both monocytes and macrophages produce caspase-1, the key enzyme responsible for pro-IL-1beta processing; macrophages are limited in their ability to activate the enzyme and release functional IL-1beta. In this context, because mutations in the pyrin gene (MEFV) cause the inflammatory disorder familial Mediterranean fever, pyrin is believed to regulate IL-1beta processing. To determine whether variations in pyrin expression explain the

difference between monocytes and macrophages in IL-1 $\beta$  processing and release, pyrin was studied in human monocytes and monocyte-derived macrophages. Although monocytes express pyrin mRNA and protein, which is readily inducible by endotoxin, monocyte-derived macrophages express significantly less pyrin mRNA and protein. Pyrin levels directly correlated with IL-1 $\beta$  processing in monocytes and macrophages; therefore, we asked whether pyrin might promote IL-1 $\beta$  processing and release. HEK293 cells were transfected with pyrin, caspase-1, apoptotic speck protein with a caspase recruitment domain, and IL-1 $\beta$ . Pyrin induced IL-1 $\beta$  processing and release in a dose-dependent manner. Conversely, pyrin small interference RNA suppressed pro-IL-1 $\beta$  processing in both THP-1 cells and fresh human monocytes. In summary, both pyrin expression and IL-1 $\beta$  processing and release are diminished upon the maturation of monocytes to macrophages. When pyrin is ectopically expressed or silenced, IL-1 $\beta$  processing and release parallels the level of pyrin. In conclusion, in the context of endotoxin-induced activation of mononuclear phagocytes, pyrin augments IL-1 $\beta$  processing and release.

**OBJECTIVE:** Colchicine is a mainstay of treatment in familial Mediterranean fever (FMF); however, 5%-10% of patients do not respond to colchicine. Adenosine triphosphate-binding cassette subfamily B member 1 (ABCB1 or MDR1) is a drug transporter that extrudes colchicine out of cells. ABCB1 gene 3435C to T polymorphism has been demonstrated to alter MDR1 expression in mononuclear cells. Thus, the amount of MDR1 in mononuclear cells may alter response to colchicine.

We investigated the association between MDR1 3435C to T polymorphism and colchicine response in patients with FMF.

METHODS: Patients (n = 120) were examined for colchicine responses. ABCB1 gene 3435C to T genotypes were determined to analyze associations with colchicine resistance.

RESULTS: Ninety-eight patients were evaluated as responders and 22 as nonresponders. The distributions of ABCB1 CC, CT, and TT genotypes were significantly different between responsive and nonresponsive groups (chi-square = 6.86, p = 0.032). Colchicine resistance was significantly higher in patients harboring the C allele than in patients with TT genotype (odds ratio 9.71, 95% CI 1.58-58.76). Similarly, the mean colchicine dose to prevent remission was significantly lower in the TT group compared with subjects with the C allele (p = 0.014).

CONCLUSION: Our study revealed an association between 3435C to T polymorphism and colchicine response in patients with FMF. Patients with the TT genotype for the ABCB1 3435C to T variant responded better to colchicine in terms of treatment efficacy and colchicine dose requirements.

In childhood and adolescence, uveitis is part of the clinical spectrum of many inflammatory-rheumatic diseases. Besides juvenile idiopathic arthritis juvenile, ankylosing spondylitis, infection-associated arthritides, infantile sarcoidosis, systemic vasculitides, inflammatory bowel diseases, hereditary autoinflammatory syndromes and the TINU syndrome have to be excluded. These inflammatory diseases can be differentiated clinically in connection with immunogenetic and molecular genetic investigations. Early diagnosis of uveitis as well as the underlying diseases is mandatory for an early treatment and therefore for a good prognosis.

(1)Genetics Unit, Faculty of Medicine, Mansoura Univ. Children Hospital, Mansoura, Egypt. settin@mans.edu.eg

**BACKGROUND:** Familial Mediterranean Fever (FMF) is an autosomal inherited disorder affecting certain races including Arabs. Diagnosis depends mainly on clinical basis, but mild forms may remain undiagnosed.

**OBJECTIVES:** This study aims at an accurate diagnosis of FMF in Egyptian children by detection of genetic mutations in addition to clinical assessment.

**SUBJECTS AND METHODS:** Subjects included 66 Egyptian cases (37 males and 29 females) with a mean age of onset of 6.9 years. They had been referred from health centers and hospitals of the Delta region, Egypt. Analysis of the clinical manifestations was performed using Tel-Hashomer criteria in addition to 10 items clinical score system. For all these cases, DNA analysis was made for three common mutations M680I, M694V, and V726A using amplification refractory mutation system (ARMS-PCR) technique.

**RESULTS:** Most of the cases had attacks ranging from 3-5 days duration with the mean of 3.6 days. Their rate of recurrence was variable but 47 % of them had suffered attacks 10-30 times/year. Abdominal pain was the most common symptom (87.9%) followed by fever (82%), arthritis or arthralgia (56.1%), chest pain (45%) and myalgia (6%). Laparotomy had been done during attacks for exploration or appen-dectomy in 27.7% of cases. Positive mutations were detected among 42 cases (63.6%), of them 14 (21.2%) were compound heterozygotes, 7 (10.6%) were had homozygotes while 21 (31.8%) were simple heterozygotes. Allele M694V was the most frequent one (18.8%) followed by V726A (17.4%) and M680I (12.1%). Taking positive mutation as a guide for diagnosis, a cutoff clinical score level was determined with =15 for unlikely, =20 for definite and 15-20 for probable diagnosis.

CONCLUSION: Diagnosis of FMF among Egyptian children cases although based mainly on clinical suspicion requires to be confirmed through detection of the corresponding mutation which can be easily made using the simple ARMS-PCR technique.

The efficacy of anakinra in an adolescent with colchicine-resistant familial Mediterranean fever.

Calligaris L(1), Marchetti F, Tommasini A, Ventura A.

Author information:

(1)Department of Pediatrics, Institute of Child Health, Children's Hospital IRCCS Burlo Garofolo, Via dell'Istria 65/1, 34137 Trieste, Italy.

Colchicine is the treatment of choice in familial Mediterranean fever (FMF) for the prevention of both attacks and secondary amyloidosis. The overall nonresponder rate is about 5-10%. Anakinra is known to have good effectiveness in a severe autoinflammatory syndrome [chronic infantile neurological cutaneous and articular (CINCA) syndrome] and other recurrent hereditary periodic fevers. Pyrin--the protein involved in FMF--has a role in activating the proinflammatory cytokine interleukin (IL)-1beta. We report the effectiveness of the addition of an IL-1-receptor inhibitor (anakinra) to colchicine in controlling the febrile attacks and acute phase response in an adolescent with FMF resistant to colchicine.

Comment in

Semin Arthritis Rheum. 2008 Oct;38(2):163; author reply 164.

**OBJECTIVE:** Schnitzler syndrome is a rare disorder characterized by a chronic urticarial rash and monoclonal gammopathy, accompanied by intermittent fever, arthralgia or arthritis, bone pain, and lymphadenopathy. Our objectives are to systematically review disease characteristics of Schnitzler syndrome and collect follow-up information to gain insight into treatment efficacy and long-term prognosis.

**METHODS:** PubMed and MEDLINE databases (1966-2006) were searched, using the key words "Schnitzler syndrome," and the combination of "urticaria" with "monoclonal gammopathy," "immunoglobulin M (IgM)," or "paraproteinemia," as well as secondary references. Data on a total of 94 patients who met the criteria for Schnitzler syndrome were reviewed. Questionnaires sent to all authors retrieved additional follow-up data on 43 patients, resulting in a mean follow-up of 9.5 years after onset of symptoms, and a follow-up of 20 years or more in 10 patients.

**RESULTS:** Symptoms, signs, and laboratory findings as found in the 94 patients are reviewed in detail. There have been promising developments in therapeutic options, especially antiinterleukin-1 treatment, which induced complete remission in all 8 patients treated so far. To date, no spontaneous complete remissions have been reported. Patients with Schnitzler syndrome showed no increased mortality during the present follow-up. However, they had a 10-year risk of 15% of developing a lymphoproliferative disorder, most notably Waldenström's macroglobulinemia. Three cases of type amyloid A (AA) amyloidosis associated with Schnitzler syndrome were reported.

**CONCLUSIONS:** Schnitzler syndrome is a disabling disorder which affects multiple systems and which can be considered as an autoinflammatory syndrome. There are new, effective treatment options, but close monitoring remains warranted because of the increased risk of lymphoproliferative disease.

Successful treatment of chronic recurrent multifocal osteomyelitis with indomethacin: a preliminary report of five cases.

Abril JC(1), Ramirez A.

Author information:

(1)Pediatrics Orthopedics Department, Hospital Niño Jesús, Madrid, Spain.  
juancabr@hotmail.com

Chronic recurrent multifocal osteomyelitis (CRMO) is a disease of children and young adults. Clinically, the disease is characterized by the insidious onset of local pain and swelling in affected bones. Its course is one of intermittent periods of exacerbation and remission with successive bones affected. The pathogenesis of CRMO remains unknown, although an autoinflammatory disorder may be the cause, with inflammation of bone. This lesion is radiologically characterized as multiple lucencies surrounded by defined zones of patchy but dense sclerosis, cortical thickening from periosteal new bone formation, and increased bone size with different bones involved. Multiple therapeutic regimens had shown only a partial or temporary response. Because indomethacin has been successfully applied in inhibition of ossification and inflammatory processes, we initiated therapy with indomethacin in patients with CRMO. We report on the cases of 5 patients who responded dramatically to treatment with indomethacin. All underwent progressive clinical improvement (mean, 2.8 months). Radiological lesions disappeared after a mean period of 10.5 months. In 1 case where treatment was started late, small osteolytic zones persisted but with no clinical consequences. There were no additional recurrences or new bones affected during follow-up period (mean, 4 years). Our observation indicates that indomethacin may be an effective treatment for CRMO.

b.p.c.hazenberg@int.umcg.nl

Erratum in

Amyloid. 2007 Dec;14(4):325.

**OBJECTIVE:** Amyloid A protein quantification in fat tissue is a new immunochemical method for detecting AA amyloidosis, a rare but serious disease. The objective was to assess diagnostic performance in clinical AA amyloidosis.

**METHODS:** Abdominal subcutaneous fat tissue of patients with AA amyloidosis was studied at the start of an international clinical trial with eprodisate (NC-503; 1,3-propanedisulfonate; Kiacta), an antiamyloid compound. All patients had renal findings, i.e. proteinuria ( $>$  or  $=$  1 g/day) or reduced creatinine clearance (20 - 60 ml/min). Controls were patients with other types of amyloidosis and arthritic patients without amyloidosis. Amyloid A protein was quantified by ELISA using monoclonal antihuman serum amyloid A antibodies. Congo red stained slides were scored by light microscopy in a semiquantitative way (0 to 4+).

**RESULTS:** Ample fat tissue ( $>$ 50 mg) was available for analysis in 154 of 183 patients with AA amyloidosis and in 354 controls. The sensitivity of amyloid A protein quantification for detection of AA amyloidosis ( $>$ 11.6 ng/mg fat tissue) was 84% (95% CI: 77 - 89%) and specificity 99% (95% CI: 98 - 100%). Amyloid A protein quantification and semiquantitative Congo red scoring were concordant. Men had lower amyloid A protein values than women ( $p < 0.0001$ ) and patients with familial Mediterranean fever had lower values than patients with arthritis ( $p < 0.001$ ) or other inflammatory diseases ( $p < 0.01$ ).

**CONCLUSIONS:** Amyloid A protein quantification in fat tissue is a sensitive and specific method for detection of clinical AA amyloidosis. Advantages are

independence from staining quality and observer experience, direct confirmation of amyloid AA type, and potential for quantitative monitoring of tissue amyloid over time.

Population genetics of familial Mediterranean fever: a review.

Yepiskoposyan L(1), Harutyunyan A.

Author information:

(1)Institute of Man, Yerevan, Armenia. lepiskop@gmail.com

In this review, some principal population genetic features of familial Mediterranean fever (FMF) are considered. These relate to the time and the place of founder mutations' origins, the role of ancient migrations and contacts between populations in the spatial spreading of the disorder, the influence of environmental factors and cultural traditions on the rate of FMF incidence, and possible selective advantage in carriers of FMF causing gene (MEFV) mutations.

Author information:

(1)Department of Pathology and Laboratory Medicine, American University of Beirut Medical Center, Riad El Solh, Beirut, Lebanon.

Familial Mediterranean Fever (FMF) is an autosomal recessive inflammatory disorder predominantly affecting people living in or originating from areas around the Mediterranean Sea, mainly Jews, Armenians, Turks, and Arabs. It is characterized by recurrent attacks of inflammation of serosal membranes and fever resulting in acute abdominal, chest, or joint pain. Over 50 Mediterranean Fever (MEFV) mutations and polymorphisms have been identified in FMF patients. The objective of this study was to analyze the distribution and frequencies of 12 MEFV mutations in 266 referred Lebanese patients using a reverse-hybridization assay. Of the 266 patients, 129 (48.5%) were positive for at least one mutation and 137 (51.5%) had no mutations detected. Of the 129 patients with mutations, 35 were homozygous, 41 were compound heterozygous and 53 were heterozygous. The five most common mutations M694V, E148Q, V726A, M694I and M680I (G/C) accounted for 26.1, 22.2, 21.3, 9.6 and 7.7%, respectively. The A744S, F479L, R761H and I692del were encountered in 2.9% of patients; P369S and M680I (G/A) were found in 1.2% of patients while K695R was absent. The spectrum of the MEFV mutations among our sampled Lebanese FMF patients shows the high heterogeneity at the allelic level when compared to Arab and non-Arab populations. The most important feature was the relatively high frequency of the E148Q in our study group that allows us to question it as a mutation rather than a polymorphism. Further studies should be conducted to evaluate the role of the E148Q allele.

Comment in

Nefrologia. 2008;28 Suppl 2:8-9.

N Engl J Med. 2007 Sep 13;357(11):1153; author reply 1153-4.

**BACKGROUND:** Deposition of amyloid fibrils derived from circulating acute-phase reactant serum amyloid A protein (SAA) causes systemic AA amyloidosis, a serious complication of many chronic inflammatory disorders. Little is known about the natural history of AA amyloidosis or its response to treatment.

**METHODS:** We evaluated clinical features, organ function, and survival among 374 patients with AA amyloidosis who were followed for a median of 86 months. The SAA concentration was measured serially, and the amyloid burden was estimated with the use of whole-body serum amyloid P component scintigraphy. Therapy for inflammatory diseases was administered to suppress the production of SAA.

**RESULTS:** Median survival after diagnosis was 133 months; renal dysfunction was the predominant disease manifestation. Mortality, amyloid burden, and renal prognosis all significantly correlated with the SAA concentration during

follow-up. The risk of death was 17.7 times as high among patients with SAA concentrations in the highest eighth, or octile, ( $\geq 155$  mg per liter) as among those with concentrations in the lowest octile ( $< 4$  mg per liter); and the risk of death was four times as high in the next-to-lowest octile (4 to 9 mg per liter).

The median SAA concentration during follow-up was 6 mg per liter in patients in whom renal function improved and 28 mg per liter in those in whom it deteriorated ( $P < 0.001$ ). Amyloid deposits regressed in 60% of patients who had a median SAA concentration of less than 10 mg per liter, and survival among these patients was superior to survival among those in whom amyloid deposits did not regress

(P=0.04).

**CONCLUSIONS:** The effects of renal dysfunction dominate the course of AA amyloidosis, which is associated with a relatively favorable outcome in patients with SAA concentrations that remain in the low-normal range (<4 mg per liter).

Nat Clin Pract Nephrol. 2007 Nov;3(11):592-3.

**BACKGROUND:** Amyloid A (AA) amyloidosis is a complication of chronic inflammatory conditions that develops when proteolytic fragments of serum amyloid A protein (SAA) are deposited in tissues as amyloid fibrils. Amyloid deposition in the kidney causes progressive deterioration in renal function. Eprodisate is a member of a new class of compounds designed to interfere with interactions between amyloidogenic proteins and glycosaminoglycans and thereby inhibit polymerization of amyloid fibrils and deposition of the fibrils in tissues.

**METHODS:** We performed a multicenter, randomized, double-blind, placebo-controlled trial to evaluate the efficacy and safety of eprodisate in patients with AA amyloidosis and kidney involvement. We randomly assigned 183 patients from 27 centers to receive eprodisate or placebo for 24 months. The primary composite end point was an assessment of renal function or death. Disease was classified as

worsened if any one of the following occurred: doubling of the serum creatinine level, reduction in creatinine clearance by 50% or more, progression to end-stage renal disease, or death.

RESULTS: At 24 months, disease was worsened in 24 of 89 patients who received eprodisate (27%) and 38 of 94 patients given placebo (40%,  $P=0.06$ ); the hazard ratio for worsening disease with eprodisate treatment was 0.58 (95% confidence interval, 0.37 to 0.93;  $P=0.02$ ). The mean rates of decline in creatinine clearance were 10.9 and 15.6 ml per minute per 1.73 m<sup>2</sup> of body-surface area per year in the eprodisate and the placebo groups, respectively ( $P=0.02$ ). The drug had no significant effect on progression to end-stage renal disease (hazard ratio, 0.54;  $P=0.20$ ) or risk of death (hazard ratio, 0.95;  $P=0.94$ ). The incidence of adverse events was similar in the two groups.

CONCLUSIONS: Eprodisate slows the decline of renal function in AA amyloidosis. (ClinicalTrials.gov number, NCT00035334.)

Behcet disease in adult Druzes in north Israel: the influence of ethnic origin on disease expression and severity.

Rozenbaum M(1), Boulman N, Slobodin G, Zisman D, Mader R, Yankevitch A, Weinberger A, Rosner I.

Author information:

(1)Rappaport Faculty of Medicine, Technion, Israel.

BACKGROUND: Behcet's disease (BD) is known to vary in severity and manifestations in different populations.

OBJECTIVE: In an attempt to sort out genetic and environmental influences on disease expression, we carried out a study to assess the clinical features of BD in the adult Druze and Arab populations in north Israel, comparing 2 disparate ethnic groups of similar genetic background inhabiting the same geographic region.

**METHODS:** We compared 23 Druze and 30 Arab patients with BD. All patients fulfilled the classification criteria of the International Study Group for BD.

**RESULTS:** Manifestations were similar in 2 groups. The most frequent BD manifestations among the Druzes were recurrent oral aphthae (100%) and genital aphthae (61%) versus 100% and 53% in Arab patients, followed by inflammatory ocular involvement, 65% versus 53%, respectively. Arthritis was noted in 39% of Druze, with 27% in Arabs. Anterior uveitis occurred in 9 Druze patients (48%) and panuveitis in 4, with no case of blindness when compared with 30% with anterior uveitis, 4 with panuveitis, and 4 cases of blindness ( $P < 0.04$ ) among the Arabs. One Druze BD patient had deep vein thrombosis versus 8 Arab patients ( $P < 0.017$ ). No pulmonary embolism, aortic aneurysm, nor valvular involvement was documented in the Druze versus 1 case of each in Arabs. No case of neuro-Behcet was reported in Druzes versus 6 cases of neuro-Behcet among Arabs ( $P < 0.023$ ). The severity score was 4.0 (SD, 1.2) in Druze and 5.8 (SD, 1.9) in Arabs ( $P = 0.0004$ ). The prevalence of HLA B51 did not differ significantly between the groups.

**CONCLUSION:** Druze BD patients in Israel have a milder disease than do Arabs, similar to observations in familial Mediterranean fever. Druze BD patients had significantly less severe ocular disease and neurologic manifestations. Our results suggest an ethnic influence on expression of BD not related to HLA B 51.

The familial Mediterranean fever (MEFV) gene may be a modifier factor of inflammatory bowel disease in infancy.

Sari S(1), Egritas O, Dalgic B.

Author information:

(1)Department of Pediatric Gastroenterology, Gazi University, Ankara, Turkey.  
drsinansari@yahoo.com

Pediatric inflammatory bowel disease (IBD) usually manifests in childhood or adolescence, but a small number of cases present in infancy. Genetic factors are more important than environmental ones in the onset of pediatric IBD. We report here the concurrent manifestation of IBD and familial Mediterranean fever (FMF) in three infants (less than 6 months of age) in whom infantile ulcerative colitis (UC) was associated with the MEFV mutation. One patient required colectomy before the diagnosis of FMF, and in the other two patients, the UC could not be controlled until colchicine was added to the drug regimen. We suggest that the onset of UC in infants should prompt a search for MEFV mutations as this association may influence the management of the disease.

A pivotal mediator of actin dynamics is the protein cofilin, which promotes filament severing and depolymerization, facilitating the breakdown of existing filaments, and the enhancement of filament growth from newly created barbed ends. It does so in concert with actin interacting protein 1 (Aip1), which serves to accelerate cofilin's activity. While progress has been made in understanding its biochemical functions, the physiologic processes the cofilin/Aip1 complex regulates, particularly in higher organisms, are yet to be determined. We have generated an allelic series for WD40 repeat protein 1 (Wdr1), the mammalian homolog of Aip1, and report that reductions in Wdr1 function produce a dramatic phenotype gradient. While severe loss of function at the Wdr1 locus causes embryonic lethality, macrothrombocytopenia and autoinflammatory disease develop in mice carrying hypomorphic alleles. Macrothrombocytopenia is the result of megakaryocyte maturation defects, which lead to a failure of normal platelet shedding. Autoinflammatory disease, which is bone marrow-derived yet nonlymphoid in origin, is characterized by a massive infiltration of neutrophils into inflammatory lesions. Cytoskeletal responses are impaired in Wdr1 mutant neutrophils. These studies establish an essential requirement for Wdr1 in megakaryocytes and neutrophils, indicating that cofilin-mediated actin dynamics are critically important to the development and function of both cell types.

**OBJECTIVES:** In a significant proportion of patients with familial Mediterranean fever (FMF), serum amyloid A (SAA) remains elevated during attack-free periods, thereby increasing the risk of developing amyloidosis. The aim of the study was to determine various correlates of elevated SAA and evaluate the role of SAA measurement in the diagnosis and management of FMF.

**METHODS:** We reviewed the medical files of all 204 patients from our FMF center in whom SAA measurements were performed. SAA levels and the resulting diagnostic and therapeutic decisions were analyzed in relation to the reasons of SAA testing and to several clinical and genetic parameters.

**RESULTS:** SAA measurements were made for diagnostic purposes in 29% of the patients. In the remainder, SAA measurements were used for adjustment of colchicine dose. Elevated SAA levels are found in a third of FMF patients during an attack-free period. The highest rate of elevated SAA levels was found in patients with proteinuria (60% of this patient group), followed by noncompliant

(40%) and genetically positive asymptomatic patients (38%). Elevated SAA levels during remission were associated with family history of FMF, M694V homozygosity, and elevated C-reactive protein (CRP) ( $P < 0.05$  for each). Patients homozygous for the M694V mutation had the highest level of SAA. SAA measurement led to a change in colchicine dose in 30% of the patients, predominantly in noncompliant patients and patients with proteinuria or with atypical manifestations.

CONCLUSIONS: Measurement of SAA level may help in the diagnosis of FMF and in adjustment of the colchicine dose.

Nonclassic neurologic features in cryopyrin-associated periodic syndromes.

Ting TV(1), Scalzi LV, Hashkes PJ.

Author information:

(1)Section of Pediatric Rheumatology, Department of Rheumatic Diseases, Cleveland Clinic, Cleveland, Ohio 44195, USA.

Neurologic manifestations in early childhood occur in the cryopyrin-associated periodic syndromes, especially in the chronic infantile neurological, cutaneous, and articular syndrome (CINCA) and the Muckle-Wells syndrome.

Cryopyrin-associated periodic syndromes are commonly linked to mutations in the cold-induced autoinflammatory syndrome gene CIAS1 (current symbol, NLRP3) on chromosome 1. We describe three children with atypical cryopyrin-associated periodic syndromes, neurologic symptoms, and a Q705K mutation.

Cryopyrin-associated periodic syndrome screening should be considered for children with neurologic and other periodic symptoms with elevated inflammatory markers. This syndrome is treatable with anakinra.

The effect of dialytic modalities on clinical outcomes in ESRD patients with familial Mediterranean fever.

Sahin S(1), Sahin GM, Ergin H, Kantarci G.

Author information:

(1)Division of Nephrology, Goztepe Research and Training Hospital, Istanbul, Turkey.

**BACKGROUND:** Familial Mediterranean fever (FMF) is an autosomal recessive disease seen primarily in Sephardic Jews, Turks, and Armenians. The disease manifests as recurrent attacks of fever and serositis. The most important complication of FMF is the development of renal failure due to AA type amyloidosis. There has not been extensive experience with renal replacement therapy in FMF amyloidosis. Nevertheless, there may be a concern about the possibility of higher rates of morbidity and mortality in amyloidotic patients maintained on chronic hemodialysis. Moreover, there is not enough experience regarding patients on chronic peritoneal dialysis. As a result, the best treatment modality of end-stage renal disease (ESRD) in these circumstances still remains unclear. This study aimed to compare the effect of hemodialysis and peritoneal dialysis modalities on clinical outcomes in ESRD patients associated with FMF amyloidosis.

**METHODS:** Forty FMF patients with ESRD due to amyloidosis were retrospectively analyzed. All 40 patients were on renal replacement therapy, 20 on hemodialysis (HD), 20 on peritoneal dialysis (PD). Peritoneal solute transport rates, weekly mean creatinine clearance, and daily mean ultrafiltration (UF) of the patients on chronic peritoneal dialysis were evaluated. Weekly dialysis durations, dialysis membrane properties, Kt/V values, interdialytic weight gains, and frequency of hypotension during dialysis were evaluated on hemodialysis patients. All of the patients were examined according to their demographic characteristics, laboratory results, duration time on dialysis, erythropoietin requirements, frequencies of infectious complications requiring hospitalization, and the two renal replacement modalities mentioned above were compared in terms of these parameters.

**RESULTS:** Serum albumin levels of the patients with FMF amyloidosis who were maintained on peritoneal dialysis treatment were lower (2.87 vs 3.45) and the frequency of infections of the same group was higher (4.2 vs 0.5) than the patients with ESRD secondary to other diseases in the CAPD group.

**CONCLUSIONS:** This retrospective analysis showed that peritoneal dialysis may have some disadvantages in amyloidotic patients. Due to the high frequency of

hypoalbuminemia and infectious complications seen in this group, peritoneal dialysis is widely accepted as an alternative choice of treatment when hemodialysis is not appropriate.

Chronic recurrent multifocal osteomyelitis: a concise review and genetic update.

El-Shanti HI(1), Ferguson PJ.

Author information:

(1)Department of Pediatrics, University of Iowa Carver College of Medicine, Iowa City, IA 52242, USA. hatem-el-shanti@uiowa.edu

Chronic recurrent multifocal osteomyelitis is an autoinflammatory disorder characterized by bone pain and fever, a course of exacerbations and remissions, and a frequent association with other inflammatory conditions. Because its etiology is largely unknown, the diagnosis is still based on clinical criteria; treatment is empiric and not always successful. The diagnosis is supported by the presence of osteolytic lesions with surrounding sclerosis apparent on radiographs, and silent asymptomatic lesions frequently appear on nuclear scans. The histologic findings in bone biopsies are nonspecific, showing inflammatory changes with granulocytic infiltration. Several observations suggest the contribution of genetic factors to the etiology of chronic recurrent multifocal osteomyelitis. Indeed, mutations in LPIN2 cause a syndromic form of chronic recurrent multifocal osteomyelitis known as Majeed syndrome, while mutations in pstpip2 cause a murine form of the disorder. The roles played by LPIN2 and the human homolog of pstpip2, PSTPIP2, in the etiology of chronic recurrent multifocal osteomyelitis are uncertain but are currently being investigated. We emphasize the need to validate diagnostic clinical criteria and develop new pathogenesis-based targeted therapy.

Childhood Henoch Schonlein purpura in Middle East countries.

Akl K.

HSP is the most common systemic vasculitis in children that is characterized by small vessel leukocytoclastic vasculitis. However, it is a self limiting disease, with few documented cases in Middle Eastern countries. Classic symptoms of the disease have been established in the literature, but new clinical features have recently been reported from Middle Eastern countries which include penile swelling, temporomandibular joint involvement, skin rash over the flexor surfaces of the extremities and pleural hemorrhagic effusion. Familial Mediterranean fever (FMF) may present as HSP. The prevalence of the FMF gene in Middle Eastern countries raises interesting questions regarding the use of colchicine in HSP patients.

(1)First Division of Internal Medicine, Democritus University of Thrace, Alexandroupolis, Greece.

Familial Mediterranean fever (FMF) is a disease characterized by recurrent, self-limiting bouts of fever and serositis and caused by altered pyrin due to mutated MEFV gene. FMF is common in the Mediterranean Basin populations, although with varying genetic patterns. The spectrum and clinical significance of MEFV alterations in Greece has yet not been elucidated. The aim of this study was to

analyze the spectrum of MEFV alterations in FMF patients and healthy individuals in Greece. A cohort of 152 Greek FMF patients along with 140 Greek healthy controls was enrolled. Non-isotopic RNase cleavage assay (NIRCA) and sequencing allowed mutational and haplotypic analysis of the entire coding sequence of MEFV. The ARLEQUIN 2.0, DNASP 4.0 and PHYLIP software were used for population genetics analysis. Among patients, 127 (83.6%) carried at least one known mutation. The most common mutations identified were M694V (38.1%), M680I (19.7%), V726A (12.2%), E148Q (10.9%) and E230K (6.1%). The total carrier rate among healthy individuals was 0.7%. The presence of R202Q homozygosity in 12 of the remaining 25 MEFV negative FMF patients might be considered as disease related in Greeks. Population genetics analysis revealed that Greeks rely closer to the eastern rather than western populations of the Mediterranean Basin.

A variant Muckle-Wells syndrome with a novel mutation in CIAS1 gene responding to anakinra.

Dalgic B(1), Egritas O, Sari S, Cuisset L.

Author information:

(1)Department of Pediatric Gastroenterology, Gazi University School of Medicine, Ankara, Turkey.

Muckle-Wells syndrome (MWS) is a subset of autoinflammatory diseases. It is characterized by recurrent inflammatory crises associated with fever, abdominal pain, persistent urticaria, arthralgia, sensorineural deafness, and possible development of multiorgan amyloid A protein (AA)-type amyloidosis. Mutations in the CIAS1 gene have been reported in MWS. Interleukin 1B (IL-1B) probably plays a major role in the pathophysiology of the disease, and IL-1B blockade may be therapeutic for this syndrome. We report here a Turkish child with MWS treated with anakinra. A novel mutation (I480F) was identified in exon 3 of the CIAS1 gene in this patient. The resolution of inflammatory symptoms, normalization of serological values, and improvement in hearing was noted with anakinra treatment.

[Clinical features of Blau syndrome and early-onset sarcoidosis and associating CARD15/NOD2 gene mutations].

[Article in Japanese]

Kanazawa N(1).

Author information:

(1)Department of Dermatology, Wakayama Medical University.

Sarcoidosis is a systemic inflammatory disease clinically characterized by swelling of bilateral hilar lymph nodes and histologically defined by non-caseating epithelioid cell granulomas. Among child cases, a special subtype, called the early-onset sarcoidosis, is known to appear in children younger than 4 years of age and to be characterized by a distinct triad of skin, joint and eye disorders without pulmonary involvement. On the other hand, autosomal dominantly-transmitted disease with a characteristic features similar to those of early-onset sarcoidosis has been reported as Blau syndrome. By a linkage analysis, the responsible gene for Blau syndrome has been mapped close to the IBD (Inflammatory Bowel Disease) 1 locus. After CARD15 (NOD2), originally identified as the susceptibility gene for Crohn's disease, was also proved to be responsible for Blau syndrome, the same gene mutations have been found in sporadic early-onset sarcoidosis cases. Nod2 recognizes a signal from bacterial cell wall component in the cytoplasm of monocytic cells to activate NF-kappaB, and thus can work as an intracellular sensor of bacteria. While the loss-of-function mutations in its LRR domain are associated with Crohn's disease, Blau syndrome and early-onset sarcoidosis are autoinflammatory diseases that are caused by the gain-of-function mutations in its NOD domain.

[Biological and clinical aspects of Muckle-Wells syndrome].

[Article in Japanese]

Kubota T(1), Koike R.

Author information:

(1)Graduate School of Health Sciences, Tokyo Medical and Dental University.

Muckle-Wells syndrome (MWS), as well as familial cold autoinflammatory syndrome (FCAS) and chronic infantile neurological cutaneous and articular syndrome (CINCA), arises from a missense mutation in the CIAS1 gene. Current progress of biology revealed that NALP3, a protein coded by the CIAS1 and expressed in monocytes, recognizes some bacterial products or harmful metabolites invaded in the cytoplasm, and forms inflammasome with other molecules. As a result, caspase-1 is activated leading to cleavage of pro-IL-1beta and extracellular release of IL-1beta. NALP3 of patients with MWS can be spontaneously activated without obvious stimulation, which causes recurrent attacks of inflammatory symptoms characterized by fever, urticarial rash, conjunctivitis and arthritis, and some patients develop amyloidosis. In addition, sensorineural hearing disturbance progresses gradually. Recently, significant efficacy of anakinra, a recombinant IL-1 receptor antagonist, has been demonstrated in treatment of MWS. So far, only a few cases have been reported from Japan, however an accurate diagnosis has to be established for the latent cases who have not received optimum treatment before occurrence of irreversible deafness or renal failure.

[Clinical features of CINCA syndrome: effects and problems of IL-1Ra].

[Article in Japanese]

Sugiura H(1), Matsubayashi T.

Author information:

(1)Department of Neonatology, Seirei Hamamatsu General Hospital.

CINCA syndrome is an autoinflammatory syndrome characterized by neonatal onset of urticarial rash, central nervous system lesions and arthropathy. Laboratory findings show leucocytosis, anemia, elevation of CRP levels and acceleration of ESR. The syndrome is associated with CIAS1 gene and its encoding protein cryopyrin. The CIAS1 gene is expressed in monocytes, polymorphonuclear cells and chondrocytes. Mutations of cryopyrin lead to the persistent production of IL-1beta and activation of NF-kappaB, followed by excessive inflammatory reactions. In spite of aggressive therapies, the inflammation persists and the lesions are progressive. Recently, there have been reports of clinical improvement using human recombinant IL-1 receptor antagonist anakinra in the patients with CINCA syndrome and its related diseases, Muckle-Wells syndrome and familial cold-autoinflammatory syndrome, suggesting that IL-1beta plays an important role in the pathogenesis of the inflammation associated with the CIAS1 gene mutations. No serious adverse reaction of anakinra has not been reported. Following the diagnosis of CINCA syndrome, anakinra therapy should be started as the first line of therapy before irreversible disabilities develop. Treatment with anakinra has just begun, therefore, it is necessary to carry out further investigations concerning the adverse effects of anakinra and long-term prognosis for CINCA syndrome treated with anakinra.

[Diagnosis and management of periodic fever with aphthous pharyngitis and adenitis (PFAPA)].

[Article in Japanese]

Murata T(1), Okamoto N, Shimizu T, Tamai H.

Author information:

(1)Department of Pediatrics, Osaka Medical College.

PFAPA is non-hereditary syndrome characterized by periodic episodes of high fever, aphthous stomatitis, pharyngitis and cervical adenitis. It manifests usually in early childhood, especially before 5 years of age, and last for several years. Its etiology is unknown, but some recent reports suggest a dysregulation of the immune response with continuous pro-inflammatory cytokine activation and a reduced anti-inflammatory response both during and between febrile attacks. The diagnosis is clinical and it is important to exclude other entities of similar presentation with periodic fever and orofacial manifestations. The findings of laboratory are unspecified and show only nonspecific acute inflammatory response. Several treatments have been performed but with various results. Most effective therapy for a fast resolution of the symptoms is one or two doses of oral prednisone, but its efficacy is not permanent. Effectiveness of cimetidine and tonsillectomy in PFAPA is not clear as yet. PFAPA is a benign syndrome and the prognosis is better than other autoinflammatory syndromes, because PFAPA patients grow normally and symptoms diminish within a few years.

[TNF receptor-associated periodic syndrome (TRAPS) in Japan: clinical characterization, pathogenesis, diagnostic criteria, and treatment].

[Article in Japanese]

Ida H(1), Eguchi K.

Author information:

(1)First Department of Internal Medicine, Graduate School of Biomedical Sciences, Nagasaki University. idah@net.nagasaki-u.ac.jp

TNF receptor-associated periodic syndrome (TRAPS) is an autosomal dominant inherited disease characterized by prolonged episodes of periodic fever and localized inflammation. The hypothetical pathogenesis of TRAPS is defective TNF receptor 1 (TNFRSF1A) shedding from cell membranes in response to a stimulus

including TNFalpha. This mechanism has recently been shown to account for a minor population of TRAPS patients and other mechanisms are reported to explain the disease, such as resistance to apoptosis, TNFRSF1A internalization, or TNFRSF1A misfolding and aggregation, leading to NF-kappaB activation and apoptosis. Until now 15 TRAPS patients from 5 pedigree including 5 different mutations (C30R, C30Y, T61I, C70S, C70G) had been reported in Japan. There were many sporadic cases of TRAPS without TNFRSF1A mutation in our epidemiological study. In this issue, we described the clinical characterization, pathogenesis, diagnostic criteria, and treatment of TRAPS according to our case and literature.

[MVK gene abnormality and new approach to treatment of hyper IgD syndrome and periodic fever syndrome].

[Article in Japanese]

Naruto T(1).

Author information:

(1)Department of Pediatrics, Yokohama City, University School of Medicine.

Hyper IgD and periodic fever syndrome (HIDS; OMIM 260920) is one of the hereditary autoinflammatory syndromes characterized by recurrent episodes of fever and inflammation.. HIDS is an autosomal recessive disorder characterized by recurrent fever attacks in early childhood. HIDS caused by mevalonate kinase (MK) mutations, also that is the gene of mevalonic aciduria (OMIM 251170). During febrile episodes, urinary mevalonate concentrations were found to be significantly elevated in patients. Diagnosis of HIDS was retrieving gene or measurement of the enzyme activity in peripheral blood lymphocyte in general. This of HIDS is an activity decline of MK, and a complete deficiency of MK becomes a mevalonic aciduria with a nervous symptom. The relation between the fever and inflammation of mevalonate or isoprenoid products are uncertain. The therapy attempt with statins, which is inhibited the next enzyme after HMG-CoA reductase, or inhibit the proinflammatory cytokines.

[Familial Mediterranean fever: MEFV gene mutations and treatment].

[Article in Japanese]

Saito M(1), Nishikomori R, Kambe N.

Author information:

(1)Department of Pediatrics, Kyoto University Graduate School of Medicine.  
msaito@kuhp.kyoto-u.ac.jp

Familial Mediterranean fever (FMF) is an autosomal recessive disease which predominantly affects certain ethnic groups mainly Sephardic Jews, Turks, Arabs and Armenians. FMF has been rarely reported in Japan. Characteristic symptoms include self-limited recurrent attacks of fever with serositis such as peritonitis, pleuritis, and arthritis. The most serious complications of FMF are secondary AA amyloidosis and subsequent chronic renal failure. FMF is caused by mutations in MEFV gene which encodes a protein called pyrin. Pyrin regulates processing of IL-1beta, NF-kappaB activation and apoptosis. Dysregulated function of pyrin results in excessive production of proinflammatory cytokine thereby evoking inflammatory attacks. The mainstay of treatment is colchicine which is effective for both relieving symptoms and preventing secondary amyloidosis.

[Article in Japanese]

Masumoto J(1), Hasegawa M, Inohara N.

Author information:

(1)Department of Pathology, Shinshu University School of Medicine.

The latest decade, our understanding of pattern-recognizing receptors involved in innate immune system has been accumulated. One class of the pattern recognizing receptors, the toll-like receptors (TLRs) are well known to detect extracellular pathogens on the cell surface membrane. On the other hand, recently discovered the nucleotide-binding oligomerization domain proteins (NODs) are involved in recognizing intracellular pathogens. Since Nod2, one of the NODs, mutations were found to associate with susceptibility of Crohn's disease, the NODs have been highlighted. For example, cryopyrin mutations have been reported to associate with Familial cold urticaria (FCU)/Familial cold autoinflammatory syndrome (FCAS), Muckle-Wells syndrome (MWS), Neonatal onset multisystem inflammatory disease (NOMID)/Chronic infantile neurologic cutaneous and articular syndrome (CINCA). Here, we summarize the discovery of the NODs and related molecules, and also discuss the function of the NODs and molecular mechanisms of the autoinflammatory diseases.

[Clinical observation of autoinflammatory diseases].

[Article in Japanese]

Agematsu K(1).

Author information:

(1)Department of Infectious Immunology and Pediatrics, Graduate School of Medicine, Shinshu University.

A disease, which repeats inflammations but is not based on infections or autoimmunity, was recently defined as autoinflammatory diseases. The

autoinflammatory diseases are a new and expanding classification of inflammatory diseases characterized by recurrent episodes of systemic inflammation in the absence of pathogens, autoantibodies or antigen specific T cells. This disease is developed by the abnormality of molecules which regulate inflammation, innate immunity and apoptosis, and patients have been suffered with treatment by the difficulty of making a diagnosis. However, a diagnosis is comparatively easy by their presenting the characteristic clinical observation. In addition, genetic analysis can put the diagnosis on a firm basis. Giving that therapies for individual disorder of autoinflammatory diseases are different, we always put these disorders in mind when we saw patients who have unknown persistent inflammation.

The inflammasome in pathogen recognition and inflammation.

Sutterwala FS(1), Ogura Y, Flavell RA.

Author information:

(1)Infectious Diseases, Yale University School of Medicine, New Haven, Connecticut 06520, USA.

The nucleotide-binding oligomerization domain-like receptor (NLR) family of

proteins is involved in the regulation of innate immune responses and cell death pathways. Some NLR family members promote the activation of proinflammatory caspases within multiprotein complexes, called inflammasomes. Recent studies analyzing mice deficient in various components of the inflammasome have provided insight into the role of these molecules in host defense against pathogens and in autoinflammatory disorders. Here, we review these studies and propose that membrane disruption leads to activation of the inflammasome.

Comment in

Arthritis Rheum. 2007 Nov;56(11):3879-80; author reply 3880.

**OBJECTIVE:** Familial Mediterranean fever (FMF), the prototype of autoinflammatory disorders, is caused by recessive mutations in the MEFV gene. Some FMF patients develop renal amyloidosis, a potentially fatal condition. This complication has mainly been associated with the M694V mutation, although the different study designs, small numbers of patients, and/or evaluation of few or no covariables calls this association into question. The aim of this study was to examine the controversial issue of amyloidosis susceptibility in FMF by determining the relative contributions of MEFV and numerous epidemiologic factors to the risk of renal amyloidosis.

**METHODS:** Online questionnaires were completed at the MetaFMF database by patients at 35 centers in 14 countries. Using a standardized mode of data collection, we retrieved crude initial data from over half of the genetically confirmed FMF patients referred worldwide until May 2003 (2,482 cases, including 260 patients who developed renal amyloidosis).

