**OBJECTIVE:** Gouty arthritis and familial Mediterranean fever (FMF) share some clinical and pathological features such as being classified as auto inflammatory disease, association with inflammasome, short-lived intermittent arthritis, and good response to colchicine and anti-interleukin-1 treatments. As Mediterranean fever (MEFV) gene is the causative factor of FMF, we aimed to investigate the prevalence of MEFV gene mutations and their effect on disease manifestations in Turkish gouty arthritis patients.

**METHODS:** Ninety-seven patients diagnosed with primary gouty arthritis (93M and 4 F, 54 [37-84] years) and 100 healthy controls (94M and 6 F, 57 [37-86] years) included in the study. All subjects were genotyped for the MEFV variations. Number of gout attacks, diuretic use, and history of nephrolithiasis and presence of tophus were also recorded.

**RESULTS:** The carriage rate of MEFV mutations for patients and controls were 22.7% (n=22) and 24% (n=24) respectively. The comparison of the patient and control groups yielded no significant difference in terms of the MEFV mutations carriage rate (p=0.87). The allelic frequencies of the MEFV mutations in patients were 11.9% (n=23) and 14% (n=28) in controls (p=0.55). The presence of MEFV variants did not show any association with clinical features of gouty arthritis. The subgroup analysis of patients revealed that gouty arthritis patients with mutations had similar frequencies of tophus, history of nephrolithiasis and podagra compared to the ones without mutations (p>0.05).

**CONCLUSIONS:** This study does not provide support for a major role of MEFV mutations in Turkish gouty arthritis patients.

Mevalonate kinase deficiency (MKD) is a rare autosomal recessive autoinflammatory metabolic disease that is caused by mutations in the MVK gene. Patients with MKD typically have an early onset in infancy. MKD is characterized by recurrent episodes of high fever, abdominal distress, diffuse joint pain, and skin rashes. In a subset of patients, MKD is also associated with elevated serum immunoglobulin D (IgD) levels (hyperimmunoglobulinemia D syndrome, HIDS). The clinical phenotype of MKD varies widely and depends on the severity of the impaired mevalonate kinase activity. Complete impairment results in the severe metabolic disease, mevalonic aciduria, while a partial deficiency results in a broad spectrum of clinical presentation, including HIDS. The precise molecular mechanisms behind the elevated serum IgD levels and inflammation that occurs in MKD remain unknown. Children who exhibit symptoms of MKD should be tested for mutations in the MKD gene. However, the complexity of MKD often results in delays in its definitive diagnosis and the outcome in adult age is not completely known. Therapeutic options for MKD are based on limited data and include non-steroidal anti-inflammatory drugs, corticosteroids, and biological agents that target specific cytokine pathways. In recent years, some studies have reported promising results for new biological drugs; however, these cases have failed to achieve satisfactory remission. Therefore, further studies are needed to understand the

pathogenesis of MKD and identify innovative therapeutic tools for its management.

Periodic fever syndromes are a group of diseases characterized by episodes of fever with healthy intervals between febrile episodes. In the first part of this paper, we presented a guideline for approaching patients with periodic fever and reviewed two common disorders with periodic fever in Iranian patients including familial Mediterranean fever (FMF) and periodic fever syndromes except for periodic fever, aphthous stomatitis, pharyngitis, and cervical adenitis (PFAPA). In this part, we review other autoinflammatory disorders including hyper IgD, tumor necrosis factor receptor-associated periodic syndrome (TRAPS), cryopyrin associated periodic syndromes, autoinflammatory bone disorders and some other rare autoinflammatory disorders such as Sweet's and Blau syndromes. In cryopyrin associated periodic syndromes group, we discussed chronic infantile neurologic cutaneous and articular (CINCA) syndrome, Muckle-Wells syndrome and familial cold autoinflammatory syndrome. Autoinflammatory bone disorders are categorized to monogenic disorders such as pyogenic arthritis, pyoderma gangraenosa and acne (PAPA) syndrome, the deficiency of interleukin-1 receptor antagonist (DIRA) and Majeed syndrome and polygenic background or sporadic group such as chronic recurrent multifocal osteomyelitis (CRMO) or synovitis, acne, pustulosis, hyperostosis and osteitis (SAPHO) syndrome are classified in sporadic group. Other autoinflammatory syndromes are rare causes of periodic fever in Iranian system registry.

Although colchicine has been a focus of research, debate, and controversy for thousands of years, the US Food and Drug Administration just approved it in 2009. Over the past decade, advances in the knowledge of colchicine pharmacology, drug safety, and mechanisms of action have led to changes in colchicine dosing and to potential new uses for this very old drug. In this review, we discuss the pharmacologic properties of colchicine and summarize what is currently known about its mechanisms of action. We then discuss and update the use of colchicine in a variety of illnesses, including rheumatic and, most recently, cardiovascular diseases.

Comment in

Anatol J Cardiol. 2015 Aug;15(8):669-70.

**OBJECTIVE:** This study assessed the early changes in regional and global systolic and diastolic myocardial functions in patients with familial Mediterranean fever without any cardiovascular symptoms using tissue Doppler and strain and strain rate echocardiography and compared them to the results of a control group.

**METHODS:** This study has a cross-sectional and observational design. FMF patients with normal left ventricular function were included in the study. We excluded

patients who had arrhythmia, acquired/congenital heart disease, pericarditis, or acute attack. We compared 45 children with familial Mediterranean fever on colchicine therapy and 45 age- and sex-matched healthy children.

**RESULTS:** The 45 patients with familial Mediterranean fever included 24 (55.3%) girls and 21 (46.7%) boys with a mean age of  $11.3 \pm 3.7$  (range 2-18) years. The mean disease duration was  $4.6 \pm 2.4$  (range 0.5-10) years. In the patient group, the homozygous M694V mutation was the most common (64.4%) mutation. The patients with familial Mediterranean fever had statistically lower longitudinal global strain, radial global strain, and strain rates ( $-14.44 \pm 4.77\%$ ,  $14.80 \pm 6.29\%$ , and  $0.59 \pm 0.24$  s, respectively) than the controls ( $-17.40 \pm 1.79\%$ ,  $17.53 \pm 4.63\%$ , and  $0.83 \pm 0.51$  s) ( $p < 0.05$ ). The circumferential global strain did not differ significantly between the groups.

**CONCLUSION:** Patients with familial Mediterranean fever who are subclinical from a cardiac aspect might have normal left ventricular function as measured by conventional echocardiography. However, the disease affects their myocardial tissue, and these patients should be followed with conventional, strain, and strain rate echocardiography techniques regularly.

Intravenous immunoglobulins (IVIG) in systemic sclerosis: a challenging yet promising future.

Cantarini L(1), Rigante D, Vitale A, Napodano S, Sakkas LI, Bogdanos DP, Shoenfeld Y.

Author information:

(1)Research Center of Systemic Autoinflammatory Diseases and Behçet's Disease Clinic, Department of Medical Sciences, Surgery and Neurosciences, University of Siena, Siena, Italy, cantariniluca@hotmail.com.

The etiology and pathogenesis of systemic sclerosis are still largely unknown, but a variety of humoral and cellular autoimmune phenomena have been documented. In addition, the rarity of the disease, the broad spectrum of clinical

manifestations, and the relevant risk of severe complications as well as the highly variable disease course render its management a major challenge. Some immunomodulatory agents have been used, but no single agent has given a convincing proof of effectiveness, and treatment has remained largely symptomatic through recent years. Novel therapies are currently being tested and may have the potential of modifying the disease process and overall clinical outcome. Efficacy of intravenous immunoglobulins (IVIG) in different regimens (1-2 g/kg of body weight, administered over 2-5 consecutive days) has been described in a limited number of trials and small case series, showing benefits in skin, articular, and lung interstitial disease symptoms. However, studies on IVIG in systemic sclerosis still remain few, and further randomized controlled trials should be undertaken to assess their clinical effectiveness or define the optimal dosage and times of administration.

**BACKGROUND:** Primary immunodeficiency disorders (PID) are a group of hereditary disorders characterized by an increased susceptibility to severe and recurrent infections, autoimmunity, lymphoproliferative disorders, and malignancy.

**OBJECTIVE:** To evaluate the demographic and clinical data of PID patients diagnosed in a referral pediatric hospital.

**METHOD:** All PID cases with a confirmed diagnosis, according to the criteria of International Union of Immunological Societies, who were referred to the Children's Medical Center in Tehran, Iran, between March 2006 and March 2013 were enrolled in this retrospective cohort study.

RESULTS: Three-hundred and seven PID patients were investigated. Predominantly antibody deficiencies were the most common group of PID observed in 118 cases (38.4%), followed by the well-defined syndromes with immunodeficiency in 52 (16.9%), congenital defects of phagocyte in 45 (14.7%), combined immunodeficiencies in 36 (11.7%), autoinflammatory disorders in 34 (11.4%), immune dysregulation in 11 (3.6%), complement deficiencies in 7 (2.3%), and defects in innate immunity in 3 (1%). Selective IgA deficiency was the most prevalent disorder which affected 46 individuals (14.9%). The median diagnostic delay was 15 months.

CONCLUSION: Increased awareness and availability of diagnostic tests could result in the better recognition of more undiagnosed PID cases and a decrease in diagnostic delay.

In this paper I describe more than 30 years of investigations of the autoinflammatory syndrome hyper-IgD syndrome (HIDS). In the first paper after the recognition of the syndrome published in 1984, we described the characteristics of this periodic fever syndrome. The hypotheses regarding the pathogenesis of the fever and the acute phase response in these patients prompted us to study interleukin-1 (IL-1), the cytokine formerly described as endogenous pyrogen and lymphocyte activating factor. Although we were unable to find elevated concentrations of IL-1 in the circulation, we discovered that white blood cells spontaneously produced elevated amounts of IL-1 $\beta$ . A major next discovery was the identification of the gene defect by us and others in 1999: quite unexpectedly the mevalonate kinase, an enzyme in the cholesterol synthesis pathway was found to be mutated. We were able to describe a founder effect and a phenotypic continuum with the classical mevalonate aciduria in the years to follow. A major step forward was the finding that recombinant interleukin-1 receptor antagonist (anakinra) was an effective treatment for the majority of patients. Thus, research over a period of three decades after the first recognition of the syndrome, has yielded much insight into the pathogenesis as well as an effective therapy for HIDS.

(#)Contributed equally

Several programmed lytic and necrotic-like cell death mechanisms have now been uncovered, including the recently described receptor interacting protein kinase-3 (RIPK3)-mixed lineage kinase domain-like (MLKL)-dependent necroptosis pathway. Genetic experiments have shown that programmed necrosis, including necroptosis, can play a pivotal role in regulating host-resistance against microbial infections. Alternatively, excess or unwarranted necroptosis may be pathological in autoimmune and autoinflammatory diseases. This review highlights the recent advances in our understanding of the post-translational control of RIPK3-MLKL necroptotic signaling. We discuss the critical function of phosphorylation in the execution of necroptosis, and highlight the emerging regulatory roles for several ubiquitin ligases and deubiquitinating enzymes. Finally, based on current evidence, we discuss the potential mechanisms by which the essential, and possibly terminal, necroptotic effector, MLKL, triggers the disruption of cellular membranes to cause cell lysis.

TNF antagonists opened the way to personalized medicine in rheumatoid arthritis.

Breedveld F(1).

Author information:

(1)Leiden University Medical Center, Leiden, The Netherlands.

Rheumatoid arthritis (RA) is an autoimmune disease resulting from a largely unknown interaction between genetically determined and environmental factors. Progress in the understanding of this chronic inflammation in the synovial lining of joints has led to the insight that one cytokine, tumor necrosis factor (TNF), has an important role. This insight started the development of a series of targeted and highly effective therapeutics for RA and a range of other autoinflammatory diseases. RA has changed from a severely debilitating disease into a disease where progression can be stopped in most of the patients.

An expanding role for interleukin-1 blockade from gout to cancer.

Dinarello CA(1).

Author information:

(1)Department of Medicine, Division of Infectious Diseases, University of Colorado Denver, Aurora, Colorado, United States of America; and Department of Medicine, Radboud University, Nijmegen, the Netherlands.

There is an expanding role for interleukin (IL)-1 in diseases from gout to cancer. More than any other cytokine family, the IL-1 family is closely linked to innate inflammatory and immune responses. This linkage is because the cytoplasmic segment of all members of the IL-1 family of receptors contains a domain, which is highly homologous to the cytoplasmic domains of all toll-like receptors (TLRs). This domain, termed "toll IL-1 receptor (TIR) domain," signals as does the IL-1 receptors; therefore, inflammation due to the TLR and the IL-1 families is nearly the same. Fundamental responses such as the induction of cyclo-oxygenase type 2, increased surface expression of cellular adhesion molecules and increased gene expression of a broad number of inflammatory molecules characterizes IL-1 signal transduction as it does for TLR agonists. IL-1 $\beta$  is the most studied member of the IL-1 family because of its role in mediating autoinflammatory disease. However, a role for IL-1 $\alpha$  in disease is being validated because of the availability of a neutralizing monoclonal antibody to human IL-1 $\alpha$ . There are presently three approved therapies for blocking IL-1 activity. Anakinra is a recombinant form of the naturally occurring IL-1 receptor antagonist, which binds to the IL-1 receptor and prevents the binding of IL-1 $\beta$  as well as IL-1 $\alpha$ . Rilonacept is a soluble decoy receptor that neutralizes primarily IL-1 $\beta$  but also IL-1 $\alpha$ . Canakinumab is a human monoclonal antibody that neutralizes only IL-1 $\beta$ . Thus, a causal or significant contributing role can be established for IL-1 $\beta$  and IL-1 $\alpha$  in human disease.

Lupus erythematosus and neutrophilic urticarial dermatosis: a retrospective study of 7 patients.

Gusdorf L(1), Bessis D, Lipsker D.

Author information:

(1)From the Faculté de Médecine (LG, DL), Université de Strasbourg; Clinique Dermatologique, Hôpitaux Universitaires de Strasbourg, Strasbourg; Faculté de Médecine (DB), Université Montpellier I; Service de Dermatologie, Hôpital Saint Eloi, CHU Montpellier; and Study Group of Systemic Diseases in Dermatology (EMSED: Etude des Maladies Systémiques en Dermatologie) (DB, DL), France.

Neutrophilic urticarial dermatosis (NUD) resembles urticaria clinically but is a neutrophilic dermatosis histopathologically. The majority of patients with NUD have an underlying systemic condition, mainly, autoinflammatory disorders such as cryopyrin-associated periodic syndromes, Schnitzler syndrome, and adult-onset Still disease, but a few also have systemic lupus erythematosus (LE). Here, we confirm these data and we report relevant clinical and histopathological data of 7 patients with LE and NUD. We retrospectively retrieved the medical records of all patients with LE in whom skin biopsy showed NUD in registers of Strasbourg and Montpellier University hospitals since 2000. All were female and aged between 13 and 45 years. Skin lesions were typically rose or red macules or slightly elevated papules occurring in a wide distribution. Individual lesions resolved within 24 hours and were not or only slightly itchy. Every patient had associated signs, most of the time polyarthritis and/or fever. NUD was the presenting mode of LE in 2 patients. NUD was misdiagnosed as a classic lupus flare and led to therapeutic intensification with the introduction of immunosuppressive drugs in 4 patients. Histopathological findings consisted of intense neutrophilic interstitial and perivascular infiltrate with leukocytoclasia and without fibrinoid necrosis of vessel walls. Direct immunofluorescence testing showed a lupus band in 4 patients. Antinuclear antibodies were always positive, anti-dsDNA antibodies were positive in 5 patients, and anti-Ro/SSA antibodies in 6 patients.