**RESULTS:** Amyloid nephropathy was present in 11.4% of the cases. In the total study population, country of recruitment was the leading risk factor for this manifestation (odds ratio 3.2 [95% confidence interval 1.8-5.9]), followed by M694V homozygosity, proband status, and disease duration. Differing results were found when countries were stratified.

**CONCLUSION:** Country of recruitment, rather than MEFV genotype, is the key risk factor for renal amyloidosis in FMF. This risk, which parallels infant mortality rates, indicates a possible environmental origin of amyloidosis susceptibility. The patient's country should be considered in addition to MEFV genotype as an indication for prophylactic colchicine, a treatment suggested for asymptomatic individuals who are incidentally discovered to be M694V homozygous.

**BACKGROUND:** Behcet's disease (BD) is an inflammatory disorder of unknown cause, associated with vasculitis. Arterial or venous thrombosis occurs in about 25% of BD patients. Familial Mediterranean fever (FMF) is another inflammatory disorder, which stems from mutations in the FMF gene (MEFV) and shares a number of features with BD.

**OBJECTIVE:** MEFV analysis in patients with BD suggests that mutated MEFV may act as a susceptibility gene in BD. We studied the rate and the clinical correlates of MEFV mutations in Israeli BD patients.

**METHODS:** Included were 54 BD patients who satisfied the International Study Group criteria for BD. All BD patients were genotyped using polymerase chain reaction (PCR) and restriction enzyme analysis for the three most common MEFV mutations (M694V, V726A, and E148Q). The association between BD manifestations and MEFV alleles was analysed.

**RESULTS:** Twenty-one BD patients were found to carry a single MEFV mutation and three additional patients were compound heterozygotes, a frequency significantly higher than that expected for ethnically matched healthy individuals. There were no statistically significant differences between carriers and non-carriers with respect to gender, frequency of HLA B5 antigen, cutaneous lesions, joint disease, and severity score. However, carriers did experience thrombosis more often [54% vs. 17%,  $p < 0.005$ , odds ratio (OR) = 6.9, 95% confidence interval (CI) 1.75-26.9] and uveitis less often (20% vs. 40%,  $p < 0.05$ , OR = 0.2, 95% CI 0.04-0.92).

**CONCLUSIONS:** MEFV appears to be a susceptibility and modifier gene in BD.

Nucleotide-binding and oligomerization domain-like receptors (NLRs) constitute a family of germline-encoded pattern-recognition receptors, which allow the host to respond rapidly to a wide variety of pathogenic microorganisms. Here, we discuss recent advances in the study of a subset of NLRs, which control the activation of caspase-1 through the assembly of large protein complexes, inflammasomes. The NALP1b inflammasome recognizes anthrax lethal toxin, and flagellin from *Salmonella* and *Legionella* induces assembly of the Ipaf inflammasome. Cryopyrin/NALP3 mediates caspase-1 activation in response to a wide variety of bacterial ligands, imidazoquinolines, dsRNA, and the endogenous danger signal uric acid. The importance of these cytosolic receptors in immune regulation is underscored by the identification of mutations in cryopyrin/NALP3, which are genetically linked to human autoinflammatory disorders.

The aim of our study was to show how the progression and severity of Familial Mediterranean Fever (FMF) is affected by procoagulant activity and alterations in the markers of thrombosis and fibrinolysis. The study cohort comprised 64 FMF patients who were classified as attack-free patients (Group 1; n = 34 patients, aged 3-19 years) and attack patients (Group 2; n = 30 patients, aged 3-21 years).

All patients were on colchicine treatment with the exception the newly diagnosed patients in Group 2. A total of 14 healthy subjects between 5-12 years of age were enrolled as controls (Group 3). Laboratory tests, including leukocyte and thrombocyte counts, erythrocyte sedimentation rate, CRP, fibrinogen, PT, aPTT, Factor VIII, vW factor, D-dimer, P-selectin, tPA and PAI-1, were carried out on all patients. Inflammation continued both during the attack and attack-free period in FMF. The prolongation of PT was observed during attacks (PT = 13.6 s in Group 2, and PT = 12.6 s in Group 3;  $p = 0.002$ ). tPA levels increased in FMF patients (tPA levels of group 1, 2 and 3 were 12.6, 13.2 and 9.7 ng/ml, respectively;  $p = 0.01$ ). P-selectin was lower in both patient groups than in the control group. During attack periods PAI-1 levels increased (PAI-1 level of Group 1: 89.6 ng/ml and PAI-1 level of Group 2: 335.7 ng/ml,  $p = 0.000$ ). Inflammation with increased acute phase reactants continued during both attack and attack-free periods in FMF patients. Prolongation of PT and differences in tPA and P-selectin levels suggest that hypercoagulability may have a role in the etiopathogenesis of FMF. It may be possible to use PAI-1 as a marker for the attacks of FMF.

The autoinflammatory disorders Muckle-Wells syndrome, familial cold urticaria and chronic infantile neurological cutaneous and articular syndrome are associated with mutations in the NALP3 (Cryopyrin) gene, which is the central platform of the proinflammatory caspase-1 activating complex, named the inflammasome. In patients with another autoinflammatory disorder, familial Mediterranean fever (FMF), mutations in the SPRY domain of the Pyrin protein are frequently found.

Recent evidence suggests that Pyrin associates with ASC, an inflammasome component, via its Pyrin domain, thereby halting the inflammatory response. This interaction, however, does not explain the effects of mutations of the SPRY domain found in FMF patients. Here we show that the Pyrin SPRY domain not only interacts with NALP3, but also with caspase-1 and its substrate pro-interleukin(IL)-1beta. Whereas a Pyrin knockdown results in increased caspase-1 activation and IL-1beta secretion, overexpression of the SPRY domain alone blocks these processes. Thus Pyrin binds to several inflammasome components thereby modulating their activity.

Comment in

This study was conducted to define the value of procalcitonin (PCT) levels in the differential diagnosis of abdominal familial Mediterranean fever (FMF) attacks from acute appendicitis. From October 2006 to January 2007, 28 FMF (12 males, 16 females) patients with acute abdominal attacks and 34 patients (18 males) with acute abdomen who underwent operation with the clinical diagnosis of acute appendicitis were consecutively enrolled in this study. FMF patients with concurrent infectious diseases were excluded. PCT values were measured by an immunofluorescent method using the B.R.A.H.M.S. PCT kit (B.R.A.H.M.S. Diagnostica, Berlin, Germany). Erythrocyte sedimentation rate (ESR), C-reactive proteins (CRP) and leucocyte levels were also noted. Mean disease duration in FMF patients was 9.6 +/- 8.1 years (range 2-33 years) and all were on colchicine therapy with a mean colchicine dosage of 1.2 +/- 0.4 mg/day. Among the operated patients, 5 were excluded: 3 patients had normal findings and 2 had intestinal perforation (PCT levels were 2.69 and 4.93 ng/ml, respectively) at operative and pathologic evaluation. There were no significant differences between the two groups with respect to gender and age (p was not significant (NS) for all). Acute phase reactants and PCT levels were increased in patients with FMF compared to patients with acute appendicitis (0.529[0.12 +/- 0.96] vs 0.095 [0.01-0.80] p < 0.001, respectively). PCT levels higher than 0.5 ng/ml were found in 11% (3/28) of FMF patients compared to 62% (18/29) of acute appendicitis patients (p < 0.001). Our results suggest that PCT could be a useful test in the differentiation of abdominal FMF attacks from acute appendicitis, though it should not supplant more conventional investigations.

Juvenile psoriatic arthritis carrying familial Mediterranean fever gene mutations in a 14-year-old Turkish girl.

Yeniay BS(1), Karaca NE, Yuksel SE, Midyat L, Kutukculer N.

Author information:

(1)Department of Pediatrics, Faculty of Medicine, Ege University, Izmir, Turkey.

Juvenile psoriatic arthritis (JPsA) is characterized by asymmetric arthritis of big and small joints, enthesitis, dactylitis, psoriatic skin lesions and nail pitting. Investigators agree that JPsA is a relatively common chronic arthropathy of childhood that differs clinically, serologically, and genetically from both juvenile idiopathic arthritis and juvenile ankylosing spondylitis. Familial Mediterranean fever (FMF) is a multisystemic autosomal recessive disease occasionally accompanied by sacroiliitis. This is characterized by recurrent self-limited attacks of fever and accompanying abdominal, chest and arthritic pain. We present a 14-year-old Turkish girl with JPsA and carrying FMF gene mutations. In this patient, JPsA was diagnosed according to her physical, laboratory and skin biopsy findings and a treatment with methotrexate and sulfasalazine was started. As an inadequate clinical and laboratory response was obtained after the first month of therapy, the patient was investigated for FMF, and was diagnosed by molecular analyses of related gene (E148Q heterozygous/V726A homozygous mutation) besides clinical findings. After 2 weeks of the colchicine treatment, symptoms of the patient regressed and acute phase reactants decreased. To our knowledge, this is the first case presenting with psoriatic arthritis and FMF gene mutations together and responds to colchicine, methotrexate and sulfasalazine dramatically in clinical and laboratory findings. This case has been presented to remind that cases with psoriatic arthritis may also carry mutations in the MEFV gene.

Nucleotide-binding oligomerization domain (Nod)2 is a sensor of muramyl dipeptides (MDP) derived from bacterial peptidoglycan. Nod2 also plays a role in some autoinflammatory diseases. Cold-induced autoinflammatory syndrome 1 (CIAS1)/NACHT domain, leucine-rich repeat, and pyrin domain-containing protein 3 (NALP3) has been suggested to be sufficient for MDP-dependent release of mature IL-1beta, but the role of Nod2 in this process is unclear. Using mice bearing selective gene deletions, we provide in vitro and in vivo data showing that MDP-induced IL-1beta release requires Nod2 and CIAS1/NALP3 as well as receptor-interacting protein-2 (Rip2), apoptosis-associated speck-like protein containing a caspase activation and recruitment domain (ASC), and caspase-1. In contrast, MDP-dependent IL-6 production only requires Nod2 and Rip2. Together, our data provide a new understanding of this important pathway of IL-1beta production and allow for further studies of the role of these proteins within the broader context of inflammatory disease.

Structural basis for PRYSPRY-mediated tripartite motif (TRIM) protein function.

James LC(1), Keeble AH, Khan Z, Rhodes DA, Trowsdale J.

Author information:

(1)Protein and Nucleic Acid Chemistry Division, Medical Research Council  
Laboratory of Molecular Biology, Cambridge CB2 2QH, UK. lcj@mrc-lmb.cam.ac.uk

The human tripartite motif (TRIM) family comprises 70 members, including HIV restriction factor TRIM5alpha and disease-associated proteins TRIM20 (pyrin) and TRIM21. TRIM proteins have conserved domain architecture but diverse cellular roles. Here, we describe how the C-terminal PRYSPRY domain mediates diverse TRIM functions. The crystal structure of TRIM21 PRYSPRY in complex with its target IgG Fc reveals a canonical binding interface comprised of two discrete pockets formed by antibody-like variable loops. Alanine scanning of this interface has identified the hot-spot residues that control TRIM21 binding to Fc; the same hot-spots control HIV/murine leukemia virus restriction by TRIM5alpha and mediate severe familial Mediterranean fever in TRIM20/pyrin. Characterization of the IgG binding site for TRIM21 PRYSPRY reveals TRIM21 as a superantigen analogous to bacterial protein A and suggests that an antibody bipolar bridging mechanism may contribute to the pathogenic accumulation of anti-TRIM21 autoantibody immune complex in autoimmune disease.

**OBJECTIVE:** The cryopyrinopathies are a group of rare autoinflammatory disorders that are caused by mutations in CIAS1, encoding the cryopyrin protein. However, cryopyrin mutations are found only in 50% of patients with clinically diagnosed cryopyrinopathies. This study was undertaken to investigate the structural effect of disease-causing mutations on cryopyrin, in order to gain better understanding of the impact of disease-associated mutations on protein function.

**METHODS:** We tested for CIAS1 mutations in 22 patients with neonatal-onset multisystem inflammatory disease/chronic infantile neurologic, cutaneous, articular syndrome, 12 with Muckle-Wells syndrome (MWS), 18 with familial cold-induced autoinflammatory syndrome (FCAS), and 3 probands with MWS/FCAS. In a subset of mutation-negative patients, we screened for mutations in proteins that are either homologous to cryopyrin or involved in the caspase 1/interleukin-1 $\beta$  signaling pathway. CIAS1 and other candidate genes were sequenced, models of cryopyrin domains were constructed using structurally homologous proteins as templates, and disease-causing mutations were mapped.

**RESULTS:** Forty patients were mutation positive, and 7 novel mutations, V262A, C259W, L264F, V351L, F443L, F523C, and Y563N, were found in 9 patients. No mutations in any candidate genes were identified. Most mutations mapped to an inner surface of the hexameric ring in the cryopyrin model, consistent with the hypothesis that the mutations disrupt a closed form of cryopyrin, thus potentiating inflammasome assembly. Disease-causing mutations correlated with disease severity only for a subset of known mutations.

**CONCLUSION:** Our modeling provides insight into potential molecular mechanisms by which cryopyrin mutations can inappropriately activate an inflammatory response. A significant number of patients who are clinically diagnosed as having cryopyrinopathies do not have identifiable disease-associated mutations.

Protracted familial mediterranean fever arthritis presenting as septic arthritis.

Usluer H(1), Bircan Z.

Author information:

(1)Department of Pediatric Nephrology, Kocaeli University Faculty of Medicine, 41380 Umuttepe, Kocaeli, Turkey.

In Familial Mediterranean Fever (FMF), arthritis is the initial symptom in 25% of patients. Although FMF arthritis is acute and self-limited, in 5% of cases protracted arthritis usually affecting large joints such as knee may occur. In this report, two cases are presented who were initially diagnosed as septic arthritis, first of which had four and the second had two synovectomy operations with the diagnosis of septic arthritis. Later on they were diagnosed as FMF with detailed history. We aimed to emphasize the importance of diagnosis of FMF, which is based mainly on history and clinical features in order to prevent unnecessary operations and suffering of the patient.

Erratum in

J Mol Diagn. 2008 Jan;10(1):109.

In the Ashkenazi Jewish population, serious and lethal genetic conditions occur with relatively high frequency. A single test that encompasses the majority of population-specific mutations is not currently available. For comprehensive carrier screening and molecular diagnostic purposes, we developed a population-specific and inclusive microarray. The arrayed primer extension genotyping microarray carries 59 sequence variant detection sites, of which 53 are detectable bi-directionally. These sites represent the most common variants in Tay-Sachs disease, Bloom syndrome, Canavan disease, Niemann-Pick A, familial

dysautonomia, torsion dystonia, mucopolidosis type IV, Fanconi anemia, Gaucher disease, factor XI deficiency, glycogen storage disease type 1a, maple syrup urine disease, nonsyndromic sensorineural hearing loss, familial Mediterranean fever, and glycogen storage disease type III. Several mutations in the selected disorders that are not prevalent per se in the Ashkenazi Jewish populations, as well pseudodeficiency alleles, are also included in the array. The initial technical evaluation of this microarray demonstrates that it is comprehensive, robust, sensitive, specific, and easily modifiable. This cost-effective array is based on a diversely applied platform technology and is suitable for both carrier screening and disease detection in Ashkenazi and Sephardic Jewish populations.

Comment in

N Engl J Med. 2007 Mar 22;356(12):1263-6.

**BACKGROUND:** Autoimmune and autoinflammatory diseases involve interactions between genetic risk factors and environmental triggers. We searched for a gene on chromosome 17p13 that contributes to a group of epidemiologically associated autoimmune and autoinflammatory diseases. The group includes various combinations of generalized vitiligo, autoimmune thyroid disease, latent autoimmune diabetes in adults, rheumatoid arthritis, psoriasis, pernicious anemia, systemic lupus erythematosus, and Addison's disease.

**METHODS:** We tested 177 single-nucleotide polymorphisms (SNPs) spanning the 17p13 linkage peak for association with disease and identified a strong candidate gene.

We then sequenced DNA in and around the gene to identify additional SNPs. We carried out a second round of tests of association using some of these additional SNPs, thus elucidating the association with disease in the gene and its extended promoter region in fine detail.

**RESULTS:** Association analyses resulted in our identifying as a candidate gene NALP1, which encodes NACHT leucine-rich-repeat protein 1, a regulator of the innate immune system. Fine-scale association mapping with the use of DNA from affected families and additional SNPs in and around NALP1 showed an association of specific variants with vitiligo alone, with an extended autoimmune and autoinflammatory disease phenotype, or with both. Conditional logistic-regression analysis of NALP1 SNPs indicated that at least two variants contribute independently to the risk of disease.

**CONCLUSIONS:** DNA sequence variants in the NALP1 region are associated with the risk of several epidemiologically associated autoimmune and autoinflammatory diseases, implicating the innate immune system in the pathogenesis of these disorders.

Widespread granulomatous dermatitis of infancy: an early sign of Blau syndrome.

Schaffer JV(1), Chandra P, Keegan BR, Heller P, Shin HT.

Author information:

(1)Ronald O. Perelman Department of Dermatology, New York University School of Medicine, New York 10016, USA. schafj04@med.nyu.edu

**BACKGROUND:** Pediatric sarcoidosis has traditionally been divided into 2 distinct groups: (1) school-aged children and adolescents with frequent involvement of the lungs and mediastinal lymph nodes (similar to adult sarcoidosis) and (2) infants and preschoolers with the triad of arthritis, uveitis, and a cutaneous eruption of discrete small papules, referred to as early-onset sarcoidosis. Blau syndrome, a rare autosomal dominant genodermatosis caused by mutations in the NOD2

(nucleotide-binding oligomerization domain 2) gene, has been considered as the familial form of early-onset sarcoidosis.

**OBSERVATIONS:** A 9-month-old boy developed an asymptomatic eruption of 1- to 2-mm, red-brown to pinkish tan, flat-topped papules on the face, trunk, and extremities. There was no evidence of ocular involvement or arthritis. The skin lesions were characterized histologically by noncaseating granulomas in a periadnexal distribution within the dermis. A family history of uveitis supported a diagnosis of Blau syndrome, and analysis of the NOD2 gene revealed a heterozygous gain-of-function missense mutation (Arg334Trp) that has previously been detected in Blau syndrome kindreds.

**CONCLUSION:** We draw attention to granulomatous dermatitis as an early manifestation of Blau syndrome and highlight emerging molecular evidence that this heritable autoinflammatory disorder and early-onset sarcoidosis represent a single disease entity.

Urinary glycosaminoglycan levels as a marker of renal amyloidosis in patients with familial Mediterranean fever.

Nadir H(1), Unver S, Ozel AM, Yazgan Y, Gultepe M, Evrenkaya TR, Demirturk L, Gurbuz AK.

Author information:

(1)GATA Haydarpasa Training Hospital Department of Internal Medicine, Istanbul, Turkey.

**INTRODUCTION AND AIM:** Familial Mediterranean Fever (FMF) is an autosomal recessive disease with a defect in the pyrine gene and is manifested with short attacks of inflammatory serositis, fever, and erysipelas-like skin lesions.

Secondary amyloidosis is the most serious complication of the disease, in which extracellular deposits of amyloid (an amorphous and eosinophilic protein) are seen in tissues. Glycosaminoglycans are mucopolysaccharide molecules that take place in amyloid deposits with fibrillar links to amyloid. They form glycoproteins by linking to proteins, and their free forms are excreted in the

urine in the form of polysaccharides. The aims of this study were to evaluate if the urinary levels of glycosaminoglycans have a predictive value in the diagnosis of amyloidosis secondary to FMF and if these levels are affected by treatment with colchicine.

**MATERIALS AND METHODS:** The study included 55 volunteer patients (age range: 18-36 years) with FMF (15 with amyloidosis) of the same socio-economic circumstances without other concomitant inflammatory, malignant, or chronic diseases, along with 20 healthy subjects as control. Urinary glycosaminoglycan levels were determined twice, once when the patients were on medication and once after they have stopped treatment for two weeks.

**RESULTS:** Initial mean urinary GAG levels were significantly lower in amyloidosis patients. Mean urinary GAG levels determined two weeks after the cessation of colchicine was also significantly lower than controls in both amyloidosis and non-amyloidosis FMF patients. Likewise, in patients with a disease duration longer than ten years, urinary GAG levels were also lower than those with a disease duration of less than three years.

**CONCLUSION:** Urinary GAG level can have a predictive value for amyloidosis in patients with FMF, and it can also be used as a non-invasive marker for screening the effects of colchicine on fibrillogenesis as well as for the follow-up of the patients.

(1)Service of Rhumatologie, Department of Medicine, Centre Hospitalier Universtaire Vaudois and University of Lausanne, 1011 Lausanne, Switzerland.  
AlexanderKai-Lik.So@chuv.ch

Monosodium urate crystals stimulate monocytes and macrophages to release IL-1beta through the NALP3 component of the inflammasome. The effectiveness of IL-1 inhibition in hereditary autoinflammatory syndromes with mutations in the NALP3

protein suggested that IL-1 inhibition might also be effective in relieving the inflammatory manifestations of acute gout. The effectiveness of IL-1 inhibition was first evaluated in a mouse model of monosodium urate crystal-induced inflammation. IL-1 inhibition prevented peritoneal neutrophil accumulation but TNF blockade had no effect. Based on these findings, we performed a pilot, open-labeled study (trial registration number ISRCTN10862635) in 10 patients with gout who could not tolerate or had failed standard antiinflammatory therapies. All patients received 100 mg anakinra daily for 3 days. All 10 patients with acute gout responded rapidly to anakinra. No adverse effects were observed. IL-1 blockade appears to be an effective therapy for acute gouty arthritis. The clinical findings need to be confirmed in a controlled study.

It is being questioned if *Helicobacter pylori* infection, which causes a chronic inflammatory response, can increase the frequency and severity of attacks in patients with Familial Mediterranean Fever (FMF) and if the impact of inflammatory response can be diminished by eradication of the infection. To evaluate if there is difference in interleukin (IL)-6 levels of *H. pylori*-positive and -negative patients both before and during FMF attacks; if there is a change in IL-6 levels following successful eradication treatment; and if MEFV gene mutations have an effect on IL-6 levels. IL-6 levels were evaluated in 47 FMF patients before and during FMF attacks. Genetic testing to determine M694V, M694I, E148Q, V726V, M680I mutations was also performed in all patients.

IL-6 levels were also determined after successful eradication of the infection in H. pylori-positive patients. IL-6 levels were compared in H. pylori-positive and -negative patients, and before and after eradication treatment in patients who cleared the infection. Number of patients in tested mutation groups was not enough to compare IL-6 levels in these groups. Thirty-four patients (73.9%) were H. pylori-positive. Before FMF attack there was no statistically significant difference in IL-6 levels of H. pylori-positive and -negative groups. IL-6 levels were significantly higher in both groups during the attacks than before the attacks ( $p < 0.05$ ). There was a statistically significant decline in IL-6 levels both before and during FMF attacks, following eradication therapy in patients who cleared the infection ( $p < 0.05$ ). In patients with homozygous M694V mutation, IL-6 levels before and during the FMF attacks were not significantly different in H. pylori-positive and -negative groups, despite a much lower level found in H. pylori-negative group ( $p > 0.05$ ). Comparisons were not performed in other mutation groups because of small number of patients in each group. C-reactive protein (CRP) and fibrinogen levels were not significantly different between the groups ( $p > 0.05$ ). We believe that the observation of IL-6 levels are lower both before and during FMF attacks both in H. pylori-negative patients and in patients who cleared the infection after eradication therapy is very important in the determination of the role of eradication of H. pylori on decreasing the frequency and severity of FMF attacks. As for today, the correlation between H. pylori infection and FMF seems unlikely; however, studies evaluating the interaction of cytokines in both diseases and their relations and roles will be needed to reach better conclusions.

Successful treatment of renal amyloidosis due to familial cold autoinflammatory syndrome using an interleukin 1 receptor antagonist.

Thornton BD(1), Hoffman HM, Bhat A, Don BR.

Author information:

(1)Division of Nephrology, University of California Davis Medical Center, La Jolla, CA, USA.

Familial cold autoinflammatory syndrome (FCAS) is an autosomal dominant disorder characterized by episodic fever, arthralgias, conjunctivitis, and rash triggered by cold exposure. FCAS is rarely associated with progressive renal insufficiency caused by renal amyloidosis. The genetic defect in patients with this disorder is caused by a mutation in the gene encoding the protein cryopyrin, leading to uninhibited activation of systemic inflammation through specific cellular signaling with increased production of a number of key cytokines, including interleukin 1. We describe the successful treatment of a patient with renal amyloidosis caused by FCAS by using a novel interleukin 1-receptor antagonist. Use of specific anticytokine therapy may be a new paradigm in the treatment of patients with renal amyloidosis caused by systemic inflammatory diseases.

Familial Mediterranean fever in children: a single centre experience in Jordan.

Al-Wahadneh AM(1), Dahabreh MM.

Author information:

(1)Paediatric Immunology Clinic, Department of Paediatrics, King Hussein Medical Centre, Amman, Jordan. awah88@hotmail.com

Familial Mediterranean fever is quite prevalent among Arabs. We reviewed the files of 56 patients diagnosed with familial Mediterranean fever and followed up at King Hussein Medical Centre in Jordan over 4 years for their clinical profile, course, genotype, treatment and complications. There were 30 males and 26 females with a mean age at onset of 5.2 years. Abdominal pain (79%) was the commonest manifestation, followed by arthritis (13%) and chest pain (4%). Family history was positive in 50% of patients. Regarding treatment, 97% of patients responded well to colchicine, and amyloidosis was not documented in any patients after 5 years follow-up. The commonest genotype was M694 (64%), followed by heterozygous M694V-V726A (23%) and E148Q (8%).

A splice site mutation confirms the role of LPIN2 in Majeed syndrome.

Al-Mosawi ZS(1), Al-Saad KK, Ijadi-Maghsoodi R, El-Shanti HI, Ferguson PJ.

Author information:

(1)Salmaniyah Medical Complex, Manama, Kingdom of Bahrain.

Majeed syndrome is an autoinflammatory disorder consisting of chronic recurrent multifocal osteomyelitis, congenital dyserythropoietic anemia, and neutrophilic dermatosis. To date, 2 unrelated families with Majeed syndrome have been reported. Mutations in LPIN2 have been found in both families. Here we report a third consanguineous family with Majeed syndrome with a novel mutation. The patient, a 3-year-old Arabic girl, had hepatosplenomegaly and anemia as a neonate. At age 15 months, she developed recurrent episodes of fever and multifocal osteomyelitis. In addition, bone marrow aspiration demonstrated significant dyserythropoiesis, suggesting Majeed syndrome. Coding sequences and splice sites of LPIN2 were sequenced in the patient and her mother. A homozygous single-basepair change was detected in the donor splice site of exon 17 (c.2327+1G>C) in the patient; her mother was heterozygous at this site. These data confirm the role of LPIN2 mutations in the etiology of Majeed syndrome.

**OBJECTIVE:** Familial Mediterranean fever (FMF) had been considered a rare disease in Japan, but since the identification of the causative gene (MEFV) for pyrin/marenostrin in 1997, the occurrence of FMF has been successively reported. We reviewed the clinical features of 7 patients diagnosed with FMF by gene analysis.

**METHODS:** During April 2003 and March 2005, we investigated the clinical symptoms, treatment and MEFV types of 7 FMF patients who consulted the General Outpatient Clinic of Chiba University Hospital.

**RESULTS:** Six patients were in their 20-30s, and one was 54 years of age. There were 4 males and 3 females including a mother and child, and an adult male and his female cousin. Three were solitary incidences. In addition to intermittent fever, 4 patients had chest pain, 1 had abdominal pain, and 1 had chest or abdominal pain. The frequency of attacks was once per 3 months to 1 year in the early stage of the disease, but it slowly increased with disease progression.

Leukocytosis and C-reactive protein (CRP) elevation were noted during attacks in all patients. On investigation of MEFV, heterozygosity for the compound pyrin L110P-E148Q/M694I, E148Q/M694I, L110P/E148Q and heterozygosity for pyrin variant M694I alone were detected. Daily administration of colchicine at 0.5 mg prevented attacks in 6 patients, however 1 patient required 1.0 mg for adequate prevention.

**CONCLUSIONS:** Although the incidence is rare, internists should be aware of the characteristic symptoms of FMF: periodic fever and serositis symptoms, and its presence in Japan despite the disease name.

Author information:

(1)Academic Unit of Ophthalmology, University of Birmingham, Birmingham, United Kingdom. g.r.wallace@bham.ac.uk

Behçet's disease (BD) is a multisystem inflammatory disease characterized by recurrent orogenital ulceration, ocular inflammation, and skin lesions. The etiology of the disease is currently unknown but evidence suggests that there is a strong genetic component mediating the chronicity of the disorder. We have examined the association between polymorphisms at position -1082, and -819 in the promoter region of the gene encoding IL-10 in patients with Behçet's disease from two distinct patient populations. The IL-10 -1082AA genotype was weakly associated with BD when all patients were analyzed as a group ( $p = 0.04$ , OR 1.4, 95% CI 1.1-1.9), but not in the UK or Middle Eastern (ME) cohorts of patients alone compared to local controls. An association with IL-10 -819T was evident in all BD patients, ( $p = 0.02$ , OR 1.5, 95% CI 1.1-2.0), and this was because of an association in the UK but not ME patients ( $p = 0.0004$ , OR 2.1, 95% CI 1.4-3.3). The -1082A/-819T haplotype, which is linked to low production of this cytokine, was not significantly associated with Behçet's disease. This link between BD, a chronic, relapsing, autoinflammatory condition, and a genotype associated with low IL-10 production provides evidence that abnormalities in the genetic control of cytokine levels may be relevant in influencing the immune response in Behçet's disease in some patient groups.

Monocytes from familial cold autoinflammatory syndrome patients are activated by mild hypothermia.

Rosengren S(1), Mueller JL, Anderson JP, Niehaus BL, Misaghi A, Anderson S, Boyle DL, Hoffman HM.

Author information:

(1)Division of Rheumatology, Allergy and Immunology, University of California at San Diego School of Medicine, La Jolla, CA 92093-0635, USA.

**BACKGROUND:** Familial cold autoinflammatory syndrome (FCAS) is characterized by rash, fever, and arthralgia in response to cold exposure. CIAS1, the gene that codes for cryopyrin, is mutated in FCAS. Treatment with anakinra (IL-1 receptor antagonist) prevents symptoms, indicating a crucial role for IL-1 in this disease.

**OBJECTIVE:** To study cytokine responses to cold exposure in monocytes from subjects with FCAS.

**METHODS:** Adherence-enriched monocytes were incubated at 32 degrees C or 37 degrees C. Transcription and release of IL-1beta, IL-6, and TNF-alpha were monitored by quantitative PCR and ELISA.

**RESULTS:** The FCAS monocytes but not control cells responded to 4 h incubation at 32 degrees C with significant secretion of IL-1beta. At 16 h, IL-1beta, IL-6, and TNF-alpha were all significantly elevated in FCAS monocytes at 32 degrees C. Increased cytokine transcription was observed in all monocytes at 4 hours, but at 16 hours it was only seen in FCAS monocytes incubated at 32 degrees C. Incubation at 32 degrees C for as little as 1 hour sufficed to induce measurable IL-1beta release. Caspase-1 inhibitors prevented the cold-induced IL-1beta release, whereas a purinergic antagonist did not. Anakinra had no effect on the early IL-1beta release but significantly reduced the late-phase transcription and release of all cytokines.

**CONCLUSION:** FCAS monocytes respond to mild hypothermia with IL-1beta release, which in turn induces autocrine transcription and secretion of IL-6 and TNF-alpha as well as stimulation of further IL-1beta production.

**CLINICAL IMPLICATIONS:** These results confirm the central role of IL-1beta in FCAS and support the use of IL-1 targeted therapy in these patients.

meyaabdelkefi@yahoo.fr

**INTRODUCTION:** Familial Mediterranean fever (FMF) is an autosomal recessive disease characterized by recurrent attacks of fever and painful episodes of sterile peritonitis, pleuritis and arthritis. Among rare symptoms of the disease, muscular manifestations, first described in 1945, sometimes as one of the main clinical manifestations or as its sole feature should be recognized. We present a patient with FMF in whom severe myalgia were predominant.

**CASE REPORT:** An 18 year-old Tunisian boy treated with corticosteroids for an "inflammatory myopathy" in another institution was admitted for abdominal pain. FMF was suspected because of a history of paroxysmal abdominal pain with fever from the age of 5 leading two times to laparotomy and one attack of left knee arthritis at the age of 14. FMF diagnosis was confirmed genetically, corticosteroids were tapered and a treatment with colchicine was started. Two years and a half later, he was admitted for severe and incapacitating myalgia of the upper and lower limbs without fever nor abdominal pain that responded well to rest and colchicine. Myalgia was then definitively attached to FMF.

**CONCLUSION:** Three clinical patterns of myalgia are now well identified in FMF: the spontaneous pattern as observed in our patient, the exercise-induced pattern and the protracted febrile myalgia syndrome. The three patterns differ in the severity of pain, grade of fever and duration of the episode.

(1)Department of Dermatology, Our Lady's Children's Hospital, Crumlin, Dublin, Ireland.

Familial cold auto-inflammatory syndrome, Muckle-Wells syndrome and chronic infantile neurologic, cutaneous, articular syndrome are related disorders associated with mutations in the CIAS1 gene. They appear to represent a continuum of one disease characterized by IL-1-mediated inflammation. Until recently, these conditions have been difficult to treat; however, with the advent of IL-1-receptor antagonist therapy, many reports of successful treatment of patients with these autoinflammatory diseases have emerged in the past 2 years. We describe an 8-year-old girl, diagnosed with Familial cold auto-inflammatory syndrome, confirmed by presence of a novel CIAS1 mutation, who was refractory to symptomatic treatment. As frequent attacks of urticaria and associated arthralgia had a debilitating effect on the child's lifestyle, a trial of IL-1-receptor antagonist (anakinra) was instituted. Dramatic sustained clinical improvement was evident within days and serum amyloid and C-reactive protein levels normalized within a month. Although several authors have reported successful use of this agent in children with chronic infantile neurologic, cutaneous, articular syndrome, we believe ours is the first report of successful treatment with anakinra in a young child with familial cold auto-inflammatory syndrome.

[Spontaneous and inducible respiratory burst of monocytes and neutrophils in periodic autoinflammatory fever].

[Article in Russian]

Avetisyan SA, Davtian TK, Akopian GS, Manukian AM, Pogolian DA.

We investigated spontaneous, chemotaxis-, phagocytosis- and protein kinase C-dependent respiratory burst of neutrophils and monocytes in the whole blood of patients with familial Mediterranean fever (FMF). We also analysed transient

activation of neutrophils and monocytes on the level of a single cell using flow cytometry. It is shown that compared to healthy donors, the respiratory burst of monocytes and neutrophils in the patients is characterized by an increase in both spontaneous and inducible production of free radicals. In FMF patients probability of transient activation of chemotaxis- and phagocytosis-dependent respiratory burst is higher. This has an important influence rather on production of free radical by activated cells than on their number.

Pombe Cdc15 homology (PCH) proteins: coordinators of membrane-cytoskeletal interactions.

Chitu V(1), Stanley ER.

Author information:

(1)Department of Developmental Biology and Molecular Biology, Albert Einstein College of Medicine, 1300 Morris Park Avenue, Bronx, New York, NY 10461, USA.

Cellular adhesion, motility, endocytosis, exocytosis and cytokinesis involve the coordinated reorganization of the cytoskeleton and of the plasma membrane. The 'Pombe Cdc15 homology' (PCH) family of adaptor proteins has recently been shown to coordinate the membrane and cytoskeletal dynamics involved in these processes by curving membranes, recruiting dynamin and controlling the architecture of the actin cytoskeleton. Mutations in PCH family members or proteins that interact with them are associated with autoinflammatory, neurological or neoplastic diseases. Here, we review the nature, actions and disease associations of the vertebrate PCH family members, highlighting their fundamental roles in the regulation of processes involving membrane-cytoskeletal interactions.

**BACKGROUND:** Cold-induced urticaria is a form of physical urticaria which is characterized by rapid onset of pruritus, erythema, and swelling after exposure to a cold stimulus. Familial cold autoinflammatory syndrome (FCAS) is a rare autosomal-dominant condition characterized by unremitting attacks of cold-induced urticaria, often accompanied by other systemic manifestations. The disorder was previously shown to be caused by mutations in CIAS1, encoding a pyrin-like protein also involved in the pathogenesis of Muckle-Wells syndrome (MWS), and chronic infantile neurological cutaneous and articular syndrome (CINCA).

**METHODS:** In the present study, using direct sequencing, we assessed a two-generation family of Jewish Ethiopian origin, including 3 members affected with FCAS.

**RESULTS:** We identified a novel CIAS1 mutation, F525C. The mutation was shown to affect a highly conserved residue of the protein and to segregate with the disease throughout the extended family.

**CONCLUSIONS:** Our results add to the expanding spectrum of mutations in CIAS1 and provide evidence for striking phenotypic heterogeneity in inherited autoinflammatory syndromes. This is the first report of inherited cold urticaria in a family of Ethiopian origin.

Colchicine is the only drug known to effectively prevent familial Mediterranean fever (FMF) attacks, as well as FMF-associated amyloidosis. Unfortunately, colchicine is neither always effective nor always well tolerated, leaving some patients and their physicians with inadequate weaponry to fight this hazardous disease. We present a patient with recurrent episodes of abdominal, scrotal, and joint attacks, who was diagnosed with FMF and advised to take colchicine. Diarrhea prevented optimal treatment with this drug and led to a trial of etanercept, with resolution of FMF manifestations. This case adds to a growing body of evidence suggesting that tumor necrosis factor (TNF) blockade may result in resolution and prevention of further FMF attacks.

Tumor Necrosis Factor Receptor Associated Periodic Syndrome (TRAPS) is an autoinflammatory disorder associated to a mutation of the Tumor Necrosis Factor Receptor 1 (TNFR1) whose clinical presentation consists on recurrent episodes of prolonged fever, abdominal pain, myalgias, migratory cutaneous erythema, conjunctivitis or periorbital edema. The diagnosis is confirmed by genetic

analysis of the TNFR1 gene. Its main complication is amyloidosis and the treatment is based on the use of corticosteroids or anti-TNF antibodies. We report a 17 year-old male and 23 year-old female with the syndrome. Both cases had heterozygous mutations of the TNFR1 gene, C30R in the first case and T50M in the second case.

Colchicine, a highly poisonous alkaloid, is a commonly used treatment for gout, Bechet's disease, and familial Mediterranean fever. Despite the knowledge of its side effects, the near universally fatal consequence of a significant overdose is commonly under-appreciated. In this report, we present a case series of 9 patients over the past 15 years (from within the Auckland region of New Zealand) that have presented with a colchicine overdose. Surprisingly, a significant number were accidental overdoses and all cases, apart from one, resulted in death. We question the current knowledge base about the toxicity of this drug amongst prescribers, patients, and their families and its use in the treatment of acute gout. Given its extremely narrow therapeutic index, should the manner in which medical practitioners prescribe this drug be reassessed?

(1)Faculté de Médecine, Laboratory of Human Genetics, 17 rue Jebel Lakhdar, Tunis 1007, Tunisia. habiba.chaabouni@rns.tn

**OBJECTIVES:** To identify the frequency and distribution of familial Mediterranean fever (FMF) gene (MEFV) mutations in Tunisian patients.

**PATIENTS AND METHODS:** This study was performed in the Genetic Department of Tunis University Hospital. A clinical diagnosis of FMF was made according to published criteria. Mutation screening of the MEFV gene was performed in the Human Genetic Laboratory of the "Faculté de Medecine de Tunis" for 8 mutations including the 5 most common known mutations M694V, V726A, M694I, M680I, and E148Q. The tests performed were polymerase chain reaction (PCR) restriction-digestion for M694V, V726A, M680I, R761H, E148Q; amplification refractory mutation system for A744S, M694I; and PCR-electrophoresis assay for I692del.

**RESULTS:** Of the 139 unrelated patients investigated, 61 (44%) had 1 or 2 mutations. In 78 (56%) probands no mutation was identified: 28 patients were homozygous; 16 were compound-heterozygous; 2 had complex alleles; and 17 had only 1 identifiable mutation. Of the mutations, M680I, M694V, M694I, V726A, A744S, R761H, I692DEL, and E148Q accounted for 32, 27, 13, 5, 3, 1, 1, and 18%, respectively.

**CONCLUSION:** The profile of the MEFV gene mutations in the Tunisian population is

concordant with other Arab populations but with some differences. M680I is the most common mutation, while V726A, the commonest mutation among Arabs, is rare in our population.

Macrophage inflammatory protein-1alpha: a link between innate immunity and familial Mediterranean fever?

Dizdar O(1), Kalyoncu U, Karadag O, Akdogan A, Kiraz S, Ertenli I, Barista I, Calguneri M.

Author information:

(1)Hacettepe University Faculty of Medicine, Department of Internal Medicine, Division of Medical Oncology, 06100 Sıhhiye, Ankara, Turkey. omerdiz@yahoo.com

The aim of this study is to investigate the relationship between chemokines and the inflammation in Familial Mediterranean Fever (FMF). Forty-nine patients with FMF (41 in remission and 8 in acute attack period) and 20 healthy controls were included in the study. Serum levels of macrophage inflammatory protein-1alpha (MIP-1alpha) were assessed in the patients and the controls, along with other parameters of disease activity, i.e., fibrinogen, C-reactive protein and erythrocyte sedimentation rate. Serum MIP-1alpha levels of the patients with FMF in acute attack period were significantly higher than the patients in remission and healthy controls ( $p=0.02$  and  $p=0.038$ , respectively). MIP-1alpha levels were weakly correlated with CRP ( $r=0.32$ ,  $p=0.032$ ) levels. MIP-1alpha may have a role in the pathogenesis of FMF attacks. MIP-1alpha and other chemokines may constitute a link between the innate immune system and FMF.

First report of macrophage activation syndrome in hyperimmunoglobulinemia D with periodic fever syndrome.

Rigante D(1), Capoluongo E, Bertoni B, Ansuini V, Chiaretti A, Piastra M, Pulitanò S, Genovese O, Compagnone A, Stabile A.

Author information:

(1)Department of Pediatric Sciences, Università Cattolica Sacro Cuore, Rome, Italy. drigante@gmail.com

We describe for the first time a case of macrophage activation syndrome in a child with hyperimmunoglobulinemia D with periodic fever syndrome who required intensive care support. Up-regulated monokine production, high serum levels of triglycerides and ferritin, clotting abnormalities with hypofibrinogenemia, and rapidly evolving pancytopenia should alert the clinician to the possible diagnosis of macrophage activation syndrome, even in autoinflammatory diseases characterized basically by the periodic recurrence of unprovoked inflammatory attacks. Bone marrow aspiration showing well-differentiated macrophages phagocytosing hematopoietic elements remains the main tool for a final diagnosis, and cyclosporine is the best strategy for treatment.