Immunosuppressive drugs such as prednisone, hydroxychloroquine, mycophenolate mofetil, and methotrexate were never effective to treat NUD. Antihistamines were effective in 1 patient and dapsone or colchicine was effective in 5 patients. NUD is not exceptional in patients with systemic LE and is easily misdiagnosed as an acute LE flare. Furthermore, we show that conventional immunosuppressive LE treatments are not efficient and we underline the major interest of dapsone and colchicine, classic neutrophil migration inhibitors, in those patients.

Neutrophilic skin lesions in autoimmune connective tissue diseases: nine cases and a literature review.

Hau E(1), Vignon Pennamen MD, Battistella M, Saussine A, Bergis M, Cavelier-Balloy B, Janier M, Cordoliani F, Bagot M, Rybojad M, Bouaziz JD.

Author information:

(1)From the Dermatology Department (EH, AS, MJ, FC, MarB, MR, JDB) and Pathology Department (MDVP, MaxB, BCB), Paris Diderot University, Sorbonne Paris Cité, AP-HP, Saint Louis Hospital, Paris, France.

The pathophysiology of neutrophilic dermatoses (NDs) and autoimmune connective tissue diseases (AICTDs) is incompletely understood. The association between NDs and AICTDs is rare; recently, however, a distinctive subset of cutaneous lupus erythematosus (LE, the prototypical AICTD) with neutrophilic histological features has been proposed to be included in the spectrum of lupus. The aim of our study was to test the validity of such a classification. We conducted a monocentric retrospective study of 7028 AICTDs patients. Among these 7028 patients, a skin biopsy was performed in 932 cases with mainly neutrophilic infiltrate on histology in 9 cases. Combining our 9 cases and an exhaustive literature review, pyoderma gangrenosum, Sweet syndrome (n = 49), Sweet-like ND (n = 13), neutrophilic urticarial dermatosis (n = 6), palisaded neutrophilic granulomatous dermatitis (n = 12), and histiocytoid neutrophilic dermatitis (n = 2) were likely to occur both in AICTDs and autoinflammatory diseases. Other NDs

were specifically encountered in AICTDs: bullous LE (n = 71), amicrobial pustulosis of the folds (n = 28), autoimmunity-related ND (n = 24), ND resembling erythema gyratum repens (n = 1), and neutrophilic annular erythema (n = 1). The improvement of AICTDS neutrophilic lesions under neutrophil targeting therapy suggests possible common physiopathological pathways between NDs and AICTDs.

**BACKGROUND AND OBJECTIVE:** Numerous inflammatory and innate immune pathways are involved in atherogenesis. We aimed to investigate the atherogenic index and other lipid parameters in individuals with familial Mediterranean fever (FMF), as a predictor of atherosclerosis.

**MATERIALS AND METHODS:** A total of 60 patients with FMF and 60 healthy age- and

sex-matched controls were included in this study. The patients with acute infection, chronic metabolic and rheumatic diseases, use of drugs other than colchicine and smoking history were excluded. CRP, ESR, total cholesterol, triglycerides, LDL-C, and HDL-C levels of patients and the control group were measured. Atherogenic index (TG/HDL-C) was calculated.

RESULTS: We found that the atherogenic index values of the patients were significantly higher than those of the control group. HDL-C levels were lower and ESR and TG levels were higher in patients. Total cholesterol, LDL-C and CRP levels did not differ significantly between the two groups. There was no significant difference in the values of total cholesterol, LDL-C, triglycerides (TG), HDL-C, and atherogenic indexes between the groups of patients with and without M694V mutation.

CONCLUSIONS: Elaboration of clinical models of inflammation-induced atherogenesis may further advance our knowledge of multiple inflammatory pathways implicated in atherogenesis and provide a useful tool for cardiovascular prevention. We believe that the atherogenic index also be used as a preliminary indication of accelerated atherosclerosis in FMF. However, large-scale prospective studies on this issue are needed.

Systemic urticaria are defined as urticaria, most often chronic, associated with systemic diseases. At present time, urticarial vasculitis and neutrophilic urticarial dermatosis associated to autoinflammatory syndromes are not considered to be subtypes of chronic spontaneous urticaria due to their distinctly clinical and histological characteristics as well different pathomechanisms. Sometimes, chronic urticaria is associated to thyroid autoimmunity. However, the majority of cases of chronic spontaneous urticaria have no discernible cause and further investigations are not necessary, as already suggested by some authors and French consensus conference more than 10 years ago.

Coexistence of familial Mediterranean fever (FMF) and other inflammatory disorders has been frequently reported, but no specific underlying factor has been identified. We report a patient with FMF who is presented with long-standing ankylosing spondylitis (AS) and cutaneous leukocytoclastic vasculitis (LV) of the lower limbs. It is the first report on combination of FMF with AS and LV. The Mediterranean Fever (MEFV) gene mutation of heterozygote (R202Q/R726A) and HLA-B27 are detected in this case, and are believed to form genetic susceptibility to LV.

MEFV mutation frequency and effect on disease severity in ankylosing spondylitis.

Maraş Y, Akdoğan A, Kisacik B, Kiliç L, Yilmaz E, Tufan A, Kalyoncu U, Apraş Bilgen ŞŞ, Kiraz S, Ertenli Aİ, Çalgüneri M.

**BACKGROUND/AIM:** To define the frequency of familial Mediterranean fever gene (MEFV) mutations in ankylosing spondylitis (AS) and describe different clinical aspects of MEFV mutation carrier and noncarrier AS patients.

**MATERIALS AND METHODS:** In 112 AS patients, Bath Ankylosing Spondylitis Disease Activity Index (BASDAI) and Bath Ankylosing Spondylitis Functional Index (BASFI) scores were calculated. The frequencies of 12 different MEFV mutations were studied by multiplex polymerase chain reaction/reverse hybridization method and were compared to those of previously studied healthy controls for 5 common MEFV mutations.

**RESULTS:** MEFV mutations were identified in 46 of 224 (20%) alleles and in 39 (35%) of AS patients. The distribution of mutations was: M694V, 30% (14); E148Q, 30% (14); P369S, 17% (8); V726A, 13% (6); A744S, 8% (4); and K695R, 2% (1). There were no significant differences between MEFV mutation carriers and noncarriers with respect to sex, age of symptom onset, disease duration, peripheral joint involvement, acute phase reactant levels, and BASDAI and BASFI scores ( $P > 0.05$  all). MEFV mutation allelic frequency was not different between AS patients and healthy controls after adjusting for mutations studied (34/224 versus 22/200;  $P > 0.05$ ).

**CONCLUSION:** Although we did not find significant clinical and laboratory differences between MEFV mutation carrier and noncarrier AS patients, further investigations are needed to define the impact of MEFV mutations on AS disease course.

Mevalonate kinase deficiency (MKD) is a rare autosomal recessive inborn error of metabolism with an autoinflammatory phenotype that may be expressed as a spectrum of disease phenotypes, from those with prevailing autoinflammatory syndrome and variable response to anti-inflammatory therapies, to mevalonic aciduria, which is associated with dysmorphic features, severe neurologic involvement, and the worst prognosis. We describe a boy, aged 2 years, 10 months, with severe phenotype of mevalonate kinase deficiency who underwent allogeneic hematopoietic stem cell transplantation (HSCT) from HLA-identical unrelated cord blood because his condition had failed to improve with antiinflammatory treatment as first-line therapy and an anticytokine drug as second-line therapy. The child had a sustained remission of febrile attacks and inflammation after transplant, and during a 5-year follow-up period, psychomotor and neurologic development were normal, without signs of underlying disease or late transplant-related effects. This case confirms that allogeneic HSCT is a safe and effective cure for patients affected by MKD in whom anticytokine drugs alone are insufficient for the management of autoinflammatory syndrome and for the unfavorable outcome of the disease.

Interleukin-1 targeting treatment in familial Mediterranean fever: an experience of pediatric patients.

Başaran Ö(1), Uncu N, Çelikel BA, Taktak A, Gür G, Cakar N.

Author information:

(1)Department of Pediatric Rheumatology, Ankara, Child Health, Hematology and Oncology Education and Research Hospital , Ankara , Turkey.

**OBJECTIVES:** The aim of this report was to evaluate and discuss treatment of pediatric familial Mediterranean fever (FMF) patients with anti-interleukin1 (IL-1) agents.

**METHODS:** Refractory or colchicine unresponsive FMF was described as severe and frequent attacks and/or having high acute phase reactance levels despite having a maximum dose of colchicine (2 mg/day). Disease course, adverse effects, duration of follow-up, treatment protocols, responses to the therapies were discussed.

**RESULTS:** Eight patients (6 male, 2 female) having refractory FMF were identified. Mediterranean fever (MEFV) gene analyses revealed homozygous M694V mutations in six patients and heterozygote M694V mutations in one patient and no mutation in one patient. They were all treated with anakinra and/or canakinumab. The use of anti-IL-1 drugs was beneficial to all patients. None of them had any severe adverse effects due to the therapy.

**CONCLUSIONS:** Anakinra and canakinumab were effective in patient refractory to colchicine treatment as shown both in our series and in the literature.

Therefore, controlled trials are needed to evaluate the safety and long-term efficacy of IL-1 targeting agents in colchicine resistant patients.

Proteasome-associated autoinflammatory syndromes: advances in pathogeneses, clinical presentations, diagnosis, and management.

McDermott A(1), Jacks J, Kessler M, Emanuel PD, Gao L.

Author information:

- (1)College of Medicine, University of Arkansas for Medical Sciences, Little Rock, AR, USA.

The disease spectrum currently known as the proteasome-associated autoinflammatory syndromes (PRAAS) was first described in 1939 in patients who presented with recurrent fevers beginning in infancy or early childhood, which were accompanied by nodular erythema, a pernio-like rash, and joint contractures. Since then, several syndromes, such as chronic atypical neutrophilic dermatosis with lipodystrophy and elevated temperature (CANDLE) syndrome, Nakajo-Nishimura syndrome (NNS), joint contractures, muscle atrophy, microcytic anemia and panniculitis-induced lipodystrophy (JMP) syndrome, and Japanese autoinflammatory syndrome with lipodystrophy (JASL), have been used to categorize patients with diseases within the same spectrum. Recently, independent studies have identified mutations in the human proteasome subunit  $\beta$  type 8 (PSMB8) gene, which result in a sustained inflammatory response in all syndromes. Further functional studies not only suggest a causative role of PSMB8 mutations but also imply that they represent one disease spectrum, referred to as PRAAS. In this paper, we review the clinical presentations and laboratory findings of PRAAS, as well as the most

recent advances in pathogenesis, diagnosis, and treatment options for patients with diseases in this spectrum.

The Worst Itch Numeric Rating Scale for patients with moderate to severe plaque psoriasis or psoriatic arthritis.

Naegeli AN(1), Flood E(2), Tucker J(2), Devlen J(2), Edson-Heredia E(1).

Author information:

(1)Eli Lilly & Co., Indianapolis, IN, USA.

(2)Oxford Outcomes, Bethesda, MD, USA.

Plaque psoriasis (PP) and psoriatic arthritis (PsA) are autoinflammatory chronic conditions associated with skin involvement. Pruritus, or itching, is a prevalent and bothersome symptom in patients with PP and is associated with reduced health-related quality of life. The Worst Itch Numeric Rating Scale (WI-NRS) has been developed as a simple, single item with which to assess the patient-reported severity of this symptom at its most intense during the previous 24-hour period. Qualitative research was undertaken to assess the content validity of the WI-NRS. Patients with moderate to severe PP and patients with PsA were recruited from clinical sites in the USA. The qualitative research entailed two-part interviews, which began with concept elicitation to gain understanding of patients' experiences of itching, followed by cognitive debriefing of the WI-NRS to assess the instrument's understandability, clarity, and degree of appropriateness from the patient's perspective. Twelve patients with PP and 22 with PsA participated in the study. Patients reported that itching was an important and relevant symptom of their psoriatic disease. The WI-NRS was reported to be complete and easy to understand; the recall period was considered appropriate, the response scale was familiar, and, overall, the instrument was found to be appropriate for assessing itching severity. Patient responses support the content validity of the WI-NRS. The psychometric properties of the tool will be evaluated in future

studies.

Chronic recurrent multifocal osteomyelitis: the prevalence of lower-limb and foot involvement.

Ferrari J, Pilkington C.

**BACKGROUND:** Chronic recurrent multifocal osteomyelitis (CRMO) is an autoinflammatory condition. The lesions are reported to present most frequently in the long bones. This study aimed to review the presenting features of CRMO in a cohort of children diagnosed as having CRMO and to compare the level of agreement between the clinical and published diagnostic criteria.

**METHODS:** A case notes review was undertaken of patients with a clinical diagnosis of CRMO. Patients were younger than 16 years at the time of diagnosis. Features were identified in each patient that agreed or disagreed with the published diagnostic criteria. The location of bone lesions in the lower limb at onset and disease progression was recorded.

**RESULTS:** A total of 37 patients were included. There was a high prevalence in white individuals. Agreement with the diagnostic criteria of Jansson et al and El-Shanti and Ferguson was poor, with levels of agreement of 40.5% and 43%, respectively, and low kappa scores ( $\kappa = 0.07$  and  $0.09$ , respectively). The lower limb was affected in 49% of patients at onset and in 72% overall.

**CONCLUSIONS:** This study presents one of the largest published cohorts of pediatric patients with CRMO and also presents racial/ethnic group data that have not previously been reported in other studies. Despite being a condition considered to affect the metaphysis of long bones, the ankle area and foot bones were also frequently affected. The agreement between the clinical diagnosis and the published diagnostic criteria was weak.

[Genetic predisposition for various forms of spondyloarthritis].

[Article in Croatian]

Lamot L, Vidović M, Perica M, Bukovac LT, Harjaček M.

In addition to the long-established association of HLA-B27 antigen and spondyloarthritis, several studies have shown a similar association with HLA-B7 antigen. But since the whole MHC region carries less than half of the risk for the development of the disease, the main goal of many recently performed researches, which implemented various high-throughput methods, was to discover the influence of genes outside the MHC region on disease development. The results showed that genes closely linked to spondyloarthritis participate in antigen processing and coding of various cytokines. This can lead to the conclusion that diseases from the spondyloarthritis group are polygenic, affected by both autoinflammatory and autoimmune mechanisms.

Neutrophil extracellular traps: a walk on the wild side of exercise immunology.

Beiter T(1), Fragasso A, Hartl D, Nieß AM.

Author information:

(1)Department of Sports Medicine, Medical Clinic, Eberhard-Karls-University of Tübingen, Hoppe-Seyler-Str. 6, 72076, Tübingen, Germany, thomas.beiter@med.uni-tuebingen.de.