Synovial angiostatic non-ELR CXC chemokines in inflammatory arthritides: does

## CXCL4 designate chronicity of synovitis?

Erdem H(1), Pay S, Musabak U, Simsek I, Dinc A, Pekel A, Sengul A.

### Author information:

(1)Division of Rheumatology, Gulhane Military School of Medicine, Ankara, Turkey.

In our previous studies, we found higher synovial fluid (SF) levels of angiogenic ELR(+) CXC chemokines such as CXCL1, CXCL5, CXCL6 and CXCL8, which play an important role in neutrophil migration and angiogenesis, and more abundant synovial CXCR2 chemokine receptor expression in patients with rheumatoid arthritis (RA) than those with Behçet's disease (BD), familial Mediterranean fever and osteoarthritis (OA). As a continuation of our previous studies, we investigated synovial levels of angiostatic non-ELR CXC chemokines (CXCL4, CXCL9 and CXCL10) in patients with RA, BD, spondyloarthritis (SpA), and OA. Seventy (17 RA, 15 BD, 19 SpA, and 19 OA) patients were enrolled in the study. The levels of CXCL4, CXCL9, and CXCL10 were measured by ELISA. The SF levels of CXCL4 in patients with RA were higher than those of the patients with BD, SpA, and OA ( $P = 0.007$ ,  $P = 0.022$ , and  $P = 0.017$ , respectively). No difference was found with respect to CXCL4 levels among the BD, SpA, and OA patients. The synovial CXCL9 levels of patients with RA and SpA were found to be higher than those of the patients with OA ( $P = 0.002$  and  $P = 0.005$ , respectively), while no statistically significant difference was detected among the other groups. With regard to SF CXCL10 levels, patients with RA had higher levels as compared to patients with OA ( $P = 0.002$ ), but no significant difference was found among the other groups. CXCL9 correlated with CXCL4 and CXCL10 ( $P < 0.05$  for both) in patients with RA. No correlation was found in other parameters. The angiostatic non-ELR CXC chemokines were expressed in synovial inflammation. We proposed that angiostatic non-ELR CXC chemokines may increase to balance angiogenic ELR (+) CXC chemokines in which increased levels were shown in patients with inflammatory arthritides and CXCL4 may contribute to designate the chronicity of synovitis in patients with RA. In addition, as CXCL-9 and CXCL-10 play crucial role in inflammation characterized by Th1 polarization, we suggested that they may contribute to the commencement and the perpetuation of synovitis seen in these groups of arthritides.

Mevalonate kinase deficiency is a rare inborn disorder of isoprenoid and sterol biosynthesis characterized by a recurrent autoinflammatory syndrome and, in most severe cases, psychomotor delay. Clinical manifestations can be very complex and, in some cases, mimic a chronic inflammatory disease. Diagnosis is also complex and often requires immunologic, genetic, and biochemical investigations. There is no standardized therapy, but biological agents could help to control inflammatory complaints in some cases. A severe case of mevalonate kinase deficiency that was associated with nephritis and successfully treated with anakinra (interleukin 1 receptor antagonist) is reported here, and new insights into diagnosis and therapy of this complex disorder are discussed.

Early ultrasonographic markers of atherosclerosis in patients with familial Mediterranean fever.

Sari I(1), Karaoglu O, Can G, Akar S, Gulcu A, Birlik M, Akkoc N, Tunca M, Goktay Y, Onen F.

Author information:

(1)Department of Internal Medicine, Division of Rheumatology, School of Medicine, Dokuz Eylul University, 35340, Inciralti, Izmir, Turkey.

Systemic inflammation plays an important role in the development of atherosclerosis (AS). The aim of this study was to evaluate the presence of early AS in patients with familial Mediterranean fever (FMF) that is characterized by recurrent inflammatory attacks of serositis. Sixty-one FMF patients (30 Male/31 Female; 31.5 [18-54] years) and 31 healthy controls (16 Male/15 Female; 31 [22-58] years) were studied. All FMF patients were on regular daily colchicine treatment and during attack-free periods. Both the FMF patients and controls with a history of diabetes mellitus (DM), hypertension, and hyperlipidemia were excluded. Body mass index (BMI) was calculated. Serum lipids, C-reactive protein (CRP), and erythrocyte sedimentation rate (ESR) were assessed. Two-hour oral glucose tolerance test was performed to rule out DM and glucose intolerance. To investigate early AS "endothelium-dependent flow-mediated dilatation (FMD%)," "nitroglycerin-induced endothelium-independent peripheral vasodilatation (NTG%)," and intima-media thickness (IMT) of common carotid arteries (CCA) were measured by ultrasonography. The median disease duration for FMF patients was 16 (1-45) years. Age, sex, BMI, smoking status, and serum lipids were comparable in patients and controls ( $p > 0.05$ ). However, ESR and standard CRP were significantly higher in the patients group ( $p < 0.05$ ). There were no differences in the measurements of right, left, and averaged IMT of CCA between patients and controls ([0.49 vs 0.5], [0.51 vs 0.52] and [0.5 vs 0.51];  $p > 0.05$ , respectively). None of the subjects had carotid artery plaques. FMD% and NTG% were also similar in patients and controls group ([18.2 vs 20.6] and [24.2 vs 22.5];  $p > 0.05$ , respectively). This study suggests that the markers of early AS

are not impaired in FMF patients on regular daily colchicine treatment.

tilmann.kallinich@charite.de

The daily application of colchicine is the standard therapy for prophylaxis of attacks and amyloid deposition in familial Mediterranean fever. However, because of many issues (eg, dosage, time of introduction, etc), no standardized treatment recommendations have been established. In this work we review the available literature on colchicine use with respect to its indication, efficacy, mode of application, and safety in children and adolescents with familial Mediterranean fever. On the basis of this analysis, a consensus statement on the application of colchicine in children and adolescents with familial Mediterranean fever was developed by caregivers from Germany, Austria, and Turkey.

Autoinflammatory diseases.

Grateau G(1).

Author information:

(1)Service de médecine interne, hôpital Tenon, Assistance publique-hôpitaux de Paris (AP-HP), Paris, France. gilles.grateau@tnn.aphp.fr

Autoinflammatory diseases can be specified as inborn errors of the innate immune system. The main component of autoinflammatory diseases is the group of hereditary periodic fevers which are characterised by intermittent bouts of clinical inflammation with focal organ involvement mainly: abdomen, musculoskeletal system and skin. The most frequent one is familial Mediterranean fever that affects patients of Mediterranean descent all over the world.

Recently, three other types have been characterised, clinically as well as genetically: Tumor Necrosis Factor receptor superfamily 1A Associated Periodic Fever Syndrome, hyperimmunoglobulinemia D and periodic fever syndrome/ mevalonate kinase deficiency, and the most recently recognised entity which includes Muckle Wells, familial cold autoinflammatory/familial cold urticaria, and the Chronic infantile neurological cutaneous and articular/Neonatal onset multisystemic inflammatory disease syndromes. A thorough diagnosis is warranted, as clinical and therapeutic management is specific for each of these diseases. In addition to hereditary periodic fever, autoinflammatory diseases also encompass Blau, Majeed, and PAPA syndromes. The underlying genetic defects of these inflammatory diseases appear to be specific for each type, involving several so far unknown proteins involved in innate immunity, and have already opened new avenues in our understanding of the inflammatory response.

Peritoneal adhesions and intestinal obstructions in patients with familial Mediterranean fever--are they more frequent?

Berkun Y(1), Ben-Chetrit E, Klar A, Ben-Chetrit E.

Author information:

(1)Department of Pediatrics, Safra Children's Hospital, Sheba Medical Center, Tel-Hashomer, Israel. berkun@md.huji.ac.il

**OBJECTIVE:** Familial Mediterranean fever (FMF) is characterized by recurrent episodes of peritonitis. A controversy exists as to whether intestinal obstruction due to peritoneal adhesions is more common among FMF patients compared with healthy controls. The aim of the study was to estimate the rate of spontaneous or postsurgical small-bowel obstruction (SBO) in FMF patients.

**METHODS:** We reviewed the charts of 560 FMF patients followed in our clinic for the occurrence of spontaneous SBO. We also assessed the occurrence of postappendectomy intestinal obstruction among 89 FMF patients compared with 417 individuals without FMF who underwent an appendectomy without other abdominal surgery in the same medical center.

**RESULTS:** Ten of 471 FMF patients (2.1%) developed spontaneous SBO, 8 of whom required laparotomy and adhesiolysis. Six of 89 FMF patients (6.7%) who underwent appendectomy developed SBO. None of the non-FMF patients developed SBO.

**CONCLUSIONS:** Our retrospective study showed that FMF patients are at a higher risk than healthy individuals for developing SBO either spontaneously or as a postsurgical complication. Physicians should be alert to this possible complication when FMF patients arrive at the emergency room.

Author information:

(1)Division of Rheumatology, Gulhane Military School of Medicine, Ankara, Turkey.  
isimsek@gara.edu.tr

Th1 type polarization has been implicated in the pathogenesis of familial Mediterranean fever (FMF). Interleukin-12 (IL-12) and IL-10 are proinflammatory cytokines, which play crucial role in Th1 and Th2 type immune response, respectively. IL-18 has a dual effect on T cell response: it was recognized as an IFN-gamma-inducing factor in T cells; acting in synergy with IL-12, leading to the development of Th1 type immune responses. But, in the absence of IL-12, IL-18 can promote the production of Th2 cytokines and take part in allergic inflammation. The aim of this study is to measure serum levels of IL-10, IL-12, and IL-18 in patients with FMF, and to investigate the relationship of their expressions with FMF attacks. Serum IL-10, IL-12, and IL-18 levels from patients with FMF were investigated. Thirty-one FMF patients with attack-free, 24 FMF patients with attack and 20 healthy controls were enrolled in the study. The levels of IL-10, IL-12p70 and IL-18 were measured by ELISA. Serum IL-10 levels were not different in FMF patients with attack and attack-free, and healthy controls. Serum IL-12 levels in FMF patients both with attack and attack-free were significantly higher than healthy controls ( $P = 0.002$  and  $P = 0.047$ , respectively). There were no differences between FMF patients with attack and attack-free with regard to serum IL-12 levels. Serum IL-18 levels in FMF patients with attack and attack-free were significantly higher than healthy controls ( $P < 0.001$  for both groups). With respect to serum IL-18 levels, no difference was found between FMF patients with attack and attack-free. Our results suggest that IL-12 and IL-18 contribute to the establishment of Th1 polarization seen in FMF and play a part in its pathogenesis. Detection of increased levels of IL-12 and IL-18 in patients with inactive disease implies that they seem to assist Th1 activation and subclinical inflammation persisting during the attack-free period of the disease.

Chronic inflammation: importance of NOD2 and NALP3 in interleukin-1beta generation.

Ferrero-Miliani L(1), Nielsen OH, Andersen PS, Girardin SE.

Author information:

(1)Department of Gastroenterology, Herlev Hospital, University of Copenhagen, Denmark. lfm@humbio.dk

Inflammation is part of the non-specific immune response that occurs in reaction to any type of bodily injury. In some disorders, the inflammatory process - which under normal conditions is self-limiting - becomes continuous and chronic inflammatory diseases might develop subsequently. Pattern recognition molecules (PRMs) represent a diverse collection of molecules responsible for sensing danger signals, and together with other immune components they are involved in the first line of defence. NALP3 and NOD2, which belong to a cytosolic subgroup of PRMs, dubbed Nod-like-receptors (NLRs), have been associated recently with inflammatory diseases, specifically Crohn's disease and Blau syndrome (NOD2) and familial cold autoinflammatory syndrome, Muckle-Wells syndrome and chronic infantile neurological cutaneous and articular syndrome (NALP3). The exact effects of the defective proteins are not fully understood, but activation of nuclear factor (NF)-kappaB, transcription, production and secretion of interleukin (IL)-1beta and activation of the inflammasome are some of the processes that might hold clues, and the present review will provide a thorough update in this area.

Author information:

(1)Department of Gastroenterology, Türkiye Yüksek İhtisas Hospital, Ankara, Turkey.

AIMS: To assess the levels of soluble vascular endothelial growth factor receptor-1 (sVEGFR-1) in patients with familial Mediterranean fever (FMF).

METHODS: Plasma levels of sVEGFR-1 were investigated in 33 FMF patients in an attack-free period (mean age 30.8 years; males/females 10/23), in 15 patients with acute FMF attack (mean age 32.7 years; males/females 7/8), and 19 healthy controls (mean age 32 years; males/females 11/8). Levels of sVEGFR-1 were also compared among patients who were receiving colchicine and those who were not.

RESULTS: Plasma sVEGFR-1 levels were  $3.49 \pm 1.10$ ,  $3.53 \pm 1.02$ , and  $0.37 \pm 0.28$  ng/ml for FMF patients in the attack-free period, FMF patients with acute attack, and healthy controls, respectively. Plasma sVEGFR-1 levels were significantly higher in FMF patients with and without acute attack compared to the control group ( $p < 0.05$ ). sVEGFR-1 levels were not statistically significant between patients with acute attack and attack-free FMF patients ( $p > 0.05$ ). The plasma levels of sVEGFR-1 were also comparable in colchicine treated and untreated patients.

CONCLUSION: Our data suggest that sVEGFR-1 may have a role in the ongoing inflammatory cascade in FMF.

Tumor necrosis factor blockade in the management of children with orphan diseases.

Brik R(1), Gepstein V, Shahar E, Goldsher D, Berkovitz D.

Author information:

(1)Department of Pediatrics, Meyer Children's Hospital of Haifa, P.O. Box 9602, Technion, Haifa 31096, Israel. r\_brik@rambam.health.gov.il

Tumor necrosis factor (TNF) blockade has been used successfully to treat a number of rheumatic disorders that have a substantial burden of illness. In children, the TNF antagonists are used mainly for the treatment of juvenile idiopathic arthritis (JIA). There are, however, a variety of rare systemic inflammatory diseases, in which TNF blockade appears promising. Preliminary data in adults suggest that several forms of vasculitis appear to be responsive to TNF antagonists- Behçet's disease, polyarteritis nodosa, Wegener granulomatosis, among others. Some of them respond better to infliximab, a chimeric monoclonal anti-TNF antibody, than to etanercept, a recombinant p75 TNF receptor. We describe our limited experience with infliximab in the treatment of three children with rare vasculitic conditions.

Autoinflammatory gene mutations in Behçet's disease.

Koné-Paut I(1), Sanchez E, Le Quellec A, Manna R, Touitou I.

Author information:

(1)Department of Pediatrics and Pediatric Rheumatology, Hôpital de Bicêtre, 78 rue du Général Leclerc, 94270 Le Kremlin Bicêtre, France.

isabelle.kone-paut@bct.aphp.fr

**BACKGROUND:** Behçet's disease (BD) shares clinical features with well-recognised autoinflammatory disorders. In addition, mutations in genes for familial Mediterranean fever and tumour necrosis factor receptor-associated periodic syndrome have been reported to have increased in patients with BD.

**PATIENTS AND METHODS:** DNA samples from 97 patients with BD and 51 matched healthy controls were analysed for the mevalonate kinase (MVK), cold-induced autoinflammatory syndrome 1 (CIAS1) and proline/serine/threonine phosphatase-interacting protein 1 (PSTPIP1) genes, responsible for mevalonate

kinase deficiency (MKD), cryopyrin associated periodic syndromes (CAPS) and pyogenic sterile arthritis, pyoderma gangrenosum and acne (PAPA) syndrome, respectively. Over 90% of known mutations were screened using restriction fragment length polymorphism analysis and/or sequencing.

RESULTS: Two patients had paired mutations in the MVK gene (genotypes V377I/V377I and V377I/S135L) and displayed typical features of BD and MKD. Another was heterozygotic for the V377I genotype. The V198M mutation in the CIAS1 gene was identified in one patient with typical BD but no symptoms of CAPS. No mutations were identified in the control group. PSTPIP1 analysis revealed a new exon 10 insertion variant (c.741+33\_741+34insGT) in 2 of 97 patients and in 1 of 51 controls ( $p>0.05$ ), indicating that it is a polymorphism rather than a true mutation.

DISCUSSION: This study could not demonstrate any significant increases in MVK, CIAS1 or PSTPIP1 mutations in patients with BD as compared with controls.

Restricted specificity of anti-ribosomal P antibodies to SLE patients in Israel.

Shovman O(1), Zandman-Goddard G, Gilburd B, Blank M, Ehrenfeld M, Bardechevski S, Stojanovich L, Langevitz P, Shoenfeld Y.

Author information:

(1)Center for Autoimmune Diseases and Dept. of Medicine B, Sheba Medical Center, Tel-Hashomer, Israel.

OBJECTIVE: Anti-ribosomal P antibodies (aRib-P Ab) are highly specific for systemic lupus erythematosus (SLE), but their correlatation with disease activity and manifestations including renal, hepatic and central nervous system (CNS) involvement is still controversial. The aim of our study was to evaluate the prevalence of aRib-P Ab and their correlation with clinical manifestations and anti-dsDNA antibodies in SLE patients from Israel.

METHODS: Elevated titers of aRib-P Ab utilizing the ELISA method were analyzed in 141 sera samples from 44 SLE patients, 20 Familial Mediterranean Fever (FMF)

patients, 22 primary antiphospholipid syndrome (PAPS) patients, 12 patients with infections, and 43 healthy individuals. The SLEDAI score was utilized for assessing SLE disease activity.

**RESULTS:** Elevated titers of aRib-P Ab were present in 11% of SLE patients (n = 6). The mean SLEDAI was 7 (range: 3-10). No statistically significant association was observed between the presence of aRib-P Ab and disease manifestations present in the SLEDAI. The 6 SLE patients had renal disease (n = 1), leucopenia (n = 1), rash (n = 3), and CNS involvement manifested as psychosis (n = 1) or depression (n = 1). Elevated titers of anti-dsDNA antibodies were found in 50% of patients with elevated titers of aRib-P Ab. Patients with PAPS, FMF, infections or healthy controls did not harbor elevated titers of aRib-P Ab.

**CONCLUSION:** Elevated titers of aRib-P Ab were restricted to SLE patients. We confirm previously reported associations of aRib-P Ab reactivity with disease activity and elevated anti-dsDNA Ab titers. No significant correlation with a specific manifestation described on the SLEDAI score was established in this small cohort of patients.

Selective serotonin reuptake inhibitors reduce the attack frequency in familial mediterranean Fever.

Onat AM(1), Oztürk MA, Ozçakar L, Ureten K, Kaymak SU, Kiraz S, Ertenli I, Calgüneri M.

Author information:

(1)Department of Rheumatology, Gaziantep University Hospitals, Mavi C 11/1, Sahinbey, Gaziantep, Turkey. mesutonat@yahoo.com

Familial Mediterranean Fever (FMF) is characterized by recurrent acute attacks of fever and serositis, and colchicine is the primary treatment. The pathogenesis of the disease has not been fully understood. Resistance to colchicine remains to be a problem in up to 30% of the patients and yet there seems to be no alternative treatment. In this study our objective was to investigate whether a selective serotonin re-uptake inhibitor (SSRI) could affect the attack frequency and acute

phase response in FMF patients who were unresponsive to colchicine. We retrospectively evaluated the hospital files of 11 colchicine-unresponsive FMF patients who had been treated with SSRIs. According to the records and re-evaluation of the patients, the total number of the FMF attacks was calculated before and after the SSRI, adjunct to colchicine. The laboratory values including erythrocyte sedimentation rate, C-reactive protein, fibrinogen and white blood cell counts were also noted before and after the SSRI treatment from their hospital files. The mean attack frequency before adding SSRI to colchicine was  $8.09 \pm 3.53$  per 6 months, and at the end of this period there was a great decline in the number of mean attack frequency ( $0.36 \pm 0.50$  attacks per 6 months) ( $p < 0.001$ ). Acute phase reactants were significantly decreased after SSRI treatment ( $p < 0.001$ ). All of the colchicine-unresponsive patients had depression and 3 of those patients also had fibromyalgia. SSRIs appear to be useful adjuncts in the management of FMF patients who continue to have attacks despite regular colchicine treatment.

Association between reduced levels of MEFV messenger RNA in peripheral blood leukocytes and acute inflammation.

Ustek D(1), Ekmekci CG, Selçukbiricik F, Cakiris A, Oku B, Vural B, Yanar H, Taviloglu K, Ozbek U, Gül A.

Author information:

(1)Istanbul University, Institute for Experimental Medical Research, Istanbul, Turkey.

**OBJECTIVE:** Familial Mediterranean fever (FMF) is associated with more than 70 missense mutations in the MEFV gene. The purpose of this study was to investigate the relative expression of messenger RNA (mRNA) for the MEFV gene in peripheral blood leukocytes (PBLs) obtained from patients with FMF during attacks of acute abdominal inflammation as well as during asymptomatic periods.

**METHODS:** We studied 16 patients with FMF during an attack of acute peritonitis and 17 otherwise healthy individuals who were undergoing surgery because of acute appendicitis. Blood samples were collected from both groups of patients during both acute inflammatory and asymptomatic periods. Relative levels of MEFV mRNA in PBLs were detected with real-time reverse transcriptase-polymerase chain reaction using LightCycler, with 2 sets of primers for the MEFV gene (exons 7-10 and exons 2-3) and with primers for CIAS1 and PSTPIP1 genes. Expression levels were compared with beta(2)-microglobulin as an internal control.

**RESULTS:** MEFV expression was reduced in FMF patients during asymptomatic periods as compared with the non-FMF controls ( $P < 0.001$ ). We observed a further decrease in MEFV expression in FMF patients during periods of inflammation ( $P = 0.01$ ).

Reduced levels of MEFV mRNA were also noted during the preoperative period as compared with asymptomatic periods in control patients with acute appendicitis ( $P = 0.01$ ). CIAS1 expression in PBLs from patients with FMF was also found to be lower than that in the control patients. However, CIAS1 expression did not change with acute inflammation.

**CONCLUSION:** This study confirmed that reduced expression of the MEFV gene is associated with inflammation and that it may be one of the pathogenic mechanisms of the attacks of inflammation in FMF patients, along with disease-associated variations in pyrin.

Ned Tijdschr Geneeskd. 2007 Apr 7;151(14):836-7; author reply 837.

A 9-month-old girl was referred to the paediatrician because of fever of unknown origin. Since the age of 4 years she had recurrent attacks of muscle, joint and abdominal pain, in addition to periodic fever. Her sister and her mother had similar symptoms. The tumour necrosis factor (TNF) receptor-associated periodic syndrome (TRAPS) was suspected and confirmed by DNA analysis. Several members of the extended family were carriers of the same mutation. In patients with recurrent unexplained periods of fever in combination with myalgia, arthralgia and abdominal pain, and in whom these symptoms also occur in members of the family, TRAPS should be considered as the cause. Glucocorticosteroids and etanercept, a TNF-receptor antagonist, may be effective in the treatment of attacks. Early recognition of this syndrome is important because of the risk of developing amyloidosis.

The most important complication of FMF is the development of amyloidosis. It is more common in the eastern Mediterranean compared to the US. The individual response to endotoxin may have a significant effect on the development of amyloidosis in FMF patients. To investigate the association between CD14 promotor C-159T polymorphism and development of amyloidosis, one hundred and forty-six patients who had FMF and had not developed amyloidosis; 26 with FMF and secondary amyloidosis and 92 controls were genotyped at the CD14-C159T locus. There was no difference between the genotype distribution of FMF patients (CC 30.0%, CT 50.0%, TT 20.0%) and controls (CC 29.2%, CT 45.8%, TT 25%); or between FMF patients with amyloidosis (CC 30.8%, CT 53.8%, TT 15.4%) or without amyloidosis (CC 29.2%, CT 45.8%, TT 25%). Our study shows that the CD14-C159T polymorphism is not associated with FMF or development of amyloidosis in the population studied. The effect of the genetic variations in the endotoxin signaling pathway under different environmental conditions such as high and low endotoxin exposure remain to be determined.

OBJECTIVE: To characterize the multisystem chronic inflammatory phenotype, dermatopathologic features, and response to therapy with interleukin 1 receptor antagonist (anakinra) in patients with mutations in the CIAS-1/NALP3 gene.

DESIGN: Retrospective review of medical records and evaluation of histologic

findings.

SETTING: The National Amyloidosis Centre, London, and a tertiary referral clinic for urticaria.

PATIENTS: Twenty-two individuals from 13 families with autoinflammatory disease associated with CIAS-1/NALP3 mutations.

MAIN OUTCOME MEASURES: Phenotype, genotype, skin histologic findings, and response to treatment with anakinra.

RESULTS: Five heterozygous missense mutations were identified in CIAS-1/NALP3. Skin histologic findings revealed marked vascular dilatation and neutrophilic infiltration involving small vessels and eccrine glands. Serologic evidence of intense inflammation was present in untreated patients, with median serum amyloid A protein and C-reactive protein levels of 141 and 38 mg/L, respectively. Fifteen patients received anakinra for up to 39 months, all of whom achieved serologic remission and complete resolution of fever, rash, conjunctivitis, and rheumatic symptoms, without any adverse effects. Six patients had AA (reactive systemic) amyloidosis, 2 of whom died of renal failure complications before interleukin 1-inhibiting therapy was available; 1 patient underwent renal transplantation and remains clinically well taking anakinra, and in the remaining 3 patients, anakinra therapy resulted in remission of their nephrotic syndrome.

CONCLUSIONS: Anakinra therapy was well tolerated and has sustained efficacy on dermatologic and rheumatic manifestations in these patients with CIAS-1/NALP3 mutations. This treatment also resulted in resolution of AA amyloidosis-associated nephrotic syndrome in all affected patients.

A cryopyrin-associated periodic syndrome with joint destruction.

Lequerré T(1), Vittecoq O, Saugier-veber P, Goldenberg A, Patoz P, Frébourg T, Le Loët X.

Author information:

(1)Department of Rheumatology, Rouen University Hospital, 76031 Rouen, Cedex, France. thierry.lequerre@univ-rouen.fr

**OBJECTIVE:** Describe four generations (11 members) of a family with a cryopyrin-associated periodic syndrome (CAPS), including joint destruction, associated with a CIAS1-gene mutation and good responses to anakinra.

**METHODS:** In addition to detailed questioning and physical examination, six family members underwent haematological, immunological and biochemical testing. Exon 3 of the CIAS1 gene was sequenced in search of a mutation in the 1q44 region.

**RESULTS:** During childhood or adolescence, four family members developed different combinations of the following CAPS manifestations: deafness (3/4); arthritis (4/4) with joint destruction for two of them; nervous (cerebral demyelination, 2/4), cutaneous (livedo and/or urticaria, 3/4) and eye lesions (episcleritis and/or papilloedema, 4/4); IgA hypergammaglobulinaemia (4/4) and inflammatory syndrome (3/4). Sequencing of six family members' CIAS1-gene exon 3 identified a heterozygous mutation, c.1043C > T. Pertinently, this CAPS is distinct from chronic infantile neurological cutaneous and arthritis syndrome/neonatal onset multisystemic inflammatory disease syndrome and Muckle-Wells syndrome (MWS), which also result from exon 3 mutations in this gene. Moreover, this family did not have the usual neurological manifestations, typical morphological features and frequent amyloidosis of MWS.

**CONCLUSIONS:** We describe a previously unreported form of CAPS with atypical neurological signs, joint destruction and livedo. This observation extends the clinical spectrum associated with CIAS1 mutations. Anakinra, an interleukin-1-receptor antagonist, prescribed to two family members, was highly effective.

Jordan: communities and community genetics.

Hamamy H(1), Al-Hait S, Alwan A, Ajlouni K.

Author information:

(1)National Center for Diabetes, Endocrinology and Genetics, Amman, Jordan.  
hhamamy@hotmail.com

The population in Jordan mounted from half a million in 1952 to 5.3 millions in

2004 and is composed of a variety of ethnic groups, the majority being Arabs. Couples nowadays tend to have fewer children, with the total fertility rate falling from 7.4 in 1976 to 3.7 in 2004. Consanguineous marriages are traditionally favored, with the preferred marriage partner being the offspring of the father's brother. First-cousin marriages declined from 28.5% for marriages contracted between 1950 and 1979 to 19.5% for marriages contracted after 1980. In the overall population, carrier rates for beta-thalassemia, alpha-thalassemia and sickle cell anemia are in the range of 2-4%, 3.2-12% of males have glucose-6-phosphate dehydrogenase deficiency, and the prevalences for familial Mediterranean fever and cystic fibrosis were estimated at around 0.04% each. A mandatory premarital screening program for beta-thalassemia carriers commenced in June 2004. The high consanguinity rate and the large family size in Jordan have contributed to the description of a number of rare and new autosomal recessive conditions. Genetic services in Jordan are still scarce and do not cover all the country due to the major impediments of a paucity of resources and trained health professionals in the area of medical genetics. The demographic data suggest that the health system in Jordan is capable of introducing some basic community genetic services into the primary health care program through comprehensive and cost-effective programs.

Author information:

(1)Department of Pathology, University Medical Center Utrecht, Utrecht, The Netherlands.

Several autoinflammatory disorders such as Muckle-Wells syndrome are characterized by mutations in the NALP3/cryopyrin gene. NALP3 and NALP1 proteins

can assemble to inflammasomes that activate caspase-1, resulting in the processing of pro-inflammatory cytokines IL-1 $\beta$  and IL-18. The present study was designed to determine which cells and tissues express NALP1 and NALP3. Monoclonal antibodies were developed and their use revealed distinct distribution profiles of NALP1 and NALP3. Granulocytes, monocytes (very weakly), dendritic cells, and B and T cells all express NALP1 and NALP3. Highest levels of NALP1 are found in T cells and Langerhans cells. Furthermore, NALP1 is present in glandular epithelial structures such as stomach, gut, lung, and, surprisingly, in neurons and testis. In contrast to NALP1, NALP3 shows a more restricted tissue distribution with expression mainly in non-keratinizing epithelia in the oropharynx, esophagus, and ectocervix. Moreover, NALP3 expression is found in the urothelial layer in the bladder. Likewise, a difference in subcellular distribution between NALP1 and NALP3 is observed because NALP1 is localized mainly in the nucleus, whereas NALP3 is predominantly cytoplasmic. We propose that the presence of NALP3 in epithelial cells lining the oral and genital tracts allows the rapid sensing of invading pathogens, thereby triggering an innate immune response.

Mutations in the cold-induced autoinflammatory syndrome 1 (CIAS1) gene are associated with a spectrum of autoinflammatory diseases, including familial cold autoinflammatory syndrome, Muckle-Wells syndrome, and chronic infantile neurologic, cutaneous, articular syndrome, also known as neonatal-onset multisystem inflammatory disease. CIAS1 encodes cryopyrin, a protein that

localizes to the cytosol and functions as pattern recognition receptor. Cryopyrin also participates in nuclear factor-kappaB regulation and caspase-1-mediated maturation of interleukin 10. In this study, we showed that disease-associated mutations in CIAS1 induced rapid cell death of THP-1 monocytic cells. The features of cell death, including 7-AAD staining, the presence of cellular edema, and early membrane damage resulting in lactate dehydrogenase (LDH) release, indicated that it was more likely to be necrosis than apoptosis, and was effectively blocked with the cathepsin B-specific inhibitor CA-074-Me. CA-074-Me also suppressed induced by disease-associated mutation lysosomal leakage and mitochondrial damage. In addition, R837, a recently identified activator of cryopyrin-associated inflammasomes, induced cell death in wild type CIAS1-transfected THP-1 cells. These results indicated that monocytes undergo rapid cell death in a cathepsin B-dependent manner upon activation of cryopyrin, which is also a specific phenomenon induced by disease-associated mutation of CIAS1.

**OBJECTIVE:** To evaluate the frequency of 5 mutations and their relationship with the Tel Hashomer criteria in 85 FMF patients.

**METHODS:** We looked for mutations in the Mediterranean fever (MEFV) gene in 84 consecutive patients who admitted to the Department of Medical Genetics of Afyon Kocatepe University, with a variable (from high to low) clinical suspicion of FMF. By using polymerase chain reaction and Hybridization-ELISA methods, 5 mutations (M694V, M694I, V726A, M680I and E148Q) have been studied between December 2002 and January 2005.

**RESULTS:** We detected homozygote mutations in 12 patients (25.3%) and heterozygote mutations in 23 patients (48.9%) out of 47 patients with high clinical suspicion of FMF using Tel Hashomer criteria. In 12 patients (25.3%), no mutation was detected despite the clinical diagnosis of FMF was likely according to the Tel Hashomer clinical criteria. On the other hand, we detected homozygote mutations in 2 patients (5.4%) and heterozygote mutations in 17 patients (45.9%) out of 37 patients with low clinical suspicion of FMF using Tel Hashomer criteria. In 18 out of 37 patients (48.6%) in this group no mutation was detected.

**CONCLUSION:** In patients with high or low clinical suspicion of diagnosis of FMF according to Tel Hashomer criteria, the frequency of homozygote patients was significantly higher than the frequency of patients with no mutation, but it was not higher than the frequency of heterozygote patients.

Defective apoptosis of peripheral-blood lymphocytes in hyper-IgD and periodic fever syndrome.

Bodar EJ(1), van der Hilst JC, van Heerde W, van der Meer JW, Drenth JP, Simon A.

Author information:

(1)Department of General Internal Medicine, Radboud University Nijmegen Medical Centre, PO Box 9101, 6500 HB Nijmegen, The Netherlands. e.bodar@aig.umcn.nl

Hereditary periodic fever syndromes are characterized by incapacitating attacks of fever and generalized inflammation. While the mutated genes for the major syndromes in this group are known, the pathogenesis remains unclear. The aim of this study was to investigate apoptosis in patients with periodic fever as a possible pathogenic factor. We measured anisomycin-induced apoptosis with annexin-V flow cytometry and caspase-3/7 activity in peripheral-blood lymphocytes from symptom-free patients with hyper-IgD and periodic fever syndrome (HIDS; n = 10), TNF-receptor-associated periodic syndrome (TRAPS; n = 7), and familial Mediterranean fever (FMF; n = 2). HIDS lymphocytes showed a decreased percentage of apoptosis during remission by both methods compared with controls (17.8% vs 55.4%), whereas no difference was observed in TRAPS or FMF lymphocytes. This defective apoptosis of lymphocytes may be a central pathogenic mechanism in HIDS, since dysfunction of one of the inhibitory mechanisms to curtail the immunologic response could cause an unbridled generalized inflammation after a trivial stimulus.

Successful pregnancies in dialysis patients including those suffering from cystinosis and familial Mediterranean fever.

Haase M(1), Morgera S, Bamberg C, Halle H, Martini S, Dragun D, Neumayer HH, Budde K.

Author information:

(1)Department of Nephrology, Charité University Medicine, Berlin-Germany.

For women on maintenance dialysis, pregnancy is still uncommon. The outcome of such pregnancies has improved in recent case series. Here, we report in detail the treatment of five successful pregnancies in dialysis patients from our centre. The present case series also includes the first successful pregnancy of a dialysis patient with underlying familial Mediterranean fever, and of a dialysis patient with cystinosis. We treated all patients with an intensified hemodiafiltration protocol, increased erythropoietin dosages, a generous application of water-soluble vitamins and trace elements in addition to a multidisciplinary clinical management approach with a very low threshold for hospital admission. Specifically, we report treatment of arterial hypertension with respect to changes in dry weight and pharmacological therapy. Mean gestational age at delivery was 32.8+/-3.3 weeks and mean birth weight was 1,765+/-554 g. All mothers and newborns were discharged healthy and in good condition. These modified management guidelines have led to a favourable outcome in all our patients including two patients with familial Mediterranean fever and with cystinosis, and may help to guide therapy in other pregnant dialysis patients.

Arthropathy of neonatal onset multisystem inflammatory disease (NOMID/CINCA).

Hill SC(1), Namde M, Dwyer A, Poznanski A, Canna S, Goldbach-Mansky R.

Author information:

(1)Diagnostic Radiology, Warren G. Magnuson Clinical Center, National Institutes of Health, 10 Center Drive, Rm # N242, Bethesda, MD 20892, USA. [shill@nih.gov](mailto:shill@nih.gov)

BACKGROUND: Neonatal onset multisystem inflammatory disease (NOMID), an

autoinflammatory disease, is characterized by fever, chronic urticarial rash, CNS manifestations, and arthropathy. Approximately 50% of patients with NOMID have de novo missense mutations in CIAS1, which is associated with modulation of the IL-1 $\beta$  and apoptotic pathways. Approximately 60% of NOMID patients have prominent arthropathy, most commonly involving the knees, the cause of which remains poorly understood.

**OBJECTIVE:** To more fully describe the findings of NOMID arthropathy on MRI and radiography and to provide a better understanding of the origin of the bony lesions.

**MATERIALS AND METHODS:** We imaged 20 patients with NOMID to further investigate NOMID-associated bony lesions.

**RESULTS:** Bony abnormalities were seen in the knees of 11/20 patients. The knee findings included enlarged, deformed femora and patellae in all and tibiae in the majority, without evidence of synovitis. Some patients had other joint involvement. Most had short stature and valgus or varus knee deformities. No association was noted between bony abnormalities and CIAS1 mutations. The abnormalities appeared to be the result of a mass-producing process. The resulting heterogeneously calcified masses appeared to originate in the physis and deformed the adjacent metaphysis and epiphysis.

**CONCLUSION:** These findings suggest that the arthropathy of NOMID is the result of abnormal endochondral bone growth. Further investigation is needed to determine whether this deformity is triggered by inflammation early in development or by CIAS1 mutations causing abnormal chondrocyte apoptosis.

(1)Department of Microbiology and Immunology, University of Michigan Medical School, 1150W Medical Center Drive, 5641 Medical Sciences II, Ann Arbor, MI 48109-0620, USA.

The molecular repertoire for innate recognition of bacterial pathogens has expanded rapidly in the past decade. These immunosensors include Toll-like receptors and the more recently defined NOD-like receptors (NLRs): NODs, NALPs, NAIP and IPAF. Toll-like receptors signal from the cell surface or endosome upon ligand binding, whereas NLRs are activated by characteristic bacterially derived molecules, such as peptidoglycan, RNA, toxins and flagellin, in the cytosol. Studies using animal and culture models of bacterial infection indicate a pro-inflammatory role for NLRs, mediated by signaling through nuclear transcription factor kappaB and activation of caspase-1 by the inflammasome. These data also support a synergistic role for extracellular and intracellular bacterial sensing in regulating inflammation. In humans, NLR mutations are often associated with autoinflammatory syndromes, suggesting a complex role for cytosolic surveillance in systemic innate immunity.

[Amyloidosis of familial Mediterranean fever (FMF)--insights to FMF phenotype II].

[Article in Hebrew]

Livneh A(1).

Author information:

(1)alivneh@post.tau.ac.il

Amyloidosis is the most grievous manifestation of Familial Mediterranean Fever (FMF), occurring in a high proportion of untreated patients. Continuously elevated serum amyloid A (SAA) levels during remissions, rather than a pulsatile rise during FMF attacks, underlies the development of amyloidosis. FMF phenotype II is one extreme of AA amyloidosis, evolving despite a complete absence of FMF attacks. FMF phenotype II is diagnosed in patients with AA amyloidosis in the context of a family history of FMF. In these patients and in patients with AA amyloidosis without family history of FMF and with unknown precipitating disease, MEFV gene analysis is mandatory. Moreover, since FMF phenotype II is an actual

hazard, a cost-benefit analysis suggests that MEFV mutation determination in all first-degree family members of FMF patients is warranted, as it will significantly reduce future patient treatment costs.

[Nephrotic syndrome as a first manifestation of familial Mediterranean fever].

[Article in Hebrew]

Gingold-Belfer R(1), Bergman M, Ori Y, Salman H.

Author information:

(1)Department of Internal Medicine C, Campus Golda-Hasharon, Rabin Medical Center, Sackler Faculty of Medicine, Tel Aviv University, Israel.

AA amyloidosis may be a complication of Familial Mediterranean Fever (FMF). This is a case history of a female patient who did not have the classic symptoms of FMF, which usually precede the renal manifestation. The patient was admitted with edema of both legs, and the nephrotic syndrome was discovered, leading to the diagnosis of AA amyloidosis on kidney biopsy. Genetic testing uncovered the homozygous M694V type mutation, the most common mutation of FMF, which renders the patients prone to amyloidosis. This case represents the phenotype II of FMF, which presents with amyloidosis without prior classic attacks of FMF. Since effective prevention of the development of amyloidosis is available, genetic testing should be considered in order to identify mutations which carry high risk for the development of amyloidosis. This is also relevant in asymptomatic individuals with family history of FMF.

In order to determine the role of levels of acute phase proteins (APPs) for the development of amyloidosis in familial Mediterranean fever (FMF) patients, the levels of serum amyloid A (SAA), C reactive protein (CRP), fibrinogen and erythrocyte sedimentation rate were measured in paired sera of 36 FMF patients during and in between acute attacks, 39 of their healthy parents (obligate heterozygotes), and 15 patients with FMF associated amyloidosis. To compare the levels of APPs, 39 patients with chronic infections or inflammatory diseases who may develop secondary amyloidosis, 20 patients with acute infections who are known to have elevated acute phase response but will never develop amyloidosis and 19 healthy controls were included. The median levels of all APPs are increased in the patients with FMF during attacks and a significant decrease was observed after the attack was over. The level of SAA was above reference range in all FMF patients during the attack free period and the level of at least one other APP was also above normal in 64% of the patients. Both CRP and SAA levels

were found to be higher in obligate heterozygotes compared to controls. The levels of SAA in patients with FMF during the attack-free period, obligate heterozygotes and patients with FMF-amyloidosis were found to be similar. The levels in each group were found to be higher than SAA levels found in healthy controls yet lower than the levels measured in the patients with acute infections and patients with chronic inflammation or chronic infections. In conclusion, our results show that SAA level reflects subclinical inflammation with high sensitivity but its value for the prediction of amyloid formation process seems to be low.

**OBJECTIVE:** To evaluate the effects of MEFV genotypes and the major histocompatibility complex class I chain-related gene A (MICA) triplet repeat polymorphism on the severity and clinical features of familial Mediterranean fever (FMF) and amyloidosis in a group of Turkish FMF patients.

**METHODS:** We evaluated 105 adult FMF patients (with or without amyloidosis, 33 and 72, respectively) along with 107 healthy controls who were neither related to the patients nor had a family history of FMF or Behcet's disease. After recording the demographic and clinical data, the predominant mutations in the MEFV gene locus (M694V, M680I, V726A, M694I, and E148Q) were investigated by direct sequencing. MICA transmembrane polymorphisms in exon 5 were studied by vertical gel electrophoresis and fragment analysis of the amplicons obtained from MICA locus with appropriate primers.

**RESULTS:** Earlier age at onset, increased frequency of attacks, arthritis attacks, erysipelas-like erythema, increased severity scores and amyloidosis were significantly more common in M694V homozygous patients compared to the patients not M694V homozygous ( $P = 0.005$ , OR 4.55;  $P = 0.001$ , OR 7.60;  $P = 0.003$ , OR 4.57;  $P = 0.002$ , OR 7.58;  $P = 0.004$ , OR 5.15 and  $P = 0.018$ , OR 3.33, respectively). We did not detect any modifying effects of MICA alleles as an independently risk factor on the amyloidosis development. However, when we examined the effects of MICA alleles on the course of the disease and development of amyloidosis in the M694V homozygous patients, A5 allele had a protective effect against the development of amyloidosis ( $P = 0.038$ , OR(adj) 0.26 with A5 and  $P = 0.009$ , OR(adj) 4.42 without A5).

**CONCLUSION:** Though the effects of the MEFV genotypes seem clear, there are definitely other modifying factors or genes on the development of amyloidosis and on the course of the disease. For example, some MICA alleles have a protective effect on the prognostic factors in FMF.

The carotid-femoral (aortic) pulse wave velocity as a marker of arterial stiffness in familial Mediterranean fever.

Yildiz M(1), Masatlioglu S, Seymen P, Aytac E, Sahin B, Seymen HO.

Author information:

(1)Sakarya University School of Health, Sakarya, Turkey. mustafayilldiz@yahoo.com

AIM: The purpose of the present study was to test the hypothesis that chronic inflammation impairs vascular function and leads to an arterial pulse wave velocity (PWV) increase in patients with familial Mediterranean fever (FMF).

PATIENTS AND METHODS: Twenty-three patients (17 women) with FMF, and 23 age- and sex-matched controls were recruited. Aortic PWV was determined by using an automatic device (Complior Colson, Createch Industrie, France) that allowed on-line pulse wave recording and automatic calculation of the PWV.

RESULTS: The PWV was slightly higher in patients with FMF than in control subjects ( $P=0.05$ ). A significant correlation between PWV and age ( $P<0.001$ ,  $r=0.67$ ), body mass index ( $P<0.001$ ,  $r=0.52$ ) and leukocytes ( $P<0.001$ ,  $r=0.66$ ) was found in both groups combined and also in patients with FMF ( $P<0.001$ ,  $r=0.73$ ;  $P=0.01$ ,  $r=0.52$ ;  $P<0.001$ ,  $r=0.69$ , respectively).

CONCLUSION: The PWV was slightly higher in patients with FMF compared with control subjects. Colchicine, an anti-inflammatory drug treatment, may have reduced the expected increased level of PWV in FMF patients. PWV is influenced by age, body mass index and leukocytes.

Author information:

(1)Interdepartmental Center for Research in Molecular Medicine, University of Pavia, Pavia, Italy.

**BACKGROUND:** Inflammation is deemed to play a crucial role in the pathogenesis of Alzheimer's disease (AD). We sought to determine whether the proinflammatory M694V mutation of pyrin, the gene responsible for familial Mediterranean fever, could lead to an increased risk for AD.

**METHODS:** We compared the M694V variant genotypes in 378 sporadic AD patients and 384 healthy control subjects of Italian descent.

**RESULTS:** After adjustment for potential confounders, the M694V mutation was found to be associated with an increased risk for AD in subjects with an age at onset of 65 years or younger (multivariate-adjusted odds ratio, OR: 3.01, 95% confidence interval, CI: 1.24-6.72,  $p = 0.021$ ), but not in patients with an age at onset older than 65 years (multivariate-adjusted OR: 0.81, 95% CI: 0.34-1.99,  $p = 0.847$ ). Kaplan-Meier analysis indicated that AD patients bearing the M694V mutation presented with disease onset 7 years earlier than carriers of the wild-type genotype (log rank = 41.61,  $p < 0.001$ ).

**CONCLUSION:** Our data indicate that the M694V sequence variant in the pyrin gene might influence the age at onset of AD in the Italian population.

masterss@mail.nih.gov

**PURPOSE OF REVIEW:** To discuss recent developments in the molecular basis of several hereditary recurrent fever syndromes, specifically the cryopyrin-associated periodic syndromes, familial Mediterranean fever and the tumor necrosis factor receptor associated periodic syndrome.

**RECENT FINDINGS:** Mutations of CIAS1, the gene encoding cryopyrin/NALP3, lead to a spectrum of disease states termed the cryopyrinopathies. Recently, cryopyrin-deficient mice have been used to show that the protein is a key regulator of interleukin-1 $\beta$  production that functions by recognizing stimuli such as bacterial RNA and infectious agents. Tumor necrosis factor receptor-associated periodic syndrome was initially thought to be caused by deficient metalloprotease-induced tumor necrosis factor receptor shedding, however new findings suggest that mutations in this receptor may result in inappropriate protein folding, leading to a host of other functional abnormalities that may cause inflammatory disease. Finally, data are emerging that address the possible function of the C-terminal B30.2 domain of pyrin, the familial Mediterranean fever protein. This motif has recently been shown to interact with and inhibit caspase-1, and the modeled structure of this complex highlights how mutations may affect the binding interface.

**SUMMARY:** Recent reports have advanced our understanding of the structural and functional biology underlying the hereditary recurrent fevers, and are beginning to suggest possible mechanisms by which specific mutations cause disease.

Tumor necrosis factor receptor-associated periodic syndrome mimicking systemic juvenile idiopathic arthritis.

Manki A(1), Nishikomori R, Nakata-Hizume M, Kunitomi T, Takei S, Urakami T, Morishima T.

Author information:

(1)Department of Pediatrics, Okayama University Graduate School of Medicine, Dentistry and Pharmaceutical Sciences, Okayama, Japan. akmanki@md.okayama-u.ac.jp

**BACKGROUND:** We report two cases of tumor necrosis factor receptor-associated periodic syndrome (TRAPS) in patients in whom systemic juvenile idiopathic arthritis (JIA) had initially been diagnosed or suspected. One patient, given a diagnosis of systemic JIA, was a 10-year-old boy who had presented with recurrent episodes of spike-fever, skin rash, arthritis, and myalgia. The other patient was his 7-year-old sister, who presented with similar symptoms and was suspected of having systemic JIA.

**METHODS:** Serum levels of soluble tumor necrosis factor receptor super family 1A (TNFRSF1A), TNF-alpha, Interleukin (IL) -6, and C-reactive protein (CRP) were

measured in two siblings and JIA patients. In addition, DNA sequencing of the TNFRSF1A gene in two siblings was also performed.

RESULTS: A detailed family history showed that their mother had an episode of recurrent fever, arthritis, and myalgia with an increased serum CRP after the delivery of a daughter. Both siblings had serum levels of soluble TNFRSF1A that were below the normal reference range, and that did not reach a level corresponding to that of systemic JIA. On TNFRSF1A gene analysis, a single missense mutation resulting in C30Y was found in both siblings.

CONCLUSIONS: Based on the clinical features and the TNFRSF1A mutation, both siblings were given a diagnosis of TRAPS. The serum levels of soluble TNFRSF1A, measured along with the CRP level, may be a useful screening marker for differentiating TRAPS from systemic JIA.

Periodic fever syndromes comprise a group of disorders characterized by attacks of seemingly unprovoked inflammation. The genetic causes of five hereditary autoinflammatory syndromes have been identified in the last few years: familial Mediterranean fever, the cryopyrinopathies [Muckle-Wells, chronic infantile neurological, cutaneous, articular syndrome (CINCA) and familial autoinflammatory syndromes], TNF-receptor associated periodic syndrome, cyclic neutropenia syndrome and periodic fever, aphthous stomatitis, pharyngitis, and cervical adenitis (PFAPA) syndrome. The study of periodic fever syndromes has progressed from clinical characterization to genetic analysis and to the definition of the functional defects linking genes or domains to apoptotic proteins and signal

transduction pathways. This new research opens the way for more specific treatment options with a further improvement in prognosis and outcome.

Colchicine today.

Niel E(1), Scherrmann JM.

Author information:

Colchicine is used chiefly in the treatment of gout but is also valuable in other inflammatory diseases such as familial Mediterranean fever (FMF). Three proteins play pivotal roles in colchicine pharmacokinetics: the colchicine receptor, tubulin, which governs the plasma elimination half-life of the drug; intestinal and hepatic CYP3A4, which is key to the biotransformation of colchicine; and P-glycoprotein, a cell efflux pump that regulates the tissue distribution of colchicine, as well as its excretion via the biliary tract and kidneys.

Pharmacokinetic studies have been performed using a radioimmunity assay to measure blood colchicine levels. Absorption after oral ingestion varies widely (from 24% to 88% of the dose), the volume of distribution is extremely large (7 l/kg), and binding to albumin is moderate. Colchicine is excreted chiefly through the liver and has an elimination half-life of 20-40 hours. With repeated doses of about 1mg/day, the steady-state is achieved within 8 days and concentrations range from 0.3 to 2.5 ng/ml. Studies of associations between pharmacokinetic parameters and pharmacodynamics show that effects are correlated, not to plasma levels, but to levels in leukocytes. Adverse events are not uncommon, most notably when colchicine is used in combination with drugs that interact with CYP3A4 and/or P-glycoprotein, thereby decreasing the renal and/or hepatic elimination of colchicine. Careful monitoring in this situation is effective in preventing the development of toxicity.

Erratum in  
Clin Exp Rheumatol. 2007 May-Jun;25(3):507-8.

**OBJECTIVE:** We aimed to compare whether carriers for the MEFV mutations display an increase or decrease in certain features. We compared the frequency of a number of inflammatory symptoms and diseases in carriers and a control population.

**METHODS:** A questionnaire was designed to be applied to parents of children with FMF and a control group of parents. Clinical features and some diseases including the frequency of febrile episodes, abdominal pain, arthralgia, prophylaxis with penicillin, acute rheumatic fever, rheumatoid arthritis, vasculitis,

spondyloarthropathy, urinary tract infection, asthma, allergy, irritable bowel disease, appendectomy and tonsillectomy were inquired. 676 parents of 440 children with FMF were surveyed in this study. Controls (n: 774) were selected as parents of healthy children.

RESULTS: The presence of febrile episodes more than four per year, arthralgia, past diagnosis for acute rheumatic fever, rheumatoid arthritis and prophylaxis of penicillin, acute rheumatic fever, and rheumatoid arthritis were significantly higher in asymptomatic parents for the MEFV mutations compared to controls. The frequency of allergy was found to be significantly lower in the asymptomatic parents as compared to controls. There was no significant difference at the frequency of urinary tract infection and tonsillectomy between the parents of the patents and controls.

CONCLUSIONS: We suggest that one MEFV mutation may indeed be conferring a heightened inflammation as suggested by the increased frequency in inflammatory symptoms. The carrier status for MEFV mutations seem to be unique, in that they cause an alteration in the state of "health".

Treatment options in colchicine resistant familial Mediterranean fever patients: thalidomide and etanercept as adjunctive agents.

Seyahi E(1), Ozdogan H, Celik S, Ugurlu S, Yazici H.

Author information:

(1)Division of Rheumatology, Department of Medicine, Cerrahpasa Medical Faculty, University of Istanbul, Istanbul, Turkey.

Erratum in

Clin Exp Rheumatol. 2007 May-Jun;25(3):507-8.

OBJECTIVE: Regular colchicine treatment cannot control the typical febrile attacks of FMF in about 5-10% of the compliant patients. Here we report the effect of thalidomide and etanercept in 5 colchicine-resistant cases.

METHODS: Five (4M/ 1F) FMF patients between April 2005 and March 2006, who were

experiencing at least 2 attacks per month, despite regular colchicine were included to the study. Four male patients were given thalidomide 100 mg/d initially. Two of these patients unresponsive to thalidomide were prescribed subcutaneous injections of etanercept 25 mg, twice a week. The female patient received etanercept as the first choice due to potential side effects. She then had to be converted to thalidomide due to a severe injection site reaction.

**RESULTS:** The median follow up period with thalidomide and etanercept was 8 months. Both thalidomide and etanercept lowered the number of the abdominal attacks.

**CONCLUSION:** Thalidomide and etanercept might be effective as additional treatment in colchicine-resistant cases of FMF.

Circulating thrombomodulin levels in familial Mediterranean fever.

Ozbalkan Z(1), Ozturk MA, Onat AM, Ureten K, Haznedaroglu IC, Kiraz S, Ertenli AI, Kirazli S, Calguneri M.

Author information:

(1)Hacettepe University School of Medicine, Internal Medicine Department, Section of Rheumatology, Ankara-Turkey. zaslar@hotmail.com

Erratum in

Clin Exp Rheumatol. 2007 May-Jun;25(3):507-8.

Increments in circulating thrombomodulin levels reflect endothelial cell injury. Thrombomodulin can also be synthesized by several inflammatory cells including monocytes, neutrophils, and thrombomodulin itself can modulate the inflammatory response. In this study, we assessed circulating thrombomodulin concentrations in patients with familial Mediterranean fever (FMF). Twenty-five patients with FMF (F/M: 14/11) (mean age: 31.1 +/- 9.7 years) and 25 healthy controls (F/M: 13/12) (mean age: 34.6 +/- 7.0 years) were involved in the study. Thrombomodulin levels were measured by commercially available enzyme-linked immunosorbant assay (ELISA) (Immunoassay of thrombomodulin Diagnostica Stago, Asnieres-Sur-Seine, France).

Twenty of the patients were in attack-free period and the remaining five had been during acute FMF attacks. Thrombomodulin levels were higher in the study group (20.9 +/- 12.1 ng/ml) than healthy controls (14.1 +/- 8.4 ng/ml) ( $p < 0.05$ ). Circulating thrombomodulin levels were also higher in attack-free FMF patients (22.4 +/- 12.9 ng/ml) than controls. This study disclosed for the first time significantly higher increments in the circulating levels of thrombomodulin in FMF. This observation could be a consequence of injured endothelium and/or activated inflammatory cells.

Spinal cord stimulation for relief of abdominal pain in two patients with familial Mediterranean fever.

Kapur S(1), Mutagi H, Raphael J.

Author information:

(1)Department of Pain Management, Russells Hall Hospital, Dudley DY1 2HQ, UK.  
drsandeepkapur@hotmail.com

Familial Mediterranean fever is a hereditary disease characterized by recurrent attacks of fever and serosal inflammation that commonly presents as severe

abdominal pain. Though colchicine remains the mainstay of treatment, a significant proportion of patients are partially responsive, unresponsive or intolerant to it. We present two such cases where spinal cord stimulation (SCS) was used to manage the paroxysmal abdominal pain associated with this disease. Abdominal visceral pain pathways and the application of SCS techniques in its management are discussed.

The expanded clinical spectrum of familial Mediterranean fever.

Ozçakar ZB(1), Yalçinkaya F, Yüksel S, Ekim M.

Author information:

(1)Division of Pediatric Nephrology, Ankara University School of Medicine, Ankara, Turkey.

The classical clinical features of familial Mediterranean fever (FMF) are recurrent self-limited attacks of fever and serositis. Amyloidosis of the AA type is the major complication of the disease. The diagnosis of FMF is still based on a history of typical acute attacks, ethnic background, and frequently, notable family history. Together with the discovery of MEFV gene, the clinical criteria for the diagnosis of the disease did not change. Although we have learned a great deal about the clinical features and the pathogenesis of FMF in the past few years, many atypical cases emerge, and caution should be exercised during diagnosis. In this report, we present three FMF patients not fulfilling clinical criteria for the diagnosis, discuss rare and unusual presentations of the disease, and emphasize the role of genetic analysis in these suspicious cases.

Tumor necrosis factor-alpha gene promoter polymorphism in patients with familial Mediterranean fever.

Celebi Kobak A(1), Kobak S, Kabasakal Y, Akarca US.

Author information:

(1)Department of Gastroenterology and Hepatology, Ege University School of Medicine, Bornova, Izmir, Turkey.

The proinflammatory cytokine tumor necrosis factor-alpha (TNF-alpha) plays an important role on the course of disease in familial Mediterranean fever (FMF). TNF-alpha gene promoter polymorphism may be a marker of susceptibility and severity of FMF. The aim of this study is to evaluate both TNF-alpha/238 and TNF-alpha/308 genotypes and allelic distribution in patients with FMF. Forty-one FMF patients and 43 healthy volunteers were included in the study. Genomic DNA was extracted from EDTA-preserved whole blood of whole series of patients and controls. Polymorphism of TNF-alpha promoter at positions -238 and -308 were detected by using amplification refractory mutation system polymerase chain reaction. TNF-alpha/238 and TNF-alpha/308 genotype distributions and allele frequencies of FMF patients and healthy volunteers were found to be similar. Moreover, there was no association between TNF-alpha/238 and TNF-alpha/308 genotypes and the frequency of acute attacks in FMF. TNF-alpha/238 and

TNF-alpha/308 promoter polymorphisms do not seem to be major genetic risk factors for susceptibility to FMF and severity of the disease.

Innate immune sensing of microbes by Nod proteins.

Kufer TA(1), Banks DJ, Philpott DJ.

Author information:

(1)Immunité Innée et Signalisation, Institut Pasteur, 28 Rue du Docteur Roux, 75724 Paris Cedex 15, France.

Nod1 and Nod2 are proteins involved in innate immune defense. These intracellular surveillance proteins detect bacterial peptidoglycan, although requiring distinct motifs to achieve sensing. Detection through Nod1 and Nod2 initiates proinflammatory signaling via NF-kappaB activation, which is necessary for clearance of infecting pathogens from the host. The peptidoglycan product sensed by Nod1 is a motif characteristic of Gram-negative bacteria plus some Gram-positive bacteria, such as *Bacillus* and *Listeria* spp. The specificity of Nod1 to detect this subset of bacteria might represent a selective advantage for the host in certain cases when Gram-negative bacteria represent the main threat, such as in the epithelial cells lining the intestinal mucosa. In contrast, Nod2 has been implicated as a general sensor for both Gram-positive and Gram-negative bacteria since muramyl dipeptide (MDP), which is the minimal motif in all peptidoglycans, is the structure recognized by Nod2. Mutations in Nod2 have been associated with autoinflammatory disease in humans, including Crohn's disease. Interestingly, the most common mutation in Nod2 associated with Crohn's disease results in protein product that no longer detects MDP. Although the implications of these findings are still not fully understood, it appears that lack of bacterial sensing through a loss of interaction between mutant Nod2 and MDP contributes to the pathology of disease. A loss of surveillance activity by Nod2 may result in the inability of local responses in the intestinal mucosa to control bacterial infection, thereby initiating systemic responses and leading to aberrant inflammation.

Rubinstein-Taybi syndrome and familial Mediterranean fever in a single patient: two distinct genetic diseases located on chromosome 16p13.3.

Kalyoncu U(1), Tufan A, Karadag O, Kisacik B, Akdogan A, Calguneri M.

Author information:

(1)Internal Medicine Division of Rheumatology, Hacettepe University, Ankara, Turkey.

Rubinstein-Taybi syndrome (RTS) is characterized by typical facies, short stature, mental retardation, broad thumbs and broad great toes. The syndrome is at least in part caused by microdeletions at chromosome 16p13.3 or by mutations in the gene for the CREB binding protein (CBP), which is located at 16p13.3. Familial Mediterranean fever (FMF) is an autosomal recessive disease, caused by mutations in the FMF-gene [Mediterranean fever (MEFV)] and characterized by recurrent attacks of fever and peritonitis, arthritis and pleuritis. The FMF gene (MEFV) has recently been cloned by two consortia and 30 point mutations, causing the disease have been identified. MEFV maps to chromosome 16p and encodes a 781-amino-acid protein called pyrin or marenostrin, which is expressed mainly in neutrophils and myeloid bone marrow precursors. Herein, we report a case with RTS and FMF.

A complex case of renal amyloidosis with a rare co-occurrence of 2 mutations in separate hereditary periodic fever syndrome-related genes.

Cigni A(1), Ledda F, Satta AE.

Author information:

(1)Department of Clinical and Medical Pathology, University of Sassari, Italy.  
cignale@hotmail.com

A 41 year-old male was admitted because of nephrotic syndrome associated with renal impairment and arterial hypertension. Renal biopsy showed a complete subverting of renal architecture with eosinophilic, amorphous deposits which stained positive for Congo red and were positive for antibodies against AA-amyloid. Abdominal fat pad aspirate confirmed the diagnosis of AA amyloidosis. Despite high values of serum amyloid A (SAA), surprisingly medical history, physical examination and all tests failed to identify any underlying inflammatory disease, even asymptomatic, at presentation and during the whole follow-up period. The patient carried a mutation (Glu148Gln) in the MEFV gene, and a mutation (Arg92Gln) in the TNFRSF1A gene, both in heterozygosity. The patient has never complained of the typical features of the Familial Mediterranean fever or of the TNF receptor-associated periodic syndrome. The patient's father carried the same mutations. His father's medical history was unremarkable; renal tests, acute-phase reactants and SAA were normal. During a trial with colchicine (while the patient was also taking atorvastatin) SAA decreased, renal function continued to deteriorate and proteinuria remained high; no cardiac involvement was detected. Six months later our patient developed rhabdomyolysis, thus accelerating the decline of renal function and requiring the start of dialysis.

Fever is one of the main symptoms leading to medical evaluation. Not only infections cause fever but also inflammatory disorders. To distinguish one from another, a thorough medical history and clinical evaluation are needed. Sometimes, only the clinical course will reveal the diagnosis. PFAPA-Syndrome (periodic fever, aphthous stomatitis, pharyngitis, adenitis) is the most frequent periodic fever syndrome in Switzerland. No diagnostic test is available to support the diagnosis. Some important diseases have to be ruled out, such as Immunodeficiency, cyclic neutropenia, chronic viral infections and rheumatologic disorders. To know the diagnosis of the PFAPA-Syndrome can help avoiding antibiotic courses for febrile episodes in infants. There is a clinical overlap to hereditary periodic fever syndromes as familial Mediterranean fever (FMF), Hyper-IgD and fever syndrome (HIDS), Tumor-necrosis factor receptor associated periodic syndrome (TRAPS) and others, in which a genetic basis for the disease has already been found.

Infliximab treatment of Familial Mediterranean fever and its effect on secondary AA amyloidosis.

Metyas S(1), Arkfeld DG, Forrester DM, Ehresmann GR.

Author information:

(1)LAC+USC Medical Center, Los Angeles, California, USA.

We describe a patient with a long history of familial Mediterranean fever who developed proteinuria as a result of secondary AA amyloidosis. In this patient, the inflammatory process, including recurrent attacks of arthritis, abdominal pain, nephrotic syndrome secondary to amyloidosis, and high sedimentation rate, was rapidly suppressed by treatment with infliximab and there was remarkable improvement of the proteinuria. Because TNF-alpha is a proinflammatory cytokine

that plays a major role in FMF and secondary amyloid, it is an appropriate target for therapy. Our case is the first case of reactive systemic amyloidosis secondary to familial Mediterranean fever, which responded favorably to infliximab.

Protracted arthritis is uncommon in familial Mediterranean fever (FMF) and rarely may result in degenerative joint damage, a well-known complication of FMF, usually affecting kidneys. We present an unusual case of FMF involving severe bilateral coxarthrosis leading to residual incapacity that was treated by total hip arthroplasty, and an unusual presentation of amyloidosis - intraosseous

amyloidosis of the femoral head.

sezaozen@hacettepe.edu.tr

**OBJECTIVE:** Familial Mediterranean fever (FMF) is an autoinflammatory disease common in eastern Mediterranean populations. The most severe complication is the development of secondary amyloidosis. Toll-like receptor (TLR-2) plays a critical role in linking the recognition of microbes to immune activation. We investigated whether the Arg753Gln TLR2 polymorphism affected the development of secondary amyloidosis in patients with FMF.

**METHODS:** We studied 75 patients with FMF, 40 patients with FMF who developed secondary amyloidosis, and 116 healthy controls. TLR2 gene Arg753Gln mutations

were analyzed with a polymerase chain reaction-restriction fragment length polymorphism method.

RESULTS: The frequency of the Arg753Gln TLR2 polymorphism among the Turkish population was 6%, whereas it was 25.2% among patients with FMF ( $p < 0.01$ ). The difference of the frequency of the polymorphism between FMF patients with and without amyloidosis was significant: 15/40 (37.5%) and 14/75 (18.6%), respectively ( $p = 0.02$ ).

CONCLUSION: The Arg753Gln polymorphism may affect the severity of this monogenic disease by influencing the innate immune response to pathogens. The presence of the polymorphism may influence the phenotype of FMF in geographic areas where bacterial insult is more common.

Changes in the liver function tests during the attacks of familial Mediterranean fever.

Korkmaz C(1), Kaşifoğlu T.

Author information:

(1)Division of Rheumatology, Department of Internal Medicine, Eskisehir Osmangazi University, Eskisehir, Turkey. ckorkmaz@ogu.edu.tr

The present study aims to investigate whether or not FMF patients display abnormal liver functions during attack periods. About 41 consecutive FMF patients with attacks were enrolled on this study. Bilirubin levels, liver transaminases, erythrocyte sedimentation rate and C-reactive protein (C-RP) levels were determined within the first 72 h after the onset of attacks. This procedure could be performed on only 28 of these 41 FMF patients, 4 weeks after the attack of the patients' had completely disappeared. As for the disease control group, 44 patients were determined to be eligible for the study. Another 31 healthy individuals were also included. Hyperbilirubinemia was determined in 11 of the 41 patients (26.8%) with FMF. The number of FMF patients with hyperbilirubinemia was significantly higher than in DC and HC ( $P < 0.001$ ,  $P = 0.03$ , respectively).

Levels of liver transaminases slightly increased in four patients with FMF during

the attack and two of these four patients had also mild hyperbilirubinemia. A significant correlation was found between C-RP levels and total and unconjugated bilirubin levels in FMF patients with attack ( $r = 0.43$ ,  $P = 0.01$ ;  $r = 0.40$ ,  $P = 0.02$ , respectively). In conclusion, mild hyperbilirubinemia may occur in one-fourth of the patients with FMF during the attack period.

Goats, germs, and fever: Are the pyrin mutations responsible for familial Mediterranean fever protective against Brucellosis?

Ross JJ(1).

Author information:

(1)Harvard Medical School, Hospitalist Service, Brigham and Women's Hospital, 15 Francis Street, PBB-B420 Boston, MA 02115, USA. jross4@partners.org

Mutations in the MEFV gene are highly prevalent in the Middle East and Mediterranean basin, with carrier rates of up to 1:3 in some populations. More than 50 mutations in the MEFV gene have been described. The high prevalence, multiple mutations, and geographic localization to the Middle East suggest a positive selection advantage for the abnormal gene operating in this area over the last several thousand years. To date, no satisfactory explanation of this phenomenon has been made. Rather, many harmful effects of these mutations have been described. MEFV gene mutations cause familial Mediterranean fever in homozygotes, a disease associated with recurrent febrile inflammatory episodes, and death from renal failure and amyloidosis. Heterozygotes with MEFV mutations are predisposed to premature coronary disease, and rheumatologic conditions such as Behçet's disease. MEFV mutations do not appear to protect against tuberculosis. Brucellosis is still highly endemic in the Middle East because of the traditional reliance for meat and dairy production on goats and sheep, the major vectors for this zoonosis. Brucellosis causes a prolonged febrile illness lasting for months and even years, and it may have exacted a major toll among Bronze Age peasant populations in the Middle East. The gene product for MEFV, pyrin, normally inhibits interleukin-1 $\beta$  production. Mutations in MEFV result

in a pro-inflammatory state, with a Th1 polarization and high levels of interferon-gamma. This may actually be protective against intracellular pathogens such as brucellosis. The possible heterozygote advantage of MEFV mutations against brucellosis may therefore be a balanced polymorphism, analogous to the protective effect against malaria that maintains high levels of sickle cell trait in sub-Saharan Africa.

Anakinra prevents symptoms of familial cold autoinflammatory syndrome and Raynaud's disease.

Metyas SK(1), Hoffman HM.

Author information:

(1)Division of Rheumatology, University of Southern California, Los Angeles, California 90033, USA. metyas@usc.edu

**OBJECTIVE:** Familial cold autoinflammatory syndrome (FCAS) is a rare, hereditary disorder characterized by cold-induced inflammation. We describe the successful longterm treatment of a patient with FCAS with anakinra, an interleukin 1 receptor antagonist (IL-1Ra). The remarkable response of FCAS and associated Raynaud's disease in this patient suggests that IL-1 is an important mediator of these inflammatory diseases. Our report supports increasing evidence that

anakinra plays an important role in the treatment of select chronic inflammatory diseases.

Is IL-1 a good therapeutic target in the treatment of arthritis?

Burger D(1), Dayer JM, Palmer G, Gabay C.

Author information:

(1)Clinical Immunology Unit, Division of Immunology and Allergy, Department of Internal Medicine, University Hospital, 24 rue Micheli-du-Crest, CH-1211 Geneva 14, Switzerland. danielle.burger@hcuge.ch

Inflammation is an important homeostatic mechanism that limits the effects of infectious agents. However, inflammation might be self-damaging and therefore has to be tightly controlled or even abolished by the organism. Interleukin 1 (IL-1) is a crucial mediator of the inflammatory response, playing an important part in the body's natural responses and the development of pathological conditions leading to chronic inflammation. While IL-1 production may be decreased or its effects limited by so-called anti-inflammatory cytokines, in vitro IL-1 inflammatory effects are inhibited and can be abolished by one particularly powerful inhibitor, IL-1 receptor antagonist (IL-1Ra). Recent research has shown that in the processes of rheumatoid arthritis (RA) IL-1 is one of the pivotal cytokines in initiating disease, and IL-1Ra has been shown conclusively to block its effects. In laboratory and animal studies the inhibition of IL-1 by either antibodies to IL-1 or IL-1Ra proved beneficial to the outcome. Because of its beneficial effects in many animal disease models, IL-1Ra has been used as a therapeutic agent in human patients. The recombinant form of IL-1Ra, anakinra (Kineret, Amgen) failed to show beneficial effects in septic shock and displays weak effects in RA patients. However, IL-1 blockade by anakinra is dramatically effective in systemic-onset juvenile idiopathic arthritis, in adult Still's disease and in several autoinflammatory disorders, most of the latter being caused by mutations of proteins controlling IL-1 $\beta$  secretion. Importantly, to be efficacious, anakinra required daily injections, suggesting that administered

IL-1Ra displays very short-term effects. Better IL-1 antagonists are in the process of being developed.

Inflammatory caspases and inflammasomes: master switches of inflammation.

Martinon F(1), Tschopp J.

Author information:

(1)Department of Biochemistry, University of Lausanne, BIL Biomedical Research Center, Epalinges, Switzerland.

Fifteen years have passed since the cloning and characterization of the interleukin-1 $\beta$ -converting enzyme (ICE/caspase-1), the first identified member of a family of proteases currently known as caspases. Caspase-1 is the prototypical member of a subclass of caspases involved in cytokine maturation termed inflammatory caspases that also include caspase-4 caspase -5, caspase -11 and caspase -12. Efforts to elucidate the molecular mechanisms involved in the activation of these proteases have uncovered an important role for the NLR family members, NALPs, NAIP and IPAF. These proteins promote the assembly of multiprotein complexes termed inflammasomes, which are required for activation of inflammatory caspases. This article will review some evolutionary aspects, biochemical evidences and genetic studies, underlining the role of inflammasomes and inflammatory caspases in innate immunity against pathogens, autoinflammatory syndromes and in the biology of reproduction.

Etanercept in the treatment of arthritis in a patient with familial Mediterranean fever.

Sakallioglu O(1), Duzova A, Ozen S.

Author information:

(1)Pediatric Nephrology and Rheumatology Unit, Department of Pediatrics, Hacettepe University Faculty of Medicine, Ankara, Turkey.

Familial Mediterranean fever (FMF) patients may present with different joint complaints, one being the 'protracted attack' that lasts for weeks. We present a 15 year-old boy with polyarthritis (right wrist, knee, shoulder, and both ankles) while on colchicine treatment for FMF. His polyarthritis was resistant to treatment with prednisolone and methotrexate, and etanercept was instituted (0.8 mg/kg/week). He responded dramatically to etanercept and remained in full remission, although the drug was stopped at 4 months due to social and financial causes. We suggest that anti-TNF drugs may be an alternative for resistant attacks. However the timing and dosage, as well as efficacy, need to be further studied.

**OBJECTIVES:** Behçet's disease (BD) is a systemic vasculitis with recurrent oral and genital ulcers and uveitis. MEFV gene, which is the main factor in familial Mediterranean fever (FMF), is also reported to be a susceptibility gene for BD. The pyrin domain of MEFV gene is a member of death-domain superfamily and has been proposed to regulate inflammatory signaling in myeloid cells. This study was designed to determine if mutations in pyrin domain of MEFV gene are involved in BD.

**METHODS:** We analyzed the pyrin domain of MEFV gene in 54 Turkish patients with BD by PCR-analysis and direct sequencing.

**RESULTS:** Neither deletion or insertion mutations nor point mutations in pyrin domain were found in any patient.

**CONCLUSION:** Although pyrin gene mutations have been reported in patients with BD, pyrin domain is not mutated. However, alterations in other regions of MEFV gene and interaction between pyrin domains are needed to be further investigated.

Successful treatment of nephrotic syndrome due to FMF amyloidosis with azathioprine: report of three Turkish cases.

Sayarlioglu H(1), Erkoc R, Sayarlioglu M, Dogan E, Soyoral Y.

Author information:

(1)Department of Internal Medicine, Division of Nephrology, Sutcu Imam University, Medical Faculty, İç Hastalıkları A.D., Nefroloji B.D., Kahramanmaraş, 46050, Turkey. hayriyesayarlioglu@yahoo.com

Secondary amyloidosis is a well-known complication of certain familial Mediterranean fever (FMF). We presented three Turkish patients with FMF and biopsy proven amyloidosis. These patients were treated with colchicine 1.5 mg/day. They have experienced five to six peritonitis attacks with fever within 1

year. On admission, the laboratory test results were as follows: serum creatinine 2.3, 0.6, and 0.5 mg/dl; albumin 4.2, 1.9, and 1.8 g/dl; and urinary protein excretion 4, 15, and 10 g/day, respectively. All the patients were started azathioprine (AZA) 100 mg/day and attacks were completely stopped. Laboratory findings were as follows after 1 year of AZA treatment: serum creatinine 1, 0.8, and 0.6 mg/dl; albumin 4.3, 3, and 3.5 g/dl; and urinary protein excretion 3, 8, and 1.5 g/day, respectively. Treatment with azathioprine in addition to colchicine could ameliorate the nephrotic syndrome and control the attacks very effectively in these cases.

An unusual complication of familial Mediterranean fever: intestinal volvulus and necrosis.

Tireli GA(1), Unal M, Sander S.

Author information:

(1)Department of Pediatric Surgery, Bakirköy Maternity and Children's Hospital, Istanbul, Turkey. gultireli@yahoo.com

Familial Mediterranean fever is an autosomal recessive disease characterized by recurring inflammatory attacks of synovial membranes. More than 95% of patients show peritoneal involvement which mimics acute abdomen and can sometimes cause unnecessary surgical intervention. The authors present two patients with the diagnosis of familial Mediterranean fever who underwent surgery because of rare abdominal complication of the disease. Two patients with the diagnosis of familial Mediterranean fever underwent laparotomy, and segmental small bowel resection was done because of the necrosis. Adhesive intestinal obstruction with associated bowel strangulation and volvulus is a rare complication of familial Mediterranean fever, and this life-threatening emergency must be kept in mind.

Pathogenesis of familial periodic fever syndromes or hereditary autoinflammatory syndromes.

Simon A(1), van der Meer JW.

Author information:

(1)Department of General Internal Medicine, Radboud University Nijmegen Medical Center, Nijmegen, The Netherlands. simona2@mail.nih.gov

Familial periodic fever syndromes, otherwise known as hereditary autoinflammatory syndromes, are inherited disorders characterized by recurrent episodes of fever and inflammation. The general hypothesis is that the innate immune response in these patients is wrongly tuned, being either too sensitive to very minor stimuli or turned off too late. The genetic background of the major familial periodic fever syndromes has been unraveled, and through research into the pathophysiology, a clearer picture of the innate immune system is emerging. After an introduction on fever, interleukin-1 $\beta$  and inflammasomes, which are involved in the majority of these diseases, this manuscript offers a detailed review of the pathophysiology of the cryopyrin-associated periodic syndromes, familial Mediterranean fever, the syndrome of pyogenic arthritis, pyoderma gangrenosum and acne, Blau syndrome, TNF-receptor-associated periodic syndrome and hyper-IgD and periodic fever syndrome. Despite recent major advances, there are still many questions to be answered regarding the pathogenesis of these disorders.

We report a case of amyloidosis in association with hyperimmunoglobulinemia D syndrome (HIDS). The patient showed typical clinical features of HIDS. He had crescentic glomerulonephritis progressing to end-stage renal disease at age 13 years. Eight years later, he developed an AA-type amyloidosis with extensive involvement of the intestine, respiratory tract, and thyroid gland. These unusual complications of HIDS seriously challenge the assumption that the disease is associated with a good prognosis.

The pharmacologic basis of treatment with colchicine in children with familial Mediterranean fever.

Rigante D(1), La Torraca I, Avallone L, Pugliese AL, Gaspari S, Stabile A.

Author information:

(1)Centre of Periodic Fevers, Department of Pediatric Sciences, Università Cattolica del Sacro Cuore, Rome, Italy. drigante@rm.unicatt.it

Familial Mediterranean fever (FMF) is the prototype of auto-inflammatory disorders and is ethnically restricted to people living in the Mediterranean basin and Middle-East. Pyrin, the protein product of the FMF gene, expressed in myeloid cells and fibroblasts, interacts with the cytoskeletal machinery and may modulate leukocyte effector functions. At present colchicine, an alkaloid with antimetabolic activity interfering with microtubule formation, which has been used to alleviate acute gout, is the only available drug for patients with FMF to

prevent both acute attacks and long-term complications such as amyloidosis. The anti-inflammatory effect of colchicine may be mediated not only through direct interaction with microtubules, but also through changes at the transcriptional level influencing cell cycle regulation and leukocyte migration. Gastrointestinal side effects may occur early and are the most frequent manifestations of colchicine toxicity in children, whilst multiple organ failure is very rarely reported as overdose expression.

Familial Mediterranean fever (FMF) is characterized by recurrent self-limiting flares of fever in the absence of pathogens, autoantibodies or antigen specific T cells and is inherited as an autosomal recessive trait probably deriving from common ancestors of Armenian, Jew, Turk and Arab origin. The underlying pathogenetic mechanisms of FMF have not been fully interpreted, but mutations in the gene MEFV encoding pyrin, a natural repressor of proinflammatory molecules, result in uncontrolled relapsing systemic inflammation, increased leukocyte migration to serosal membranes or joints and inappropriate response to inflammatory stimuli. FMF heterogeneous phenotypic expression could originate both from allelic heterogeneity or from the existence of modulating genes. Proper diagnosis of FMF is needed to begin both specific clinical management and treatment based on continuous prophylactic administration of colchicine, preventing flares or at least the onset of amyloidosis.

Comment in

Nat Clin Pract Rheumatol. 2006 Dec;2(12):646-7.

**BACKGROUND:** Neonatal-onset multisystem inflammatory disease is characterized by fever, urticarial rash, aseptic meningitis, deforming arthropathy, hearing loss, and mental retardation. Many patients have mutations in the cold-induced autoinflammatory syndrome 1 (CIAS1) gene, encoding cryopyrin, a protein that regulates inflammation.

**METHODS:** We selected 18 patients with neonatal-onset multisystem inflammatory disease (12 with identifiable CIAS1 mutations) to receive anakinra, an interleukin-1-receptor antagonist (1 to 2 mg per kilogram of body weight per day subcutaneously). In 11 patients, anakinra was withdrawn at three months until a flare occurred. The primary end points included changes in scores in a daily diary of symptoms, serum levels of amyloid A and C-reactive protein, and the erythrocyte sedimentation rate from baseline to month 3 and from month 3 until a disease flare.

**RESULTS:** All 18 patients had a rapid response to anakinra, with disappearance of rash. Diary scores improved ( $P<0.001$ ) and serum amyloid A (from a median of 174 mg to 8 mg per liter), C-reactive protein (from a median of 5.29 mg to 0.34 mg per deciliter), and the erythrocyte sedimentation rate decreased at month 3 (all  $P<0.001$ ), and remained low at month 6. Magnetic resonance imaging showed improvement in cochlear and leptomeningeal lesions as compared with baseline.

Withdrawal of anakinra uniformly resulted in relapse within days; retreatment led to rapid improvement. There were no drug-related serious adverse events.

CONCLUSIONS: Daily injections of anakinra markedly improved clinical and laboratory manifestations in patients with neonatal-onset multisystem inflammatory disease, with or without CIAS1 mutations. (ClinicalTrials.gov number, NCT00069329 [ClinicalTrials.gov].).

Colchicine therapy and the cognitive status of elderly patients with familial Mediterranean fever.

Leibovitz A(1), Lidar M, Baumoebl Y, Livneh A, Segal R.

Author information:

(1)Shmuel Harofeh Hospital, Geriatric Medical Center, Beer Yaakov, Israel.

**BACKGROUND:** [corrected] Colchicine is widely used for treating gout and familial Mediterranean fever. However, studies in animal models have reported ill effects of colchicine on the central nervous system, including cognitive function.

**OBJECTIVES:** To evaluate the cognitive status of elderly FMF patients on long-term colchicine treatment.

**METHODS:** The study group consisted of 55 FMF patients aged 74 +/- 5, attending an FMF outpatient clinic and receiving colchicine treatment for 25.1 +/- 8.9 years.

The Mini-Mental State Examination was used for cognitive evaluation. Patients' scores were compared with accepted age- and education-adjusted cutoff scores, population-based norms, and scores of a matched control group of 56 subjects.

**RESULTS:** Individually, all colchicine-treated FMF patients scored well above the age- and education-corrected cutoff scores. Overall, there was a large difference, 5.0 +/- 1.6, from the expected cutoff points, in favor of the study group scores ( $P < 0.001$ ). The individual scores of the control group were also above the cutoff points, however with a lower but still statistically significant difference (3.71 +/- 1.15 points,  $P < 0.001$ ). Compared to population-based norms adjusted by age and education, the study group had significantly higher mean MMSE scores (27.2 +/- 2.2 vs. 25.5 +/- 2.4,  $P < 0.001$ ). The control group's scores were also somewhat higher than expected, but not significantly so.

**CONCLUSIONS:** Our results do not support the view that prolonged colchicine treatment may be associated with cognitive impairment. On the contrary, it is possible that long-term colchicine treatment may even confer protection against cognitive decline in patients with FMF.

Inflammation-responsive transcription factor SAF-1 activity is linked to the development of amyloid A amyloidosis.

Ray A(1), Shakya A, Kumar D, Benson MD, Ray BK.