Intense exercise evokes a rapid and transient increase in circulating cell-free DNA (cf-DNA), a phenomenon that is commonly observed in a variety of acute and chronic inflammatory conditions. While the potential value of cf-DNA for the prediction of disease outcome and therapeutic response is well documented, the release mechanisms and biological relevance of cf-DNA have long remained enigmatic. The discovery of neutrophil extracellular traps (NETs) provided a novel mechanistic explanation for increased cf-DNA levels. Now there is increasing evidence that NETs may contribute to cf-DNA in diverse infectious, non-infectious and autoinflammatory conditions, as well as in response to acute exercise. NETs have now been firmly established as a fundamental immune mechanism used by neutrophils to respond to infection and tissue injury. On the other side, aberrant formation of NETs appears to be a driving force in the pathogenesis of autoimmunity and cardiovascular disease. Thus, the emergence of NETs in the 'exercising vasculature' raises important questions considering beneficial effects, as well as occasional adverse effects, of exercise on immune homeostasis. This review gives an overview of the current state of research into the mechanisms of how NETs are released, contribute to host defence and participate in inflammatory disorders. We discuss the impact of exercise-induced NETs, considering a potentially beneficial role in the prevention of lifestyle-related diseases, as well as putative detrimental effects that may arise in elite sports. Finally, we propose that exercise-induced cf-DNA responses could be exploited for diagnostic/prognostic purposes to identify individuals who are at increased risk of cardiovascular events or autoimmunity.

Erratum in

Medicine (Baltimore). 2015 Feb;94(8):1.

Medicine (Baltimore). 2015 Apr;94(15):1.

The association of pyoderma gangrenosum, acne, and suppurative hidradenitis (PASH) has recently been described and suggested to be a new entity within the spectrum of autoinflammatory syndromes, which are characterized by recurrent episodes of sterile inflammation, without circulating autoantibodies and autoreactive T-cells. We conducted an observational study on 5 patients with PASH syndrome, analyzing their clinical features, genetic profile of 10 genes already known to be involved in autoinflammatory diseases (AIDs), and cytokine expression pattern both in lesional skin and serum. In tissue skin samples, the expressions of interleukin (IL)-1 $\beta$  and its receptors I and II were significantly higher in PASH ( $P = 0.028$ ,  $0.047$ , and  $0.050$ , respectively) than in controls. In PASH patients, chemokines such as IL-8 ( $P = 0.004$ ), C-X-C motif ligand (CXCL) 1/2/3 ( $P$

= 0.028), CXCL 16 (P = 0.008), and regulated on activation, normal T cell expressed and secreted (RANTES) (P = 0.005) were overexpressed. Fas/Fas ligand and cluster of differentiation (CD)40/CD40 ligand systems were also overexpressed (P = 0.016 for Fas, P = 0.006 for Fas ligand, P = 0.005 for CD40, and P = 0.004 for CD40 ligand), contributing to tissue damage and inflammation. In peripheral blood, serum levels of the main proinflammatory cytokines, that is, IL-1 $\beta$ , tumor necrosis factor- $\alpha$ , and IL-17, were within the normal range, suggesting that in PASH syndrome, the inflammatory process is mainly localized into the skin. Four out of our 5 PASH patients presented genetic alterations typical of well-known AIDs, including inflammatory bowel diseases, and the only patient lacking genetic changes had clinically evident Crohn disease. In conclusion, overexpression of cytokines/chemokines and molecules amplifying the inflammatory network, along with the genetic changes, supports the view that PASH syndrome is autoinflammatory in origin.

Protracted febrile myalgia syndrome in a Japanese patient with fasciitis detected on MRI.

Fujikawa K(1), Migita K, Tsukada T, Kawakami A, Eguchi K.

Author information:

(1)Department of Rheumatology, Japan Community Health Care Organization (JCHO), Isahaya General Hospital, Japan.

Protracted febrile myalgia syndrome (PFMS) is a rare manifestation of familial Mediterranean fever characterized by prolonged severe myalgia. We herein describe a case of PFMS with fasciitis on magnetic resonance imaging. The response to corticosteroid therapy was prompt, as is typical for PFMS. An MEFV gene analysis revealed the patient to be homozygous for E148Q and compound heterozygous for P369S-R408Q. This is the first case report of a Japanese patient with PFMS. MRI findings may help to diagnose such cases.

(2)Department of Dermatology, Ghent University Hospital, De Pintelaan 185, 9000 Ghent, Belgium.

Vitiligo is a recalcitrant depigmentary skin disorder with significant effects on the quality of life and a frequent association with other autoimmune disorders. The results of the current therapeutic options remain variable and treatment resistance is often encountered. The mainstay of treatment remains topical corticosteroids, topical calcineurin inhibitors and UVB therapy. In more extensive or progressive cases, systemic corticosteroids are effective although their prolonged use is hampered due to safety concerns. A lot of topical and systemic treatments have been investigated during the last decades. Given the elevated TNF- $\alpha$  levels in vitiligo lesions, the failure and even paradoxal effects of TNF- $\alpha$  inhibitors were highly remarkable. Nonetheless, a lot of progress has been made to unravel the pathophysiology of vitiligo. In this review, we provide an overview of the currently known underlying mechanisms leading to vitiligo and link this to the success or failure of treatments that have been used in clinical trials. We believe that this overview can direct future vitiligo research and rationalise the treatment options.

Recent studies have identified new roles for mitochondria in the regulation of autoinflammatory processes. Emerging data suggests that the release of danger signals from mitochondria in response to stress and infection promotes the formation of the inflammatory signaling platform known as inflammasomes. Activation of inflammasomes by damaged mitochondria results in caspase-1-dependent secretion of the inflammatory cytokines interleukin-1 $\beta$  (IL-1 $\beta$ ) and IL-18, and an inflammatory form of cell death referred to as pyroptosis. Here, we review recently described mechanisms that have been proposed to be involved in mitochondria-mediated regulation of inflammasome activation and inflammation. In addition, we highlight how aberrant regulation of mitochondria-induced inflammasome activation centrally contributes to the inflammatory process that is responsible for obesity and associated metabolic diseases.

Members of the two-pore domain K(+) channel (K2P) family are increasingly recognized as being potential targets for therapeutic drugs and could play a role in the diagnosis and treatment of neurologic disorders. Their broad and diverse expression pattern in pleiotropic cell types, importance in cellular function, unique biophysical properties, and sensitivity toward pathophysiologic parameters represent the basis for their involvement in disorders of the central nervous system (CNS). This review will focus on multiple sclerosis (MS) and stroke, as there is growing evidence for the involvement of K2P channels in these two major CNS disorders. In MS, TASK1-3 channels are expressed on T lymphocytes and are part of a signaling network regulating Ca(2+)- dependent pathways that are mandatory for T cell activation, differentiation, and effector functions. In addition, TASK1 channels are involved in neurodegeneration, resulting in autoimmune attack of CNS cells. On the blood-brain barrier, TREK1 channels regulate immune cell trafficking under autoinflammatory conditions. Cerebral ischemia shares some pathophysiologic similarities with MS, including hypoxia and extracellular acidosis. On a cellular level, K2P channels can have both proapoptotic and antiapoptotic effects, either promoting neurodegeneration or protecting neurons from ischemic cell death. TASK1 and TREK1 channels have a neuroprotective effect on stroke development, whereas TASK2 channels have a detrimental effect on neuronal survival under ischemic conditions. Future research in preclinical models is needed to provide a more detailed understanding of the contribution of K2P channel family members to neurologic disorders, before translation to the clinic is an option.

Increased proteasome activator 28 gamma (PA28 $\gamma$ ) levels are unspecific but correlate with disease activity in rheumatoid arthritis.

Gruner M, Moncsek A, Rödiger S, Kühnhardt D, Feist E(1), Stohwasser R.

Author information:

(1)Department of Rheumatology and Clinical Immunology and Autoinflammatory Reference Centre at Charité, Charité-Universitätsmedizin Berlin, Charitéplatz 1, D-10117 Berlin, Germany. eugen.feist@charite.de.

**BACKGROUND:** PA28 $\gamma$  (also known as Ki, REG gamma, PMSE3), a member of the ubiquitin-and ATP-independent proteasome activator family 11S, has been proved to show proteasome-dependent and -independent effects on several proteins including tumor suppressor p53, cyclin-dependent kinase inhibitor p21 and steroid receptor co-activator 3 (SCR-3). Interestingly, PA28 $\gamma$  is overexpressed in pathological tissue of various cancers affecting e. g. breast, bowel and thyroids. Furthermore, anti-PA28 $\gamma$  autoantibodies have been linked to several autoimmune disorders. The aim of this study was to develop and evaluate a novel and sensitive PA28 $\gamma$  sandwich ELISA for the quantification of PA28 $\gamma$  serum levels in patients with cancer and autoimmune diseases for diagnostic and prognostic purposes.

**METHODS:** PA28 $\gamma$ -specific polyclonal antibodies and recombinant His-tagged PA28 $\gamma$  were purified and used to develop a sandwich ELISA for the detection of circulating PA28 $\gamma$ . With this new assay, PA28 $\gamma$  serum levels of patients with various cancers, rheumatoid arthritis (RA), Sjögren's syndrome (SS), adult-onset Still's disease (AOSD) and different connective-tissue diseases (CTD) were compared with healthy control subjects. Anti-PA28 $\gamma$  autoantibodies were additionally confirmed using a newly developed microbead assay.

**RESULTS:** The developed PA28 $\gamma$  sandwich ELISA showed a high specificity with a detection limit of 3 ng/ml. A significant up-regulation of circulating PA28 $\gamma$  was detected in the sera of patients with cancer, RA, SS and CTD. A significant correlation was observed dependent on age as well as anti-PA28 $\gamma$  autoantibody levels with circulating PA28 $\gamma$  protein levels. Furthermore, PA28 $\gamma$  serum levels showed a correlation with disease activity in patients with RA under treatment with the T-cell directed biological compound abatacept according to disease activity score 28 (DAS28) and erythrocyte sedimentation rate (ESR).

**CONCLUSION:** The application of PA28 $\gamma$  as a novel biomarker for diagnostic purposes of a specific disease is limited, since elevated levels were observed in different disorders. However, the correlation with disease activity in patients with RA suggests a prognostic value, which needs to be addressed by further

studies. Therefore our results show that PA28γ is a useful marker which should be included in studies related to novel treatments, e.g. abatacept.

Prevalence of chronic rhinosinusitis in the setting of Behçet disease.

Verim A(1), Cebeci F, Başer E, Çalim ÖF, Kadioğlu D, Kocagöz GD.

Author information:

(1)From the Departments of \*Otorhinolaryngology/Head and Neck Surgery and †Dermatology, Haydarpaşa Numune Educational and Research Hospital, Istanbul; ‡Department of Otorhinolaryngology/Head and Neck Surgery, Edirne State Hospital, Edirne; §Department of Otorhinolaryngology/Head and Neck Surgery, Bağcılar Medipol Hospital, Istanbul; ||Department of Otorhinolaryngology/Head and Neck Surgery, Medical Park Hospital, Gebze; and ¶Department of Otorhinolaryngology/Head and Neck Surgery, Ünye State Hospital, Ünye, Turkey.

Behçet disease (BD) is a systemic autoimmune/autoinflammatory, T helper 1-mediated condition. It is well known that the prevalence of a T helper 1-mediated disease increases in the presence of another T helper 1-mediated comorbidity. The purpose of this study was to investigate the prevalence of T helper 1-mediated chronic rhinosinusitis without nasal polyposis (CRSsNP) and T helper 2-mediated chronic rhinosinusitis with polyposis in the presence of comorbid BD. Sixty-nine patients and 74 healthy controls were included in the study. Participants were asked to complete a questionnaire for symptoms of rhinosinusitis. Nasal cavities were scored using the Lund-Kennedy endoscopy scores. Paranasal sinus computed tomography imagings were scored according to Lund-Mackay radiology scores. Skin prick tests were carried out for all participants to determine the predisposing role of allergy (T helper 2 disease) in the etiopathogenesis of rhinosinusitis among patients and controls. Patients' endoscopy, radiology, and skin prick testing scores were evaluated with regard to BD activity. The prevalence of CRSsNP was 23.2 % in BD and 2.7% in normal population. The CRSsNP was more frequently seen in patients than in the healthy

controls ( $P = 0.002$ ). The BD patients displayed worse scores on their left sinonasal endoscopy. No statistically significant difference was seen between BD and control groups with regard to Lund-Mackay radiology scores of both sides. The presence of an allergic response to a specific allergen in skin-prick testing were confirmed in 25 patients (36.2%) and 17 controls (23.0%). However, the difference was not statistically significant. There were positive responses to more allergens when BD activity was reduced. The CRSsNP thought to be of T helper 1-mediated origin was more frequently seen in the presence of comorbid BD.

Hemophagocytic lymphohistiocytosis (HLH) comprises a group of life-threatening immune disorders classified into primary or secondary HLH. The former is caused by mutations in genes involved in granule-mediated cytotoxicity, the latter occurs in a context of infections, malignancies or autoimmune/autoinflammatory disorders. Both are characterized by systemic inflammation, severe cytokine storms and immune-mediated organ damage. Despite recent advances, the pathogenesis of HLH remains incompletely understood. Animal models resembling

different subtypes of HLH are therefore of great value to study this disease and to uncover novel treatment strategies. In this review, all known animal models of HLH will be discussed, highlighting findings on cell types, cytokines and signaling pathways involved in disease pathogenesis and extrapolating therapeutic implications for the human situation.

Adult-onset Still's disease is a rare and difficult to diagnose multisystemic

disorder considered as a multigenic autoinflammatory syndrome. Its immunopathogenesis seems to be at the crossroads between inflammasomopathies and hemophagocytic lymphohistiocytosis, the most severe manifestation of the disease. According to recent insights in the pathophysiology and thanks to cohort studies and therapeutic trials, two phenotypes of adult-onset Still's disease may be distinguished: a systemic pattern, initially highly symptomatic and with a higher risk to exhibit life-threatening complications such as reactive hemophagocytic lymphohistiocytosis, where interleukin-1 blockade seems to be very effective, a chronic articular pattern, more indolent with arthritis in the foreground and less severe systemic manifestations, which would threat functional outcome and where interleukin-6 blockade seems to be more effective. This review focuses on these data.

Self-DNA has long been considered a key cause of inflammatory and autoimmune disease, although the exact origin and general mechanisms of action have remained to be elucidated. Recently, new insight has been gained into our understanding of those innate immune pathways and sensors that are responsible for instigating self-DNA triggered autoinflammatory events in the cell. One such sensor referred to as STING (for stimulator of interferon genes) has been found to be seminal for controlling cytosolic-DNA induced cytokine production, and may be responsible for a wide variety of inflammatory diseases including systemic lupus erythematosus (SLE), Aicardi-Goutieres syndrome (AGS) and STING-associated vasculopathy with onset of infancy (SAVI). STING may also be involved with augmenting certain types of carcinogen induced cancer. Aside from generating valuable information into mechanisms underlining innate immune gene regulation, these findings offer new opportunities to generate innovative therapeutics which may help treat such diseases.

The study of fundamental mechanisms of autoimmunity has been instrumental to clinical progress in the diagnosis and treatment of a range of immune-mediated inflammatory disorders. Dutch immunology has made major contributions to these developments, ranging from fundamental studies on immune cells, antibodies and cytokines to translational and clinical studies with targeted therapies in patients. In this paper we illustrate the progress made in our understanding of autoimmunity and the translational implications for human disease management by focusing on three areas: the autoantibody response in rheumatoid arthritis (RA), T-B cell interactions in Sjögren's syndrome (SS), and cytokine targeting in spondylarthritis (SpA).

Comment in

Trends Cardiovasc Med. 2015 Feb;25(2):137-9.

Colchicine is one of the oldest available drugs. It has been used for centuries to treat and prevent gouty attacks and more recently to prevent attacks of autoinflammatory diseases such as Familial Mediterranean Fever. Its main mechanism of action is the capability to block the polymerization of tubulin, thus affecting the function of microtubules. The capability to concentrate in white blood cells, especially granulocytes, and interfere with their function explains its potentiality as an anti-inflammatory drug. Colchicine (0.5mg twice daily for patients >70kg or once daily for those weighing less) in addition to standard anti-inflammatory therapy, in either acute or recurrent pericarditis, may hasten the response to anti-inflammatory therapy and reduce the subsequent risk of recurrences. After exclusion of contraindication and appropriate dose adjustment, the drug is safe and well tolerated. The more common side effect is gastrointestinal intolerance occurring in 5-10% of cases and may be controlled by dose reduction or temporary discontinuation.

The innate immune system is critically important for the primary sensing of invading pathogens. Over the past decade, the cellular sensors important for recognizing microbial entry into the host cell have been largely elucidated. These sensors, some of which are evolutionarily conserved, include the Toll-like receptor (TLR) and RIG-I-like helicase family (RLH) pathway that can recognize bacterial and viral non-self nucleic acid. In addition, a cellular sensor referred to as STING (for stimulator of interferon genes) has been shown to be critical for triggering host defense countermeasures, including stimulation of the adaptive immune response, following the detection of cytosolic DNA species. The STING pathway has now been shown to be critical for activating innate immune gene transcription in response to infection by DNA pathogens such as herpes simplex virus 1 (HSV1) as well as retroviruses. In addition, it is clear that chronic STING activation can also cause autoinflammatory disease manifested by self-DNA. Here we review recent developments in our understanding of STING function, including importance in the control of microbial disease.

(4)Chemical Department, National Hepatology and Tropical Medicine Research Institute, Cairo, Egypt.

**BACKGROUND/AIMS:** An association of type 1 DM and familial Mediterranean fever (FMF) has been newly reported in the medical literature. The aim of the present work was to investigate frequency of MEFV gene mutations in Egyptian children with type 1 diabetes mellitus.

**METHODS:** Forty five children with type 1 DM were screened for Mediterranean Fever (MEFV) gene mutation. Forty one healthy control subjects were included.

Identification of FMF gene mutation was done based on polymerase chain reaction (PCR) and reverse hybridization. The assay covers 12 mutations in the FMF gene: E148Q - P369S - F479L - M680I (G/C) - M680I (G/A) - I692del - M694V - M694I - K695R-V726A - A744S and R761H.

**RESULTS:** Among the screened diabetics, the overall frequency of MEFV gene mutations was 42.2% and among the control group it was 34.1% with no significant difference. Fourteen out of 45 diabetic children (31.1%) were heterozygous (E148Q

in 7 children, A744S in 3 children, V726A in 2 children, M680I (G/C) in 1 child and P369S in 1 child), while 5 children (11.1%) were compound heterozygous (M694V/M694I in 2 children, E148Q/K695R mutations in 1 child, E148Q/M694I in 1 child and E148Q/V726A in 1 child). The control group showed heterozygous mutation in 34.1% of cases (E148Q mutation in 14.6%, V726A in 12.2%, M680I (G/C) in 4.9% and M694V in 2.4%).

CONCLUSION: No significant difference in mutation frequency between diabetic and non-diabetic children. We have high carrier rate of MEFV gene mutations among Egyptian population probably due to high consanguinity.

Update on ankylosing spondylitis: current concepts in pathogenesis.

Smith JA(1).

Author information:

(1)Department of Pediatrics, Division of Allergy, Immunology and Rheumatology, School of Medicine and Public Health, University of Wisconsin-Madison, 600 Highland Ave, H4/472 CSC, Madison, WI, 53709-4108, USA, jsmith27@pediatrics.wisc.edu.

Ankylosing spondylitis is an insidiously progressive and debilitating form of arthritis involving the axial skeleton. The long delay in diagnosis and insufficient response to currently available therapeutics both advocate for a greater understanding of disease pathogenesis. Genome-wide association studies of this highly genetic disease have implicated specific immune pathways, including the interleukin (IL)-17/IL-23 pathway, control of nuclear factor kappa B (NF- $\kappa$ B) activation, amino acid trimming for major histocompatibility complex (MHC) antigen presentation, and other genes controlling CD8 and CD4 T cell subsets. The relevance of these pathways has borne out in animal and human subject studies, in particular, the response to novel therapeutic agents. Genetics and the findings of autoantibodies in ankylosing spondylitis revisit the question of autoimmune

vs. autoinflammatory etiology. As environmental partners to genetics, recent attention has focused on the roles of microbiota and biomechanical stress in initiating and perpetuating inflammation. Herein, we review these current developments in the investigation of ankylosing spondylitis pathogenesis.

1825. Isr Med Assoc J. 2014 Oct;16(10):659-61.

Cryopyrin-associated periodic syndrome.

Giat E, Lidar M.

CAPS is a rare autoinflammatory disease associated with mutations in the NLRP3 gene that result in overactivation of the inflammasome, increased secretion of IL-1 $\beta$  and IL-18, and systemic inflammation. Genetic testing has allowed for grouping of the three, previously distinct clinical syndromes of FCAS, MWS and NOMID, into a single syndrome termed CAPS. The clinical features include urticarial rash and fever, CNS and musculoskeletal involvement, ocular disorders and progressive deafness. Onset, severity and complications (mainly retardation, seizures, destructive arthropathy and amyloidosis) depend on the specific mutation. Diagnosis is determined by genetic tests but is often delayed due to lack of awareness. In Israel, the relative abundance of other autoinflammatory disorders (FMF, Behçet's disease) may result in misdiagnosis. Treatment is based on IL-1 antagonism, which usually results in prompt clinical response and may prevent amyloidosis.

Bacterial components are recognized by the immune system through activation of the inflammasome, eventually causing processing of the proinflammatory cytokine interleukin-1 $\beta$  (IL-1 $\beta$ ), a pleiotropic cytokine and one of the most important mediators of inflammation, through the protease caspase-1. Synthesis of the precursor protein and processing into its bioactive form are tightly regulated, given that disturbed control of IL-1 $\beta$  release can cause severe autoinflammatory diseases or contribute to cancer development. We show that the bacterial *Pasteurella multocida* toxin (PMT) triggers IL1 $\beta$  gene transcription in macrophages independently of Toll-like receptor signaling through RhoA/Rho-kinase-mediated

NF- $\kappa$ B activation. Furthermore, PMT mediates signal transducer and activator of transcription (STAT) protein-controlled granzyme A (a serine protease) expression in macrophages. The exocytosed granzyme A enters target cells and mediates IL-1 $\beta$  maturation independently of caspase-1 and without inducing cytotoxicity. These findings show that macrophages can induce an IL-1 $\beta$ -initiated immune response independently of inflammasome activity.

**OBJECTIVE:** Inflammation is known to alter lipid profiles and to induce insulin resistance. This study was planned to test the hypothesis that familial Mediterranean fever (FMF) patients and their first-degree asymptomatic relatives may have lipid profile changes and/or insulin resistance, similar to other inflammatory diseases.

**MATERIAL AND METHODS:** We studied 72 FMF patients, 30 asymptomatic first-degree relatives, and 75 healthy controls. Fasting and 2-hour postprandial glucose, insulin, apolipoprotein (Apo) A1, Apo B, acute phase reactants, and lipid profiles of all subjects were studied. Insulin resistance was determined by the

HOMA (Homeostasis Model Assessment) index.

RESULTS: There was no difference between the groups with regard to sex, mean systolic and diastolic blood pressure, body mass index, smoking status, fasting and postprandial 2-hour glucose, insulin, acute phase reactants, and HOMA index levels. High-density lipoprotein cholesterol (HDL-C) levels were similar between FMF patients and FMF relatives ( $48.9 \pm 12.4$  mg/dL vs  $49.3 \pm 13.8$  mg/dL;  $p = \text{NS}$ ), and both were lower than controls ( $48.9 \pm 12.4$  mg/dL vs  $59.6 \pm 15.1$  mg/dL;  $p < 0.001$  and  $49.3 \pm 13.8$  mg/dL vs  $59.8 \pm 15.1$  mg/dL;  $p = 0.001$ , respectively). Apo A1 levels in FMF patients and asymptomatic first-degree FMF relatives were both lower than in controls, similar to the HDL-C levels ( $126.1 \pm 25.7$  mg/dL vs  $151.2 \pm 31.4$  mg/dL;  $p < 0.001$  and  $129.5 \pm 29.0$  mg/dL vs  $151.2 \pm 31.4$  mg/dL;  $p = 0.002$ , respectively). TG levels were significantly higher in FMF relatives as compared to controls ( $113.4 \pm 53.6$  mg/dL vs  $97.1 \pm 54.9$  mg/dL;  $p = 0.025$ ).

CONCLUSION: Low HDL-C and low Apo A1 levels are found in FMF patients and their first-degree asymptomatic relatives. Low-grade inflammation caused by MEFV mutations may be responsible for these lipid profile changes.

The inflammasomes and autoinflammatory syndromes.

Broderick L(1), De Nardo D, Franklin BS, Hoffman HM, Latz E.

Author information:

(1)Department of Pediatrics and.

Inflammation, a vital response of the immune system to infection and damage to tissues, can be initiated by various germline-encoded innate immune-signaling receptors. Among these, the inflammasomes are critical for activation of the potent proinflammatory interleukin-1 cytokine family. Additionally, inflammasomes can trigger and maintain inflammatory responses aimed toward excess nutrients and the numerous danger signals that appear in a variety of chronic inflammatory diseases. We discuss our understanding of how inflammasomes assemble to trigger

caspase-1 activation and subsequent cytokine release, describe how genetic mutations in inflammasome-related genes lead to autoinflammatory syndromes, and review the contribution of inflammasome activation to various pathologies arising from metabolic dysfunction. Insights into the mechanisms that govern inflammasome activation will help in the development of novel therapeutic strategies, not only for managing genetic diseases associated with overactive inflammasomes, but also for treating common metabolic diseases for which effective therapies are currently lacking.

Connecting two pathways through Ca<sup>2+</sup> signaling: NLRP3 inflammasome activation induced by a hypermorphic PLCG2 mutation.

Chae JJ, Park YH, Park C, Hwang IY, Hoffmann P, Kehrl JH, Aksentijevich I, Kastner DL.

**OBJECTIVE:** We previously reported that p.Ser707Tyr, a novel variant in phospholipase C $\gamma$ 2 (PLC $\gamma$ 2), is the cause of a dominantly inherited autoinflammatory disease, autoinflammation and PLC $\gamma$ 2-associated antibody deficiency and immune dysregulation (APLAID). The hypermorphic mutation enhances PLC $\gamma$ 2 activity and causes an increase in intracellular Ca<sup>2+</sup> release from endoplasmic reticulum stores. Because increased intracellular Ca<sup>2+</sup> signaling has been associated with NLRP3 inflammasome activation, we studied the role of the NLRP3 inflammasome in the pathogenesis of APLAID.

**METHODS:** Human peripheral blood mononuclear cells (PBMCs) were isolated from healthy control subjects and 2 patients with APLAID. Inflammasome activation was analyzed by Western blotting. Intracellular Ca<sup>2+</sup> levels were measured with a FLIPR Calcium 4 assay kit.

**RESULTS:** Cells from the patients had elevated basal levels of intracellular Ca<sup>2+</sup>, and the intracellular Ca<sup>2+</sup> flux triggered by extracellular CaCl<sub>2</sub> was substantially enhanced. Patient PBMCs secreted interleukin-1 $\beta$  in response to lipopolysaccharide priming alone, and this effect was attenuated by treatment with a PLC inhibitor, intracellular Ca<sup>2+</sup> blockers, or an adenylate cyclase activator.

**CONCLUSION:** Our findings suggest that the inflammation in patients with APLAID is partially driven by activation of the NLRP3 inflammasome. These data link 2 seemingly distinct molecular pathways and provide new insights into the pathogenesis of APLAID and autoinflammation.

Pyroptosis is a caspase-1-dependent pro-inflammatory form of programmed cell death implicated in the pathogenesis of autoinflammatory diseases as well as in disorders characterized by excessive cell death and inflammation. Activation of NLRP3 inflammasome is a key event in the pyroptotic cascade. In this study, we describe the synthesis and chemical tuning of  $\alpha,\beta$ -unsaturated electrophilic warheads toward the development of antipyroptotic compounds. Their pharmacological evaluation and structure-activity relationships are also described. Compound 9 was selected as a model of this series, and it proved to be a reactive Michael acceptor, irreversibly trapping thiol nucleophiles, which prevented both ATP- and nigericin-triggered pyroptosis of human THP-1 cells in a time- and concentration-dependent manner. Moreover, 9 and other structurally related compounds, inhibited caspase-1 and NLRP3 ATPase activities. Our findings can contribute to the development of covalent, multitarget antipyroptotic compounds targeting molecular components of the NLRP3 inflammasome regulatory pathway.

OBJECTIVE: Observed low prevalence of SLE among familial Mediterranean fever (FMF) patients in several large cohorts suggests a possible protective effect of the MEFV mutations from SLE. In contrast, SLE patient carriers for the common MEFV mutations had rather complex disease expression with an increased frequency of febrile episodes and pleurisy and a decreased renal complication rate. Our aim

was to investigate the prevalence of MEFV gene mutations in patients with SLE and their effect on organ involvement in a well-defined group of biopsy-proven SLE nephritis patients.

**MATERIAL AND METHOD:** The prevalence of four MEFV gene mutations (M694V, M680I, V726A and E148Q) was investigated in 114 SLE patients and effect on disease severity was analyzed in patients with biopsy-proven SLE nephritis.

**RESULTS:** None of the SLE patients fulfilled the revised Tel-Hashomer criteria. Fourteen of 114 SLE patients (12.2%) were found to carry at least one MEFV mutation. A single patient in the SLE-Nephritis group was compound heterozygous for M694V/M680I mutations and only one patient in the SLE-Mild group was homozygous for E148Q mutation. Carrier frequency was similar to controls in SLE patients (12.2 vs 18.8%,  $p = 0.34$ ). After the exclusion of the less penetrant E148Q mutation, re-analysis revealed an association between exon 10 mutations and SLE nephritis ( $p = 0.050$ , odds ratio (OR) = 4.16, 95% confidence interval (CI) = 1.04-16.6). Carrier rate for the E148Q mutation decreased in the SLE group (controls vs. SLE = 20/186 vs. 3/114,  $p = 0.08$ ) and E148Q mutation was absent in SLE nephritis (controls vs. SLE nephritis = 20/186 vs. 0/47,  $p = 0.016$ , OR = 11.69, 95% CI = 0.69-197.13).