Author information:

(1)Department of Veterinary Pathobiology, University of Missouri, 126A Connaway Hall, Columbia, MO 65211, USA. [royal@missouri.edu](mailto:royal@missouri.edu)

Abundantly expressed serum amyloid A (SAA) protein under chronic inflammatory conditions gives rise to insoluble aggregates of SAA derivatives in multiple organs resulting in reactive amyloid A (AA) amyloidosis, a consequence of rheumatoid arthritis, Crohn's disease, ankylosing spondylitis, familial Mediterranean fever, and Castleman's disease. An inflammation-responsive transcription factor, SAF (for SAA activating factor), has been implicated in the sustained expression of amyloidogenic SAA under chronic inflammatory conditions. However, its role in the pathogenesis of AA amyloidosis has thus far remained obscure. In this paper we have shown that SAF-1, a major member of the SAF family, is abundantly present in human AA amyloidosis patients. To assess whether SAF-1 is directly linked to the pathogenesis of AA amyloidosis, we have developed a SAF-1 transgenic mouse model. SAF-1-overexpressing mice spontaneously developed AA amyloidosis at the age of 14 mo or older. Immunohistochemical analysis confirmed the nature of the amyloid deposits as an AA type derived from amyloidogenic SAA1. Furthermore, SAF-1 transgenic mice rapidly developed severe AA amyloidosis in response to azocasein injection, indicating increased susceptibility to inflammation. Also, during inflammation SAF-1 transgenic mice exhibited a prolonged acute phase response, leading to an extended period of SAA synthesis. Together, these results provide direct evidence that SAF-1 plays a key role in the development of AA amyloidosis, a consequence of chronic inflammation.

Comment on

J Clin Invest. 2006 Aug;116(8):2262-71.

Gout is an autoinflammatory disorder associated with deposition of monosodium urate (MSU) crystals in joints and periarticular tissues. Recent advances suggest that the innate immune system may drive the gouty inflammatory response to MSU. These findings prompt questions concerning how the innate immune system recognizes MSU and the identities of the receptors involved. In this issue of the JCI, Chen et al. show that the IL-1 receptor and its signaling protein myeloid differentiation primary response protein 88 (MyD88) but not the "classical" innate immune receptors, TLRs, are central for MSU-induced inflammation (see the related article beginning on page 2262).

Serum leptin is not a diagnostic marker for familial Mediterranean fever attacks.

Toy B(1), Tarçin O, Bağcı S, Ustündağ Y, Inal A, Tiftikçi A.

Author information:

(1)Department of Gastroenterology, Gülhane Military Medical Academy, Ankara 06018, Turkey.

The aim of our study is to determine whether there is a relationship between familial Mediterranean fever (FMF) attacks and serum leptin levels. We enrolled 25 patients (22 males and 3 females) and 25 healthy controls (21 males and 4 females) with a mean age of  $24.42 \pm 1.22$  (Mean  $\pm$  SEM) years and  $24.30 \pm 1.19$  years (Mean  $\pm$  SEM), respectively. We investigated serum levels of leptin, interleukin-6 (IL-6) erythrocyte sedimentation rate (ESR), C-reactive protein (CRP), fibrinogen, and leukocyte counts before the attack and 8-12 hours after the attack started. The same parameters have been investigated in the control subjects. The mean serum leptin levels before the attacks were  $6.45 \pm 1.05$  (Mean  $\pm$  SEM) and during the attacks were  $7.59 \pm 1.3$  (Mean  $\pm$  SEM) in FMF group, respectively. There was a slight increase in serum leptin levels during the attacks but it was not statistically significant ( $P > .05$ ). The mean serum leptin

levels were 16.12 +/- 2.81 in the control group which were not different from the mean serum leptin levels before and during the attack periods in the study group ( $P > .05$ ). However, there were statistical differences in the serum levels of IL-6, ESR, CRP, fibrinogen, and leukocyte counts before and during the attack periods ( $P > .05$ ). No correlation was found between serum leptin levels and IL-6, ESR, CRP, fibrinogen, and leukocyte counts ( $P > .05$ ). Serum leptin levels do not increase during FMF attacks and therefore it is not useful for diagnostic purposes and follow-up during treatment.

Pulmonary amyloidosis in familial Mediterranean fever.

Sahan C(1), Cengiz K.

Author information:

(1)Ondokuz Mayıs University, School of Medicine, Department of Nephrology, Samsun, Turkey.

Familial Mediterranean Fever (FMF) is a hereditary periodic fever syndrome expressed by acute episodes of fever and painful manifestations. The gravest consequence of FMF is kidney involvement by secondary amyloidosis of AA type, which gradually leads to nephrotic syndrome and uremia. Nephropathic amyloidosis of the AA type, which complicates FMF in most untreated patients, may progress to affect other organs, including the lungs. This kind of organ involvement rarely produces noticeable symptoms and is associated with symptomatic involvement of other organs while remaining subclinical in itself. In this report, one case who had nephropathic and pulmonary amyloidosis of the secondary amyloidosis of AA type, which complicates the FMF was presented and the pulmonary manifestations of FMF were reviewed.

Serum amyloid A1 -13 T/C alleles in Turkish familial Mediterranean fever patients with and without amyloidosis.

Akar N(1), Hasipek M, Oztürk A, Akar E, Tekin M.

Author information:

(1)Pediatric Molecular Genetics Department, Ankara University, School of Medicine, Ankara, Turkey. akar@medicine.ankara.tr

Previously reported studies concerning the effect of homozygosity of the 1.1 allele of the SAA gene found a correlation between this haplotype and susceptibility to amyloidosis in FMF patients. Another report revealed a strong association between SAA1 -13T/C and secondary amyloidosis in the rheumatoid arthritis patient group. In this study, we aimed to determine the effect of SAA1 -13T/C in FMF patients with and without amyloidosis. The study cohort, consisting

of 166 patients with FMF was divided into two groups, according to the presence (n=66) or absence (n=100) of renal amyloidosis at study entry. MEFV gene mutation analysis and allelic variant of SAA1 gene -13 T/C was analyzed according to the previously described techniques. SAA1 -13 T allele frequencies were 0.5816, 0.23 and 0.4242 in controls, FMF patients and FMF-amyloidosis patients respectively. The difference between controls vs. FMF patients and FMF-amyloidosis patients were 0.0002 and 0.1673 respectively. It was 0.0071 for FMF-patients vs. FMF-amyloidosis. When 694 M/V homozygous nonamyloid-FMF group was compared with 694 M/V carriers of the FMF-amyloidosis group, the difference was 0.049. When carrying TT allele was considered, the difference between controls vs. FMF patients and FMF-amyloidosis patients were 0.0001 and 0.58. It was 0.0003 for FMF patients vs. FMF-amyloidosis. When 694 M/V homozygous nonamyloid-FMF group was compared with 694 M/V carriers of the FMF-amyloidosis group, the difference was 0.03. Carrying SAA -13T in homozygote state revealed a 7.9 (95% CI 3.6 -17.5) fold risk for the occurrence of amyloidosis when compared with FMF patients without amyloidosis. This was 8.75 (95% CI 3.0 - 25.1) when 694 M/V homozygotes were taken into consideration. Our data revealed that the genotype SAA1 -13T has at least an effect on the development of amyloidosis. As more data on this polymorphism accumulate, we will understand its effect on the pathogenesis of amyloidosis in FMF.

Modeling of tumor necrosis factor receptor superfamily 1A mutants associated with tumor necrosis factor receptor-associated periodic syndrome indicates misfolding consistent with abnormal function.

Rebello SL(1), Bainbridge SE, Amel-Kashipaz MR, Radford PM, Powell RJ, Todd I, Tighe PJ.

Author information:

(1)University of Nottingham, Nottingham, UK. mrxslr@nottingham.ac.uk

**OBJECTIVE:** To investigate the effect of mutations in the tumor necrosis factor receptor superfamily 1A (TNFRSF1A) gene on the conformation and behavior of the

TNFRSF1A protein. Mutations in TNFRSF1A cause the autosomal-dominant, autoinflammatory TNFR-associated periodic syndrome (TRAPS).

**METHODS:** The expression of recombinant TNFRSF1A was compared in SK-HEp-1 endothelial cells and HEK 293 epithelial cells stably transfected with full-length R347A or Deltasig constructs of wild-type or TRAPS-associated mutant TNFRSF1A. TNF binding was assessed in HEK 293 cell lines expressing R347A wild-type or mutant TNFRSF1A. Homology modeling of the 3-dimensional structure of the ectodomains of wild-type and mutant TNFRSF1A was performed.

**RESULTS:** TRAPS-associated mutant and wild-type TNFRSF1A behaved differently and had different localization properties within the cell, as a direct result of mutations in the ectodomains of TNFRSF1A. From a structural perspective, mutants with a predicted structure similar to that of the wild-type protein (e.g., R92Q) behaved similarly to wild-type TNFRSF1A, whereas forms of TNFRSF1A with mutations predicted to drastically destabilize the protein structure (e.g., cysteine mutations) showed defects in cell surface expression and TNF binding.

**CONCLUSION:** The results obtained from the in vitro experiments, in combination with the modeled structures, indicate that the phenotype and clinical differences between different TRAPS-associated mutants of TNFRSF1A result from different conformations of the TNFRSF1A ectodomains.

Treatment with anakinra in the hyperimmunoglobulinemia D/periodic fever syndrome.

Rigante D(1), Ansuini V, Bertoni B, Pugliese AL, Avallone L, Federico G, Stabile A.

Author information:

(1)Department of Pediatric Sciences, Center of Periodic Fevers, Università Cattolica Sacro Cuore, Rome, Italy. drigante@gmail.com

Hyperimmunoglobulinemia D/periodic fever syndrome is caused by recessively inherited mutations in the mevalonate kinase gene and is characterized by persistently high polyclonal serum IgD titre and recurrent febrile attacks. No conventional therapy exists for preventing the typical recurrent inflammatory

picture of patients. A host of studies have evidenced that elevated levels of various cytokines, such as interleukin-1 (IL-1), mark febrile attacks in this disease and that IL-1 might represent a suitable therapeutic target. We describe the case of a 7-year-old female-child with an established diagnosis of hyperimmunoglobulinemia D/periodic fever syndrome in whom anakinra, IL-1 receptor antagonist, was daily administered at the dosage of 1 mg/kg/day by subcutaneous injection for 18 months after numerous disappointing attempts with non-steroidal anti-inflammatory drugs, steroids, colchicine and etanercept through the years. The clinical response under anakinra treatment was recorded through a standardized diary, whilst inflammation parameters were serially measured in comparison with the half-year before starting anakinra. Frequency and severity of fever attacks were totally reduced by anakinra and this is the first child demonstrating that symptoms of hyperimmunoglobulinemia D/periodic fever syndrome might be at least extenuated by anakinra, though not abolished.

An intronic variable number of tandem repeat polymorphisms of the cold-induced autoinflammatory syndrome 1 (CIAS1) gene modifies gene expression and is associated with essential hypertension.

Omi T(1), Kumada M, Kamesaki T, Okuda H, Munkhtulga L, Yanagisawa Y, Utsumi N, Gotoh T, Hata A, Soma M, Umemura S, Ogihara T, Takahashi N, Tabara Y, Shimada K, Mano H, Kajii E, Miki T, Iwamoto S.

Author information:

(1)Division of Human Genetics, Center for Community Medicine, Jichi Medical School, Minamikawachi-machi, Tochigi 329-0498, Japan.

Cold-induced autoinflammatory syndrome 1 (CIAS1) gene is a member of the NALP subfamily of the CATERPILLER protein family that is expressed predominantly in peripheral blood leukocytes, which is to regulate apoptosis or inflammation through the activation of NF-kappaB and caspase. Recent genetic analyses suggested an association between inflammation and oxidative stress-related genes in the development of hypertension. This is the first genetic study indicating an

association between the CIAS1 gene and susceptibility to essential hypertension (EH). The frequency of subject with the homozygote of 12 repeat allele was significantly higher in patients with hypertension compared with control subjects (987 cases, 924 controls) ( $P=0.030$ ; odds ratio=1.24) at a novel VNTR polymorphism of CIAS1 intron 4 loci. We also found that the mean of systolic blood pressure of homozygotes of 12 repeat allele was 6.4 mmHg higher than those of homozygotes of non-12 repeat allele in male random population ( $P=0.009$ ). The frequency of six SNPs spanning of the CIAS1 gene was not significantly between patients and controls. The real-time PCR analysis showed that among healthy young adults, 12-12 subjects expressed CIAS1 mRNA in peripheral leukocytes significantly more abundantly than homozygote of non-12 repeat alleles subjects ( $P<0.05$ ). Reporter gene assay of the CIAS1-VNTR in HL60 stimulated by lipopolysaccharides showed that the intronic sequence involving 12 repeat increased the expression of luciferase compared with 9, 7, and 6 repeats. Thus, we propose here the CIAS1 is associated with EH through the dominant expression of transcripts, which may depend on the CIAS1-VNTR genotype.

A 47-year-old man from Armenia presented at the emergency department with abdominal pain. He had had a kidney transplant 2 years earlier for renal failure caused by amyloidosis that was secondary to familial Mediterranean fever. He was also known to have chronic hepatitis B with persistent viraemia. He had not received any prophylactic anti-tuberculosis treatment due to impaired liver function, but an extensive work-up was performed prior to transplant, including chest radiography, a Mantoux tuberculin skin test and cultures from 3 consecutive fasting gastric lavage samples, which were all negative for active or latent tuberculosis infection. The patient had presented at the emergency department repeatedly with abdominal pain that was attributed to the familial Mediterranean fever. During his last visit his complaints were accompanied by vomiting, coughing, night sweats and weight loss. He was diagnosed with an intestinal perforation with faecal peritonitis and underwent several laparotomies to treat the faecal peritonitis. Histopathological examination of resected bowel tissue revealed granulomatous inflammation, and acid-fast bacilli were seen with appropriate staining. Later, cultures appeared to be positive for normally sensitive *Mycobacterium tuberculosis*. The patient died as a result of the disseminated tuberculosis. In immunocompromised patients, tuberculosis often has an atypical course and an increased chance of dissemination that may be difficult to recognize.

**INTRODUCTION:** PRKAG2 plays a role in regulating metabolic pathways, and mutations in this gene are associated with familial ventricular preexcitation, hypertrophic cardiomyopathy, and atrioventricular conduction disturbances. Clinico-pathologic and experimental data suggest the hypothesis of a glycogen storage disease.

**OBJECTIVE:** To report a unique pattern of clinical features observed in individuals with a mutant PRKAG2 from two unrelated families.

**METHODS AND RESULTS:** We studied two large families and found a total of 20 affected individuals showing a combination of sinus bradycardia, short PR interval, RBBB, intra and infrahisian conduction disturbances often requiring a pacemaker, and atrial tachyarrhythmias. Three individuals died suddenly at a young age. No patient had the Wolff-Parkinson-White (WPW) syndrome, and only two patients (10%) had myocardial hypertrophy. We performed screening of the exons and exon-intron boundaries of PRKAG2. Genetic analysis revealed a missense mutation (Arg302Gln) in the affected individuals from both families. This mutation had been described before and has been associated with the familial form of the WPW syndrome and with a high prevalence of left ventricular hypertrophy.

**CONCLUSION:** PRKAG2 mutations are responsible for a diverse phenotype and not only the familial form of the WPW syndrome. Familial occurrence of right bundle branch block, sinus bradycardia, and short PR interval should raise suspicion of a mutant PRKAG2 gene.

Mutational spectrum and genotype-phenotype correlations in mevalonate kinase deficiency.

Mandey SH(1), Schneiders MS, Koster J, Waterham HR.

Author information:

(1)Laboratory Genetic Metabolic Diseases, Departments of Clinical Chemistry and Pediatrics, Emma Children's Hospital, Academic Medical Center, University of Amsterdam, Amsterdam, The Netherlands. h.r.waterham@amc.uva.nl

Mevalonate kinase deficiency (MKD) is an autosomal recessive autoinflammatory disorder caused by mutations in the MVK gene resulting in deficient activity of mevalonate kinase (MK). Depending on the clinical severity, MKD may present as hyper-IgD and periodic fever syndrome (HIDS) or the more severe mevalonic aciduria (MA). We analyzed the MVK gene in 57 patients with MKD and found 39 different mutations including 15 novel mutations, expanding the total mutational spectrum of MKD to 63 mutations. To get more insight into the genotype-phenotype correlation in MKD, we studied the effect of selected missense mutations on MK protein stability and activity in various patient fibroblast cell lines. All MKD cell lines showed markedly decreased MK activities that correlated well with the clinical severity and, for most of the cell lines, with the amount of MK protein. When fibroblasts of MKD patients were cultured under conditions known to promote a more controlled protein folding, all cell lines of patients with the HIDS phenotype and few cell lines of patients with the MA phenotype showed an increase in the residual MK activity. This increase in enzyme activity correlates well with an increase in the MK protein levels in these cell lines, indicating that most of the mutations in MKD affect stability and/or folding of the MK protein rather than affecting the catalytic properties of the enzyme. The finding that the residual activity in MKD can be manipulated by environmental conditions may offer therapeutic options to alleviate or prevent the clinical symptoms associated with MKD.

Arthroscopy of the knee in pre-adolescent children.

Sarpel Y(1), Ozkan C, Toğrul E, Tan I, Gülşen M.

Author information:

(1)Department of Orthopaedics and Traumatology, Cukurova University Faculty of Medicine, Balcali, 01330, Adana, Turkey. ysarpel@yahoo.com

**INTRODUCTION:** Arthroscopic operations performed in the pediatric age group constitute less than 5% of all arthroscopies. Diagnostic accuracy is reported to be lower than the procedures in adult patients. The incidence of pathologies also varies in the literature. We aimed at assessing the diagnostic accuracy of arthroscopy and review the incidence of pathologies in pre-adolescent patients.

**MATERIALS AND METHODS:** In the period April 1990-January 2002, 50 pre-adolescent patients underwent knee arthroscopy after clinical and radiological assessment.

Average age was 10.24 (1-13) with a male-to-female ratio of 34:16.

**RESULTS:** Discoid lateral meniscus was found to be the most common pathology encountered in 17 cases followed by infection and synovitis in 8 cases each.

Diagnostic accuracy of arthroscopy correlated with preoperative clinical and radiologic evaluation was 90%. Arthroscopy findings were negative in two cases. Two cases of plica syndrome and one case of chondral injury were mistaken for medial meniscal tear. Final diagnosis was familial Mediterranean fever in one case of synovitis and knee fusion was performed at follow-up due to progressive degenerative changes. No other patient required reoperation.

**CONCLUSION:** Arthroscopy is a safe procedure with minor morbidity allowing treatment of various intraarticular knee disorders. Diagnostic accuracy of the procedure may increase with careful preoperative work-up.

Patients with many recurrences of acute pericarditis are commonly alarmed by the

fear of constriction. We studied their long-term outcome and the possible presence of systemic diseases. Sixty-one Italian patients (36 men) were followed for an average of 8.3 years according to a predefined protocol, including testing for autoimmune diseases and familial Mediterranean fever. Symptomatic pericarditis lasted from 1 to 43 years (mean 5.4 years). Fifty-two patients had been referred to us after failure of previous therapies, including steroids. We observed 378 attacks with a mean of 1.6 per patient per year and 156 hospital admissions. Thirteen patients had a post-cardiac injury syndrome. In 43 (70.5%), the pericarditis remained idiopathic, whereas we made a new diagnosis of rheumatoid arthritis in 1 and of Sjogren's syndrome in 4 patients, but in these patients pericarditis represented the dominant clinical manifestation. Cardiac tamponade occurred during the initial attacks in 4 patients (6.5%) but never recurred. Pleural effusions were present during the first attack in 22 patients (36.0%) and liver involvement in 5 (8%). No patients developed constrictive pericarditis. Echocardiographic examination produced no evidence of chronic myocardial disease. Response to therapy was good. Thirty-one patients (50.8%) are in sustained remission, without any therapy; their total observation period has averaged 10.3 years. In idiopathic patients, antinuclear antibodies were present in 56.2% and anti-Ro/SSA in 8.3%. Mutations linked to familial Mediterranean fever were absent. In conclusion, in this large series of difficult patients with recurrent acute pericarditis and a very long follow-up, the long-term prognosis is good.

[Immunogenetic blood markers as a risk factor of development of periodic disease in Armenian population].

[Article in Russian]

Nersisian VM, Astvatsatrian VA, Zakharian AG, Musaelian NO, Martirosian IG.

AIM: To reveal characteristic associations between various markers of immunogenetic (HLA--A, B, C, DR), erythrocytic (ABO, Rh-Hr, MNSs, Pp, Kell-Chellano, Lewis), serum (Gm, Inv) systems and familial Mediterranean fever

(FMF) in Armenian population.

**MATERIAL AND METHODS:** From 41 to 125 patients (depending on systems studied) were examined. HLA-antigens of A-, B-, C-classes were detected by the microcytotoxic test in a total population of lymphocytes, HLA-DR antigens--by a prolonged test in B-lymphocytes, erythrocytic antigens--by hemagglutination technique and indirect Coombs' reaction, serum antigens--by the method of hemagglutination suppression.

**RESULTS:** Confidential positive associative relations between antigens HLA-A1 and A9 (RR = 2.2 and 2.4), HLA B5 and B35 (RR = 3.03 and 3.2), HLA-Cw4 (RR = 4.3), HLA-DR3 (RR = 2.6), phenotypes AB (RR = 2.86) and MN (RR = 2.2), serum antigen Gmx+ (RR = 2.87) were demonstrated. Simultaneous expression of phenotype MN and antigen Gmx+ is a marker of high predisposition to the disease (RR = 4.7).

Negative associative relations were found between FMF and antigens HLA-B12 and B18 (RR = 0.6 and 0.1), HLA DR4 (RR = 0.1) and phenotype MM (RR = 0.37).

**CONCLUSION:** A simultaneous complex investigation of the markers of various immunogenetic systems allows detection of genetic markers of predisposition to FMF (HLA-B5, B35, Cw4, DR3, AB, Gmx+, MN) and the resistance to this disease (HLA-B12, B18, DR4) in a population of Armenians.

Comment in

Arthritis Rheum. 2007 Jun;56(6):2099-101; author reply 2101-2.

In this report we describe a case of severe chronic infantile neurologic, cutaneous, articular (CINCA) syndrome with a novel G307V cryopyrin mutation and all of the characteristic clinical and laboratory features of this autoinflammatory disease. There was no clear response to standard therapies, including human interleukin-1 (IL-1) receptor antagonist (anakinra) and soluble tumor necrosis factor receptor (etanercept). The patient finally had a partial clinical response (reduction in fever and irritability) and complete laboratory response (improved C-reactive protein and serum amyloid A levels) to humanized anti-IL-6 receptor antibody (MRA), but died from congestive heart failure and interstitial pneumonia 2 months after initiation of therapy. We serially measured the serum cytokine levels and expression of NF-kappaB activation in the patient's peripheral blood mononuclear cells before and during consecutive therapies. Pathologic examination of autopsy specimens was also performed. This case illustrates the continued difficulty in management of patients with CINCA syndrome and the complexity of the inflammatory pathways in this disorder.

Manipulation of isoprenoid biosynthesis as a possible therapeutic option in mevalonate kinase deficiency.

Schneiders MS(1), Houten SM, Turkenburg M, Wanders RJ, Waterham HR.

Author information:

(1)Laboratory Genetic Metabolic Diseases (F0-224), Departments of Clinical Chemistry and Pediatrics, Academic Medical Center, University of Amsterdam, 1100 DE Amsterdam, The Netherlands.

**OBJECTIVE:** In cells from patients with the autoinflammatory disorder mevalonate kinase (MK) deficiency, which includes the hyperimmunoglobulin D with periodic fever syndrome, MK becomes the rate-limiting enzyme in the isoprenoid biosynthesis pathway. This suggests that up-regulation of residual MK activity in these patients could be a way in which to prevent or alleviate the associated symptoms. We studied the effect of 2 specific inhibitors of isoprenoid biosynthetic enzymes on the residual activity of MK in cells from patients with MK deficiency.

**METHODS:** Skin fibroblasts from MK-deficient patients and from controls were cultured for 7 days with either simvastatin, an inhibitor of 3-hydroxy-3-methylglutaryl coenzyme A reductase, or zaragozic acid A, an inhibitor of squalene synthase. Following culture, MK activity, MK protein levels, MVK messenger RNA levels, and the effect on the pathway flux toward non-sterol isoprenoid biosynthesis were determined.

**RESULTS:** Treatment of the fibroblasts with either of the inhibitors led to a marked increase in residual MK enzyme activity, which was largely attributable to increased MVK gene transcription. This effect was even more pronounced when the cells were cultured in lipoprotein-depleted medium. The flux toward nonsterol isoprenoid end-product synthesis was reduced when cells were treated with simvastatin but was partly restored by concomitant treatment with zaragozic acid A.

**CONCLUSION:** Our results indicate that manipulations of the isoprenoid biosynthesis pathway that promote the synthesis of nonsterol isoprenoids may provide an interesting therapeutic option for the treatment of MK deficiency.

Left-sided paraduodenal hernia: report of a case.

Cingi A(1), Demirkalem P, Manukyan MN, Tuney D, Yegen C.

Author information:

(1)Department of General Surgery, Marmara University School of Medicine, Tophanelioglu cad Altunizade, Istanbul, Turkey.

Paraduodenal hernias are rare congenital malformations consisting of incomplete rotation of the midgut, which may lead to intestinal obstruction or simply be detected as an incidental finding at autopsy or laparotomy. We report a case of left paraduodenal hernia diagnosed preoperatively by computed tomography and operated on in an emergency setting for signs of peritoneal irritation. A misdiagnosis had been made when the patient suffered his first attack 6 months earlier and he had been treated for familial Mediterranean fever. We reduced the small bowel loops from the left paraduodenal hernia sac with ligation and transection of the inferior mesenteric vessels. The patient was discharged from hospital on postoperative day 4 after an uneventful recovery.

Impaired endotoxin tolerance induction in patients with familial Mediterranean fever.

Davtyan TK(1), Hakopyan GS, Avetisyan SA, Mkrtchyan NR.

Author information:

(1)Laboratory of Immunology and Virology, Armenicum Research Center, Yerevan State Medical University, Republic of Armenia. tigdav@excite.com

**OBJECTIVE:** To investigate periodic disturbances in proinflammatory activation of neutrophils and monocytes in patients with familial Mediterranean fever (FMF) both during an attack and in remission.

**METHODS:** 20 FMF patients, who were naive to colchicine treatment and did not have amyloidosis, and 10 patients with Behçet's disease (BD) were enrolled in this study. Phagocytosis, respiratory burst, CD11a/CD18 expression and intracellular cytokine synthesis were determined by flow cytometry. Endotoxin tolerance induction was defined by a reduced capacity of monocytes to respond to lipopolysaccharide (LPS) activation following a first exposure to LPS.

**RESULTS:** In FMF patients, we observed upregulation of neutrophil and monocyte phagocytic activity and oxidative burst during remission and downregulation of phagocytic activity and stimulus-dependent oxidative burst during an attack. A comparative analysis of oxidative burst has revealed that while the neutrophil population shows a certain periodicity in the increase (during remission) and decrease (during attacks) in the spontaneous and inducible respiratory burst, periodicity in the monocyte population is very poor. In addition, LPS-induced oxidative burst and CD11a/CD18 integrin surface expression is higher in patients during an attack compared to patients in remission. The induction of homologous tolerance of monocytes to the repeated action of LPS is observed in FMF patients during an attack, normal donors and patients with BD, whereas monocytes from patients in remission failed to induce LPS homologous tolerance and exhibited heightened sensitivity to bacterial endotoxin. We found that colchicine is able to restore impaired LPS homologous tolerance induction in FMF patients in remission upon increased synthesis of IL-4 in FMF patient monocytes.

**CONCLUSION:** Chronic inflammation during FMF is characterized by periodic changes in monocyte and neutrophil activation and heightened sensitivity to endotoxin, which is associated with the episodic nature of FMF. Increased endotoxin sensitivity in the period of remission could result from a shift in the monocyte activation program from 'alternatively' into 'classically' activated monocytes, which may have important implications for the treatment of FMF.

The B30.2 domain of pyrin, the familial Mediterranean fever protein, interacts directly with caspase-1 to modulate IL-1beta production.

Chae JJ(1), Wood G, Masters SL, Richard K, Park G, Smith BJ, Kastner DL.

Author information:

(1)Genetics and Genomics Branch, National Institute of Arthritis and Musculoskeletal and Skin Diseases, National Institutes of Health, Bethesda, MD 20892, USA. chaej@exchange.nih.gov

Familial Mediterranean fever (FMF) is a recessively inherited autoinflammatory disorder with high carrier frequencies in the Middle East. Pyrin, the protein mutated in FMF, regulates caspase-1 activation and consequently IL-1beta production through cognate interaction of its N-terminal PYRIN motif with the ASC adaptor protein. However, the preponderance of mutations reside in pyrin's C-terminal B30.2 domain. Here we demonstrate direct interaction of this domain with caspase-1. In lysates from cells not expressing ASC, reciprocal GST pull-downs demonstrated the interaction of pyrin with the p20 and p10 catalytic subunits of caspase-1. Coimmunoprecipitations of pyrin and caspase-1 from THP-1 human monocytic cells were consistent with the interaction of endogenous proteins. The C-terminal B30.2 domain of pyrin is necessary and sufficient for the interaction, and binding was reduced by FMF-associated B30.2 mutations. Full-length pyrin attenuated IL-1beta production in cells transfected with a caspase-1/IL-1beta construct, an effect diminished by FMF-associated B30.2 mutations and in B30.2 deletion mutants. Modeling of the crystal structure of caspase-1 with the deduced structure of the pyrin B30.2 domain corroborated both the interaction and the importance of M694V and M680I pyrin mutations. Consistent with a net inhibitory effect of pyrin on IL-1beta activation, small interfering RNA (siRNA)-mediated pyrin knockdown in THP-1 cells augmented IL-1beta production in response to bacterial LPS. Moreover, the IL-1 receptor antagonist anakinra suppressed acute-phase proteins in a patient with FMF and amyloidosis. Our data support a direct, ASC-independent effect of pyrin on IL-1beta activation and suggest heightened IL-1 responsiveness as one factor selecting for pyrin mutations.

Patterns of hypocapnia on tilt in patients with fibromyalgia, chronic fatigue syndrome, nonspecific dizziness, and neurally mediated syncope.

Naschitz JE(1), Mussafia-Priselac R, Kovalev Y, Zaigraykin N, Slobodin G, Elias N, Rosner I.

Author information:

(1)Department of Internal Medicine A, the Bnai-Zion Medical Center and Bruce Rappaport Faculty of Medicine, Technion-Israel Institute of Technology, Haifa, Israel. Naschitz@tx.technion.ac.il

**OBJECTIVES:** To assess whether head-up tilt-induced hyperventilation is seen more often in patients with chronic fatigue syndrome (CFS), fibromyalgia, dizziness, or neurally mediated syncope (NMS) as compared to healthy subjects or those with familial Mediterranean fever (FMF).

**PATIENTS AND METHODS:** A total of 585 patients were assessed with a 10-minute supine, 30-minute head-up tilt test combined with capnography. Experimental groups included CFS (n = 90), non-CFS fatigue (n = 50), fibromyalgia (n = 70), nonspecific dizziness (n = 75), and NMS (n = 160); control groups were FMF (n = 90) and healthy (n = 50). Hypocapnia, the objective measure of hyperventilation, was diagnosed when end-tidal pressure of CO<sub>2</sub> (PETCO<sub>2</sub>) less than 30 mm Hg was recorded consecutively for 10 minutes or longer. When tilting was discontinued because of syncope, one PETCO<sub>2</sub> measurement of 25 or less was accepted as hyperventilation.

**RESULTS:** Hypocapnia was diagnosed on tilt test in 9% to 27% of patients with fibromyalgia, CFS, dizziness, and NMS versus 0% to 2% of control subjects. Three patterns of hypocapnia were recognized: supine hypocapnia (n = 14), sustained hypocapnia on tilt (n = 76), and mixed hypotensive-hypocapnic events (n = 80). Hypocapnia associated with postural tachycardia syndrome (POTS) occurred in 8 of 41 patients.

**CONCLUSIONS:** Hyperventilation appears to be the major abnormal response to postural challenge in sustained hypocapnia but possibly merely an epiphenomenon in hypotensive-hypocapnic events. Our study does not support an essential role

for hypocapnia in NMS or in postural symptoms associated with POTS. Because unrecognized hypocapnia is common in CFS, fibromyalgia, and nonspecific dizziness, capnography should be a part of the evaluation of patients with such conditions.

The prodrome: a prominent yet overlooked pre-attack manifestation of familial Mediterranean fever.

Lidar M(1), Yaqubov M, Zaks N, Ben-Horin S, Langevitz P, Livneh A.

Author information:

(1)Heller Institute of Medical Research, Sheba Medical Center, Tel-Hashomer 52621, Israel.

**OBJECTIVE:** To identify and characterize pre-attack symptoms (prodrome) in patients with familial Mediterranean fever (FMF).

**METHODS:** Forty-eight patients with FMF whose attacks are preceded by a prodromal period composed the study population. Clinical, demographic, and genetic characteristics of the study group were compared to those of a control group of 48 patients with FMF whose attacks begin without a premonitory phase. Patients of both groups were recruited consecutively, during their routine followup visit to the FMF clinic.

**RESULTS:** A prodrome was found to be a common manifestation of FMF, experienced by about 50% of the patients. Overall, demographic, clinical, and genetic variables were comparable between study and control groups. In affected patients prodrome recurs in most attacks, lasts a mean of 20 hours, and manifests with either a mildly unpleasant sensation at the site of the forthcoming spell (discomfort prodrome), or with a spectrum of physical, emotional, and neuropsychological complaints (variant prodrome). The 2 types of prodromata are frequently accompanied by a host of constitutional symptoms.

**CONCLUSIONS:** A prodromal period heralding attacks is a newly defined and reliable FMF manifestation that reproducibly predicts attacks and may help prevent attacks and elucidate the pathogenesis of the disease.

Hereditary auto-inflammatory disorders and biologics.

Church LD(1), Churchman SM, Hawkins PN, McDermott MF.

Author information:

(1)Academic Unit of Musculoskeletal Disease, Leeds Institute of Molecular Medicine, Epidemiology and Cancer Research, University of Leeds, Leeds, UK.

The term auto-inflammatory disorders has been coined to describe a group of conditions characterized by spontaneously relapsing and remitting bouts of systemic inflammation without apparent involvement of antigen-specific T cells or significant production of auto-antibodies. The hereditary periodic fever syndromes are considered as the prototypic auto-inflammatory diseases, and genetic studies have yielded important new insights into innate immunity. DNA analysis has greatly enhanced the clinical characterization of these conditions, and elucidation of their molecular aetiopathogenesis has suggested that therapies may be aimed at specific targets within the immune cascade. The availability of biologic response modifiers such as inhibitors of tumour necrosis factor (TNF) and interleukin-1beta has greatly improved the outlook for some of these disorders, although effective therapies remain elusive in patients with certain conditions, including hyperimmunoglobulinaemia-D with periodic fever syndrome (HIDS) and a proportion of those with TNF-receptor associated periodic syndrome (TRAPS). Indeed, outstanding challenges and the unique potential to further elucidate molecular mechanisms in innate immunity are illustrated by the dashed early hope that TNF blockade would be a panacea for TRAPS: not only is etanercept (Enbrel) ineffective in some cases, but there are anecdotal reports of this condition being greatly exacerbated by infliximab (Remicade).

Familiar Mediterranean fever mimicking septic arthritis: distinguishing with diffusion weighted imaging.

Oner AY(1), Ucar M, Akpek S, Tokgoz N.

Author information:

(1)Department of Radiology, Gazi University School of Medicine, 06510  
Besevler-Ankara, Turkey. yusuf@tr.net

FMF arthritis is generally monoarticular in origin. The affected joint is hot, tender, red and mimics septic arthritis. Conventional imaging findings, including magnetic resonance imaging (MRI) and ultrasound, do not help differentiate between these two entities. The final diagnosis depends on culture of the synovial fluid, and therefore initiation of proper drug therapy can be delayed. Diffusion weighted imaging (DWI), with its ability to detect altered water-proton mobility, might play an important role as a fast and non-invasive problem-solving tool in this setting. We here present MRI and DWI findings of a case of FMF arthritis mimicking septic arthritis.

SAA1 alpha/alpha alleles in amyloidosis.

Kelkitli E(1), Bilgici B, Tokgöz B, Dilek M, Bedir A, Akpolat I, Utaş C, Akpolat T.

Author information:

(1)Ondokuz Mayıs University School of Medicine, Samsun, Turkey.

**BACKGROUND:** Amyloidosis, mainly AA type, is one of the common diseases in nephrology clinics in Turkey. AA type amyloidosis is a complication of various chronic infections or inflammatory diseases such as familial Mediterranean fever (FMF), rheumatoid arthritis (RA), tuberculosis and bronchiectasis. A controversy exists in the literature regarding the relationship between SAA1 genotypes and AA type amyloidosis. This study aimed to investigate SAA1 gene polymorphism in different patient groups: 1) amyloidosis, 2) FMF and 3) healthy controls.

**METHODS:** Eighty-two patients from the three groups were included in the study: 1) amyloidosis, 2) FMF without amyloidosis, and 3) healthy controls. SAA1 genotypes were studied by the polymerase chain reaction/restriction fragment length

polymorphism (PCR-RFLP) method.

RESULTS: The homozygous alpha/alpha genotype is the most common SAA1 genotype among patient groups with amyloidosis, and the alpha/alpha genotype frequency is significantly higher than in healthy controls (68 vs. 38%,  $p < 0.05$ ).

CONCLUSIONS: The SAA1 alpha/alpha genotype is a risk factor for AA type amyloidosis in Caucasoid populations and more studies are needed to investigate why the gamma/gamma genotype is associated with AA type amyloidosis in Japan.

AA amyloidosis is the most serious potential complication of the inherited autoinflammatory syndromes and frequently results in end-stage renal failure. Although this complication is well recognized in familial Mediterranean fever, tumor necrosis factor receptor-associated periodic syndrome, and Muckle-Wells syndrome, there is only 1 previous published report of its occurrence in

hyperimmunoglobulinemia D with periodic fever syndrome (HIDS). We report 2 further cases of patients with AA amyloidosis in HIDS, both of whom developed dialysis-dependent renal failure, and we describe the outcome of the first renal transplant in this setting.

guolielmos@med.uoc.gr

Familial Mediterranean fever (FMF) is an autosomal, recessively inherited disease, characterized by recurrent fever and serositis that affects mainly patients of the Mediterranean basin. The gene responsible for FMF, named MEFV, was cloned and several missense mutations were found to be responsible for the disease. Based on a recent molecular analysis of MEFV gene mutations in 43 patients from Crete aiming to correlate specific genotypes and clinical manifestations of FMF, we were prompted to construct a three-dimensional model (3-D model) of the PRYSPRY domain of pyrin. The majority of the known MEFV mutations located on this domain have been classified, according to disease severity, and localized on this 3-D model. The functional consequences of these mutations and their implications on disease severity are discussed. Moreover, we report a putative novel missense mutation, S702C, which we identified in exon 10 of the MEFV gene and localized on the constructed 3-D model.

The systemic autoinflammatory diseases: inborn errors of the innate immune system.

Brydges S(1), Kastner DL.

Author information:

(1)Genetics and Genomics Branch, National Institute of Arthritis and Musculoskeletal and Skin Diseases, National Institutes of Health, Bethesda, MD 20892-1820, USA. brydgress@mail.nih.gov

The autoinflammatory syndromes are a newly recognized group of immune disorders that lack the high titers of self-reactive antibodies and T cells characteristic of classic autoimmune disease. Nevertheless, patients with these illnesses experience unprovoked inflammatory disease in the absence of underlying infection. Here we discuss recent advances in eight Mendelian autoinflammatory diseases. The causative genes and the proteins they encode play a critical role in the regulation of innate immunity. Both pyrin and cryopyrin, the proteins mutated in familial Mediterranean fever and the cryopyrinopathies, respectively, are involved in regulation of the proinflammatory cytokine, IL-1 $\beta$ , and may influence the activity of the transcription factor, NF $\kappa$ B. NOD2, the Blau syndrome protein, shares certain domains with cryopyrin and appears to be a sensor of intracellular bacteria. PSTPIP1, mutated in the syndrome of pyogenic arthritis with pyoderma gangrenosum and acne, interacts both with pyrin and a protein tyrosine phosphatase to regulate innate and adaptive immune responses. Somewhat unexpectedly, mutations in the p55 TNF receptor lead not to immunodeficiency but to dramatic inflammatory disease, the mechanisms of which are still under investigation. Finally, the discovery of the genetic basis of the hyperimmunoglobulinemia D with periodic fever syndrome has provided a fascinating but incompletely understood link between cholesterol biosynthesis and autoinflammation. In this manuscript, we summarize the current state of the art with regard to the diagnosis, pathogenesis, and treatment of these inborn errors of the innate immune system.

Vasculitis in siblings with familial Mediterranean fever: a report of three cases and review of the literature.

Balbir-Gurman A(1), Nahir AM, Braun-Moscovici Y.

Author information:

(1)B. Shine Department of Rheumatology, Rambam Medical Center, POB 9602, Haifa 31096, Israel. a\_balbir@rambam.health.gov.il

Familial Mediterranean Fever (FMF) is characterized by recurrent attacks of self-limited polyserositis and fever. Several types of vasculitis are associated with FMF: polyarteritis nodosa, Henoch-Schonlein purpura (HSP), and protracted febrile myalgia (PFM). We describe three cases of vasculitis in four siblings of a Sephardic Jewish family with FMF and reviewed the literature. One brother and one sister developed severe HSP with intestinal involvement while another brother developed PFM. Genetic tests in three brothers confirmed the M694V mutation on both alleles. Vasculitides may be a clinical feature of FMF with a higher familial prevalence. MEFV mutations may act as a genetic susceptibility factor for vasculitides in FMF patients.

Hypercoagulability: interaction between inflammation and coagulation in familial Mediterranean fever.

Aksu G(1), Ozturk C, Kavakli K, Genel F, Kutukculer N.

Author information:

(1)Division of Immunology, Department of Pediatrics, Ege University Medical School, 35100, Bornova-Izmir, Turkey. guzide.aksu@ege.edu.tr

Familial Mediterranean fever (FMF) patients in clinical remission are reported to have increased baseline inflammation. Normal function of the natural

anticoagulant pathways is particularly needed in diminishing inflammatory responses. In the presence of subclinical inflammation, natural anticoagulant response may be exaggerated. We aimed to observe the anticoagulant-procoagulant status in attack-free FMF patients. Twenty-seven FMF patients diagnosed in accordance with Tel-Hashomer criteria, and 26 healthy controls were included. All patients were attack-free under regular colchicine treatment. Amyloidosis, autoimmunity, accompanying liver and renal disease, and vasculitis were excluded. Predisposing factors for thrombosis were not present. Acute phase reactants (APRs), anticardiolipin antibody positivity, prothrombin time (PT), activated prothrombin time, thrombin time (TT) and d-dimer, protein C activity, activated protein C resistance, free protein S, antithrombin, lupus anticoagulant, human prothrombin fragment F 1 + 2, and human thrombin/antithrombin III complex were analyzed for all subjects. APRs were comparable with controls. Autoimmune markers were negative in all. Anti-streptolysin titers were significantly different than the control group. PT, TT, protein C activity, and F 1 + 2 levels were significantly different from those of healthy controls. Shortened PT and TT, decreased protein C activity vs increased levels of F 1 + 2 suggested a hypercoagulable state in our patients. The hypercoagulable state detected in FMF patients suggests that screening with abnormal coagulation tests may be beneficial for tracing the future consequences of subclinical inflammation in these patients. Studies covering larger groups of patients are needed to verify the currently observed hypercoagulable status in FMF.