**CONCLUSIONS:** Carrier rate for the studied MEFV mutations was slightly lower in the SLE group, which is in agreement with previous observations that FMF may confer some protection from SLE. Exon 10 mutations were associated with SLE nephritis after the exclusion of the E148Q mutation. The significance of the E148Q as a disease-causing mutation is controversial, and whether E148Q substitution is a polymorphism generally affecting inflammatory pathways is not addressed in the current literature. In this regard, absence of the E148Q mutation in SLE nephritis may serve as a clue for further investigation into its role as a general modulatory polymorphism for inflammation. This clarification is necessary to conclude whether other more penetrant MEFV gene mutations confer susceptibility to nephritis in SLE.

Evidence of Crohn's disease-related anti-glycoprotein 2 antibodies in patients with celiac disease.

Roggenbuck D, Vermeire S, Hoffman I, Reinhold D, Schierack P, Goihl A, von Arnim U, De Hertogh G, Polymeros D, Bogdanos DP, Bossuyt X.

**BACKGROUND:** Autoantibodies to exocrine-pancreatic glycoprotein 2 (anti-GP2) are Crohn's disease (CD) markers. However, CD-specific antibodies have also been found in celiac-disease (CeD) patients, in which type 1 diabetes-specific autoantibodies against endocrine pancreatic targets can be present. We investigated whether anti-GP2 are also present in CeD, a disease like CD which is also characterised by intestinal mucosal inflammation with barrier impairment.

**METHODS:** Antibodies against GP2, tissue transglutaminase (tTG), deamidated gliadin (dGD), glutamic decarboxylase (GAD), and islet antigen-2 (IA2) were tested in sera from 73 CD patients, 90 blood donors (BD), and 79 (58 de novo) CeD patients (2 consecutive sera were available from 40 patients).

**RESULTS:** IgA and/or IgG anti-GP2 were found in 15/79 (19.0%) CeD patients on at least one occasion, in 25/73 (34.2%) CD patients, and in 4/90 (4.4%) BD (CeD vs. CD,  $p=0.042$ ; BD vs. CeD and CD,  $p<0.001$ , respectively). Amongst the 58 de novo CeD patients, anti-GP2 IgA and/or IgG were present in 11 (19.0%). Anti-GP2 IgA was significantly less prevalent in CeD compared with CD ( $p=0.004$ ). Anti-GP2 IgA and IgG in CD patients demonstrated a significantly higher median level compared to patients with CeD ( $p<0.001$ ,  $p=0.008$ , respectively). IgA anti-GP2 levels correlated significantly with IgA anti-tTG and anti-dGD levels in CeD Spearman's coefficient of rank correlation ( $\rho=0.42$ , confidence interval (CI): 0.26-0.56,  $p<0.001$ ;  $\rho=0.54$ , CI 0.39-0.65,  $p<0.001$ , respectively).

**CONCLUSIONS:** The presence of anti-GP2 in CeD patients supports the notion that loss of tolerance to GP2 can probably be a manifestation of an autoinflammatory process in this intestinal disorder.

The discriminative capacity of soluble Toll-like receptor (sTLR)2 and sTLR4 in inflammatory diseases.

Ten Oever J, Kox M, van de Veerdonk FL, Mothapo KM, Slavcovici A, Jansen TL, Tweehuysen L, Giamarellos-Bourboulis EJ, Schneeberger PM, Wever PC, Stoffels M, Simon A, van der Meer JW, Johnson MD, Kullberg BJ, Pickkers P, Pachot A, Joosten LA, Netea MG.

**BACKGROUND:** The extracellular domains of cytokine receptors are released during inflammation, but little is known about the shedding of Toll-like receptors (TLR) and whether they can be used as diagnostic biomarkers.

**METHODS:** The release of sTLR2 and sTLR4 was studied in in-vitro stimulations, as well as in-vivo during experimental human endotoxemia (n = 11, 2 ng/kg LPS), and in plasma of 394 patients with infections (infectious mononucleosis, measles, respiratory tract infections, bacterial sepsis and candidemia) or non-infectious inflammation (Crohn's disease, gout, rheumatoid arthritis, autoinflammatory syndromes and pancreatitis). Using C-statistics, the value of sTLR2 and sTLR4 levels for discrimination between infections and non-infectious inflammatory diseases, as well as between viral and bacterial infections was analyzed.

**RESULTS:** In-vitro, peripheral blood mononuclear cells released sTLR2 and sTLR4 by exposure to microbial ligands. During experimental human endotoxemia, plasma concentrations peaked after 2 hours (sTLR4) and 4 hours (sTLR2). sTLR4 did not correlate with cytokines, but sTLR2 correlated positively with TNF $\alpha$  (rs = 0.80, P < 0.05), IL-6 (rs = 0.65, P < 0.05), and IL-1Ra (rs = 0.57, P = 0.06), and

negatively with IL-10 ( $r_s = -0.58$ ,  $P = 0.06$ ), respectively. sTLR4 had a similar area under the ROC curve [AUC] for differentiating infectious and non-infectious inflammation compared to CRP: 0.72 (95% CI 0.66-0.79) versus 0.74 (95% CI 0.69-0.80) [ $P = 0.80$ ], while sTLR2 had a lower AUC: 0.60 (95% CI 0.54-0.66) [ $P = 0.0004$ ]. CRP differentiated bacterial infections better from viral infections than sTLR2 and sTLR4: AUC 0.94 (95% CI 0.90-0.96) versus 0.58 (95% CI 0.51-0.64) and 0.75 (95% CI 0.70-0.80), respectively [ $P < 0.0001$  for both].

CONCLUSIONS: sTLRs are released into the circulation, and suggest the possibility to use sTLRs as diagnostic tool in inflammatory conditions.

Yellow fever is an infectious disease, endemic in South America and Africa. This is a potentially serious illness, with lethality between 5 and 40% of cases. The most effective preventive vaccine is constituted by the attenuated virus strain 17D, developed in 1937. It is considered safe and effective, conferring protection in more than 90% in 10 years. Adverse effects are known as mild reactions (allergies, transaminases transient elevation, fever, headache) and

severe (visceral and neurotropic disease related to vaccine). However, little is known about its potential to induce autoimmune responses. This systematic review aims to identify the occurrence of autoinflammatory diseases related to 17D vaccine administration. Six studies were identified describing 13 possible cases. The diseases were Guillain-Barré syndrome, multiple sclerosis, multiple points evanescent syndrome, acute disseminated encephalomyelitis, autoimmune hepatitis, and Kawasaki disease. The data suggest that 17D vaccination may play a role in the mechanism of loss of self-tolerance.

Author information:

(1)Department of Nephrology, Gulhane Military Academy of Medicine, Haydarpasa Training Hospital, Istanbul, Turkey, ilhankurultak@yahoo.co.uk.

Familial Mediterranean fever (FMF) is an autosomal recessive disorder characterized by episodic, recurrent, self-limited attacks of fever and serositis (sterile peritonitis, pleuritis, arthritis, etc). The insufficiency in restriction of mild inflammation contributes this consequence in FMF. Intrauterine devices (IUDs) have been widely used in the world for contraception by gynecologists as an effective and safe method. Herein, we present a woman with FMF as the first case, whose attacks were triggered by copper-containing IUD. Our hypothesis in the present case was that sterile mild inflammation in the uterus caused by copper-containing IUD may be the initial source of systemic inflammatory response. In our opinion, clinicians should consider that the copper-containing IUDs may be another cause of FMF attacks in women using this contraceptive method.

Neutrophilic dermatosis: disease mechanism and treatment.

Maalouf D(1), Battistella M, Bouaziz JD.

Author information:

(1)Department of Dermatology and Pathology, Université Paris Diderot, Sorbonne Paris Cité, Saint Louis Hospital, Paris, France.

**PURPOSE OF REVIEW:** The purpose of this review is to describe the physiopathological and therapeutic aspects of neutrophilic dermatosis, taking into account their most frequent associated conditions.

**RECENT FINDINGS:** In autoinflammatory syndromes featuring neutrophilic dermatosis, the role of interleukin-1 and tumor necrosis factor (TNF)- $\alpha$  cytokines in the immunopathogenesis of neutrophilic dermatosis has supported their classification as autoinflammatory diseases. In malignancy-associated neutrophilic dermatosis, the role of the malignant clone in myeloid neoplasms and the role of the monoclonal gammopathy and/or of the malignant plasmocyte clone in myeloma have been underlined.

**SUMMARY:** Recent insights into neutrophilic dermatosis' pathophysiology have encouraged the use of targeted biological therapies for their treatment. Although systemic glucocorticoids remain the mainstay of treatment for Sweet's syndrome and pyoderma gangrenosum, anti-TNF- $\alpha$  is becoming the preferred treatment when pyoderma gangrenosum is accompanied by inflammatory bowel disease or rheumatoid arthritis. Interleukin-1 receptor inhibitor anakinra is a promising therapeutic alternative for refractory Sweet's syndrome.

Familial Mediterranean fever associated with MEFV mutations in a large cohort of

Cypriot patients.

Neocleous V(1), Costi C, Kyriakou C, Kyriakides TC, Shamma C, Skordis N, Toumba M, Kyriakou S, Koliou M, Kousparou M, Onoufriou M, Hadjipanayis A, Iasonides M, Atamyan VN, Pierides A, Christophidou-Anastasiadou V, Tanteles GA, Phylactou LA.

Author information:

(1)Department of Molecular Genetics, Function and Therapy, The Cyprus Institute of Neurology and Genetics, Nicosia, Cyprus.

Familial Mediterranean fever (FMF) is caused by mutations in the MEFV gene and the spectrum of mutations among Greek-Cypriots with FMF-related symptoms was examined. Sequence analysis for exons 2, 3, 5, and 10 of the MEFV gene was performed in a cohort of 593 patients. A total of 70 patients carried mutations in the homozygote or compound heterozygote state, 128 were identified with one MEFV mutation and 395 had no mutations. Of the 268 identified alleles, p.Val726Ala (27.61%) was the most frequent followed by p.Met694Val (19.40%). The missense mutations p.Arg761His (3.73%) and p.Ala744Ser (2.24%) were identified as the rarest. An interesting finding is the high frequency (18.28%) of the complex p.Phe479Leu-p.Glu167Asp that was identified in 49 of the mutated alleles. The MEFV genotypes did not follow a binomial distribution and proved not to satisfy the HWE ( $P < 0.001$ ). The high percentage (66.61%) of patients with unidentified mutations could be due to mutations in the rest of the coding or noncoding MEFV gene or due to mutations in other genes that are also causing Hereditary Recurrent Fevers. Results from this work indicate the high incidence of FMF in Cyprus and describe the spectrum of the mutations which occur in the country.

Adult-onset Still's disease (AOSD) is a rare inflammatory disease characterized by the classical triad of daily fever, arthritis, and typical salmon-colored rash. Recent accumulation of knowledge, mostly arising from hereditary autoinflammatory diseases and from the systemic-onset juvenile idiopathic arthritis (sJIA), has given rise to new hypotheses on the pathophysiology of AOSD. In this review, we first discuss on the continuum between AOSD and sJIA. Then, we summarize current hypotheses on the underlying pathogenesis: (1) an infectious hypothesis; (2) an autoinflammatory hypothesis; (3) a lymphohistiocytic hypothesis; and (4) a hyperferritinemic hypothesis. Finally, we present the recent data suggesting that patients with AOSD fall into two distinct subgroups with different courses, one with prominent systemic features and one with chronic arthritis.

J Exp Med. 2014 Nov 17;211(12):2329.

Autoinflammatory syndromes cause sterile inflammation in the absence of any signs of autoimmune responses. Familial cold autoinflammatory syndrome (FCAS) is characterized by intermittent episodes of rash, arthralgia, and fever after exposure to cold stimuli. We have identified a missense mutation in the NLRC4 gene in patients with FCAS. NLRC4 has been known as a crucial sensor for several Gram-negative intracellular bacteria. The mutation in NLRC4 in FCAS patients promoted the formation of NLRC4-containing inflammasomes that cleave procaspase-1 and increase production of IL-1 $\beta$ . Transgenic mice that expressed mutant Nlrc4 under the invariant chain promoter developed dermatitis and arthritis. Inflammation within tissues depended on IL-1 $\beta$ -mediated production of IL-17A from neutrophils but not from T cells. Our findings reveal a previously unrecognized link between NLRC4 and a hereditary autoinflammatory disease and highlight the importance of NLRC4 not only in the innate immune response to bacterial infections but also in the genesis of inflammatory diseases.

Pyoderma gangrenosum as a first presentation of inflammatory bowel disease.

Shahid S(1), Myszor M(1), De Silva A(1).

Author information:

(1)Department of Gastroenterology, Royal Berkshire Hospital, Reading, UK.

Up to 40% of patients with inflammatory bowel disease (IBD) develop an extraintestinal manifestation of the disease with the skin being the most commonly involved organ. Pyoderma gangrenosum (PG), an autoinflammatory non-infectious neutrophilic dermatosis, occurs in 1-2% of patients with IBD. PG can follow a course independent to that of the bowel disease, however, most reported cases describe PG occurring in patients with an established diagnosis of IBD. We present a case of a young patient who presented with axillary skin ulceration, which was subsequently diagnosed as PG. On further investigation for a possible underlying cause, she was found to have Crohn's disease. She had not developed any preceding change in her bowels and did not have abdominal pain; the IBD was diagnosed on endoscopic findings. This case is also unusual for the distribution of the PG lesions that typically occur in the lower limbs.

Blau syndrome (BS) is an autosomal dominant autoinflammatory disease associated with NOD2 gene mutations. It is characterized by arthritis, skin rash, and uveitis. Here, we report contrasting outcomes of a daughter and her mother with BS. Their long-term follow-up revealed the efficacy of anti-tumor necrosis factor inhibitor (TNF) with respect to BS. Joint findings of BS feature tenosynovitis over articular synovitis on ultrasonography. BS might be one of the differential diagnoses of juvenile idiopathic arthritis and rheumatoid arthritis.

Author information:

(1)University Children's Hospital, Steinwiesstrasse 75, 8032, Zurich, Switzerland, guido.laube@kispi.uzh.ch.

The spectrum of pathology in native kidney biopsies varies considerably between different countries. Based on similar biopsy policy and joint workup, biopsy data

of native kidneys of children in Yerevan (Armenia) and Zurich (Switzerland) were compared over a period of two decades (1993-2002 and 2003-2012). A total of 487 renal biopsies in Yerevan (EVN), n = 253; median age 11.2 years (range 0.8-18; 56 % males) and in Zurich (ZRH), n = 234; median age 8.7 years (range 0.1-18; 61 % males) were analyzed. Biopsies from EVN were locally analyzed by light microscopy (LM) and sent to ZRH for electron microscopy (EM) and immunohistochemistry. Biopsies from ZRH were evaluated by LM, EM, and immunofluorescence. The significant difference concerns the high frequency of amyloidosis in EVN (25.4 % in the first and 19.4 % in the second decade vs. 0 % in ZRH) and of IgA nephropathy in ZRH (30.2 % in the first and 26.1 % in the second decade vs. 8.1 in EVN). Certain forms of glomerulonephritis (membranoproliferative type I and membranous) and primary focal segmental glomerulosclerosis tended to be more frequent in EVN than in ZRH. Amyloid nephropathy due to familial Mediterranean fever is still highly frequent in Armenia with a slight decrease in the second decade. In Switzerland, the most common finding was IgA nephropathy.

1849. Amyloid. 2015 Mar;22(1):1-7. doi: 10.3109/13506129.2014.980942. Epub 2014 Nov 7.

Risk factors for AA amyloidosis in Germany.

Blank N(1), Hegenbart U, Lohse P, Beimler J, Röcken C, Ho AD, Lorenz HM, Schönland SO.

Author information:

(1)Department of Medicine V, Amyloidosis Center and Division of Rheumatology, University of Heidelberg , Heidelberg , Germany .

**OBJECTIVE:** To identify risk factors for serum amyloid-A (AA) amyloidosis in patients living in Germany.

**METHODS:** Clinical and genetic data were obtained from 71 patients with AA amyloidosis. SAA1 genotypes were analyzed in 231 individuals. Control groups comprised 45 patients with long-standing inflammatory diseases without AA amyloidosis and 56 age-matched patients without any inflammatory disease.

**RESULTS:** The most frequent underlying diseases of AA amyloidosis were familial Mediterranean fever (FMF) (n = 24, 34%) and inflammatory rheumatic diseases

(n = 30, 42%). Patients without any known underlying disease (n = 11, 16%) were considered as having idiopathic AA amyloidosis. Patients with FMF were significantly younger at disease onset and younger at diagnosis of AA amyloidosis compared with patients with rheumatic diseases. Patients with idiopathic AA amyloidosis were older than patients with definite rheumatic diseases. Patients with FMF and high penetrance MEFV gene mutations had a relative risk of 1.73 for AA amyloidosis. Patients with FMF or a rheumatic disease and the SAA1  $\alpha/\alpha$  genotype had a relative risk of 4.86 and 2.53, respectively, for developing an AA amyloidosis. The prevalence of this risk genotype was 36% in German patients without an inflammatory disease, 92% in German patients with AA amyloidosis and 100% in German patients with idiopathic AA amyloidosis.

CONCLUSIONS: Risk factors for AA amyloidosis are the presence of a hereditary autoinflammatory or chronic rheumatic disease, elevated C-reactive protein and SAA serum levels, a long delay of a sufficient therapy, an advanced age and the SAA1 $\alpha/\alpha$  genotype.

Comment in

Scand J Gastroenterol. 2015 Mar;50(3):378.

OBJECTIVE: Familial Mediterranean fever (FMF) is the most common form of autoinflammatory diseases. We aimed to evaluate the small bowel mucosa by capsule

endoscopy (CE) in FMF patients for investigation of other possible causes of abdominal pain.

**MATERIAL AND METHODS:** The study group consisted of 41 patients with FMF. A standard questionnaire was used to record the gastrointestinal symptoms, other clinical findings, Mediterranean fever gene (MEFV) mutations, and history of medications including non-steroidal anti-inflammatory drugs (NSAIDs).

Gastroscopy, colonoscopy and small bowel CE were performed in all patients, and biopsies were taken from terminal ileum and duodenum.

**RESULTS:** The mean age of the patients was  $34 \pm 11$  years, 63% of them were female, and 76.5% of them were carrying MEFV exon 10 mutations. Only one patient used NSAIDs in addition to colchicine. In endoscopic investigations, gastric erosion was detected in only one patient, and no significant findings were detected in colonoscopy. CE showed small bowel mucosal defects in 44% (erosions in 26.8%, ulcer in 17.1%) and edema in 29.3% of the patients. Most (64%) of the ulcer and erosions were localized to jejunum, and only 24% were in ileum. Mitotic changes as an indirect finding of colchicine toxicity were not different from the changes observed in samples of independent group of patients with irritable bowel syndrome.

**CONCLUSION:** Mucosal defect was observed in half of the FMF patients, which may be associated with underlying inflammation or chronic colchicine exposure. Detection of nonspecific chronic inflammation without mitotic changes supports that mucosal defects may be associated with the autoinflammatory process.

Misregulation of innate immunity leads to autoinflammation. Behçet disease is an autoinflammatory condition involving recurrent attacks of inflammation in skin, eyes, joints, and even the nervous system. The etiology may involve vascular inflammation. Central nervous system involvement in neuro-Behçet disease (NBD) comes in the form of parenchymal NBD or nonparenchymal NBD. The parenchymal form has a predilection for the brainstem, diencephalon and cerebral hemispheres, and represents a meningoencephalitis thought to be related to small vessel vasculitis. Cerebral venous sinus thrombosis, arising from a vasculitic process of large veins, comprises the majority of vascular NBD cases. The rarer monogenetic autoinflammatory syndromes are characterized by periodic fever, and typically present in the pediatric population. Neurologic involvement in these syndromes typically presents in the form of an aseptic meningitis. Treatment of autoinflammatory disorders involves immune modulation with corticosteroids, disease-modifying antirheumatic medications, and increasingly antibodies targeting cytokines like tumor necrosis factor  $\alpha$  and interleukin 1.

Mutations in the caspase recruitment domain, family member 14 (CARD14) gene have recently been described in psoriasis patients, and explain the psoriasis susceptibility locus 2 (PSORS2). CARD14 is a scaffolding protein that regulates NF- $\kappa$ B activation, and psoriasis-associated CARD14 mutations lead to enhanced NF- $\kappa$ B signaling. CARD14 is expressed mainly in epidermal keratinocytes, but also in unidentified dermal cells. In this manuscript, the identity of the dermal cell types expressing CARD14, as well the potential functional consequence of overactive CARD14 in these dermal cell types, was determined. Using two-color immunofluorescence, dermal CARD14 did not co-localize with T-cells, dendritic cells, or macrophages. However, dermal CARD14 did highly co-localize with CD31(+) endothelial cells (ECs). CARD14 was also expressed non-dermal endothelial cells, such as aortic endothelial cells, which may indicate a role of CARD14(+)ECs in the systemic inflammation and cardiovascular comorbidities associated with psoriasis. Additionally, phosphorylated NF- $\kappa$ B was found in psoriatic CARD14(+) CD31(+) ECs, demonstrating this pathway is active in dermal ECs in psoriasis. Transfection of dermal ECs with psoriasis-associated CARD14 mutations resulted in increased expression of several chemokines, including CXCL10, IL-8, and CCL2. These results provide preliminary evidence that CARD14 expression in ECs may contribute to psoriasis through increased expression of chemokines and facilitating recruitment of immune cells into skin.

Targeted delivery systems for biological therapies of inflammatory diseases.

Tran TH(1), Amiji MM.

Author information:

Department of Pharmaceutical Sciences , Boston, MA 02115 , USA +1 617 373 3137 ;  
+1 617 373 8886 ; m.amiji@neu.edu.

**INTRODUCTION:** Inflammatory diseases, including autoimmune diseases and autoinflammatory diseases, are characterized by the imbalance of pro-inflammatory cytokines and anti-inflammatory cytokines. Targeted systems allow for specific delivery and sustained release of biological agents to inflamed tissues and macrophages, hence reducing their side effects.

**AREAS COVERED:** This review discusses various targeting strategies for biological therapies of inflammatory diseases, with a focus on modulating macrophage functional polarization from an M1 to M2 phenotype. Furthermore, recent advances in the development of targeted delivery systems for gene therapy against inflammatory diseases including liposomal therapeutics, polymeric nanoparticles and microspheres, and multi-compartmental delivery systems are summarized.

**EXPERT OPINION:** Molecular advances have uncovered various targets for biological therapies against inflammatory diseases. Despite substantial promise, the potential translation from the bench to the clinic is limited due to poor systemic stability of the delivery systems, low tissue distribution, and safety concerns. In order to develop clinically translatable targeted delivery systems, thorough evaluation of the efficacy and toxicity in relevant animal models and in different inflammatory diseases is needed. In addition, issues related to long-term storage stability, scale-up and manufacturing of the systems need to be addressed.

Autophagy has a large range of physiological functions and its dysregulation contributes to several human disorders, including autoinflammatory/autoimmune diseases such as inflammatory myopathies (IIMs). In order to better understand the pathogenetic mechanisms of these muscular disorders, we sought to define the role of autophagic processes and their relation with the innate immune system in the three main subtypes of IIM, specifically sporadic inclusion body myositis (sIBM), polymyositis (PM), dermatomyositis (DM) and juvenile dermatomyositis (JDM). We found that although the mRNA transcript levels of the autophagy-related genes BECN1, ATG5 and FBXO32 were similar in IIM and controls, autophagy activation in all IIM subgroups was suggested by immunoblotting results and confirmed by immunofluorescence. TLR4 and TLR3, two potent inducers of autophagy, were highly increased in IIM, with TLR4 transcripts significantly more expressed in PM and DM than in JDM, sIBM and controls, and TLR3 transcripts highly up-regulated in all IIM subgroups compared to controls. Co-localization between autophagic marker, LC3, and TLR4 and TLR3 was observed not only in sIBM but also in PM, DM and JDM muscle tissues. Furthermore, a highly association with the autophagic processes was observed in all IIM subgroups also for some TLR4 ligands, endogenous and bacterial HSP60, other than the high-mobility group box 1 (HMGB1). These findings indicate that autophagic processes are active not only in sIBM but also in PM, DM and JDM, probably in response to an exogenous or endogenous 'danger signal'. However, autophagic activation and regulation, and also interaction with the innate immune system, differ in each type of IIM. Better understanding of these differences may lead to new therapies for the different IIM types.

**BACKGROUND:** Amyloid A (AA) amyloidosis is a multisystem, progressive and fatal disease. Renal involvement occurs early in the course of AA. We aimed to investigate the etiology, clinical and laboratory features, and outcome of patients with biopsy-proven renal AA amyloidosis.

**MATERIALS AND METHODS:** A total of 121 patients (male/female: 84/37, mean age  $42.6 \pm 14.4$  years) were analyzed retrospectively between January of 2001 and May of 2013. Demographic, clinical and laboratory features and outcomes data were obtained from follow-up charts.

**RESULTS:** Familial Mediterranean fever (37.2%) and tuberculosis (24.8%) were the most frequent causes of amyloidosis. Mean serum creatinine and proteinuria at diagnosis were  $2.3 \pm 2.1$  mg/dL and  $6.7 \pm 5.3$  g/day, respectively. Sixty-eight (56.2%) patients were started dialysis treatment during the follow-up period. Mean duration of renal survival was  $64.7 \pm 6.3$  months. Age, serum creatinine and albumin levels were found as predictors of end-stage renal disease. Fifty patients (%41.3) died during the follow-up period. The mean survival of patients was  $88.7 \pm 7.8$  months (median:  $63 \pm 13.9$ ). 1, 2 and 5 years survival rates of patients were 80.7%, 68.2% and 51.3%, respectively. Older age, male gender, lower levels of body mass index, estimated glomerular filtration rate, serum albumin, calcium, and higher levels of phosphor, intact parathyroid hormone and proteinuria were associated with a higher mortality. Higher serum creatinine, lower albumin, dialysis requirement and short time to dialysis were predictors of mortality.

**CONCLUSION:** The outcome of patients with AA amyloidosis and renal involvement is poor, particularly in those who had massive proteinuria, severe hypoalbuminemia and dialysis requirement at the outset.

Author information:

(1)Chronic Kidney Disease Research Center, Tabriz University of Medical Science, Tabriz, Iran. ardalan34@hotmail.com.

Familial Mediterranean fever (FMF) is an inherited auto-inflammatory disorder. Secondary AA amyloidosis is the most devastating complication of FMF. Nonamyloid renal involvements have also been reported in association with FMF, including vasculitis, focal and diffuse glomerulonephritis, and IgA nephropathy. We describe a patient with FMF and E148Q mutation who presented with massive proteinuria, elevated serum creatinine level, and acute glomerulonephritis picture. Disease remission was achieved after treatment with corticosteroids and colchicine.

**BACKGROUND:** The group of autoinflammatory syndromes associated with Pyoderma gangrenosum, Acne, and Suppurative Hidradenitis are poorly defined and difficult to control with currently available treatment modalities.

**OBJECTIVES:** We describe a patient with PASH syndrome and report about the successful multimodal treatment with infliximab, cyclosporine, and dapsone.

**METHODS:** A review of the available literature to date about this group of autoinflammatory diseases was performed. We performed genetic analysis for PSTPIP1 mutations associated with PAPA syndrome.

**RESULTS:** A 22-year-old woman presented to our department with pyoderma gangrenosum, concomitant acne, and suppurative hidradenitis. She had previously been treated unsuccessfully with etanercept, adalimumab, fumaric acid and the IL-1 receptor antagonist (IL-1RA) anakinra without prolonged remission. Treatment with intravenous infliximab in combination with cyclosporine and dapsone lead to sudden and prolonged improvement of the clinical symptoms that we classified as PASH syndrome. We review the literature about this group of diseases and report the third case of PASH syndrome to date.

**CONCLUSION:** PASH syndrome and associated diseases should be considered whenever hidradenitis suppurativa is found in association with pyoderma gangrenosum. We

provide a systematic overview about PASH syndrome and suggest a novel multimodal therapeutic regimen beyond isolated inhibition of TNF or IL-1.

Neonatal onset multisystem inflammatory disease (NOMID)/chronic infantile neurologic cutaneous and articular (CINCA) syndrome is a rare, early-onset autoinflammatory disorder and the most severe form of cryopyrin-associated periodic syndrome, which is associated with overproduction of interleukin (IL)-1 $\beta$ . This is a case report of a 70-day-old boy, who was diagnosed with NOMID/CINCA syndrome and who has been treated with anti-IL-1 $\beta$  monoclonal antibody (canakinumab) since then, despite his early infancy. The patient presented with fever, aseptic meningitis, and rash. The clinical manifestations combined with the elevated acute-phase reactants strengthened the suspicion of the diagnosis of NOMID/CINCA syndrome. Specific immunologic workup revealed high levels of serum amyloid A and IL-6. The clinical diagnosis was confirmed by the detection of a de novo mutation of the CIAS1/NLR3 gene (p.Thr348Met), and canakinumab was started

at a dose of 4 mg/kg, higher than the recommended dose for older age. White blood cell, serum amyloid A, C-reactive protein, and IL-6 levels quickly decreased and became normal within a month, and the clinical condition of the patient improved significantly. The infant remains without recurrence of disease or further complications and with satisfactory mental development with anti-IL-1 $\beta$  monoclonal antibody treatment for >2 years. This report indicates the importance of early diagnosis of NOMID/CINCA syndrome and medication with IL-1 blockers as soon as possible for the improvement of the prognosis of cryopyrin-associated periodic syndrome and of a better patient outcome.

When less is more: primary immunodeficiency with an autoinflammatory kick.

Giannelou A(1), Zhou Q, Kastner DL.

Author information:

(1)Inflammatory Disease Section, Intramural Research Program, National Human Genome Research Institute, National Institutes of Health, Bethesda, Maryland, USA.

**PURPOSE OF REVIEW:** Next-generation sequencing is revolutionizing the molecular taxonomy of human disease. Recent studies of patients with unexplained autoinflammatory disorders reveal germline genetic mutations that target important regulators of innate immunity.

**RECENT FINDINGS:** Whole-exome analyses of previously undiagnosed patients have catalyzed the recognition of two new disease genes. First, a phenotypic spectrum, including livedo racemosa, fever with early-onset stroke, polyarteritis nodosa, and Sneddon syndrome, is caused by loss-of-function mutations in cat eye syndrome chromosome region, candidate 1 (CECR1), encoding adenosine deaminase 2. Adenosine deaminase 2 is a secreted protein expressed primarily in myeloid cells, and a regulator of macrophage differentiation and endothelial development.