Author information:

(1)Department of Pediatrics, Medical Faculty, Gaziantep University, Gaziantep, Turkey. aysebalat@hotmail.com

AIM: Familial Mediterranean fever (FMF) is the most frequent periodic syndrome

characterised by recurrent attacks of polyserositis. However, recent studies revealed that there might be an ongoing subclinical inflammation between the attacks. As nitric oxide (NO) and adrenomedullin (AM) are both synthesised in the endothelium, and mediates many functions within immune system, we considered them to be an interesting target of investigation in FMF.

**METHODS:** Fifteen children with FMF receiving regular colchicine, ranging in age from 3 to 16 years, were investigated in comparison with 15 healthy age- and sex-matched controls. The mean age of the patients was 9.7 +/- 3.9 years. Total nitrite, a stable product of NO, was quantitated by means of the Griess reaction, while AM was measured by HPLC.

**RESULTS:** Plasma-urinary AM and total nitrite levels were significantly higher in children with FMF. Plasma AM levels (pmol/mL) in patients and controls were 40.95 +/- 5.99 vs. 34.86 +/- 5.24,  $P < 0.05$ , and urinary AM excretion (pmol/mg creatinine) was 51.16 +/- 28.15 vs. 37.5 +/- 24.26,  $P < 0.05$  respectively. Plasma total nitrite levels (micromol/L) in patients and controls were 44.80 +/- 10.36 vs. 32.13 +/- 9.28,  $P < 0.05$ , and urinary nitrite excretion (micromol/mg creatinine) was 2.24 +/- 1.71 vs. 1.09 +/- 0.96,  $P < 0.05$  respectively.

**CONCLUSION:** This study considered that AM and NO may have a role in the immuno-inflammatory process of FMF, although, whether these act to preserve, or protect against, further inflammatory injury is not clear. Our results further supports the hypothesis that these patients have subclinical inflammation between attacks.

A decision tree for genetic diagnosis of hereditary periodic fever in unselected patients.

Federici L(1), Rittore-Domingo C, Koné-Paut I, Jorgensen C, Rodière M, Le Quellec A, Touitou I.

Author information:

(1)Laboratoire de Génétique, Hôpital A de Villeneuve, CHU de Montpellier, 34295 Montpellier Cedex 5, France.

**BACKGROUND:** The diagnostic value of molecular analysis of the familial Mediterranean fever (FMF) gene (Mediterranean fever (MEFV)) has been well established only in patients selected on the basis of ethnic background or clinical criteria. Genetic diagnosis for other hereditary periodic fever syndromes has been poorly evaluated.

**OBJECTIVE:** To determine the diagnostic contribution of genetic tests for hereditary periodic syndromes in a large, unselected series of patients.

**METHODS:** A retrospective study was conducted on 1941 patients referred to us for FMF genetic tests between 1997 and 2005. MEFV genotypes were compared with clinical data to appraise criteria for FMF diagnosis. Genetic tests for tumour necrosis factor receptor-associated periodic syndrome (TRAPS), hyperimmunoglobulinaemia D syndrome (HIDS) and cryopyrin-associated periodic syndromes (CAPS) were also reviewed.

**RESULTS:** 71% of the 1574 patients with enough data had a clinical diagnosis of FMF according to the widely used Israeli criteria. Two MEFV mutations were found in only 409 patients of this subgroup (sensitivity = 37%) and in 15 (3.3%) of the patients with an improbable clinical diagnosis of FMF (specificity = 97%).

Molecular diagnosis for alternate hereditary periodic syndromes was carried out in 456 of the patients having a non-conclusive FMF genetic test. A positive diagnosis was obtained in 31 of these patients (TRAPS (n = 19), HIDS (n = 4) and CAPS (n = 8)).

**CONCLUSIONS:** First-line MEFV mutation screening in patients with clinically typical FMF may be appropriate only in particular areas. To optimise genetic diagnosis, we propose a decision tree, which, with the advice of an expert

practitioner, could help redirect test indications towards non-FMF hereditary periodic syndromes.

Early and severe amyloidosis in a patient with concurrent familial Mediterranean fever and pseudoxanthoma elasticum.

Cattan D(1), Bouali B, Chassaing N, Martinez F, Dupont JM, Dode C, Martin L.

Author information:

(1)Department of Hepatogastroenterology, Centre Hospitalier, 94195 Villeneuve-Saint-Georges, France.

A young woman patient had early and extensive familial Mediterranean fever (FMF)-related amyloidosis and pseudoxanthoma elasticum (PXE). She had the novel G1042S mutation in the ATP-binding cassette subfamily C member 6 (ABCC6) gene, responsible for PXE, and the mutation M694I in MEFV, the FMF gene. Both mutations were homozygous, in agreement with consanguinity in the parents. ABCC6 deficiency may have increased the severity of amyloidosis by increasing the deposition in target tissues of heparan sulphate, which colocalizes spatially and temporally with amyloid proteins, and/or by decreasing the therapeutic activity of colchicine.

A Japanese case of familial Mediterranean fever with onset in the fifties.

Yamane T(1), Uchiyama K, Hata D, Nakamura M, Ishii T, Koido S, Fujise K, Tajiri H.

Author information:

(1)Division of Gastroenterology and Hepatology, Department of Internal Medicine, The Jikei University Kashiwa Hospital, Kashiwashita, Chiba.

The patient was a 63-year-old woman with attacks of fever and abdominal pain, starting from the age of 53 years and recurring every month. Despite various examinations at another hospital, the etiology remained unclear. She was under symptomatic treatment, and was referred to our department for further evaluation. Although she had onset in middle age, the clinical symptoms and examination findings suggested familial Mediterranean fever, and administration of colchicine inhibited the attacks completely. Therefore, the patient was diagnosed as having the disease. We were not able to analyze the entire MEFV gene, but detected only a heterozygous M694I mutation. Amyloidosis did not develop as a complication. The disease is rare in Japan, and its onset in the fifties is extremely rare in the world.

Tumor necrosis factor (TNF) receptor-associated periodic syndrome (TRAPS) is an autosomal dominant systemic autoinflammatory disease associated with heterozygous mutations in TNF receptor 1 (TNFR1). Here we examined the structural and functional alterations caused by 9 distinct TRAPS-associated TNFR1 mutations in transfected cells and a mouse "knock-in" model of TRAPS. We found that these TNFR1 mutants did not generate soluble versions of the receptor, either through membrane cleavage or in exosomes. Mutant receptors did not bind TNF and failed to function as dominant-negative inhibitors of TNFR1-induced apoptosis. Instead, TRAPS mutant TNFR1 formed abnormal disulfide-linked oligomers that failed to interact with wild-type TNFR1 molecules through the preligand assembly domain (PLAD) that normally governs receptor self-association. TRAPS mutant TNFR1 molecules were retained intracellularly and colocalized with endoplasmic reticulum (ER) markers. The capacity of mutant receptors to spontaneously induce both apoptosis and nuclear factor kappaB (NF-kappaB) activity was reduced. In contrast, the R92Q variant of TNFR1 behaved like the wild-type receptor in all of these assays. The inflammatory phenotype of TRAPS may be due to consequences of mutant TNFR1 protein misfolding and ER retention.

Sonographic evaluation of the tendons in familial Mediterranean fever and Behçet's disease.

Ozçakar L(1), Onat AM, Ureten K, Cetin A, Kiraz S, Ertenli I, Calgüneri M, Akinci A.

Author information:

(1)Department of Physical Medicine and Rehabilitation, Hacettepe University Medical School, Ankara, Turkey. lozcakar@yahoo.com

**OBJECTIVES:** There have been some studies on the burden of certain rheumatological disorders on the tendons; however, patients with familial Mediterranean fever (FMF) and Behçet's disease (BD) have not, up to now, been studied in this regard in the literature. Thus, this current study centers on ensuing changes in the tendons of these patients.

**METHODS:** The study comprised 32 patients with FMF (13 male, 19 female), 31 with BD (18 male, 13 female) and 35 control subjects (17 male, 18 female).

Sonographical evaluations were performed from the triceps, quadriceps and Achilles tendons on the non-dominant extremities of the individuals using a linear array probe of 8-16 MHz.

**RESULTS:** The mean triceps tendon (TT) thickness value of FMF patients was greater than that of BD patients ( $P=0.03$ ) or the controls' ( $P=0.02$ ). The mean quadriceps tendon (QT) thickness value of BD patients was greater than that of FMF patients ( $P=0.00$ ) or the controls' ( $P=0.01$ ). The mean Achilles tendon (AT) thickness value of BD patients was greater than that of controls' ( $P=0.05$ ) only. There was not any difference between the tendon thickness measurements of either group of patients with and without arthritic involvement.

**CONCLUSION:** Our first and preliminary findings pertaining to increased tendon thicknesses in FMF (TT) and BD (QT and AT) patients should be complemented with future histological and clinical studies. The functional relevance of tendon thickening, its probable reflection on the rupture risk and the role of each disease related contributing factor remain to be uncovered.

Muckle-Wells syndrome (MWS) is a dominantly inherited autoinflammatory disease characterized by rashes, fever, arthralgia, sensorineural deafness, and the possible development of systemic AA amyloidosis. We used anakinra to treat a 22-year-old patient with MWS who had deafness and a high serum level of C-reactive protein (CRP). Following treatment with anakinra, the patient's CRP level normalized, and she recovered from deafness. The fact that this occurrence has never been previously reported strengthens the role of anakinra in MWS but also raises new questions about the physiopathology of such deafness.

Author information:

(1)Department of Diagnostic Radiology, American University of Beirut Medical Center, P.O. Box 11-0236, Beirut, Lebanon.

**PURPOSE:** The aim of this study was to study the imaging findings of familial Mediterranean fever (FMF).

**MATERIALS AND METHODS:** We performed a retrospective review of the medical records and imaging studies of 38 patients with proven FMF, diagnosed between 1992 and 2002.

**RESULTS:** The most common clinical manifestation was recurrent peritoneal attacks with abdominal pain (76.3%) and fever (42.1%). Abdominal imaging findings included ileus (n=12), splenomegaly (n=5), hepatomegaly (n=2), ascitis (n=2), focal peritonitis (n=2), mesenteric streaking (n=1), and enlarged mesenteric lymph node (n=1). One patient developed fatal peritoneal mesothelioma, and 13.1% of the patients developed amyloidosis with sonographic findings of renal parenchymal disease or cardiomyopathy. Arthritis was second in frequency, occurring in 34.2% of patients; radiographs were normal (n=4) or showed joint effusion and periarticular soft tissue swelling (n=4) due to synovitis. One patient developed seronegative destructive arthropathy. Skin lesions were noted in 23.6% of patients. Pleuritis was encountered in 13.1% and pericarditis in 5.2%. Polyarteritis nodosa (PAN) was present in two patients, multiple sclerosis in one, and autoimmune hemolytic anemia in one patient.

**CONCLUSION:** FMF predominantly involves abdominal viscera but can affect other organs. The majority of patients have nonspecific imaging findings, and the radiologic diagnosis is rarely considered. Amyloidosis, mesothelioma, and

destructive arthropathy are potential serious complications of FMF. PAN, multiple sclerosis, and autoimmune hemolytic anemia are probably rare associations or rather than coincident with FMF.

Classical pathway complement activity in Familial Mediterranean fever.

Mkrtchyan GM(1), Boyajyan AS, Ayvazyan AA, Beglaryan AA.

Author information:

(1)Institute of Molecular Biology of Armenian National Academy of Sciences, 7 Hasratyan St., 375014, Yerevan, Armenia.

**OBJECTIVES:** The present study emphasizes the important role of the immune reactions in the pathogenesis of Familial Mediterranean fever. In the present study, the total hemolytic activity of the complement and the activities of individual complement components, C1, C2, C3, and C4, were determined in the blood serum of 32 patients with FMF and 28 healthy subjects.

**DESIGN AND METHODS:** Hemolytic assay was applied, measuring THAC and individual complement components' activities. The patients were divided into 3 groups upon the regularity of colchicine therapy: patients receiving regular, irregular and not receiving colchicine treatment for at least 1 year.

**RESULTS:** No significant changes in the hemolytic activities of the C1, C2, C3, and C4 complement components were found between the healthy subjects and those FMF patients, who were receiving regular colchicine treatment.

**CONCLUSIONS:** Our data obtained have raised a number of important questions relevant to FMF pathogenesis and once again confirms the efficiency of regular colchicine treatment.

Familial Mediterranean fever in the Syrian population: gene mutation frequencies, carrier rates and phenotype-genotype correlation.

Mattit H(1), Joma M, Al-Cheikh S, El-Khateeb M, Medlej-Hashim M, Salem N, Delague V, Mégarbané A.

Author information:

(1)Biochemistry Department, Faculty of Pharmacy, Damascus University, Damascus, Syria.

**BACKGROUND:** Familial Mediterranean fever (FMF) is an autosomal recessive disease mainly affecting particularly Arabs, Non-Ashkenazi Jews, Armenians, and Turks. It is an autoinflammatory periodic disorder characterized by febrile and painful attacks due to inflammation involving the serosal membranes in the abdomen, chest or joints. Over 50 mutations have been identified in the MEFV gene responsible for FMF.

**OBJECTIVE:** To identify the distribution and the frequency of the MEFV gene mutations in Syrian FMF patients and population and perform a genotype/phenotype correlation in the patients' cohort.

**PATIENTS AND METHODS:** The study was carried out on 83 clinically diagnosed Syrian FMF patients and 242 healthy subjects. The tested individuals were screened for the most common five MEFV mutations (M694V, M694I, M680I, V726A and E148Q) by restriction fragment length polymorphism. Sequencing of exon 10 was performed only for the patients' DNA where just one or no mutation was detected.

**RESULTS AND DISCUSSION:** Of the 83 patients studied, 74 (89%) were positive either for one, two or three mutations and nine (11%) had no mutations detected. Of those positive for mutations, 25 were homozygous, 30 were compound heterozygotes, three had complex alleles, and 16 patients had only one mutation. The M694V, V726A, M694I, M680I and E148Q mutations accounted for 45.8%, 26%, 13.9%, 4.8% and 6% of the alleles, respectively. The carrier rate in the Syrian population for the tested mutations was 17.5%, E148Q being the most common mutation, followed by V726A and M694V. The severity of the disease and development of amyloidosis seem to have an association with M694V, the most common mutation in Syrian FMF patients.

The MEFV gene, responsible for familial Mediterranean fever (FMF), is involved in inflammatory reactions through altered leukocyte apoptosis, secretion of interleukin (IL)-1 $\beta$ , and activation of the NF- $\kappa$ B pathway. Ulcerative Colitis (UC) and FMF are both characterized by a recurrent pattern of presentation with periods of remission and flares associated with neutrophilic infiltration at the site of injury. The aim of this study was to investigate the possible correlation between UC and MEFV gene alterations. Twenty-five consecutive, first-diagnosed and untreated UC patients, 28 control patients with rheumatoid arthritis, and 65 normal individuals were analyzed. Nonisotopic RNase Cleavage Assay (NIRCA) was applied as a first-step mutational screening method of exons 10 and 2 of MEFV gene; direct sequencing was subsequently performed to confirm the results. MEFV mutations were identified in 7 (3 M694V/0, 2 M680I/0, 1 E148Q/E148Q, and 1 A744S/0) out of 25 UC patients versus 1 (M694V/0) out of 28 rheumatoid arthritis patients ( $P = .0199$ ) and 1 (M694V/0) out of 65 healthy controls ( $P = .0004$ ). Four out of 7 patients with MEFV mutations had inflammatory arthritis, a clinical finding that was not observed in the 18 UC patients with unmutated MEFV ( $P = .0028$ ). Patients with UC almost universally carried the T A C G MEFV exon 2 haplotype in contrast with normal individuals ( $P < .0001$ ) and FMF patients ( $P = .0310$ ). In conclusion the increased frequency of mutations of MEFV in UC patients, especially in those with episodic arthritis, suggests a possible modifying effect of MEFV in the disease process and its localization within the joint. The difference in distribution of MEFV exon 2 haplotypes between UC patients and both FMF patients and normal individuals, suggests that UC patients constitute a genetically distinct population. Larger, longitudinal studies are needed to confirm these initial findings.

[Modulation of endotoxin-induced respiratory splash of granulocytes and monocytes in patients with Familial Mediterranean Fever by iodine-lithium-alpha-dextrin and sodium thiosulfate].

[Article in Russian]

Avetisian SA, Akopian GS, Davtian TK.

The effect of an endotoxin--E. coli liposaccharide (LPS) of serotype 026:B6--on the respiratory splash (RS) of neutrophils and monocytes in peripheral blood of patients with Familial Mediterranean Fever (FMF) was studied. It is shown that FMF patients have a periodic increase (during an attack) and a decrease (in the period of remission) in endotoxin-induced RS of neutrophils and monocytes. LPS stimulates chemotoxis-induced RS of neutrophils and monocytes in patients both in the period of remission and during the attack equally effectively.

Iodine-lithium-alpha-dextrin and sodium thiosulfate have a marked anti-endotoxic effect which manifests with quick neutralization of endotoxin activity on RS of monocytes and neutrophils in FMF patients both during the attack and remission.

Autoinflammatory diseases are characterised by seemingly unprovoked inflammation. They can be categorised as: hereditary (monogenic) autoinflammatory diseases, complex (polygenic/multifactorial) autoinflammatory diseases, and diseases where the course is affected by mutations in the defined autoinflammatory disease genes. Identification of the inflammatory pathways involved has opened up new areas of research which have implications for the treatment of these disorders and the pathogenesis of common inflammatory diseases.

Comment in

J Clin Rheumatol. 2006 Oct;12(5):265-6.

Familial Mediterranean fever is characterized by recurrent polyserositis episodes associated with fever. However, the clinical spectrum of this disease has been expanded recently and myalgia is now a frequently recognized component. Protracted febrile myalgia syndrome was first described in patients with familial Mediterranean fever in 1994. This syndrome is characterized by severe paralyzing myalgia, high fever, abdominal pain, diarrhea, arthritis/arthralgia, and transient vasculitic rashes mimicking Henoch-Schonlein purpura. Recently, we evaluated 6 patients with the clinical picture of protracted febrile myalgia syndrome in our clinic. One of them was a patient with known familial Mediterranean fever, but the others were subsequently diagnosed to have familial

Mediterranean fever by mutational analyses. Thus, introduction of genetic analysis would possibly change the diagnostic criteria for familial Mediterranean fever. In addition, all 6 patients presented in the spring months when streptococcal infections are at their peak rate and 3 of them had elevated ASO levels indicating that streptococci could be one of the agents triggering protracted febrile myalgia syndrome.

Author information:

(1)Department of Pediatrics, Pediatric Rheumatology, Meir Medical Center, Kfar Saba, Israel. uziely@zahav.net.il

**OBJECTIVE:** To describe the outcome of children with recurrent transient synovitis (TS) of the hip.

**METHODS:** A retrospective chart review of children with at least 2 separate episodes of TS between 1986 and 2003. We described the diagnostic investigations and outcome of these patients. A followup telephone survey for disability and pain scores was performed in 2004.

**RESULTS:** We studied 39 children, 26 boys and 13 girls, from 6 pediatric rheumatology centers. The mean age at initial episode was 6 +/- 2.6 years. There were a total of 102 episodes (mean 2.9 +/- 1.6, median 2, range 2-10). All but 2 children had normal plain radiographs of the hip. All patients were contacted 4.2 +/- 2.5 years after the first episode. None developed clinical Perthes disease or other chronic orthopedic condition. Three (8%) patients developed chronic disease: one had familial Mediterranean fever and 2 developed spondyloarthropathies, 0.5, 2, and 6 years after presentation. At followup 26 of 36 patients were asymptomatic, and 10 reported rare hip pain after intensive physical effort.

CONCLUSION: Children with recurrent TS usually have a benign course. In some patients recurrent TS may be the presenting feature of a chronic inflammatory condition. No progression to chronic orthopedic conditions was observed.

The estrogen-responsive B box protein: a novel enhancer of interleukin-1beta secretion.

Munding C(1), Keller M, Niklaus G, Papin S, Tschopp J, Werner S, Beer HD.

Author information:

(1)Department of Biology, Institute of Cell Biology, ETH Zurich, ETH Honggerberg, CH-8093 Zurich, Switzerland.

The estrogen-responsive B box protein (EBBP) and Pyrin belong to a family of structurally related proteins. While mutations in the pyrin gene cause an autoinflammatory disease, the biological function of EBBP is unknown. In this study, we identified the proinflammatory cytokine interleukin-1beta (IL-1beta) as an EBBP-binding partner. Furthermore, caspase-1 and NACHT, LRR and Pyrin domain containing protein (NALP) 1, two components of the recently identified inflammasome, a platform for the activation of caspase-1, also interact with EBBP. These proteins bind to the RFP domain of EBBP, suggesting that this domain of so far unknown function is an important protein-binding domain. EBBP was secreted in a caspase-1-dependent manner from cultured cells, and its secretion was enhanced by IL-1beta. Vice versa, endogenous and overexpressed EBBP increased IL-1beta secretion. These results provide evidence for a role of EBBP in innate immunity by enhancing the alternative secretion pathway of IL-1beta.

Renal amyloidosis in a child with sickle cell anemia.

Simşek B(1), Bayazit AK, Ergin M, Soran M, Dursun H, Kilinc Y.

Author information:

(1)Department of Pediatric Nephrology, Cukurova University, Balcali, Adana 01120, Turkey. drmago@hotmail.com

The kidney is frequently affected in patients with sickle cell syndrome, i.e., homozygous and heterozygous patients, with a consequently large spectrum of renal abnormalities that may range from minimal functional changes to chronic renal failure. Here, we present a 13-year-old boy with sickle cell anemia (SCA) (HbSS) who was referred to our unit with nephrotic syndrome. Renal biopsy revealed AA type amyloidosis on the basis of light microscopic findings, indicating Congo red staining and immunohistochemistry. He had neither a family history of familial Mediterranean fever (FMF) nor any complaint of recurrent abdominal pain, arthritis, and fever, but frequent painful vaso-occlusive crises. The patient was found to have no MEFV gene (Mediterranean fever) mutations either. Painful episodic attacks might provoke recurrent acute inflammation, leading to repeated stimulation of acute phase responses and cause secondary amyloidosis. To our knowledge, this boy is the first case of SCA complicated by renal amyloidosis observed in childhood.

Clinical significance of P46L and R92Q substitutions in the tumour necrosis factor superfamily 1A gene.

Ravet N(1), Rouaghe S, Dodé C, Bienvenu J, Stirnemann J, Lévy P, Delpech M, Grateau G.

Author information:

(1)Service de Médecine Interne, Hôpital Tenon, 4 rue de la Chine, 75970 Paris Cedex 20, Paris, France. nathalie.ravet@tnn.aphp.fr

**OBJECTIVE:** Tumour necrosis factor receptor-associated periodic syndrome (TRAPS) has been associated with several mutations in the TNF receptor super family 1A (TNFRSF1A), including most cysteine substitutions. However, the nature of two substitutions, P46L and R92Q, remains a topic of discussion. The aim of this study was to assess the actual role of these two sequence variations in a series of patients with TRAPS.

**METHODS:** The main clinical data of 89 patients with TRAPS have been prospectively registered on a standard form. 84 patients or members of families with recurrent episodes of inflammatory symptoms spanning a period of more than 6 months and harbouring a TNFRSF1A mutation were studied. Clinical data have been analysed according to the nature of the mutation-P46L, R92Q or others.

**RESULTS:** P46L is often seen in patients from Maghreb and is associated with a mild phenotype. P46L appears as a polymorphism with a non-specific role in inflammation. R92Q is associated with a variable phenotype and presents as a low-penetrance mutation. Interpreting these results will require a comparison with clinical signs and genetic background.

Familial mediterranean fever in Arabs.

El-Shanti H(1), Majeed HA, El-Khateeb M.

Author information:

(1)Department of Pediatrics, Division of Medical Genetics, University of Iowa, Iowa City, IA, USA. [hatem-el-shanti@uiowa.edu](mailto:hatem-el-shanti@uiowa.edu)

Autoinflammatory diseases are a group of disorders characterised by seemingly unprovoked inflammation in the absence of high-titre autoantibodies or antigen-specific T cells, and include the hereditary periodic fever syndromes. Familial Mediterranean fever (FMF) is an archetypal autoinflammatory disorder, which is autosomal recessive and has a high prevalence in non-Ashkenazi Jews, Armenians, Turks, and Arabs. The classic clinical picture is recurrent acute short-lived febrile and painful attacks with variable periods of remission. In a

subset of patients, the disorder is complicated by amyloidosis that leads to renal failure. The gene responsible for FMF--MEFV--has been identified and its role in inflammation is being assessed. There seems to be a distinctive clinical picture in Arab patients with FMF, and the range and distribution of MEFV mutations is different from that noted in other affected ethnic groups. Here, we discuss the clinical and molecular aspects of FMF in Arabs.

INTRODUCTION: Usually, temporal arteritis progresses as a chronic disease.

CASE REPORT: The authors report the observation of a 74-year-old woman who presented with two acute flares of temporal arteritis with headache, fever and inflammatory syndrome, which have spontaneously resolved.

DISCUSSION: The observations of auto-inflammatory attacks of arteritis disease are rare, but maybe underestimated. The pathophysiology remains unclear.

Familial Mediterranean fever and growth: effect of disease severity and colchicine treatment.

Zung A(1), Barash G, Zadik Z, Barash J.

Author information:

(1)Pediatric Endocrinology Unit, Kaplan Medical Center, Rehovot, Israel.

amzung2@bezeqint.net

**OBJECTIVE:** To evaluate the effect of disease severity and colchicine treatment on height and weight parameters in children with familial Mediterranean fever (FMF).

**METHODS:** Thirty prepubertal children (19 M, 11 F) were studied retrospectively.

Z-score values of height, growth velocity, weight and body mass index were obtained over 1.84 +/- 1.14 years before and 2.58 +/- 1.55 years during colchicine therapy. Disease severity was evaluated by a specific score for FMF.

**RESULTS:** By comparison to growth before treatment, during colchicine therapy height SDS increased from -1.00 +/- 1.17 to -0.54 +/- 0.96 ( $p < 0.001$ ) and weight SDS increased from -0.74 +/- 1.09 to -0.47 +/- 1.06 ( $p = 0.008$ ). An effect of disease severity on growth pattern could not be detected. Height SDS during therapy was negatively correlated with age at colchicine initiation.

**CONCLUSIONS:** Colchicine therapy has a positive effect on both height and weight parameters in children with FMF. Early initiation of treatment is beneficial for height gain.

Caspases at the crossroads of immune-cell life and death.

Siegel RM(1).

Author information:

(1)Immunoregulation Unit, Autoimmunity Branch, NIAMS, National Institutes of Health, Building 10 Room 9N238, Bethesda, Maryland 20892, USA. rsiegel@nih.gov

Caspases are responsible for crucial aspects of inflammation and immune-cell death that are disrupted in a number of genetic autoimmune and autoinflammatory diseases. The caspase family of proteases can be divided into pro-apoptotic and pro-inflammatory members based on their substrate specificity and participation

in separate signalling cascades. However, as discussed here, evidence has emerged over the past few years that a number of the caspases thought to be involved solely in apoptosis also contribute to specific aspects of immune-cell development, activation and differentiation, and can even protect cells from some forms of cell death.

Population screening for single genes that codetermine common diseases in adulthood had limited effects.

Lamberts SW(1), Langeveld CH, Vandenbroucke JP.

Author information:

(1)Department of Medicine, Erasmus Medical Center, 40 Molenwaterplein, 3015 GD Rotterdam, The Netherlands. s.w.j.lamberts@erasmusmc.nl

**BACKGROUND AND OBJECTIVE:** Familial hemochromatosis (FHEM), familial hypercholesterolemia (FH), familial mediterranean fever (FMF), and familial thrombophilia (FT) are relatively common genetically determined diseases of (early) adulthood. Chances, shortcomings, and practical aspects of population screening were considered.

**METHODS:** The literature, as well as existing data concerning the treatment of these diseases in The Netherlands, were studied.

**RESULTS:** In these four diseases there are so many modifying genes and environmental and lifestyle influences that accurate predictive testing at the population level is currently not sufficiently effective. The data indicate that the implementation of family clinics for FHEM and FH are necessary. There is need for further sociologic studies in the moslim population of Mediterranean and North African origin about acceptance of DNA diagnostics in relation to consanguinity and into the problem of "pseudodominance." There seems no need for early detection and preventive measures for FT in asymptomatic persons.

**CONCLUSION:** No population screening for these four genetically determined diseases of (early) adulthood is sufficiently effective at the present time. We propose to call these diseases "chronic diseases with a single gene component."

Does colchicine have an antifibrotic effect on development of interstitial fibrosis in renal allografts of recipients with familial Mediterranean fever?

Ozdemir BH(1), Ozdemir FN, Sezer S, Sar A, Haberal M.

Author information:

(1)Department of Pathology, Baskent University, Faculty of Medicine, Ankara, Turkey. handan27@hotmail.com

Colchicine, which has been reported to inhibit fibrosis, has been successfully used to treat fibrotic disorders, such as liver cirrhosis, scleroderma, and idiopathic pulmonary fibrosis. We hypothesized that besides its ability to prevent amyloid deposition, colchicine may prevent the development of interstitial fibrosis (IF) in amyloidosis patients who had undergone renal transplantation. We evaluated the influence of colchicine therapy on the development of IF in 25 patients with systemic amyloidosis secondary to familial Mediterranean fever (group 1). Twenty-five nonamyloidotic patients who did not receive colchicine therapy served as controls (group 2). The incidences of recurrence and development of IF in the first, second, and third years after transplantation were evaluated from follow-up allograft biopsies. Only four patients showed amyloid recurrence in their renal allografts. IF developed in 44% (11/25) of group 1 patients and 80% (20/25) of group 2 patients during the 36 months posttransplantation ( $P < .01$ ). Development of IF in the first, second, and third years posttransplantation was significantly greater among group 2 recipients than group 1 recipients ( $P < .01$ ). The overall 1-, 2-, and 3-year graft survival rates for group 1 recipients were 96%, 92%, and 80%, and those for group 2 recipients were 96%, 88%, and 60%, respectively. Our results support the thesis that colchicine therapy may help prevent the development of interstitial fibrosis in renal allografts.

ali.celik@deu.edu.tr

The aim of this retrospective study was to investigate the results of kidney transplantation in patients with renal amyloidosis. We analyzed the results of renal transplantation in 13 amyloidotic transplant recipients compared with those in a control group of 13 nonamyloidotic patients. While the etiology of amyloidosis was rheumatoid arthritis in one patient, in all of the others it was secondary to familial Mediterranean fever. Acute rejection episodes developed once in six and twice in one patient. The renal function in these patients was improved by antirejection treatment. Chronic rejection did not develop in any patient. However six patients (46%) died due to various complications despite functional grafts. The others are still being followed with well-functioning grafts. Among the control group, acute and chronic rejection were diagnosed in three and two patients, respectively: one patient returned to hemodialysis after 26 months of transplantation, while the others are still alive with functional grafts. There was no death in the control group. The 5- and 10-year actuarial patient survival rates of the amyloidosis and control groups were 52.2%, 26.6%, and 100%, 100%, respectively ( $P = .002$ ). However, the graft survivals of the amyloidosis versus control groups were 100%, 100%, versus 87.5%, 87.5%, respectively ( $P = .47$ ). In conclusion, we observed a high rate of early mortality among recipients with amyloidosis associated with infectious complications. Moreover, patient survivals were lower among amyloidotic renal recipients.

Comment in

Immunity. 2006 Mar;24(3):241-3.

Mutations in the NALP3/CIAS1/cryopyrin gene are linked to three autoinflammatory disorders: Muckle-Wells syndrome, familial cold autoinflammatory syndrome, and chronic infantile neurologic cutaneous and articular syndrome. NALP3, with the adaptor molecule ASC, has been proposed to form a caspase-1-activating "inflammasome," a complex with pro-IL1beta-processing activity. Here, we demonstrate the effect of NALP3 deficiency on caspase-1 function. NALP3 was essential for the ATP-driven activation of caspase-1 in lipopolysaccharide-stimulated macrophages and for the efficient secretion of the caspase-1-dependent cytokines IL-1alpha, IL-1beta, and IL-18. IL-1beta has been shown to play a key role in contact hypersensitivity; we show that ASC- and NALP3-deficient mice also demonstrate an impaired contact hypersensitivity response to the hapten trinitrophenylchloride. NALP3, however, was not required for caspase-1 activation by *Salmonella typhimurium*, and NALP3 deficiency only partially protects mice from the lethal effects of endotoxin. These data suggest that NALP3 plays a specific role in the caspase-1 activation pathway.

Autoinflammatory diseases have a quite similar clinical picture and are characterised by recurrent episodes of fever, joint features, abdominal features and skin features. Auto-inflammatory syndrome are related to mutations in genes implied in apoptosis or inflammation. FMF's gene is MEFV, present on the short arm of the chromosom 6, encoding the pyrin or marenostrie which is widely expressed in neutrophils and monocyts and implied in the control of the inflammation. Muckle wells syndrome and Familial cold urticaria are related to CIAS1 gene mutations which are located on the long arm of the chromosome 1 and encodes cryopyrine involved in apoptosis. TRAPS gene is present on the chromosome 12, the majority of mutations are located in the extra cellular region of the receptor.

Hearing improvement in a patient with variant Muckle-Wells syndrome in response to interleukin 1 receptor antagonism.

Rynne M(1), Maclean C, Bybee A, McDermott MF, Emery P.

Author information:

(1)Academic Unit of Musculoskeletal Disease, Department of Rheumatology, Leeds General Infirmary, UK.

BACKGROUND: Muckle-Wells syndrome (MWS), familial cold autoinflammatory syndrome, and neonatal onset multisystem inflammatory disease, also called chronic, infantile, neurological, cutaneous, and articular syndrome, are three hereditary autoinflammatory syndromes caused by mutations affecting the CIAS1/NALP3 gene on chromosome 1q44. The proinflammatory cytokine, interleukin 1beta, is believed to have a fundamental role in their pathogenesis.

CASE REPORT: The case is described of a 59 year old white woman who presented

with increasingly severe MWS-type features over a 15 year period. The response to interleukin 1beta inhibition with anakinra was dramatic, including a reduction in intracranial pressure with associated auditory improvement, as demonstrated by serial audiometry.

**CONCLUSIONS:** The confirmed improvement in hearing after initiation of interleukin 1 receptor antagonism corroborates previous reports that specific blockade of this single cytokine reverses most of the symptoms of this group of CIAS1/NALP3 related autoinflammatory conditions, including the sensorineural deafness, which has not been previously reported.

Peculiarities of PAPA syndrome.

Tallon B(1), Corkill M.

Author information:

(1)Rheumatology Department, Level 3, North Shore Hospital, Auckland, New Zealand.

**OBJECTIVES:** To describe a family from New Zealand with the pyogenic arthritis, pyoderma gangrenosum and acne (PAPA) syndrome, an autoinflammatory, variably expressed, erosive destructive form of arthritis.

**METHODS:** Information was gained through medical records and interviews of the affected patients and wider family. DNA sequencing was performed at Seay Center for Musculoskeletal Research Texas Scottish Rite Hospital for Children.

**RESULTS:** Five patients were affected over three generations with an E250Q mutation found on the CD2BP1 gene on chromosome 15. Common features included a severe, pauciarticular-onset, destructive peripheral arthritis, beginning at ages 5, 5, 2, 3 and 1(1/2) years. This combination marked cervical ankylosis (in two members), micrognathia and a more severe phenotype is unique. A third-generation family member treated early with DMARDs is following a less severe course. The skin involvement was variable, all with degrees of acne from puberty, though only one patient displayed pyoderma gangrenosum. A clear pattern of the arthritis switching off in adolescence and the triggering of skin disease was observed.

**CONCLUSIONS:** Differing degrees of joint destruction, and cervical ankylosis in this family with the E250Q mutation demonstrate PAPA syndrome's variable expression. Further understanding of this rare condition and its pathway may allow better targeting of treatments, not just for families with this specific syndrome but also for other, more common, forms of arthritis.

Hydrocephalus in CINCA syndrome treated with anakinra.

Rigante D(1), Ansuini V, Caldarelli M, Bertoni B, La Torraca I, Stabile A.

Author information:

(1)Centre of Periodic Fevers, Dipartimento di Scienze Pediatriche Medico-Chirurgiche e Neuroscienze dello Sviluppo, Catholic University Medical School, Policlinico A. Gemelli, Largo A. Gemelli, 8, 00168 Rome, Italy.  
drigante@gmail.com

**INTRODUCTION:** Chronic infantile neurologic, cutaneous, articular (CINCA) syndrome is a rare congenital autoinflammatory disease characterized by neonatal-onset chronic meningitis, hydrocephalus, sensorineural hearing loss, persistent urticarial rash, deforming arthritis, and recurrent fever. This clinical entity is believed to result from dysregulation of cytokine production. No recommended treatment protocol exists so far for CINCA syndrome.

**CASE REPORT:** We report a 7-year-old child affected with CINCA syndrome in whom no therapy had resulted effective. Anakinra, an interleukin-1-receptor antagonist, was administered in a 1-year period with complete inflammatory symptom remission and dramatically ameliorated laboratory tests. This optimal response has been supported by the demonstration of a stabilized hydrocephalus upon magnetic resonance imaging and by an overall improvement of the neurodevelopmental issues.

**DISCUSSION:** This paper emphasizes and discusses the medical approach with anakinra in CINCA syndrome presenting with hydrocephalus in which a consistent control of the neurological picture can be obtained.

Two sisters with familial Mediterranean fever: lack of correlation between genotype and phenotype?

Kutlay S(1), Sengul S, Keven K, Erturk S, Erbay B.

Author information:

(1)Ankara University School of Medicine, Department of Nephrology, Turkey.  
skutlay@hotmail.com

Familial Mediterranean fever (FMF) is an autosomal recessive disorder characterized by attacks of fever and serositis. The most important complication of FMF is renal amyloidosis, which determines the prognosis. The gene coding the disease (MEFV) is identified on the 16th chromosome. The most common MEFV mutations are M694V, M680I, V726A and M694I located on exon 10 and E148Q located on exon 2. Unfortunately, genotype-phenotype correlation is not well established and there are unexplained ethnic differences in amyloidosis rates. We report two sisters with a common genotype (M694V/M694V) presenting with different phenotypic characteristics: one complaining of intermittent abdominal pain, arthritis and fever, while the other was suffering from intermittent pleuritis and fever during attacks. The observation of different phenotypic presentations with a common genotype in two family members shows that different phenotypes cannot be explained by particular mutations. To understand the correlation between genotypic and phenotypic FMF variants the existence of complex alleles, modifier loci, genetic heterogeneity and possible epigenetic factors should be studied

extensively.

[A respiratory splash of monocytes and neutrophils in familial Mediterranean fever].

[Article in Russian]

Davtian TK, Avetisian SA, Akopian GS, Arutiunian VM.

AIM: To study spontaneous chemotaxis-, phagocytosis-, and proteinkinase C-mediated respiratory splash (RS) of neutrophils and monocytes in colchicin-untreated patients with familial Mediterranean fever (FMF).

MATERIAL AND METHODS: Of 17 FMF patients, 8 ones were examined during the attack, 9 patients--in fever-free period. Spontaneous and induced RS of peripheral blood neutrophils and monocytes was investigated with quantitative flow-cytofluorimetric method.

RESULTS: Compared to healthy donors, RS is characterized with activation of both spontaneous and induced production of free radicals. The activity and intensity of the RS in FMF was low in the attack vs in the attack-free period but monocytes population has a stable high activity of the RS.

CONCLUSION: Activation of neutrophilic RS in FMF patients is characterized by periodicity the direction of which is opposite to induced monocyte activation in the attack and in attack-free interval.

[Study of volatile fatty acids in the blood of patients with periodic disease].

[Article in Russian]

Karagezian KG, Beloborodova NV, Ktsoian ZhA, Khachatryan ZA, Bořko NB, Kazarian KA, Sarkisian NN, Akopian GS.

Microecological "failures" are an important pathogenetic factor of different diseases and, in the authors' opinion, periodic disease (PD) is one of them. PD is a recessive disease characterized by fever attacks and neutrophil-mediated serous inflammation. A genetic factor has been established to be responsible for half the cases of PD, the influence of non-hereditary factors, particularly a role of the host automicroflora in the genesis of an inflammatory process, has been little studied. The authors' early studies indicate that there are changes in the qualitative and quantitative composition of microbial molecules in the blood of patients with PD. The anaerobic bacterial metabolites that are volatile fatty acids (VFAs) represent biologically active substances that affect the growth of the microflora, on the one hand, and the host's immunological responsiveness, on the other. Out of VFAs, only is acetic acid detectable in small quantities in the blood of healthy individuals. The other VFAs, namely propionic, valeric, butyric, and caproic acids and their isomers, are absent. Gas chromatography was used for qualitative and quantitative determination of the metabolites of anaerobic microorganisms in the blood of patients with PD (n = 13) during an attack and remission and in that of healthy volunteers (Armenians) (n = 5) of a control group from one Yerevan region. The blood samples from all the patients with PD displayed a significantly higher concentration of caproic acid while the latter was absent in the blood of the controls. This finding suggests that there is a specific shift in the structure of the microbiocenosis in patients with PD. It is conceivable that caproic acid plays a certain role in the pathogenesis of the disease under study. Further studies will deal with the association of some microbial molecules with the manifestation of an attack of PD, which may provide the key to the goal-oriented regulation of detected homeostatic disorders and to the management of the frequency of its attacks.

Inflammatory/demyelinating central nervous system involvement in familial Mediterranean fever (FMF): coincidence or association?

Akman-Demir G(1), Gul A, Gurol E, Ozdogan H, Bahar S, Oge AE, Gurvit H, Saruhan-Direskeneli G, Yazici H, Eraksoy M.

Author information:

(1)Istanbul University, Istanbul Faculty of Medicine, Department of Neurology (Nöroloji), Capa 34390, Istanbul, Turkey. akmandem@istanbul.edu.tr

**BACKGROUND AND OBJECTIVE:** Familial Mediterranean fever (FMF) is an inherited inflammatory disease characterized by recurrent febrile polyserositis. Central nervous system (CNS) involvement in FMF is uncommon, but recently cases with multiple sclerosis (MS) and FMF have been reported. Here we assess patients with both FMF and MS, in order to clarify any relationship between FMF and MS, and to evaluate disease characteristics.

**PATIENTS AND METHODS:** Our MS database between 1986-2005 was screened retrospectively, and patients with both FMF and inflammatory/demyelinating CNS disease were evaluated among a total of 2800 patients including definite MS (n = 2268) and other demyelinating disorders.