Disease-associated mutations impair anti-inflammatory M2 macrophage differentiation. Second, patients presenting with cold-induced urticaria, granulomatous rash, autoantibodies, and common variable immunodeficiency, or with blistering skin lesions, bronchiolitis, enterocolitis, ocular inflammation, and mild immunodeficiency harbor distinct mutations in phospholipase  $Cy_2$ , encoding a signaling molecule expressed in natural killer cells, mast cells, and B lymphocytes. These mutations inhibit the function of a phospholipase  $Cy_2$  autoinhibitory domain, causing increased or constitutive signaling.

**SUMMARY:** These findings underscore the power of next-generation sequencing, demonstrating how the primary deficiency of key molecular regulators or even regulatory motifs may lead to autoinflammation, and suggesting a possible role for cat eye syndrome chromosome region, candidate 1 and phospholipase  $Cy_2$  in common diseases.

Amyloid goiter due to familial mediterranean Fever in a patient with byler syndrome: a case report.

Ciğerli O(1), Unal AD(2), Parıldar H(1), Demiralay E(3), Tarçın O(2).

Author information:

(1)Department of Family Medicine, Başkent University Hospital, İstanbul, Turkey.

(2)Department of Endocrinology, Başkent University Hospital, İstanbul, Turkey.

(3)Department of Pathology, Başkent University Hospital, İstanbul, Turkey.

**BACKGROUND:** Familial Mediterranean Fever (FMF), also inherited with autosomal recessive trait, is characterized by recurrent episodes of fever, arthritis, and serositis. Congenital Byler Syndrome (Progressive Familial Intrahepatic Cholestasis) inherited with autosomal recessive trait and characterized by defective secretion of bile acids. FMF associated Amyloid A deposition occurs in many tissues and organs, but amyloid goiter is a rare entity that leads to enlargement and dysfunction of the thyroid.

**CASE REPORT:** We present a rare case of 24 year old male patient who had liver and kidney transplantation due to Byler Syndrome and secondary amyloidosis related to FMF, diagnosed as rapidly growing large amyloid goiter. Deposits of extracellular amyloid and dense adipose metaplasia diagnostic for amyloid goiter are determined upon histopathological examination of thyroidectomy material.

**CONCLUSION:** When goiter was detected in cases with history of systemic amyloidosis and rapidly growing goitre, amyloid goiter should be remembered at first. This case is unique since two autosomal genetic disorders are together in the same patient and important as it emphasizes the consequences of consanguineous marriage, early diagnosis and treatment compliance of FMF and the awareness of amyloid goiter in patients followed by primary care physicians and healthcare professionals.

(2)Department of Internal Medicine I, Marienhospital Herne, Medical Center of Ruhr University Bochum, Herne, Germany (A.Ö., M.K., B.F.H., N.P., A.G.); Institute for Diagnostic and Interventional Radiology and Nuclear Medicine, University Medical Center Bergmannsheil, Ruhr University Bochum, Bochum, Germany (A.Ö.); and Department of Internal Medicine I, St Josef-Hospital, Medical Center of Ruhr University Bochum, Bochum, Germany (R.S., W.S., A.G.). arnd.giese@rub.de.

**OBJECTIVES:** Familial Mediterranean fever (FMF) can be associated with splenomegaly. Prospective quantitative data are lacking. We performed a sonographic assessment of spleen size in patients with FMF and healthy control participants to assess its diagnostic value.

**METHODS:** Patients with FMF according to the criteria of Livneh et al (Arthritis Rheum 1997; 40:1879-1885) who were in an asymptomatic interval and control participants were prospectively included in this study in Germany and underwent sonographic measurement of the spleen as well as a structured interview and a physical examination. Patients and controls were Turkish migrants.

**RESULTS:** Thirty-six patients and 27 controls were included. Patients and controls did not differ significantly in age (mean  $\pm$  SD,  $34.8 \pm 9.7$  versus  $33.3 \pm 10.0$  years, respectively;  $P = .56$ ), sex, height, weight, or body mass index ( $26.7 \pm 4.7$  versus  $26.1 \pm 4.3$  kg/m<sup>2</sup>;  $P = .63$ ). Spleen size was greater in patients than controls in width ( $4.3 \pm 1.0$  versus  $3.7 \pm 0.7$  cm;  $P = .008$ ) and also length ( $12.1 \pm 1.9$  versus  $10.5 \pm 1.4$  cm;  $P = .001$ ). Twenty-six of 36 patients (72.2%) had a history of appendectomy compared to 3 of 27 controls (11.1%;  $P < .001$ ). The combination of an enlarged spleen (length  $>11$  cm and/or width  $>4$  cm) gave specificity of 100% (95% confidence interval, 87%-100%) and a positive predictive value of 100% (95% confidence interval, 78%-100%) for the diagnosis of FMF in our study.

**CONCLUSIONS:** Spleen size as evaluated by sonography is larger in patients with

FMF compared to healthy controls. Most patients with FMF included in this study had undergone appendectomy. Familial Mediterranean fever should be considered as a differential diagnosis in Turkish migrants in Germany if the spleen is enlarged and a history of appendectomy is reported.

Familial Mediterranean fever (FMF) is a genetic disease with autosomal

inheritance characterized by recurrent fever, abdominal pain, and serositis attacks. It is relatively common in the races and ethnical groups around Mediterranean Sea (Sephardic Jews, Armenians, Turks and Arabians). Hereditary elliptocytosis (HE) is common genetic defect of the red blood cell membrane skeleton. Spectrin mutations are the predominant causes of HE. Hypereosinophilia is defined as a number of eosinophil granulocytes equal or greater than  $0.5 \times 10^9/L$  of circulating blood. The main causes are allergies and parasitic infections. This case report describes a Turkish female HE patient who presented with FMF and hypereosinophilia. Genetic analysis revealed heterozygous mutation in exon 10 of the MEFV gene (V726A). The patient was successfully treated with colchicine and steroid treatment at 3-month follow-up. To the best of our knowledge, this is the first report of association between FMF, HE, and hypereosinophilia.

Autoimmunity and autoinflammation are generally considered as mutually exclusive mechanisms of diseases but may concur to specific syndromes. Idiopathic recurrent acute pericarditis (IRAP) is defined as the recurrence of pericardial symptoms at any point following the prior cessation of acute pericarditis, and the latency is generally 6 weeks. Manifestations of pericarditis such as pericardial friction rub, electrocardiographic changes, and pericardial effusion are less frequent in the subsequent episodes compared to the index attack, and in some cases the only clinical sign is represented by a suggestive chest pain. Several autoimmune diseases may manifest with pericarditis which is often related to viral infections, while postviral pericarditis may in turn display a nonspecific autoimmune background. Similarly, autoinflammatory syndromes such as familial Mediterranean fever and tumor necrosis factor receptor-associated periodic syndrome are characterized by self-limiting pericardial symptoms. Corticosteroids are generally effective, thus supporting the autoimmune nature of IRAP, but

dramatic results are obtained with interleukin-1 blocking agents in corticosteroid-dependent cases, pointing to a pathogenic role for the inflammasome. Based on these observations, we submit that IRAP represents a paradigmatic example of the putative coexistence of autoimmunity and autoinflammation: the main aim of this review is to critically discuss the hypothesis as well as the current understanding of this enigmatic clinical condition.

Immunological function of familial Mediterranean fever disease protein Pyrin.

Yang J(1), Xu H, Shao F.

Author information:

(1)National Institute of Biological Sciences, Beijing, 102206, China.

Pyrin, encoded by MEFV gene, is conserved in humans and mice. Mutations in the MEFV gene are associated with the human autoinflammatory disease familial Mediterranean fever (FMF). Pyrin can interact with the inflammasome adaptor ASC and induce inflammatory caspase-1 activation in monocytic cells, but the physiological function of Pyrin has been unknown for many years. Here we summarize previous studies of Pyrin function under the context of FMF and immunity, and discuss a recent study demonstrating that Pyrin forms an inflammasome complex for caspase-1 activation in innate immunity. Pyrin inflammasome detects inactivating modifications of host Rho GTPases by diverse bacterial toxins and infections, including *Clostridium difficile* glucosylating cytotoxin TcdB, FIC-domain adenyltransferase effectors from *Vibrio parahaemolyticus* and *Histophilus somni*, ADP-ribosylating *Clostridium botulinum* C3 toxin as well as *Burkholderia cenocepacia* infection. The mode of Pyrin action, i.e., sensing pathogen virulence activity rather than directly recognizing a microbial molecule, represents a new paradigm in innate immunity.

Comment in

Nat Rev Immunol. 2014 Dec;14(12):780-1.

Intracellular ISG15 is an interferon (IFN)- $\alpha/\beta$ -inducible ubiquitin-like modifier which can covalently bind other proteins in a process called ISGylation; it is an effector of IFN- $\alpha/\beta$ -dependent antiviral immunity in mice. We previously published a study describing humans with inherited ISG15 deficiency but without unusually severe viral diseases. We showed that these patients were prone to mycobacterial disease and that human ISG15 was non-redundant as an extracellular IFN- $\gamma$ -inducing molecule. We show here that ISG15-deficient patients also display unanticipated cellular, immunological and clinical signs of enhanced IFN- $\alpha/\beta$  immunity, reminiscent of the Mendelian autoinflammatory interferonopathies Aicardi-Goutières syndrome and spondyloenchondrodysplasia. We further show that an absence of intracellular ISG15 in the patients' cells prevents the accumulation of USP18, a potent negative regulator of IFN- $\alpha/\beta$  signalling, resulting in the enhancement and amplification of IFN- $\alpha/\beta$  responses. Human ISG15, therefore, is not only redundant for antiviral immunity, but is a key negative regulator of IFN- $\alpha/\beta$  immunity. In humans, intracellular ISG15 is IFN- $\alpha/\beta$ -inducible not to serve as a substrate for ISGylation-dependent antiviral immunity, but to ensure USP18-dependent regulation of IFN- $\alpha/\beta$  and prevention of IFN- $\alpha/\beta$ -dependent autoinflammation.

Enhanced chondrogenesis of induced pluripotent stem cells from patients with neonatal-onset multisystem inflammatory disease occurs via the caspase 1-independent cAMP/protein kinase A/CREB pathway.

Yokoyama K(1), Ikeya M, Umeda K, Oda H, Nodomi S, Nasu A, Matsumoto Y, Izawa K, Horigome K, Kusaka T, Tanaka T, Saito MK, Yasumi T, Nishikomori R, Ohara O, Nakayama N, Nakahata T, Heike T, Toguchida J.

**OBJECTIVE:** Neonatal-onset multisystem inflammatory disease (NOMID) is a dominantly inherited autoinflammatory disease caused by NLRP3 mutations. NOMID pathophysiology is explained by the NLRP3 inflammasome, which produces interleukin-1 $\beta$  (IL-1 $\beta$ ). However, epiphyseal overgrowth in NOMID is resistant to anti-IL-1 therapy and may therefore occur independently of the NLRP3 inflammasome. This study was undertaken to investigate the effect of mutated NLRP3 on chondrocytes using induced pluripotent stem cells (iPSCs) from patients with NOMID.

**METHODS:** We established isogenic iPSCs with wild-type or mutant NLRP3 from 2 NOMID patients with NLRP3 somatic mosaicism. The iPSCs were differentiated into chondrocytes in vitro and in vivo. The phenotypes of chondrocytes with wild-type and mutant NLRP3 were compared, particularly the size of the chondrocyte tissue produced.

**RESULTS:** Mutant iPSCs produced larger chondrocyte masses than wild-type iPSCs owing to glycosaminoglycan overproduction, which correlated with increased expression of the chondrocyte master regulator SOX9. In addition, in vivo transplantation of mutant cartilaginous pellets into immunodeficient mice caused disorganized endochondral ossification. Enhanced chondrogenesis was independent of caspase 1 and IL-1, and thus the NLRP3 inflammasome. Investigation of the human SOX9 promoter in chondroprogenitor cells revealed that the CREB/ATF-binding site was critical for SOX9 overexpression caused by mutated NLRP3. This was supported by increased levels of cAMP and phosphorylated CREB in mutant

chondroprogenitor cells.

CONCLUSION: Our findings indicate that the intrinsic hyperplastic capacity of NOMID chondrocytes is dependent on the cAMP/PKA/CREB pathway, independent of the NLRP3 inflammasome.

Systemic lupus erythematosus (SLE) is characterized by prominent autoinflammatory tissue damage associated with impaired removal of dying cells and DNA. Self DNA-containing immune complexes are able to activate both innate and adaptive immune responses and play an important role in the maintenance and exacerbation of autoimmunity in SLE. In this study, we used DNA from lymphocytes that have undergone activation-induced cell death (AICD-DNA) and analyzed its role on the activation and differentiation of B cells from normal BALB/c mice as well as lupus-prone MRL+/+ and MRL/lpr mice. We found that AICD-DNA directly increased the expression of costimulatory molecules and the survival of naïve B cells in vitro. Although AICD-DNA alone had little effect on the proliferation of naïve B cells, it enhanced LPS-activated B cell proliferation in vitro and in vivo. In addition, AICD-DNA increased plasma cell numbers and IgG production in LPS-stimulated cultures of naïve B cells, in part via enhancing IL-6 production. Importantly, B cells from lupus mice were hyperresponsive to AICD-DNA and/or LPS relative to normal control B cells in terminal plasma cell differentiation, as evidenced by increases in CD138+ cell numbers, IgM production, and mRNA levels of B lymphocyte-induced maturation protein-1 (Blimp-1) and the X-box binding protein 1 (XBP1). Furthermore, AICD-DNA enhanced CD40-activated naïve B cell proliferation. Collectively, these data indicate that self DNA can serve as a DAMP (damage-associated molecular pattern) that cooperates with signals from both innate and adaptive immunity to promote polyclonal B cell activation, a common characteristic of autoimmune diseases.

Chronic non-bacterial osteomyelitis (CNO) is an autoinflammatory disease with unpredictable, painful courses of osteolytic lesions in the bones. CNO is frequently associated with psoriasis and inflammatory bowel disease. In cases with multifocal lesions the term chronic recurrent multifocal osteomyelitis (CRMO) is preferably used. SAPHO (synovitis, acne, pustulosis palmoplantaris, hyperostosis and osteitis) syndrome is regarded as CRMO in adults. New knowledge of the hereditary forms like Majeed syndrome, deficiency of IL-1-receptor antagonist and cherubism is described.

AIM: The aim of the current study is to investigate the prevalence of familial Mediterranean fever gene (MEFV) mutations in a cohort of Egyptian children with inflammatory bowel disease (IBD), and to characterize familial Mediterranean fever (FMF)-IBD patients, helping better understanding of IBD pathogenesis.

METHODS: The study enrolled 17 patients with ulcerative colitis (UC), 15 with Crohn's disease(CD), 10 with indeterminate colitis (IC) and 33 healthy children as controls. All cases and controls were tested for 12 FMF gene mutations by reverse hybridization after multiplex polymerase chain reaction amplification and DNA sampling.

RESULTS: Eighty-eight percent of the IBD patients carried the mutations, with Sequence variant V627A being the commonest versus 42.4% of controls. No

associations were found between MEFV gene mutations, and phenotypic characteristics of IBD patients.