**RESULTS:** There were 12 patients with FMF, who developed a CNS disorder with multifocal white matter lesions. Median age at onset of FMF was 7 years, and median age at neurological onset was 26.8 years. Nine patients (including two siblings) had definite MS according to clinical and MRI findings, whereas 3 patients had atypical features suggesting other demyelinating disorders. Disease severity varied among the patients between very mild to a fatal course. All 8 patients evaluated for oligoclonal IgG bands in CSF were positive.

**CONCLUSION:** The rate of FMF among our patients with definite MS is almost 4 times the expected prevalence in Turkey. Our series including a sibling pair concordant for FMF and MS may suggest that similar genetic susceptibility and environmental factors might be responsible, although coincidence still remains a possibility. A prospective study on a larger sample seems to be justified.

(1)Istituto G. Gaslini, Genoa, Italy.

**OBJECTIVE:** To explore tumor necrosis factor (TNF)-induced apoptosis in neutrophils from patients with TNF receptor-associated periodic syndrome (TRAPS) and to correlate the results with the different kinds of TNFRSF1A mutations.

**METHODS:** Two hundred sixty-five patients with clinically suspected inherited autoinflammatory syndrome were screened for mutations of the TNFRSF1A gene. Neutrophils were isolated from heparinized blood by dextran sedimentation and incubated with and without cycloheximide (CHX) and TNFalpha. Cell apoptosis was assessed by human annexin V binding, and caspase 8 activation was assessed by flow cytometry.

**RESULTS:** Twenty-one patients were found to carry a variant of the TNFRSF1A gene: 13 patients had an R92Q substitution, and 8 patients presented other missense substitutions, 1 splicing mutation, and 1 in-frame interstitial deletion.

Neutrophil stimulation with TNF and CHX was associated with induction of apoptosis in 12 normal controls and in 10 subjects with the R92Q mutation. Conversely, neutrophils from 8 TRAPS patients with mutations of cysteine or threonine residues or interstitial deletion did not show any induction of apoptosis after stimulation. The incidence of the R92Q mutation among patients with recurrent autoinflammatory syndromes was similar to that observed in the normal population.

**CONCLUSION:** Resistance to TNF-mediated apoptosis is a feature in TRAPS patients who have mutations of cysteine residues or interstitial deletion, and may play a pathogenic role. The R92Q mutation does not appear to be significantly associated with TRAPS.

The newly described CATERPILLER family (also known as NOD-LRR or NACHT-LRR) is comprised of proteins with a nucleotide-binding domain and a leucine-rich region. This family has gained rapid prominence because of its demonstrated and anticipated roles in immunity, cell death and growth, and diseases. CATERPILLER proteins are structurally similar to a subgroup of plant-disease-resistance (R) proteins and to the apoptotic protease activating factor 1 (APAF1). They provide positive and negative signals for the control of immune and inflammatory responses, and might represent intracellular sensors of pathogen products. Most importantly, they are genetically linked to several human immunological disorders.

Scientists who study neutrophils often have backgrounds in cell biology, biochemistry, haematology, rheumatology or infectious disease. Paradoxically, immunologists seem to have a harder time incorporating these host-defence cells into the framework of their discipline. The recent literature discussed here indicates that it is appropriate for immunologists to take as much interest in

neutrophils as in their lymphohaematopoietic cousins with smooth nuclei. Neutrophils inform and shape immune responses, contribute to the repair of tissue as well as its breakdown, use killing mechanisms that enrich our concepts of specificity, and offer exciting opportunities for the treatment of neoplastic, autoinflammatory and autoimmune disorders.

Structural and functional insights into the B30.2/SPRY domain.

Woo JS(1), Imm JH, Min CK, Kim KJ, Cha SS, Oh BH.

Author information:

(1)Division of Molecular and Life Sciences, Department of Life Sciences, Center for Biomolecular Recognition, Pohang University of Science and Technology, Pohang, Kyungbuk, Korea.

The B30.2/SPRY domain is present in approximately 700 eukaryotic (approximately 150 human) proteins, including medically important proteins such as TRIM5alpha and Pyrin. Nonetheless, the functional role of this modular domain remained unclear. Here, we report the crystal structure of an SPRY-SOCS box family protein GUSTAVUS in complex with Elongins B and C, revealing a highly distorted two-layered beta-sandwich core structure of its B30.2/SPRY domain. Ensuing studies identified one end of the beta-sandwich as the surface interacting with an RNA helicase VASA with a 40 nM dissociation constant. The sequence variation in TRIM5alpha responsible for HIV-1 restriction and most of the mutations in Pyrin causing familial Mediterranean fever map on this surface, implicating the corresponding region in many B30.2/SPRY domains as the ligand-binding site. The amino acids lining the binding surface are highly variable among the B30.2/SPRY domains, suggesting that these domains are protein-interacting modules, which recognize a specific individual partner protein rather than a consensus sequence motif.

Involvement of a tissue-specific autoantibody in skin disorders of murine systemic lupus erythematosus and autoinflammatory diseases.

Nishimura H(1), Strominger JL.

Author information:

(1)Department of Molecular and Cellular Biology, Harvard University, Cambridge, MA 02138, USA.jlstrom@fas.harvard.edu

Human systemic lupus erythematosus (SLE) and its murine model, MRL lpr/lpr mice, are well known to develop a wide range of symptoms, such as glomerulonephritis, dermatitis, and arthritis, as an immune-complex disease. However, the deposition of circulating immune complex does not fully explain the tissue specificity of disease. Tissue-specific autoantigens may also be involved in tissue inflammation. In this study, desmoglein 3 (Dsg3), a major component of epidermal desmosomes, was identified as a skin-specific autoantigen. Several murine models of skin inflammation were found to develop autoantibodies to Dsg3 tightly correlated with disease aggravation, especially in MRL lpr/lpr mice. Furthermore, SLE-prone skin disease-free FcgammaRIIb-deficient mice developed skin inflammation upon immunization with Dsg3. Taken together with histological

studies, we concluded that skin-specific Dsg3 serves as an autoantigen in chronic skin inflammatory diseases accompanied by mast cell degranulation, including both murine SLE and other autoinflammatory diseases.

Diffuse pulmonary amyloidosis that mimics interstitial lung disease in a patient with familial Mediterranean fever.

Erdem H(1), Simşek I, Pay S, Dinc A, Deniz O, Ozcan A.

Author information:

(1)Department of Medicine, Division of Rheumatology, Gülhane Military School of Medicine, Etlik/Ankara, 06018, Turkey. herdem67@gata.edu.tr

Familial Mediterranean fever (FMF) is an autosomal-recessive disorder characterized by recurrent attacks of fever, serositis, and arthritis.

Amyloidosis, which mostly affects the kidneys, represents the most serious

complication of the disease. The lungs, particularly after the onset of renal failure, may be asymptotically involved in some of the patients with AA amyloidosis secondary to FMF. However, clinically detectable pulmonary amyloidosis is quite rare, and only 2 cases of pulmonary amyloidosis secondary to FMF have been reported so far. We describe a patient with pulmonary amyloidosis who had pulmonary hypertension and presented with clinical and radiologic features highly suggestive of interstitial lung disease. Amyloidosis was diagnosed only after lung biopsy. FMF was confirmed by molecular analysis.

The autoinflammatory disorders are a new and expanding classification of inflammatory diseases characterized by recurrent episodes of systemic inflammation in the absence of pathogens, autoantibodies or antigen specific T cells. These disorders are caused by primary dysfunction of the innate immune system, without evidence of adaptive immune dysregulation. Innate immune abnormalities include aberrant responses to pathogen associated molecular patterns (PAMPs) like lipopolysaccharide and peptidoglycan, prominent neutrophilia in blood and tissues, and dysregulation of inflammatory cytokines (IL-1 $\beta$ , TNF- $\alpha$ ) or their receptors. The autoinflammatory diseases comprise both hereditary (Familial Mediterranean Fever, FMF; Mevalonate Kinase Deficiency, MKD; TNF Receptor Associated Periodic Syndrome, TRAPS; Cryopyrin Associated Periodic Syndrome, CAPS; Blau syndrome; Pyogenic sterile Arthritis, Pyoderma gangrenosum and Acne syndrome, PAPA; Chronic Recurrent Multifocal Osteomyelitis, CRMO) and multifactorial (Crohn's and Behçet's diseases) disorders. Mutations responsible for FMF, TRAPS, CAPS, PAPA are in proteins involved in modulation of inflammation and apoptosis.

PYPAF1 nonsense mutation in a patient with an unusual autoinflammatory syndrome: role of PYPAF1 in inflammation.

Jéru I(1), Hayrapetyan H, Duquesnoy P, Sarkisian T, Amselem S.

Author information:

(1)INSERM U.654, Hôpital Henri-Mondor, Creteil, France.

**OBJECTIVE:** To gain insight into the pathophysiology of an unusual autoinflammatory syndrome, in a patient of Armenian origin, that mimicked familial Mediterranean fever (FMF) but with episodes triggered by generalized exposure to cold, and to further elucidate the controversial function of the protein encoded by PYPAF1, whose mutations (exclusively missense to date) have been identified in 3 hereditary recurrent fever syndromes.

**METHODS:** The patient's DNA was screened for mutations in both MEFV, the gene responsible for FMF, and PYPAF1. The ability of different recombinant PYPAF1 isoforms, expressed in HEK 293 cells, to regulate NF-kappaB signaling was subsequently assessed.

**RESULTS:** No disease-causing mutation was found in MEFV. However, a nonsense mutation (p.Arg554X) was identified in PYPAF1; this defect resulted in a truncated protein lacking all leucine-rich repeats. Study of the wild-type and mutant PYPAF1 recombinant proteins revealed that PYPAF1 inhibited NF-kappaB proinflammatory pathways, and that the identified nonsense mutation impaired this property.

**CONCLUSION:** These molecular and clinical findings, together with the clinical manifestations in the patient, which call into question the current nosology of the hereditary recurrent fever syndromes, are consistent with the hypothesis that PYPAF1 acts as an inhibitor of NF-kappaB signaling. They also provide a clear elucidation of the functional consequences of this nonsense PYPAF1 mutation not previously described in the literature, which result in a partial loss of function and may thereby explain the pathophysiology of the autoinflammatory syndrome observed in this patient.

TNF-receptor-associated periodic syndrome (TRAPS): an autosomal dominant multisystem disorder.

Rezaei N(1).

Author information:

(1)Immunology, Asthma and Allergy Research Institute, Tehran University of Medical Sciences, Tehran, Iran. rezaei\_nima.hbi.ir

The TNF-receptor-associated periodic syndrome (TRAPS) is an autosomal dominant auto-inflammatory disorder, characterized by recurrent febrile attacks and localized inflammation. TRAPS is caused by mutations in the gene encoding the TNF Receptor Super Family 1A (TNFRSF1A) on chromosome 12p13. However, the incomplete penetrance and genetic heterogeneity have been reported in this syndrome. Although the ethnic diversity and clinical heterogeneity may propose the role of other genes in the pathogenesis of TRAPS, some low-penetrance TNFRSF1A variants contribute to atypical inflammatory responses in other autoimmune diseases. Furthermore, molecular studies on TRAPS and other auto-inflammatory disorders could be suggested to identify additional genes coding the molecules in the TNF signalling process.

Author information:

(1)Service de Biochimie and Fédération de Génétique, Centre Hospitalier Victor-Dupoy, France. dimitri.tchernitchko@im3.inserm.fr

**BACKGROUND:** Familial Mediterranean fever (FMF) is the most frequent of the recurrent inherited fevers. This autosomal recessive disorder is characterised by periodic episodes of fever and serositis that commonly affect the people of Arab, Armenian, Sephardic Jewish and Turkish origin. Most of the described MEFV gene anomalies responsible for the disease are missense mutations. In the absence of any functional test, epidemiological studies or pedigree analyses are the only means of proving the deleterious character of these sequence variations. Evidence was provided by our recent study using a population-based approach, that the p.E148Q allele is probably a benign polymorphism and not a disease-causing mutation. Its implication in FMF remains, however, controversial.

**OBJECTIVE:** To evaluate the segregation of the p.E148Q MEFV allele with FMF disease by using pedigree analysis.

**PARTICIPANTS:** 21 patients and 48 unaffected relatives belonging to 18 independent families with FMF.

**RESULTS:** Segregation analysis of the p.E148Q allele was compatible with a Mendelian autosomal recessive transmission of the disease phenotype in only three families. In 15 of 18 families, segregation was partly or completely defective. The p.E148Q allele was not transmitted to 14 of 19 (74%) affected children.

**CONCLUSIONS:** No evidence of preferential transmission of p.E148Q from heterozygous parents to their affected offspring was observed. MEFV is not

associated with the clinical manifestations of several patients carrying this variant. Considering p.E148Q to be a benign polymorphism should reduce the possibility of false-positive diagnoses, while highlighting genetic heterogeneity in FMF.

Author information:

(1)Laboratoire de génétique, Institut national d'hygiène, 11400 Rabat, Morocco.

Familial Mediterranean fever (FMF) is an autosomal recessive inherited disease caused by mutations in MEFV. This disease is characterized by recurrent episodes of fever accompanied with topical signs of inflammation. Some patients can develop renal amyloidosis. We prospectively investigated MEFV mutations in a cohort of 209 unrelated Arab patients from Maghreb (85 Algerians, 87 Moroccans, and 37 Tunisians) with a clinical suspicion of FMF. FMF is the main cause of periodic fever syndrome in Maghreb. The most frequent MEFV mutations in this cohort were M694V and M694I. These mutations account for different proportions of the MEFV mutations in Algeria (5%, 80%), Morocco (49%, 37%), and Tunisia (50%, 25%) patients. M694I mutation is specific to the Arab population from Maghreb. Other rare mutations were observed: M680L, M680I, A744S, V726A, and E148Q. We estimated the frequency of MEFV mutation carriers among the Arab Maghrebian population at around 1%, which is significantly lower than in non-Ashkenazi Jews, Armenians or Turks.

Four diseases presenting mainly as intermittent bouts of inflammatory symptoms have been clinically and genetically characterized. At the head of this group is familial Mediterranean fever, which affects thousands of patients of Mediterranean ancestry. The other three entities are the tumor necrosis factor receptor superfamily 1A-associated periodic fever syndrome (TRAPS) with a dominant mode of inheritance; hyperimmunoglobulinemia D and periodic fever syndrome (HIDS); and the most recently recognized entity, which includes Muckle Wells syndrome, familial cold urticaria, and the chronic infantile neurological cutaneous and articular (CINCA) syndrome. Proper diagnosis of these entities is needed to begin specific clinical and therapeutic management.

Author information:

(1)Department of Medicine, Helsinki University Central Hospital, Helsinki, Finland.

Tumour necrosis factor (TNF) receptor-associated periodic syndrome (TRAPS) is an

autoinflammatory disorder characterized by periodic attacks of fever and inflammation, due to mutations in the gene coding for the TNF type I receptor (TNFRSF1A). A 16-year-old patient with the diagnosis of TRAPS was admitted to hospital because of fever and abdominal pain. Initially, the symptoms were interpreted as manifestations of another TRAPS attack, but the patient's condition worsened, despite treatment with corticosteroids and antibiotics. A repeated computer tomography revealed an intra-abdominal abscess, which necessitated urgent surgical intervention. This case stresses the importance of differential diagnostic vigilance when dealing with patients with rare genetic diseases.

HLA class II haplotype DRB1\*04-DQB1\*0301 contributes to risk of familial generalized vitiligo and early disease onset.

Fain PR(1), Babu SR, Bennett DC, Spritz RA.

Author information:

(1)Human Medical Genetics Program, University of Colorado at Denver and Health Sciences Center, Aurora, USA.

Generalized vitiligo is a common autoimmune disorder characterized by white patches of skin and overlying hair caused by loss of pigment-forming melanocytes from involved areas. Familial clustering of vitiligo is not uncommon, and patients and their relatives are at increased risk for a specific complex of other autoimmune diseases. Compared with sporadic vitiligo, familial vitiligo is characterized by earlier disease onset and greater risk and broader repertoire of autoimmunity, suggesting a stronger genetic component, and perhaps stronger associations with specific alleles. To determine whether the major histocompatibility complex (MHC) contributes to the familial clustering of vitiligo and vitiligo-associated autoimmune/autoinflammatory diseases, we performed case-control and family-based association analyses of HLA class II-DRB1 and -DQB1 alleles and haplotypes in affected probands and their parents from 76 European-American Caucasian families with familial vitiligo. Affected probands

showed a significantly increased frequency of DRB1\*04-DQB1\*0301 and a significantly decreased frequency of DRB1\*15-DQB1\*0602 compared with a large sample of reference chromosomes. Family-based association analyses confirmed these results. Probands with DRB1\*04-DQB1\*0301 developed vitiligo an average of 13.32 yr earlier than probands with DRB1\*15-DQB1\*0602. Overall, our results indicate that specific MHC-linked genetic variation contributes to risk of familial vitiligo, although HLA does not completely explain familial clustering of vitiligo-associated autoimmune/autoinflammatory diseases.

(1)Department of Pediatrics, Section of Pediatric Neurology, Hacettepe University Faculty of Medicine, Ankara, Turkey. hozyurekibu@hotmail.com

Reversible posterior leukoencephalopathy syndrome is characterized clinically by headache, abnormalities of mental status and visual perception, and seizures. Despite its diverse causes, common precipitating factors are defined as abrupt elevations of blood pressure, renal decompensation, fluid retention, and immunosuppressive therapy. We report three children with reversible posterior leukoencephalopathy syndrome presenting with generalized seizures and headache. The causes of reversible posterior leukoencephalopathy syndrome were considered to be acute hypertension and immunosuppressive therapy in case 1 with systemic lupus erythematosus, chemotherapy (vincristine and/or actinomycin-D) and hyponatremia in case 2, and acute hypertension in case 3, admitted with a familial Mediterranean fever attack. In light of these cases, we review the literature for the etiology, clinical and laboratory findings, and pathogenetic mechanisms of the disease.

(1)Department of Veterans Affairs Medical Center, Portland, OR 97239-2999, USA.  
daveym@ohsu.edu

Mutations in the human NOD2/CARD15 gene cause Blau syndrome, an autoinflammatory disorder involving the joints, skin and eyes. Insights into the mechanism of this association may be gained by a further understanding of where NOD2 is expressed. The objective of this study was to analyze ocular endothelial cells for NOD2 expression. Human ocular tissue was analyzed by immunohistology using anti-NOD2 antisera. RNA isolated from iris, choroid and endothelial cell lines was analyzed by reverse transcription-PCR and real-time quantitative PCR. Gene regulation was studied by treating endothelial cells with TNF-alpha and IFN-gamma. Functional responses were assessed by measuring IL-6 release from endothelial cells treated with muramyl dipeptide (MDP), synthetic lipopeptide (Pam3CSK4) and lipopolysaccharide (LPS). Immunohistological analysis revealed staining of endothelial cells in the uveal tract. NOD2 expression was detected in primary ocular endothelial cell cultures, and levels increased in response to inflammatory cytokines. Endothelial cells from choroid demonstrated enhanced release of IL-6 in response to MDP, and synergy was observed following treatment with MDP and either Pam3CSK4 or LPS. The observations that endothelial cells express NOD2, upregulate NOD2 in response to stimuli known to promote NOD2 expression and show synergistic cytokine responses to MDP and TLR ligands previously shown to be mediated by NOD2 are informative since they may be relevant to pathogenic mechanisms leading to the spectrum of inflammation seen in Blau syndrome.

A crucial part of the innate immune response is the assembly of the inflammasome, a cytosolic complex of proteins that activates caspase-1 to process the proinflammatory cytokines interleukin (IL)-1 $\beta$  and IL-18. The adaptor protein ASC is essential for inflammasome function, binding directly to caspase-1 (refs 3, 4), but the triggers of this interaction are less clear. ASC also interacts with the adaptor cryopyrin (also known as NALP3 or CIAS1). Activating mutations in cryopyrin are associated with familial cold autoinflammatory syndrome, Muckle-Wells syndrome and neonatal onset multisystem inflammatory disease, diseases that are characterized by excessive production of IL-1 $\beta$ . Here we show that cryopyrin-deficient macrophages cannot activate caspase-1 in response to Toll-like receptor agonists plus ATP, the latter activating the P2X7 receptor to decrease intracellular K<sup>+</sup> levels. The release of IL-1 $\beta$  in response to nigericin, a potassium ionophore, and maitotoxin, a potent marine toxin, was also found to be dependent on cryopyrin. In contrast to Asc<sup>-/-</sup> macrophages, cells deficient in the gene encoding cryopyrin (Cias1<sup>-/-</sup>) activated caspase-1 and secreted normal levels of IL-1 $\beta$  and IL-18 when infected with Gram-negative *Salmonella typhimurium* or *Francisella tularensis*. Macrophages exposed to Gram-positive *Staphylococcus aureus* or *Listeria monocytogenes*, however, required both ASC and cryopyrin to activate caspase-1 and secrete IL-1 $\beta$ . Therefore, cryopyrin is essential for inflammasome activation in response to signalling pathways triggered specifically by ATP, nigericin, maitotoxin, *S. aureus* or *L. monocytogenes*.

Gout-associated uric acid crystals activate the NALP3 inflammasome.

Martinon F(1), Pétrilli V, Mayor A, Tardivel A, Tschopp J.

Author information:

(1)Department of Biochemistry, University of Lausanne, Chemin des Boveresses 155, 1066 Epalinges, Switzerland.

Development of the acute and chronic inflammatory responses known as gout and pseudogout are associated with the deposition of monosodium urate (MSU) or calcium pyrophosphate dihydrate (CPPD) crystals, respectively, in joints and periarticular tissues. Although MSU crystals were first identified as the aetiological agent of gout in the eighteenth century and more recently as a 'danger signal' released from dying cells, little is known about the molecular mechanisms underlying MSU- or CPPD-induced inflammation. Here we show that MSU and CPPD engage the caspase-1-activating NALP3 (also called cryopyrin) inflammasome, resulting in the production of active interleukin (IL)-1 $\beta$  and IL-18. Macrophages from mice deficient in various components of the inflammasome such as caspase-1, ASC and NALP3 are defective in crystal-induced IL-1 $\beta$  activation. Moreover, an impaired neutrophil influx is found in an in vivo model of crystal-induced peritonitis in inflammasome-deficient mice or mice deficient in the IL-1 $\beta$  receptor (IL-1R). These findings provide insight into the molecular processes underlying the inflammatory conditions of gout and pseudogout, and further support a pivotal role of the inflammasome in several autoinflammatory diseases.

Missense mutations in the CIAS1 gene cause three autoinflammatory disorders: familial cold autoinflammatory syndrome, Muckle-Wells syndrome and neonatal-onset multiple-system inflammatory disease. Cryopyrin (also called Nalp3), the product of CIAS1, is a member of the NOD-LRR protein family that has been linked to the activation of intracellular host defence signalling pathways. Cryopyrin forms a multi-protein complex termed 'the inflammasome', which contains the apoptosis-associated speck-like protein (ASC) and caspase-1, and promotes caspase-1 activation and processing of pro-interleukin (IL)-1 $\beta$  (ref. 4). Here we show the effect of cryopyrin deficiency on inflammasome function and immune responses. Cryopyrin and ASC are essential for caspase-1 activation and IL-1 $\beta$  and IL-18 production in response to bacterial RNA and the imidazoquinoline compounds R837 and R848. In contrast, secretion of tumour-necrosis factor- $\alpha$  and IL-6, as well as activation of NF- $\kappa$ B and mitogen-activated protein kinases (MAPKs) were unaffected by cryopyrin deficiency. Furthermore, we show that Toll-like receptors and cryopyrin control the secretion of IL-1 $\beta$  and IL-18 through different intracellular pathways. These results reveal a critical role for cryopyrin in host defence through bacterial RNA-mediated activation of caspase-1, and provide insights regarding the pathogenesis of autoinflammatory syndromes.

[The effect of colchicine on the periodicity of the spontaneous and induced respiratory burst of granulocytes and monocytes during familial Mediterranean fever].

[Article in Russian]

Akopian VP, Avetisian SA, Davtian TK.

The influence of colchicine on the spontaneous and chemotaxis-, protein kinase C-, and phagocytosis-induced respiratory burst of neutrophils and monocytes in the peripheral blood of patients with familial Mediterranean fever (FMF) has been studied. The transient activation of neutrophils and monocytes on the level of a single cell has been monitored by means of flow cytofluorimetry. It is shown that colchicine blocks the induction of chemotaxis-, phagocytosis-, and protein kinase C-dependent respiratory burst in vitro, as well as the increased pro-oxidant transient activation of neutrophils and monocytes of FMF patients, both in the period of remission and during the FMF attack. Colchicine stimulates the intensity of the spontaneous respiratory burst of neutrophils and monocytes in patients in the course of remission and during the FMF attack. At the same time, the drug effectively suppresses the periodicity of the multidirectional transient activation of the respiratory burst of effector cells during FMF.

**OBJECTIVE:** To prospectively monitor inflammatory activity over a prolonged period in a cohort of Turkish patients with FMF, their healthy relatives and healthy controls and to relate this to their MEFV genotypes.

**METHODS:** 43 patients with FMF and 75 of their asymptomatic relatives underwent fortnightly assessments and venesection for measurement of CRP and SAA over 5 months. 50 unrelated healthy population matched controls were also studied. MEFV genotyping was performed on all participants and comparisons were made between the different groups.

**RESULTS:** Paired MEFV mutations were detected in 84% of FMF patients and single mutations in 12%. Substantial acute phase reactivity was seen among the patients with FMF during attacks (median SAA 693 mg/l, CRP 115 mg/l). Between attacks there was also some inflammatory activity (median SAA 6 mg/l, CRP 4 mg/l). Among healthy controls 16% were heterozygotes for MEFV mutations and 4% had two mutations. As expected there was a substantial carrier rate among healthy relatives with mutations detected in almost 92%. Asymptomatic MEFV heterozygotes had elevated acute phase proteins compared to wild type subjects.

**CONCLUSION:** Substantial sub-clinical inflammation occurs widely and over prolonged periods in patients with FMF, indicating that the relatively infrequent clinically overt attacks represent the 'tip of the iceberg' in this disorder.

Both basal and peak acute phase protein concentrations were greater in MEFV heterozygotes than in wild-type controls, regardless of mutation demonstrating a 'pro-inflammatory' phenotype among FMF carriers. Upregulation of the acute phase response among carriers of FMF may augment their innate host response and contribute to better resistance to infection.

Severe TNF receptor-associated periodic syndrome due to 2 TNFRSF1A mutations including a new F60V substitution.

Haas SL(1), Lohse P, Schmitt WH, Hildenbrand R, Karaorman M, Singer MV, Böcker U.

Author information:

(1)Department of Medicine II, University Hospital Mannheim, Mannheim, Germany.

Tumor necrosis factor receptor-associated periodic syndrome (TRAPS) is typically characterized by episodic fever, myalgia, skin rash, conjunctivitis, and abdominal cramps. Recently, mutations in the TNFRSF1A gene on chromosome 12p13 encoding tumor necrosis factor receptor type 1 have been linked to this autoinflammatory syndrome. We report the case of a 29-year-old white woman who experienced periodic inflammatory manifestations with fever up to 40 degrees C, leukocytosis, and elevation of C-reactive protein level (>100 mg/L) in conjunction with acute peritonitis of unknown origin since the age of 19 years. The patient had undergone 2 laparotomies with appendectomy and left hemicolectomy. Familial Mediterranean fever was excluded by sequencing of the MEFV gene. In view of the possibility of TRAPS, sequence analysis of the TNFRSF1A gene was also performed. The patient carried a novel T-->G substitution in exon 3, leading to the replacement of phenylalanine by valine at amino acid position 60 (F60V), as well as the common R92Q low-penetrance mutation, encoded by exon 4. Upon the next flare, the patient started corticosteroid therapy, resulting in complete relief and normalization of elevated C-reactive protein levels. To the best of our knowledge, we report the first case of compound heterozygosity for 2 TNFRSF1A gene mutations, including a novel one that causes a severe form of TRAPS that responds to anti-inflammatory treatment. A history of recurrent sterile peritonitis should prompt genotyping for periodic fever syndromes.

Plasma interleukin-10 and interleukin-12 levels in patients with familial Mediterranean fever.

Erken E(1), Ozer HT, Gunesacar R.

Author information:

(1)Department of Medicine, Division of Rheumatology-Immunology, Faculty of Medicine, Cukurova University, Balcali, PO Box (PK) 5, 01330 Adana, Turkey.  
eerken@cu.edu.tr

Familial Mediterranean fever (FMF) is an autosomal recessive disorder characterized by recurrent attacks of fever, polyserositis and arthritis. A vast array of cytokines were analysed in these patients, however, little is known about the pro-inflammatory cytokine interleukin (IL)-12. Plasma IL-12 and IL-10 were measured in 24 patients with FMF (19 active, 5 inactive) and 18 healthy controls by ELISA. From 15 active patients blood was also drawn in attack-free period. Mean plasma IL-12 levels of the FMF patients (mean  $\pm$  SEM,  $6.84 \pm 3.59$  pg/ml) were higher than the controls ( $0.13 \pm 0.09$  pg/ml,  $P < 0.001$ ). Mean IL-12 levels of active ( $7.02 \pm 5.23$  pg/ml) and inactive patients ( $6.89 \pm 5.61$  pg/ml) were comparable, and they were higher compared to controls ( $P \leq 0.001$ ). Mean plasma IL-10 levels of the total FMF patients ( $3.01 \pm 1.53$  pg/ml) were also higher than the controls ( $P = 0.024$ ). Patients had higher IL-10 levels in attacks ( $3.83 \pm 2.02$  pg/ml) compared to levels when they were in remission ( $1.86 \pm 1.59$  pg/ml,  $P = 0.046$ ). Significantly elevated IL-12 levels in FMF patients regardless of activity may suggest the presence of a pro-inflammatory state also in the inactive period of FMF. Significant increase in IL-10 levels in FMF group may point to the compensatory suppression of inflammation in active periods of the disease.

Mutation of mouse Mayp/Pstpip2 causes a macrophage autoinflammatory disease.

Macrophage actin-associated tyrosine phosphorylated protein (MAYP)/PSTPIP2, a PCH protein, is involved in the regulation of macrophage motility. Mutations in a closely related gene, PSTPIP1/CD2BP1, cause a dominantly inherited autoinflammatory disorder known as PAPA syndrome. A mutant mouse obtained by chemical mutagenesis exhibited an autoinflammatory disorder characterized by macrophage infiltration and inflammation, leading to osteolysis and necrosis in

paws and necrosis of ears. Positional cloning of this recessive mutation, termed Lupo, identified a T to A nucleotide exchange leading to an amino acid substitution (I282N) in the sequence of MAYP. Mayp(Lp/Lp) disease was transferable by bone marrow transplantation and developed in the absence of lymphocytes. Consistent with the involvement of macrophages, lesion development could be prevented by the administration of clodronate liposomes. MAYP is expressed in monocytes/macrophages and in a Mac1<sup>+</sup> subfraction of granulocytes. LPS stimulation increases its expression in macrophages. Because of the instability of the mutant protein, MAYP expression is reduced 3-fold in Mayp(Lp/Lp) macrophages and, on LPS stimulation, does not rise above the level of unstimulated wild-type (WT) cells. Mayp(Lp/Lp) mice expressed elevated circulating levels of several cytokines, including MCP-1; their macrophages exhibited altered cytokine production in vitro. These studies suggest that MAYP plays an anti-inflammatory role in macrophages.

Role of the pyrin M694V (A2080G) allele in acute myocardial infarction and longevity: a study in the Sicilian population.

A proinflammatory genotype seems to contribute significantly to the risk of developing coronary heart disease (CHD). Conversely, the susceptibility alleles to inflammatory disease should be infrequent in the genetic background favoring longevity. In fact, in a modern environment, attainment of longevity is facilitated by an anti-inflammatory status. To evaluate whether inflammatory alleles of pyrin, the gene responsible for familial Mediterranean fever (FMF) may play an opposite role in CHD and in longevity, we examined three FMF-associated

mutations, M694V (A2080G), M694I (G2082A), and V726A (T2177C), encoded by the FMF gene (MEFV) in 121 patients affected by acute myocardial infarction (AMI), in 68 centenarians, and in 196 age-matched controls from Sicily. None of the Sicilian subjects studied carried the V726A and the M694I FMF-related mutations. The proinflammatory M694V (A2080G) mutation was the only one we found, which was over-represented significantly in CHD patients and under-represented in oldest old, and intermediate values were in healthy, young controls. After adjustment for well-recognized AMI risk factors, the M694V allele still predicted a significant risk to develop AMI. So, according to these results, we suggest that carrying the proinflammatory M694V pyrin allele may increase the risk to develop AMI. Conversely, the wild-type pyrin genotype may predispose to a greater chance to live longer in a modern environment with reduced pathogen load and improved control of severe infections by antibiotics. All these data indicate a strong relationship among inflammation, genetics, CHD, and longevity.

**OBJECTIVE:** To assess the effectiveness of the combined use of fecal calprotectin (FC), anti-Saccharomyces cerevisiae antibody (ASCA), perinuclear staining antineutrophil antibody (pANCA), small intestinal permeability test (IP), and bowel wall ultrasonography measurement (BWUS) in the diagnostic work-up of children with suspected inflammatory bowel disease (IBD).

**METHODS:** All children referred for initial assessment of possible IBD were eligible. Patients with symptoms or signs (right-lower quadrant mass, perianal disease, or hematochezia) mandating a complete work-up for IBD were excluded. All

enrolled patients underwent a clinical, laboratory, radiographic, and endoscopic evaluation including biopsy examinations. The immunoglobulin (Ig)G and IgA ASCA, IgG pANCA, FC, IP, and BWUS were tested in all patients at the initial assessment.

**RESULTS:** A final diagnosis of IBD was made in 27 patients: 17 Crohn disease and 10 ulcerative colitis. Eighteen children had other gastrointestinal diagnoses (8 functional bowel disorders, 5 food allergy-mediated diseases, 4 infectious enterocolitis, 1 familial Mediterranean fever). In patients with simultaneous abnormal values of FC, BWUS, and ASCA/pANCA, the estimated probability of having IBD was 99.47%. Patients with negative results on all tests had a 0.69% of probability of IBD.

**CONCLUSIONS:** The incorporation of noninvasive diagnostic tests into the initial diagnostic approach may avoid unnecessary invasive procedures and facilitate clinical decision-making when the diagnosis of IBD in children is initially uncertain.

Familial Mediterranean fever (FMF) in Lebanon and Jordan: a population genetics study and report of three novel mutations.

Medlej-Hashim M(1), Serre JL, Corbani S, Saab O, Jalkh N, Delague V, Chouery E, Salem N, Loiselet J, Lefranc G, Mégarbané A.

Author information:

(1)Unité de Génétique Médicale, Faculté de Médecine, Université Saint Joseph, Beyrouth, Lebanon.

Familial Mediterranean fever (FMF) is an autosomal recessive disease mostly frequent in Mediterranean populations. Over 50 mutations have been identified in the gene responsible for the disease, MEFV. The present study reports the frequencies of MEFV mutations in 558 Lebanese and 55 Jordanian FMF patients and points out the severity of the M694V frequently observed mutation among these patients. Three novel mutations, T177I, S108R and E474K were also identified in the Lebanese group. An excess of homozygotes and a deficit of heterozygotes were

observed in both samples when compared to the expected number of observed genotypes under the Hardy-Weinberg hypothesis. Homozygotes for M694V and M694I were still in excess in the Lebanese group of patients, even after consanguinous homozygotes were removed, or population structure was considered. This excess is therefore neither due to consanguinity nor to subgroups in the Lebanese population, but rather to more remote consanguinity or to a selection bias favoring the census of these genotypes. The fact that FMF female patients were less censused than male patients may be due to the greater resistance of females to pain and to the possibility of confusing abdominal and gynecological pain. The phenotypic heterogeneity of the FMF could then originate both from genetic causes like allelic heterogeneity or modulating genes, and cultural background facing the physiological consequences of genotypes at risk.

Hereditary periodic fever syndrome sans fever or distinct periodicity presenting with psychosis.

Hurst M(1), Hull K, Nicholls D, Ameratunga R.

Author information:

(1)Department of Clinical Immunology, Auckland Hospital, New Zealand.

The genetic basis for several hereditary periodic fever syndromes has been identified and consequently, the phenotypic spectrum of these disorders has broadened. We describe a young woman with tumor necrosis factor receptor-associated periodic syndrome (TRAPS), proven by mutational analysis, who presented with psychosis but without fever, symptom periodicity, or similar family medical history. This patient represents the first case of TRAPS-associated psychosis. This case illustrates the importance of mutation analysis for this group of disorders in individuals presenting with unexplained inflammatory symptoms and recurrent psychoses.

Structure of the PRYSPRY-domain: implications for autoinflammatory diseases.

Grütter C(1), Briand C, Capitani G, Mittl PR, Papin S, Tschopp J, Grütter MG.

Author information:

(1)Department of Biochemistry, University of Zürich, CH-8057 Zürich, Switzerland.

We determined the first structure of PRYSPRY, a domain found in over 500 different proteins, involved in innate immune signaling, cytokine signaling suppression, development, cell growth and retroviral restriction. The fold encompasses a 7-stranded and a 6-stranded antiparallel beta-sheet, arranged in a beta-sandwich. In the crystal, PRYSPRY forms a dimer where the C-terminus of an acceptor molecule binds to the concave surface of a donor molecule, which represents a putative interaction site. Mutations in the PRYSPRY domains of Pyrin, which are responsible for familial Mediterranean fever, map on the putative PRYSPRY interaction site.

Familial Mediterranean fever in a childhood population in eastern Turkey.

Ertekin V(1), Selimoğlu MA, Pirim I.

Author information:

(1)Department of Pediatric Gastroenterology, Hepatology and Nutrition, Atatürk University Faculty of Medicine, Erzurum, Turkey. vildanertekin@hotmail.com

**BACKGROUND:** Familial Mediterranean fever (FMF) is an autosomal recessive disease characterized by recurrent attacks of inflammation of serosal membranes.

Amyloidosis is the most severe complication of the disease. The aim of this study was to explore the magnitude of the FMF problem and to describe clinical phenotypic and genotypic profile in the childhood population in Eastern Turkey.

**METHODS:** In this study, 52 patients who were diagnosed as FMF between January 2000 and January 2003 in Department of Pediatrics, Ataturk University Hospital, were included. The diagnosis of FMF was based on typical clinical and laboratory features. The 12 FMF mutations were investigated in the patients.

**RESULTS:** Of the 52 patients, 30 (57.7%) were girls, 22 (42.3%) were boys, and the age ranged from 9 months to 15 years (8.5 +/- 3.2 years). A positive family history for FMF was noted in 33 (63.5%) patients. The mean onset age was 6 +/- 3.4 (from 8 months to 14 years). Nineteen children (36.5%) were symptomatic below the age of 5 years. Abdominal pain was observed in 50 (96.2%), fever in 42 (80.8%), arthralgia in 29 (55.8%), arthritis in 18 (34.6%), splenomegaly in 11 (21.2), hepatomegaly in 15 (28.8%), myalgia in 11 (26.2%), erysipelas-like erythema in 10 (19.2%), thoracic pain in four (7.7%), protracted febrile myalgia in three (5.8%), and seizures in two (3.8%). The most frequent mutation was the M694V/M694V. Clinical presentation of the patients was not different in respect with genotypes ( $P > 0.05$ ). Two patients had chronic renal disease suggestive of amyloidosis.

**CONCLUSION:** It was noted that the FMF patients in this study had a broad spectrum of mutation combination, which might reflect the intercultural interactions of ancient ethnic groups that lived in Anatolia, and these mutations were not significantly different in respect to clinical presentations.

Familial Mediterranean fever and the other autoinflammatory syndromes: evaluation of the patient with recurrent fever.

Samuels J(1), Ozen S.

Author information:

(1)Department of Rheumatology, Hospital for Special Surgery, New York, NY 10021, USA. samuelsj@hss.edu

**PURPOSE OF REVIEW:** The aim of this article is to summarize recent clinical, genetic and pathophysiologic findings of familial Mediterranean fever and several of the other systemic autoinflammatory diseases, a recently recognized group of disorders characterized by seemingly unprovoked inflammation but lacking high-titer autoantibodies. Genetic and clinical tools are improving the ability of the clinician to better approach patients with periodic fever and inflammation.

**RECENT FINDINGS:** The spectrum of reported genetic mutations and susceptible ethnicities for the hereditary periodic fever subset of the autoinflammatory diseases has continued to expand. At the same time, the pathogeneses of many of these diseases are now understood to involve different aspects of a common pathway, largely affecting inflammatory cascades related to IL-1 or tumor necrosis factor-alpha. Three of these diseases which have been grouped as the cryopyrin-associated periodic syndromes result from defects in the same gene, and all three appear to respond well to anti-IL-1 therapy although controlled trials are still in progress. In addition, cytokine-based therapies are also now under investigation for hyperimmunoglobulinemia D with periodic fever syndrome and pyogenic sterile arthritis, pyoderma gangrenosum, and acne syndrome.

**SUMMARY:** The identification of the genes and proteins mutated in many of the autoinflammatory diseases has broadened our understanding of the regulation of inflammation and the immune system, and provided the basis for the use of targeted therapies in these syndromes. We propose an algorithm for the evaluation of a patient with periodic fever, taking into account the patient's age, ethnicity, symptoms and signs, and results from laboratory and genetic testing.

Sustained, progressive, nonresolving abdominal pain: a previously undescribed clinical presentation of familial Mediterranean fever.

Radisic M(1), Santamarina J, Froment R.

Author information:

(1)Internal Medicine, Sanatorio de la Trinidad (Palermo), Capital Federal, Argentina. mradisic@intramed.net.ar

Familial Mediterranean fever (FMF) is a genetic disorder characterized by sporadic, acute attacks of fever and serosal inflammation. Typical manifestations are recurrent febrile episodes of acute instauration for brief duration (1 to 4 days) that is associated with severe pain due to serositis at one or more sites. Abdominal crisis occurs in 95% of the patients. Treatment with colchicine is highly effective as preventive treatment, but it is considered to be ineffective for the treatment of established acute attacks. As mentioned, untreated crisis resolves spontaneously in 1 to 4 days. Prolonged, nonresolving crisis of abdominal pain refractory to nonsteroidal anti-inflammatory drugs (NSAIDs) and opioids, with fever and elevation of acute phase reactants that resolves after the administration of colchicine, is a clinical presentation undescribed hitherto. The aim of this paper is to report a patient with this distinctively unusual clinical presentation of FMF.

Familial mediterranean fever-related nephrotic syndrome and successful full-term pregnancy.

Tutuncu L(1), Atasoyu EM, Evrenkaya R, Mungen E.

Author information:

(1)Department of Obstetrics and Gynecology, Haydarpasa Training Hospital, Istanbul, Turkey. Itutuncu@yahoo.com

Familial Mediterranean fever (FMF) is a systemic disease with an autosomal recessive inheritance. The most serious complication of FMF is renal amyloidosis. Pregnancy may adversely affect renal function in FMF patients with amyloidosis and nephrotic syndrome. A 20-year-old woman with FMF related nephrotic syndrome became pregnant while receiving colchicine therapy. Colchicine treatment was continued during pregnancy with close observation. She gave birth to a 2400 g healthy female newborn at the 38th week of gestation. Pregnancy and neonatal outcome were uneventful. It is advisable to continue colchicine treatment during conception and pregnancy in FMF patients with amyloid related nephrotic syndrome. Colchicine treatment with bed rest, protein reinforcement, acetylsalicylic acid administration and close follow-up may improve the outcome of pregnancy in FMF patients.

Author information:

(1)Department of Neurosurgery, Faculty of Medicine, University of Kirikkale, Turkey. bademci70@yahoo.com

A unique case of bilateral severe carpal tunnel syndrome due to familial Mediterranean fever is reported. The syndrome was diagnosed by clinical examination and electrophysiological studies. Bilateral transverse carpal ligaments were released and the biopsy specimens revealed systemic type A amyloidosis. Up to our knowledge, the co-existence of bilateral carpal tunnel syndrome and familial Mediterranean fever has not been reported previously in the literature.

**BACKGROUND:** Tumour necrosis factor (TNF) receptor associated periodic syndrome (TRAPS) is caused by dominant mutations in the TNFRSF1A gene. In typical cases TRAPS begins early in childhood and is characterised by high and remittent fever over a period of 1-4 weeks or longer, accompanied by systemic and local inflammation.

**CASE REPORTS:** Patient 1 presented with recurrent episodes of weakness, migrating myalgias, arthralgias, exanthema, and chest pain lasting for 1-4 weeks, but without any fever over an initial period of 4 years at least. Diagnosis of TRAPS was confirmed by the heterozygous mutation Y20H in TNFRSF1A. Patient 2, a 23 year old woman never had any symptoms indicative of TRAPS. Genetic evaluation of all members of her family with a TRAPS index patient disclosed the T50M mutation in TNFRSF1A. A medical check up showed proteinuria, and renal biopsy disclosed AA amyloidosis.

**CONCLUSIONS:** TRAPS associated mutations can induce considerable inflammation that is not necessarily accompanied by fever. Even monosymptomatic severe amyloidosis can occur in these patients. Genetic counselling and appropriate management to prevent or mitigate amyloidosis may be necessary.

The association of familial Mediterranean fever (FMF) with juvenile idiopathic arthritis (JIA) or ankylosing spondylitis (AS), most commonly with negative HLA-B27 antigen, was described in several previous reports, although the pathogenic mechanism of this association still remains unknown. Herein we report an uncommon association of FMF with HLA-B27 positive AS as an occasional coincidence in a patient who had been diagnosed as having JIA 23 years previously.

Hereditary periodic fever syndromes.

Kastner DL(1).

Author information:

(1)Genetics and Genomics Branch, National Institute of Arthritis and Musculoskeletal and Skin Diseases, National Institutes of Health, Bethesda, MD 20892, USA. kastnerd@mail.nih.gov

The hereditary periodic fevers are a group of Mendelian disorders characterized by seemingly unprovoked fever and localized inflammation. Recent data indicate that these illnesses represent inborn errors in the regulation of innate immunity. Pyrin, the protein mutated in familial Mediterranean fever, defines an N-terminal domain found in a large family of proteins involved in inflammation and apoptosis. Through this domain pyrin may play a role in the regulation of interleukin (IL)-1beta, nuclear factor (NF)-kappaB, and leukocyte apoptosis. Cryopyrin/NALP3, another protein in this family, is mutated in three other hereditary febrile syndromes and participates in the inflammasome, a newly recognized macromolecular complex crucial to IL-1beta activation. Somewhat unexpectedly, mutations in the 55 kDa receptor for tumor necrosis factor also give rise to a dominantly inherited periodic fever syndrome, rather than immunodeficiency, a finding that has stimulated important investigations into both pathogenesis and treatment. Finally, the discovery of the genetic basis of the hyperimmunoglobulinemia D with periodic fever syndrome suggests an as yet incompletely understood connection between the mevalonate pathway and the regulation of cytokine production. These insights extend our understanding of the regulation of innate immunity in man, while providing the conceptual basis for the rational design of targeted therapies, both for the hereditary periodic fevers themselves and other inflammatory disorders as well.

Previous studies of acute generalized exanthematous pustulosis, a peculiar drug hypersensitivity reaction, suggested that CXCL8-producing T cells regulate sterile, polymorphonuclear neutrophil-rich skin inflammations. In this study, we test the hypothesis of whether CXCL8-producing T cells are present in autoinflammatory diseases like pustular psoriasis and Behçet's disease. Immunohistochemistry of normal skin revealed few CD4+ and CD8+ T cells, few CXCL8+ cells, and no neutrophilic infiltration, whereas in acute exacerbations of atopic dermatitis, numerous CD4+ T cells but few CD8+ T cells, neutrophils, or CXCL8+ cells were detected. In contrast, a pronounced infiltration of neutrophils and of predominantly CD4+ T cells was observed in skin biopsies from pustular psoriasis, Behçet's disease, and acute generalized exanthematous pustulosis, with infiltrating T cells strongly positive for CXCL8 and the chemokine receptor CCR6. Skin-derived T cell clones from pustular skin reactions were positive for CCR6 but negative for CCR8 and secreted high amounts of CXCL8 and GM-CSF, often together with IFN-gamma and TNF-alpha after in vitro stimulation. Moreover, some skin-derived T cell clones from Behçet's disease and from pustular psoriasis predominantly produced CXCL8 and GM-CSF, but failed to secrete IL-5 and IFN-gamma. These cells might represent a particular subset as they differ from both Th1 as well as Th2 T cells and are associated with a unique, neutrophil-rich sterile inflammation. Our findings suggest that CXCL8/GM-CSF-producing T cells may orchestrate neutrophil-rich pathologies of chronic autoinflammatory diseases like pustular psoriasis and Behçet's disease.

Autosomal dominant periodic fever with AA amyloidosis: tumor necrosis factor receptor-associated periodic syndrome (TRAPS) in a Turkish family.

Dinc A(1), Erdem H, Rowczenio D, Simsek I, Pay S, Bahce M, Lachmann H.

Author information:

(1)Department of Medicine, Division of Rheumatology, Gulhane Military School of Medicine, Ankara, Turkey.

We investigated the presence of tumor necrosis factor receptor-associated periodic syndrome (TRAPS) in a Turkish family with recurrent fever and systemic reactive (AA) amyloidosis. A missense mutation in exon 3 of the TNFRSF1A gene, resulting in an amino acid substitution Phe60Leu (F60L) was found in the proband and his father. These are the first confirmed TRAPS cases in the Turkish population. This family highlights the importance of considering all the causes of inherited fevers and performing thorough clinical and genetic investigations to secure a diagnosis, even in populations in which familial Mediterranean fever (FMF) is highly prevalent.

Interleukin-6 (IL-6) -174 G/C polymorphism in familial Mediterranean fever patients with and without amyloidosis.

Karahan ZC(1), Ozturk A, Akar E, Akar N.

Author information:

(1)Pediatric Molecular Genetics Department, Ankara University, School of Medicine, Ankara--Turkey.

Familial Mediterranean fever (FMF) is a recessive disorder characterized by attacks of fever and inflammation. A sustained inflammatory reaction is observed in the disease course, and cytokine levels such as interleukin (IL)-1, IL-6 and tumor necrosis factor-alpha (TNF-alfa) are shown to increase during and between

the attacks. In this study, we investigated the role of the functionally important IL-6 -174 G/C polymorphism in the clinical outcome of FMF and amyloidosis. One hundred and fifty-six FMF patients (80 with amyloidosis) and 90 healthy controls were studied. The genotype distributions and allele frequencies of the patients and the controls were found to be similar, and the differences between the groups were not statistically significant. The results show that IL-6 -174 G/C polymorphism is not associated with FMF and amyloidosis. The increase observed in cytokine levels during and between the attacks is more likely due to the inflammatory nature of the disease.

Generalized vitiligo is an acquired disorder in which patches of depigmented skin, overlying hair, and oral mucosa result from progressive autoimmune loss of melanocytes from the involved areas. Although vitiligo is perhaps the most common pigmentary disorder, insufficiently clear clinical definition of the disorder and lack of a good laboratory animal model have inhibited progress in understanding its pathobiology, its environmental triggers, and in developing specific and effective therapeutic approaches. Vitiligo results from a complex interaction of environmental, genetic, and immunologic factors, which ultimately contribute to melanocyte destruction, resulting in the characteristic depigmented lesions. In the past few years, studies of the genetic epidemiology of generalized vitiligo have led to the recognition that vitiligo is part of a broader, genetically-determined, autoimmune/autoinflammatory diathesis. Attempts to identify genes involved in vitiligo susceptibility have involved both allelic association studies of candidate genes and genome-wide linkage analyses to discover new genes, and these studies have begun to shed light on the mechanisms

of vitiligo pathogenesis. It is anticipated that the discovery of biological pathways of vitiligo pathogenesis will provide novel therapeutic and prophylactic targets for future approaches to the treatment and prevention of vitiligo and its associated autoimmune diseases.

Systemic cytokine levels and the effects of etanercept in TNF receptor-associated periodic syndrome (TRAPS) involving a C33Y mutation in TNFRSF1A.

Nowlan ML(1), Drewe E, Bulsara H, Esposito N, Robins RA, Tighe PJ, Powell RJ, Todd I.

Author information:

(1)Division of Immunology, University of Nottingham, Queen's Medical Centre, Nottingham NG7 2UH, UK.

**OBJECTIVE:** To investigate the levels of the pro-inflammatory cytokines IL-6, TNF-alpha, IL-1beta, IL-8, IL-10 and IL-12p70 in the plasma of patients with TNF receptor-associated periodic syndrome (TRAPS) in relation to CRP levels and treatment with etanercept.

**METHODS:** Cytokine concentrations were measured in sequential plasma samples obtained from eight patients with a C33Y mutation in TNFRSF1A and diagnosed with TRAPS, using cytokine bead array. The TRAPS samples were compared with samples from normal controls and rheumatoid arthritis patients.

**RESULTS:** Levels of IL-6 were significantly elevated in C33Y TRAPS patients and these correlated with CRP levels in some of the patients. IL-8 levels were also significantly elevated in the TRAPS patients. However, neither TNF-alpha nor IL-1beta demonstrated a similar increase. This differed from the patients with rheumatoid arthritis, for whom levels of IL-6, IL-8, TNF-alpha, IL-1beta and IL-10 were significantly elevated. The levels of detectable TNF-alpha in the TRAPS patients' plasma were elevated during etanercept treatment.

**CONCLUSIONS:** The cytokine profile of C33Y TRAPS differs from that of a typical autoimmune inflammatory condition such as rheumatoid arthritis, as only IL-6 and IL-8 were elevated in C33Y TRAPS patients, as distinct from a generalized

elevation of pro-inflammatory cytokines. However, only some of the C33Y patients tested showed a relationship between elevated IL-6 and CRP. This is consistent with clinical observations that there is marked heterogeneity between individuals with TRAPS, including those in the same family cohort. Although etanercept has a therapeutic effect in some TRAPS patients, it induces increased plasma concentrations of TNF-alpha, possibly by increasing TNF-alpha stability.

Hereditary periodic fever syndromes (HPF) are a group of diseases characterised by recurrences of fever and inflammation separated by symptom-free intervals. Familial Mediterranean fever (FMF) is the most frequent entity within this group of disorders which further consists of hyperimmunoglobulinaemia D and periodic fever syndrome (HIDS), tumour necrosis factor receptor-associated periodic syndrome (TRAPS) and cryopyrin-associated periodic syndrome (CAPS). In recent years the causative genes have been identified. Reactive amyloidosis is a severe complication of HPFs. This is caused by deposition of fibrils that consist of the proteolytically cleaved acute phase protein serum amyloid A (SAA). Several factors have been identified that modulate the risk for developing amyloidosis, including SAA concentrations, polymorphisms in the SAA gene and ethnic origin. Furthermore, the risk of developing amyloidosis varies widely between the different HPFs. Colchicine is the cornerstone in the management of FMF, as it reduces the severity and frequency of attacks and is also effective in preventing amyloidosis. In the other HPFs, the introduction of anticytokine-based therapies is a promising new option in treating these inflammatory conditions and they potentially can prevent amyloidosis.

fatos.onen@deu.edu.tr

Familial Mediterranean fever (FMF) is the most frequent hereditary inflammatory disease characterized by self-limited recurrent attacks of fever and serositis. It is transmitted in an autosomal recessive pattern and affects certain ethnic groups mainly Jews, Turks, Arabs, and Armenians. FMF is caused by mutations in MEFV gene, which encodes pyrin. This protein is expressed mainly in myeloid/monocytic cells and modulates IL-1 $\beta$  processing, NF- $\kappa$ B activation, and apoptosis. A mutated pyrin probably results in uncontrolled inflammation. The most devastating complication of FMF is amyloidosis, leading to chronic renal failure. M694V homozygosity, male gender and the  $\alpha/\alpha$  genotype of serum amyloid A1 gene are the currently established risk factors for development of amyloidosis. Daily colchicine is the mainstay of the therapy for the disease, resulting in complete remission or marked reduction in the frequency and duration of attacks in most patients. It is also effective in preventing and arresting renal amyloidosis.

Neutrophil chemotaxis in a patient with neonatal-onset multisystem inflammatory disease and Muckle-Wells syndrome.

Lokuta MA(1), Cooper KM, Aksentijevich I, Kastner DL, Huttenlocher A.

Author information:

(1)Department of Pediatrics, University of Wisconsin Medical School, Madison, Wisconsin 53706, USA.

**BACKGROUND:** Neonatal-onset multisystem inflammatory disease (NOMID)/chronic infantile neurologic, cutaneous, and articular syndrome is an autoinflammatory disease characterized by urticarial rash, arthropathy, and central nervous system inflammation.

**OBJECTIVE:** To describe a 13-year-old girl with overlapping symptoms of NOMID and Muckle-Wells syndrome who has a mutation in cryopyrin (NALP3).

**METHODS:** We examined neutrophil migration using transwell assay and time-lapse videomicroscopy. We also examined p38 mitogen-activated protein kinase (MAPK) activation in patient and control neutrophils using Western blot analysis.

**RESULTS:** Neutrophil defects in chemotactic migration were found to a variety of chemoattractants, including interleukin 8, N-formyl-methionyl-leucyl-phenylalanine, complement C5a, and leukotriene B4. Her neutrophils exhibited elevated basal and stimulated p38 MAPK activation in response to interleukin 8, N-formyl-methionyl-leucyl-phenylalanine, complement C5a, and leukotriene B4.

**CONCLUSIONS:** This study is the first, to our knowledge, to demonstrate defects in neutrophil chemotaxis and p38 MAPK signaling in a patient with NOMID and Muckle-Wells syndrome and a cryopyrin mutation.

[Pharmacological modulation of phagocytosis of granulocytes and monocytes in patients with familial Mediterranean fever].

[Article in Russian]

Avetisyan SA.

Disturbances in the regulation of phagocytic activity of neutrophils and monocytes (PANM) in whole peripheral blood of patients with Familial Mediterranean Fever (FMF), which had not receive treatment with colchicines, and the effect of drugs from various pharmacological groups on the PANM in the blood of these patients were studied in vitro by quantitative flow cytofluorimetry. A comparative study of the drug action showed that the most effective PANM inhibitors during FMF are colchicine and iodine-lithium-alpha-dextrin (armenicum), while synthetic glucocorticoids and sodium thiosulfate showed low activity and produced no significant effect. It was established that armenicum is capable of modulating the PANM-inhibition effect of colchicine, neutralizing the effect of TNF, and increasing the effect of glucocorticoids. was observed. Sodium thiosulfate produces inhibition of the activity of armenicum.

[The effect of colcichine and iodine-lithium-alpha-dextrin on the phagocytosis of granulocytes and monocytes in patients with familial Mediterranean fever].

[Article in Russian]

Akopian VP, Avetisian SA, Davtian TK.

Disturbances in the regulation of phagocytic activity of neutrophils and monocytes (PANM) in whole peripheral blood of patients with familial Mediterranean Fever (FMF), which had not received treatment with colchicines, were determined by quantitative flow cytofluorimetry. The effect of iodine-lithium-alpha-dextrin (armenicum) and colchicine on the PANM in the blood of FMF patients was studied in vitro. The intensity of phagocytosis in populations of neutrophils and monocytes in FMF patients (n = 6) during the remission period is higher than that during the FMF attack (n = 6) and higher than in healthy donors (n = 9). The PANM in patients during the FMF attack is higher compared to that in healthy donors. Iodine-lithium-alpha-dextrin (armenicum) and colchicine inhibited the phagocytosis of effector cells in FMF patients in a dose-dependent and time-dependent manner. It was shown that the suppressive effect of the drugs increased with decreasing bacteria/effector cells

ratio.

Oxidative burst response to monosodium urate crystals in patients with Behçet's syndrome.

Gogus F(1), Fresko I, Elbir Y, Eksioglu-Demiralp E, Direskeneli H.

Author information:

(1)Department of Physical Medicine and Rehabilitation, Division of Rheumatology, Gazi Medical Faculty, Ankara, Turkey. mtalat@ttnet.net.tr

**OBJECTIVE:** An erythematous response to intradermal injection of monosodium urate crystals (MSU) has been demonstrated in Behçet's syndrome (BS). To further elucidate the pathogenesis of this response, the effects of MSU on in vitro oxidative burst reaction of neutrophils and monocytes were investigated.

**METHODS:** Peripheral blood mononuclear cells from patients with Behçet's syndrome (BS), rheumatoid arthritis (RA), familial Mediterranean fever (FMF) and healthy controls (HC) were incubated with 100 ng/ml phorbol myristate acetate (PMA) and MSU at different dosages (25-500 microg/ml). Oxidative burst reaction was evaluated in neutrophils and monocytes by flow cytometry.

**RESULTS:** In patients with BS, oxidative burst of neutrophils was significantly increased compared to HC at 125 microg/ml and 250 microg/ml dosages of MSU ( $p < 0.001$  and  $0.004$  respectively). In patients with FMF; there was also an

increased oxidative burst reaction at 75 microg/ml, 250 g/ml and 500 microg/ml ( $p \leq 0.007$ ; 0.001 and 0.004 respectively). In patients with BS, oxidative burst of monocytes was increased only at 125 g/ml dosage of MSU ( $p \leq 0.002$ ). However, in patients with FMF monocyte burst response was increased at 25 microg/ml, 75 microg/ml and 125 g/ml ( $p \leq 0.004$ ;  $< 0.0001$ ;  $< 0.0001$  and 0.002 respectively). In RA group, stimulation with PMA resulted in a higher oxidative burst reaction than FMF and BS ( $p \leq 0.000$  and  $p \leq 0.008$ ). No correlation was observed between oxidative burst of neutrophils or monocytes and intradermal responses to MSU crystals.

**CONCLUSION:** Oxidative burst reaction with MSU is augmented in neutrophils and monocytes of BS. However, the response is not specific and is unassociated with skin dermal test which has a high specificity for BS.

Serum interleukin 17 and interleukin 18 levels in familial Mediterranean fever.

Haznedaroglu S(1), Oztürk MA, Sancak B, Goker B, Onat AM, Bukan N, Ertenli I, Kiraz S, Calguneri M.

Author information:

(1)Department of Rheumatology, Gazi University School of Medicine, Ankara, Turkey.

**OBJECTIVE:** Familial Mediterranean fever (FMF) attacks are characterized by serosal inflammation rich in PMNL leukocytes and activation of a definite cytokine network. Moreover, there is sustained inflammation in attack-free FMF patients. Interleukin (IL)-17 and IL-18 are recently described proinflammatory cytokines, which can modulate certain neutrophil functions. In this study we measured serum levels of IL-17 and IL-18 in FMF patients.

**METHODS:** The study groups comprised of 18 FMF patients in attack-free period (mean age: 30.2  $\pm$  9.5 years; male/female: 10/8), and 18 patients with an acute FMF attack (mean age: 25.4  $\pm$  4.9 years; male/female: 10/8). Twenty age-matched healthy subjects were included as a control group (male/female: 10/10). Levels of IL-17 and IL-18 were determined by commercial ELISA kits (Biosource

International, USA).

**RESULTS:** Serum IL-17 levels were  $42.8 \pm 3.7$ ,  $42.7 \pm 3.2$ , and  $39.9 \pm 2.3$  pg/mL for FMF patients in attack-free period, FMF patients with acute attack, and healthy controls, respectively. Serum IL-18 levels were  $878.8 \pm 315.0$ ,  $854.2 \pm 261.4$ , and  $314.6 \pm 80.8$  pg/mL for FMF patients in an attack-free period, FMF patients with acute attack, and healthy controls, respectively. Levels of both IL-17 and IL-18 were significantly higher in FMF patients with and without acute attack compared to control group ( $p < 0.05$ ). Concentrations of those cytokines were comparable in FMF patients with acute attack and in attack-free period ( $p > 0.05$ ).

**CONCLUSION:** Our data suggest that IL-17 and IL-18 contribute to the cytokine network in the inflammatory cascade of FMF. However, their roles for the initiation of FMF attacks remain to be established.

Behçet's disease and hereditary periodic fever syndromes: casual association or causal relationship?

Espinosa G(1), Arostegui JI, Plaza S, Rius J, Cervera R, Yagüe J, Font J.

Author information:

(1)Systemic Autoimmune Diseases Unit, Institut d 'Inves- tigacions Biomèdiques August Pi i Sunyer, Hospital Clinic, Barcelona, Catalonia, Spain.  
gespino@clinic.ub.es

**OBJECTIVE:** Mutations in the MEFV and the type 1 TNF receptor (TNFRSF 1A) genes have recently been linked to familial Mediterranean fever (FMF) and TNF receptor-associated periodic syndrome (TRAPS), respectively. A higher prevalence of Behçet's disease (BD) among FMF patients has been described compared to the general population. The aim of this study was to evaluate whether FMF TRAPS and BD could be genetically related.

**METHODS:** We screened a cohort of 50 BD patients and 100 healthy subjects for the common MEFV and TNFRSF 1A mutations. An initial screening of exons 10 and 2 of the MEFV gene and exon 4 of the TNFRSF 1A was performed in all chromosomes.

RESULTS: The heterozygous MEFV mutation (K695R) was found in one (2%) BD patient. Analysis for FMF mutations in the control group revealed that 5 (5%) individuals bore MEFV gene mutations (3 were heterozygous for the E148Q and 2 were heterozygous for the A744S). At codon 202, there were no differences in allele frequencies between BD and control population: 73%R 27%Q in the BD patients vs 75%R 25%Q in controls. Concerning mutations in the TNFRSF 1A gene, the R92Q mutation was present in heterozygous state in one (2%) BD patient and in 4 (4%) controls without differences between allele frequencies: 99%R 1%Q in BD patients vs 98%R 2%Q in controls, respectively. There was no association between the clinical manifestations of BD patients and the presence of a particular polymorphism or a mutation.

CONCLUSIONS: Neither FMF nor TRAPS are genetically associated with BD in our cohort of Spanish patients.

Erratum in

Clin Rheumatol. 2006 Nov;25(6):937. Tansu, Sav [corrected to Sav, Tansu]; Omer, Ozbakir [corrected to Ozbakir, Omer]; Fahrettin, Kelestimur [corrected to Kelestimur, Fahrettin]; Sebnem, Gursoy [corrected to Gursoy, Sebnem]; Mevlut, Baskol [corrected to Baskol, Mevlut]; Mustafa, Kula [correct.

OBJECTIVE: Familial Mediterranean fever (FMF) is a hereditary disease characterized by recurrent attacks of fever with peritonitis, arthritis, pleuritis or erysipelas-like rash. It is unclear what effects of FMF itself on endocrine system and hormones are. None of the FMF patients without amyloidosis have been reported to have any endocrine disorders, except those who developed colchicine-induced diabetes insipidus. There is a large body of evidence to show that cytokines (IL-1, IL-6 and TNF-alpha) activate the hypothalamic-pituitary-adrenal (HPA) axis. We have designated this study to investigate the HPA axis in FMF patients without amyloidosis.

**METHODS:** Twenty-one patients with FMF were included. ACTH stimulation test was performed on the healthy subjects and during attack period in the patients. In the patient group, same test was repeated during remission period.

**RESULTS:** Peak cortisol levels were significantly higher in the attack period than those in the remission period of patients ( $p<0.05$ ).

**CONCLUSION:** The cytokines play a role on the activation of the HPA axis; we thought the axis would be affected in this disease. The response of cortisol to 250 mug ACTH was significant in attack period when compared with remission period. This result reveals that HPA axis is more activated in an FMF attack. Previous studies suggest that the adrenal hormones increase in acute inflammatory events, and eventually, the changes on these hormones are related to TNF and IL-6 levels. During the FMF attack, HPA axis may be stimulated by cytokines. It seems that HPA axis is regulated normally in FMF patients.

Author information:

(1)Department of Pediatric Rheumatology, Children's Hospital, Olgahospital, Bismarckstrasse 8, D-70176 Stuttgart, Germany. a.hospach@olgahospital.de

Hyperimmunoglobulinemia D with periodic fever syndrome (HIDS) is a recessively inherited recurrent fever syndrome. We describe a family of 2 monozygotic twins and their mother with characteristic symptoms of HIDS, but normal levels of IgD and IgA, and with a dominant inheritance pattern. Mevalonate kinase (MK) activity was deficient in both children, and analysis of the MVK gene revealed compound heterozygosity for 2 new mutations, G25G and R277H. Being positioned adjacent to a donor splice site, the G25G mutation was shown by reverse transcription-polymerase chain reaction analyses to cause aberrant splicing of the MVK messenger RNA, thus being disease-relevant. The mother, who was also symptomatic during her childhood and adolescence, was a compound heterozygote for I268T and R277H. Our findings expand the genetic and ethnic spectrum of HIDS and show that the possible presence of this disease cannot be excluded based solely on inheritance patterns. In each case in which HIDS is clinically suspected, analysis of MK activity and/or the MVK gene (especially exons 9 and 11) should be performed.

MEFV analysis is of particularly weak diagnostic value for recurrent fevers in Western European Caucasian patients.

Tchernitchko D(1), Moutereau S, Legendre M, Delahaye A, Cazeneuve C, Lacombe C, Grateau G, Amselem S.

Author information:

(1)Service de Biochimie et de Génétique Moléculaire, INSERM U654, Hôpital Henri-Mondor, 51 Avenue de Maréchal de-Lattre-de-Tassigny, 94010 Creteil, France. dimitri.tchernitchko@im3.inserm.fr

**OBJECTIVE:** Familial Mediterranean fever (FMF) is an autosomal-recessive disorder characterized by recurrent attacks of fever, with abdominal, thoracic, or articular pain. FMF is particularly common in Mediterranean populations, while

other populations are rarely affected. MEFV gene analysis provides the only objective diagnostic criterion for FMF. However, the spectrum of MEFV mutations, which was first established in classically affected populations, remains insufficiently studied in other populations. The purpose of this study was to assess involvement of MEFV in the phenotype of western European Caucasian patients with a clinical diagnosis of FMF.

**METHODS:** Mutation analysis was performed in 208 Caucasian patients from western Europe, by screening for the most common MEFV mutations in exons 2, 3, 5, and 10, and by sequencing the promoter region and the whole MEFV coding sequence in 21 of these patients.

**RESULTS:** None of the patients carried 2 mutated alleles. Only 2 patients carried 1 mutated allele.

**CONCLUSION:** FMF-like syndromes in western European Caucasian populations cannot be explained by MEFV mutations. These results should be helpful in avoiding laborious and costly MEFV molecular analyses that, at the population level, seem to be of poor diagnostic value in the case of western European Caucasian patients, and rather should prompt a search for other causes in those patients.

The anemia of familial Mediterranean fever disease.

Celkan T(1), Celik M, Kasapçopur O, Ozkan A, Apak H, Ocak S, Arisoy N, Yildiz I.

Author information:

(1)Department of Pediatric Hematology-Oncology, Istanbul University Faculty of Medicine, Istanbul, Turkey. tirajecelkan@yahoo.com

The aim of this study was to evaluate the incidence of anemia detected in familial Mediterranean fever (FMF) and the effect of disease activity and colchicine therapy along with interleukins to laboratory tests, including serum transferrin receptor (TfR), in the diagnosis of anemia seen in FMF in children. After detecting anemia in 63.4% of 172 FMF patients followed up by our rheumatology outpatient polyclinics, it was decided to study 3 groups of patients: group 1, 17 newly diagnosed FMF patients; group 2, 36 FMF patients on

colchicine therapy; and group 3, 17 healthy children as control for the symptom of anemia. All 3 groups of patients were investigated for their hematological parameters, iron status, including soluble transferrin receptor (sTFR) concentrations and sTFR index, and IL-6 levels. Anemia ratio was 9/17, 53%; 11/36, 31%; and 1/17, 5% in the groups 1, 2 and 3, respectively. There was a significant difference between hemoglobin (Hb) values in the first group and the second (patients who were on colchicine therapy). Furthermore, in the second group there was a significant difference between the Hb concentrations at the time of diagnosis and after colchicine therapy ( $p = .003$ ). There was a positive correlation between Hb and plasma iron and transferrin saturation in group 1 and disease beginning age, iron, transferrin saturation, and erythrocyte sedimentation rate (ESR) in the second group. In the first group the anemic patients' iron and transferrin saturation were significantly lower than normal, while ferritin levels were higher. In the second group, a good correlation was found with ESR and Hb levels; the higher ESR values were detected in patients with lower Hb values. Of the anemic and nonanemic patients of the first and second groups, values for interleukin 6 and iron parameters, including sTFR, were found similar. Anemia detected in FMF patients was found related to iron status more than interleukins. Colchicine therapy had a positive effect on anemia as well as on disease activity. Resolution of symptoms of FMF occurred with correction of the anemia, if the patient ESR values also decreased on colchicine therapy.

**BACKGROUND/AIMS:** Three missense mutations clustered on the carboxyl-terminal portion of the MEFV gene (M680I, M694V, and V726A) have been observed in over 80% of affected alleles in several ethnic groups of familial Mediterranean fever patients. Several immunologic abnormalities were found both in cellular and humoral components in Mediterranean fever patients. Those observations have pointed the way for analysis of the HLA region in Mediterranean fever. We intended to compare HLA DR/DQ alleles with those major mutations in the MEFV gene in Mediterranean fever patients.

**METHODS:** The distribution of MEFV gene mutations and HLA-DR, HLA-DQ alleles were analyzed in 40 index Turkish Mediterranean fever patients, 28 family members and 42 healthy controls. M680I, M694V, and V726A mutations were studied by amplification refractory mutation system-polymerase chain reaction (ARMS-PCR) analysis. HLA-DR and DQ allele subgroups were studied using SSP-PCR technique.

**RESULTS:** A total of 37 (92.5%) patients in 40 Mediterranean fever index patients were found to carry one of the three missense mutations. The HLA-DR4 allele frequency was significantly higher in the Mediterranean fever patient group. When comparisons were made between Mediterranean fever mutations and HLA allele frequencies, M694V mutation with HLA DR3, DR11/5 and DR 13/6 and M680I mutation with DR7 allele subgroups were statistically significant. DQ6/1, DQ7/3, and DQ8/3 allele with M694V, DQ2 allele with M680I, and DQ6/1 with V726A mutations were also statistically significant.

**CONCLUSIONS:** Our results indicate a relationship between some HLA-DR/DQ alleles and MEFV mutations in Mediterranean fever patients. We suggest HLA-DR/DQ alleles and their role in the pathogenesis of Mediterranean fever need further analysis and comparative studies.

Approach to genetic analysis in the diagnosis of hereditary autoinflammatory syndromes.

Simon A(1), van der Meer JW, Vesely R, Myrdal U, Yoshimura K, Duys P, Drenth JP; International HIDS Study Group.

Author information:

(1)Division of General Internal Medicine, 541, Department of Medicine, Radboud University Nijmegen Medical Centre, Nijmegen, The Netherlands.  
a.simon@aig.umcn.nl

**OBJECTIVE:** Hereditary autoinflammatory syndromes are characterized by recurrent episodes of fever and inflammation. Seven subtypes have been described, caused by mutations in four different genes. Apart from a common phenotype of lifelong recurrent inflammatory attacks, all subtypes have distinct features and specific therapeutic options, which emphasizes the need for a specific diagnosis in each case. Our aim was to examine whether genetic screening would allow classification of previously unclassified patients, and whether individual patients suffering from an autoinflammatory syndrome carry additional mutations in one of the other autoinflammatory genes.

**METHODS:** We included 60 patients with an unclassified autoinflammatory syndrome, 87 patients diagnosed with either hyper-IgD syndrome, familial Mediterranean fever (FMF) or tumour necrosis factor (TNF)-receptor-associated periodic syndrome and 50 healthy controls. Deoxyribonucleic acid samples were screened for the most prevalent mutations in the MEFV, TNFRSF1A, MVK and CIAS1 genes.

**RESULTS:** We found only one possible diagnosis of FMF in the 60 previously unclassified patients. Two low-penetrance mutations were found in equal numbers in the groups of patients and controls.

**CONCLUSIONS:** Screening of highly prevalent mutations in known genes involved in these disorders does not yield additional relevant information. Differential diagnosis of hereditary autoinflammatory syndromes can be made by thorough clinical examination followed by targeted genetic analysis of the one or two most likely syndromes. High-prevalence low-penetrant mutations from autoinflammatory genes do not occur more frequently in patients with hereditary autoinflammatory syndromes compared with the general population.

Familial Mediterranean fever (FMF) is an autosomal recessive inherited disease characterized by recurrent fever, serositis and arthritis. The disease is highly prevalent in Mediterranean basin populations. Recently, the gene responsible for FMF (MEFV) was cloned and at least 40 MEFV gene mutations have been identified. The most frequently observed mutations in the MEFV gene are M694V, M694I, M680I, and V726A. These occur within exon 10 of the gene, and account for 85% of the known MEFV alleles. In this study, the reliability and economical aspects of amplification refractory mutation system (ARMS) and polymerase chain reaction-restriction fragment length polymorphism (PCR-RFLP) techniques were compared for analyzing the frequencies of the major point mutations of 90 unrelated patients with FMF from the Cukurova region in Turkey. Both techniques yielded similar results: The ratio of independent alleles of 90 patients carrying one of the tested mutations was 81.1%; patients consisted of 12 different genotypes. In 64 of 90 patients (71.1%) mutations were observed in both alleles. Thirty-six patients (40%) were homozygous for the same mutation, 28 (31.1%) were heterozygous for different mutations. Eighteen patients (20%) were heterozygous for one allele with one of the four mutations but the other allele was unknown. In 8 patients (8.8%) no mutation could be detected. The most frequently observed mutation was M694V (51.66%), followed by M680I (17.22%), V726A (10.55%), and M694I (1.66%). In conclusion ARMS and PCR-RFLP techniques were equally reliable to detect the mutations in Turkish FMF patients. However, the ARMS technique was found to be more rapid and economical than the PCR-RFLP techniques.

antonio.brucato@ospedaleniguarda.it

Idiopathic recurrent acute pericarditis (IRAP) is suspected to be an autoimmune phenomenon. We studied 46 consecutive patients. We looked for: 1) the occurrence of new diagnoses of autoimmune diseases during our follow up; 2) HLA typing; and 3) the presence of the most frequent mutations linked to familial Mediterranean fever (FMF gene or MEFV). HLA typing was done in 21 patients at loci B, DRB1, DQA1 and DQB1. MEFV gene was looked in 23 patients using specific primers. During the follow-up we made a new diagnosis of primary Sjögren's syndrome in four patients (8.7%) and of rheumatoid arthritis in one patient (2.2%). HLA B14, DRB1\*01 and DQB1\*0202 were significantly more prevalent, but we did not find a typical HLA typing. MEFV gene was searched: exon 10 was checked by sequence and the E148Q mutation by restriction site analysis. No mutations were found. In conclusion, the prevalence of definite immunorheumatological diseases and the absence of the mutations linked to FMF reinforce the notion that idiopathic acute recurrent pericarditis is an autoimmune condition.

stojanos@mail.nih.gov

The tumour necrosis factor receptor (TNFR)-associated periodic syndrome (TRAPS) is an autosomal dominant, multisystemic, autoinflammatory disorder caused by mutations in the TNFR1 gene ( TNFRSF1A ). Traps seems to be the most common hereditary periodic fever (HPF) syndrome in some western populations, and the second most prevalent HPF worldwide, behind familial mediterranean fever (FMF). The proteins involved in susceptibility to TRAPS (TNFRSF1A) and FMF (pyrin) are both members of the death-domain-fold superfamily. Mutations affecting these proteins might cause dysregulation of innate immune responses, with a propensity to autoinflammation. Most TRAPS patients have reduced blood levels of soluble TNFRSF1A between attacks, with an inappropriately small increase during bouts of fever. The pathogenesis of the 'hyperinflammatory state' in TRAPS has been variously ascribed to a shedding defect of TNFRSF1A from the cell surface resulting in increased TNF inflammatory signalling, or impaired TNF apoptotic signalling. Some low-penetrance TNFRSF1A variants also contribute to the clinical phenotype in individuals carrying other HPF-associated mutations, and have been reported in several disorders such as Behçet's disease and systemic lupus erythematosus. Synthetic anti-TNF agents provide a rational form of therapy for TRAPS, and have been shown to delay or indeed prevent development of systemic amyloidosis (AA type), a life-threatening complication in this condition.

Author information:

(1)Baskent University, Department of General Surgery, Transplantation Unit, Ankara, Turkey.

Amyloidosis is characterized by the accumulation of an amorphous material in various organs and tissues secondary to a variety of inflammatory, immune, infectious, and hereditary diseases. Since 1975, our transplantation team has performed 1470 renal transplantations. Between 1985 and July 2004, among 1159

kidney transplantations, 953 (82.3%) were from living donors and 206 (17.7%) from cadaveric donors. There were 32 recipients (28 men, 4 women; mean age, 31.4 +/- 1.7 years; range, 21 to 48 years) with amyloidosis, including, 28 (87.5%) who received grafts from living donors and 4 (12.5%) from cadaveric donors.

Amyloidosis was secondary to familial Mediterranean fever in 22 (68.7%) patients and rheumatoid arthritis in 1 (3.1%). The remaining 9 (28.1%) patients had primary amyloidosis. The mean follow-up time was 51.2 +/- 5.7 months (range, 2-124 months). Mean HLA mismatch rate was 2.2 +/- 1. Twenty-six (81.2%) patients are alive at this time with functioning grafts, and a mean serum creatinine value of 2.1 +/- 1.5 ng/dL. The 1- and 5-year patient and graft survival rates were 90.6% and 84.3%, and 81.2% and 68.7%, respectively. We conclude that patients with amyloidosis may undergo kidney transplantation safely expecting outcomes similar to those patients who receive transplantations for other reasons.

**OBJECTIVES:** Recent identification of several mechanisms by which statins decrease recruitment of monocytes and T cells into the arterial wall and inhibit both T-cell and B-cell activation and proliferation in vitro prompted us to study the immunomodulatory effects of statins. In this study, we examined the effect of simvastatin therapy on lymphocyte cross-match positivity in kidney transplantation candidates.

**METHODS:** Simvastatin therapy (20 mg/d) was administered to 25 patients (18 men, 7 women of mean age 34 +/- 11.7 years who displayed positive lymphocyte cross-matches between July 2002 and October 2004. The etiologies of end-stage

renal disease were vesicoureteral reflux (n = 5), urinary stone disease (n = 4), glomerulonephritis (n = 6), amyloidosis secondary to familial Mediterranean fever (n = 1), and unknown (n = 9).

RESULTS: The lymphocyte cross-match became negative in 10 patients 4-9 months, and successful kidney transplantation was performed in 6 of them. The serum creatinine levels of these patients ranged between 0.8 and 1.4 mg/dL. Two patients required higher doses, but none suffered from adverse effects. The remaining 4 patients are still undergoing pretransplantation evaluation.

CONCLUSION: Simvastatin therapy seems to be a cost-effective and useful method for lymphocyte cross-match-positive kidney transplantation candidates compared with immunoadsorption or intravenous immunoglobulin use.

Chromosomal abnormalities and birth defects among couples with colchicine treated familial Mediterranean fever.

Berkenstadt M(1), Weisz B, Cuckle H, Di-Castro M, Guetta E, Barkai G.

Author information:

(1)Danek Gertner Institute of Human Genetics, Sheba Medical Center, Tel Hashomer, Israel. mberken@sheba.health.gov.il

OBJECTIVE: To determine whether colchicine prescribed for familial Mediterranean fever is teratogenic.

STUDY DESIGN: Reproductive histories were analyzed from 326 couples referred for prenatal diagnosis because 1 partner was affected. Numbers of chromosomal abnormalities and birth defects were compared with numbers expected from published rates.

RESULTS: There were 901 pregnancies, and amniocentesis had been performed in 566, all but 3 conceived while taking colchicine. Seven numerical chromosomal abnormalities were found, not statistically significantly greater than the 4.99 expected from maternal age and gestation of diagnosis ( $P = .24$ ): unbalanced structural abnormalities were 6, compared with 3.22 expected ( $P = .11$ ). There were 7 birth defects, a considerably lower rate than reported in local

malformation registers.

**CONCLUSION:** The current policy of routine amniocentesis in pregnancies of couples taking colchicine should not be changed until sufficient data accumulates to establish whether the higher number of chromosomal anomalies in this group is significant.

skaslan@science.ankara.edu.tr

Familial Mediterranean Fever (FMF) is an autosomal recessive hereditary disease leading mostly to renal failure and nephrotic syndrome. The ultrastructure of kidney has not been fully investigated in FMF associated renal disease. The aim of this study is to provide further evidence on the ultrastructure of kidney in patients with FMF who suffer from renal disease. Renal biopsies obtained from two patients who were diagnosed with FMF renal disease complications were examined. Examination of renal tissue by light and electron microscopy identified degenerations both in tubules and the filtration barrier. Foot processes were partly effaced. Amorphous material was found in thickened glomerular basement membranes. Fibrous material deposits in thick Bowman's capsule wall were also seen. Finally, degeneration in the form of folding of plasma membrane and vacuolization as well as fusion in mitochondria cristae, was observed. Accumulation of tissue remnants in the lumen was also found in tubules.

[Periodic fever: the first Portuguese case-report of hyper-IgD syndrome (HIDS)].

[Article in Portuguese]

Abreu TT(1).

Author information:

(1)Serviço de Medicina 2, Hospital do Espírito Santo, Evora.

**BACKGROUND:** Periodic fever can have one of multiple causes. Among the hereditary periodic fever syndromes, hyper-IgD syndrome (HIDS) is a possible diagnosis, although, until now, no cases had been described in Portugal.

**CASE-REPORT:** We report a 25-year-old woman, with periodic fever since she was 8 months old. She had high serum IgD levels, and a molecular study of the mevalonate kinase gene was performed. A compound heterozygote was found for two mutations: V377I and T237S. This last mutation had not been observed before.

**DISCUSSION:** We analyse the clinical features that made us think on HIDS as a possible diagnosis, and we highlight the features that are important for the differential diagnosis between HIDS and other periodic fevers.

**CONCLUSIONS:** HIDS is a possible diagnosis for patients with periodic fever, even in Portugal.