CONCLUSION: IBD patients, in populations with a high background carrier rate of MEFV variants, should be screened for MEFV gene mutations, especially those diagnosed as indeterminate colitis. Testing larger numbers of healthy Egyptian children for MEFV gene mutation is important to further determine the allele frequency in Egypt.

Autoinflammatory diseases include a large spectrum of monogenic diseases, e.g. familial Mediterranean fever (FMF), as well as complex genetic trait diseases, e.g. adult-onset Still's disease (AOSD). In populations where FMF is common, an increased MEFV mutation rate is found in patients with rheumatic diseases. The aim of this study was to examine MEFV mutations in Japanese patients with AOSD. Genomic DNA was isolated from 49 AOSD patients and 105 healthy controls, and exons 1, 2, 3 and 10 of the MEFV gene genotyped by direct sequencing. MEFV mutation frequencies in AOSD patients were compared with controls. We found no significant difference in overall allele frequencies of MEFV variants between AOSD patients and controls. However, MEFV exon 10 variants (M694I and G632S) were significantly higher in AOSD patients than controls (6.1 versus 0%). In addition, there was no significant difference between MEFV variant carriers and non-carriers with clinical manifestations, but the monocyclic clinical course of

the AOSD disease phenotype was observed less frequently in patients without MEFV variants. AOSD patients had significantly higher frequencies of MEFV exon 10 mutations, suggesting that low-frequency variants of MEFV gene may be one of the susceptibility factors of AOSD.

Interleukin-18 (IL-18), a pro-inflammatory cytokine belonging to the interleukin-1 (IL-1) family, is involved in the pathogenesis of autoimmune/autoinflammatory and allergic diseases such as juvenile idiopathic arthritis and bronchial asthma. IL-18 forms a signalling complex with the IL-18 receptor  $\alpha$  (IL-18R $\alpha$ ) and  $\beta$  (IL-18R $\beta$ ) chains; however, the detailed activation mechanism remains unclear. Here, the IL-18-IL-18R $\alpha$  binary and IL-18-IL-18R $\alpha$ -IL-18R $\beta$  ternary complexes were purified and crystallized as well as IL-18 alone. An X-ray diffraction data set for IL-18 was collected to 2.33 Å resolution from a crystal belonging to space group P2<sub>1</sub>, with unit-cell parameters  $a = 68.15$ ,  $b = 79.51$ ,  $c = 73.46$  Å,  $\beta = 100.97^\circ$ . Crystals of both the IL-18 binary

and ternary complexes belonging to the orthorhombic space groups P21212 and P212121, respectively, diffracted to 3.10 Å resolution. Unit-cell parameters were determined as a = 135.49, b = 174.81, c = 183.40 Å for the binary complex and a = 72.56, b = 111.56, c = 134.57 Å for the ternary complex.

Uveitis, a group of conditions characterized by intraocular inflammation, is a major cause of sight loss in the working population. Most uveitis seen in Western countries is noninfectious and appears to be autoimmune or autoinflammatory in nature, requiring treatment with immunosuppressive and/or anti-inflammatory drugs. In this educational review, we outline the ideal characteristics of drugs for uveitis and review the data to support the use of current and emerging therapies in this context. It is crucial that we continue to develop new therapies for use in uveitis that aim to suppress disease activity, prevent

accumulation of damage, and preserve visual function for patients with the minimum possible side effects.

Update on skin allergy.

Schlapbach C(1), Simon D.

Author information:

(1)Department of Dermatology, Inselspital, Bern University Hospital, University of Bern, Bern, Switzerland.

Skin diseases with an allergic background such as atopic dermatitis, allergic contact dermatitis, and urticaria are very common. Moreover, diseases arising from a dysfunction of immune cells and/or their products often manifest with skin symptoms. This review aims to summarize recently published articles in order to highlight novel research findings, clinical trial results, and current guidelines on disease management. In recent years, an immense progress has been made in understanding the link between skin barrier dysfunction and allergic sensitization initiating the atopic march. In consequence, new strategies for treatment and prevention have been developed. Novel pathogenic insights, for example, into urticaria, angioedema, mastocytosis, led to the development of new therapeutic approaches and their implementation in daily patient care. By understanding distinct pathomechanisms, for example, the role of IL-1, novel entities such as autoinflammatory diseases have been described. Considerable effort has been made to improve and harmonize patient management as documented in several guidelines and position papers.

[Purpose] The aim of this study was to measure bone mineral density, serum and urinary bone turnover parameters, and to evaluate the influence of demographic and genetic factors on these parameters in FMF patients. [Subjects and Methods] Twenty-seven attack-free patients who were diagnosed with FMF (in accordance with Tel Hashomer criteria) were recruited at outpatient rheumatology clinics. We investigated whether there were any differences between the FMF patients and a control group in terms of lumbar and femur bone mineral density (BMD), standard deviation scores (Z scores and T scores) and bone markers. [Results] In terms of the median values of lumbar BMD ( $p = 0.21$ ), lumbar T ( $p = 0.098$ ) and Z ( $p = 0.109$ ) scores, femoral neck BMD, femoral T and Z scores and total femur BMD, T ( $p = 0.788$ ) and Z scores, there were no significant differences. [Conclusion] In our study, no statistically significant differences were found between FMF patients and a control group in terms of osteoporosis. The 25-OH vitamin D was found to be significantly lower in FMF patients than in the control group.

The incidences of chronic inflammatory disorders have increased considerably over the past three decades. Recent shifts in dietary consumption may have contributed importantly to this surge, but how dietary consumption modulates inflammatory disease is poorly defined. *Pstpip2(cmo)* mice, which express a homozygous Leu98Pro missense mutation in the Pombe Cdc15 homology family protein PSTPIP2 (proline-serine-threonine phosphatase interacting protein 2), spontaneously develop osteomyelitis that resembles chronic recurrent multifocal osteomyelitis in humans. Recent reports demonstrated a crucial role for interleukin-1 $\beta$  (IL-1 $\beta$ ) in osteomyelitis, but deletion of the inflammasome components caspase-1 and NLRP3 failed to rescue *Pstpip2(cmo)* mice from inflammatory bone disease. Thus, the upstream mechanisms controlling IL-1 $\beta$  production in *Pstpip2(cmo)* mice remain to be identified. In addition, the environmental factors driving IL-1 $\beta$ -dependent inflammatory bone erosion are unknown. Here we show that the intestinal microbiota of diseased *Pstpip2(cmo)* mice was characterized by an outgrowth of *Prevotella*. Notably, *Pstpip2(cmo)* mice that were fed a diet rich in fat and cholesterol maintained a normal body weight, but were markedly protected against inflammatory bone disease and bone erosion. Diet-induced protection against osteomyelitis was accompanied by marked reductions in intestinal *Prevotella*

levels and significantly reduced pro-IL-1 $\beta$  expression in distant neutrophils. Furthermore, pro-IL-1 $\beta$  expression was also decreased in Pstpip2(cmo) mice treated with antibiotics, and in wild-type mice that were kept under germ-free conditions. We further demonstrate that combined deletion of caspases 1 and 8 was required for protection against IL-1 $\beta$ -dependent inflammatory bone disease, whereas the deletion of either caspase alone or of elastase or neutrophil proteinase 3 failed to prevent inflammatory disease. Collectively, this work reveals diet-associated changes in the intestinal microbiome as a crucial factor regulating inflammasome- and caspase-8-mediated maturation of IL-1 $\beta$  and osteomyelitis in Pstpip2(cmo) mice.

Henoch-Schönlein purpura (HSP) is a vasculitic disorder resulting from autoinflammatory-mediated tissue injury. Procalcitonin (PCT) and C-reactive protein (CRP) are two biomarkers of the immune response that recognize bacterial infection and inflammation, respectively. This study tested whether levels of PCT and CRP were associated with selected clinical features, disease severity, and organ damage in HSP. Eighty-nine pediatric patients with HSP were analyzed for clinical manifestations and organ damage. Serum CRP, PCT, and occult blood in the urine and stool (prior to steroid therapy) were measured. Disease severity was classified according to previously established clinical classifications. Sixty

patients (67.4 %) had a low clinical score (LCS) of  $<4$  (group A) while 29 patients (32.5 %) had a high clinical score (HCS) of  $\geq 4$  (group B). When patients were then classified by the presence of gastrointestinal bleeding, 66 (74.2 %) cases lacked alimentary tract hemorrhage (group C) while 23 (25.8 %) cases presented with gastrointestinal bleeding (group D). There were no significant differences in CRP (group A: median = 5.26, range = 1.00-77.60 vs. group B: median = 8.59, range = 1.00-144.00 mg/l;  $u = 1.397$ ) or PCT levels (group A: median = 0.05, range = 0.05-0.24 vs. group B: median = 0.08, range = 0.05-1.02 ng/ml;  $u = 1.709$ ) between groups A and B. When serum PCT levels were examined in relation to gastrointestinal bleeding, the levels of serum PCT were higher in group D than group C patients (group D: median = 0.09, range = 0.05-1.02 vs. group C: median = 0.05, range = 0.05-0.32 ng/ml;  $u = 2.849$ ). It is important to note that the average PCT level was below the threshold for a systemic bacterial infection (0.5 ng/ml). We did not observe a correlation between CRP levels and the absence or presence of GI bleeding in groups C or D (group C: median = 4.66, range = 1.00-144.00 vs. group D: median = 9.44, range = 1.06-124.00 mg/l;  $u = 1.783$ ), respectively. In all patients, there was a significant correlation between the concentrations of PCT and CRP ( $r = 0.721$ ,  $p = 0.002$ ). In patients with HSP, inflammatory markers are not uniformly associated with the disease and instead, show variable association depending on the clinical severity and level of organ damage. In patients with severe HSP, elevated serum PCT was significantly associated with gastrointestinal bleeding. In contrast, CRP was not a specific predictor for different clinical classifications of HSP, despite a similar pattern of concentration changes to PCT.

[Still's disease--juvenile arthritis with systemic onset].

[Article in Finnish]

Kröger L, Putto-Laurila A, Vähäsalo P, Malin M, Aalto K.

Systemic onset juvenile idiopathic arthritis is a rare form of juvenile arthritis in which, contrary to autoimmune diseases in general, no association with a

certain tissue type has been detected. Together with this fact, the lack of autoantibodies and the general symptoms belonging to the diagnostic criteria of the illness such as high fever, rather speak for its classification into autoinflammatory diseases. Treatment is usually started with anti-inflammatory drugs, often requiring combination with a systemic glucocorticoid. Recognition of interleukins 1 and 6 as central mediators in the pathogenesis of the disease has brought new possibilities for its treatment.

[Familial Mediterranean fever (paroxysmal polyserositis, familial recurring polyserositis, periodic disease)].

[Article in Russian]

Shamov IA.

Paroxysmal polyserositis is an orphan disease most often affecting Mediterranean populations. It is caused by a mutation on chromosome 16 leading to pyrine synthesis disorder. The disease has a characteristic clinical picture, the most prominent manifestation being recurrent aseptic inflammation of serous membranes especially in peritoneum, marked temperature reaction, and apparent spontaneous recovery in the attack-free period. Inadequate or excessively intense treatment may cause complication in the form of secondary amyloidosis of internal organs. The most effective therapeutic modality is daily intake of colchicine at a dose of 1-1.5 mg.

**OBJECTIVE:** Inflammatory attacks of familial Mediterranean fever (FMF) are characterised by circulation and influx of high number of polymorphonuclear neutrophils (PMN) in the affected sites and profound therapeutic effect of IL-1 $\beta$  inhibitors. We investigated the role of neutrophil extracellular traps (NET) in the pathogenesis of FMF, and their involvement in IL-1 $\beta$  production.

**METHODS:** Blood samples were obtained from six FMF patients during remissions and from three patients during attacks. NET formation and NET components were studied by fluorescence techniques, immunoblotting and MPO-DNA complex ELISA.

**RESULTS:** PMNs from patients released NETs decorated with IL-1 $\beta$  during disease attacks. On the other hand, PMNs from patients during remission were resistant to inflammatory stimuli that induce NET release in PMNs from control subjects. Lower basal autophagy levels were identified in PMNs during remission, while induction of autophagy facilitated NET release, suggesting that autophagy is involved in the regulation of NET release. During the resolution of attacks, inhibition of NET formation by negative feedback mechanism was also observed. The anti-inflammatory agents, colchicine and DNase I, inhibited IL-1 $\beta$  production in PMNs and IL-1 $\beta$  activity in NETs, respectively.

**CONCLUSIONS:** We suggest two additive events for triggering the FMF attack; the production of IL-1 $\beta$  by PMNs and its release through NETs. At the same time NETs, homeostatically, downregulate further NETosis, facilitating the resolution of attack. Compensatorily, lower basal autophagy of PMNs may protect from crises by attenuating the release of pro-inflammatory NETs.

Genotype-phenotype correlation in Japanese patients with familial Mediterranean fever: differences in genotype and clinical features between Japanese and Mediterranean populations.

Kishida D, Nakamura A, Yazaki M, Tsuchiya-Suzuki A, Matsuda M, Ikeda S.

**INTRODUCTION:** Familial Mediterranean fever (FMF) is a hereditary autoinflammatory disease characterized by recurrent self-limiting fever and serositis that mainly affects Mediterranean populations. Many patients with FMF have been reported in Japan due to increasing recognition of this condition and the availability of genetic analysis for the gene responsible, MEFV. The present study was performed to elucidate the clinical characteristics of Japanese FMF patients and to examine the precise genotype-phenotype correlation in a large cohort of Japanese FMF patients.

**METHODS:** We analyzed the MEFV genotypes and clinical manifestations in 116 patients clinically diagnosed as having FMF and with at least one mutation.

**RESULTS:** The most frequent mutation in Japanese patients was E148Q (40.2%), followed by M694I (21.0%), L110P (18.8%), P369S (5.4%), and R408Q (5.4%). In contrast, common mutations seen in Mediterranean patients, such as M694V, V726A, and M680I, were not detected in this population. The clinical features with M694I were associated with more severe clinical course compared to those seen with E148Q. P369S/R408Q showed variable phenotypes with regard to both clinical manifestations and severity. Patients with M694I showed a very favorable response to colchicine therapy, while those with P369S and R408Q did not.

**CONCLUSIONS:** Clinical features and efficacy of treatment in Japanese FMF patients vary widely according to the specific MEFV gene mutation, and therefore genetic analysis should be performed for diagnosis in cases of Japanese FMF.

Familial Mediterranean fever in which Crohn's disease was suspected: a case report.

Matsumoto S(1), Urayoshi S, Yoshida Y.

Author information:

(1)Department of Gastroenterology, Saitama Medical Center, Jichi Medical University, 1-847 Amanuma, Omiya, Saitama, Saitama 330-8503, Japan.  
s.w.himananon@ac.auone-net.jp.

**BACKGROUND:** Familial Mediterranean fever is a hereditary autoinflammatory disease, mainly characterized by periodic fever and serositis. The level of awareness about familial Mediterranean fever is far from sufficient, and it is assumed that there may be many patients with this disease who are under observation without an accurate diagnosis.

**CASE PRESENTATION:** A 30-year-old Japanese man presented to us with a few years' history of recurrent episodes of fever, abdominal pain and diarrhea. He often visited a hospital when the attacks occurred; however, acute enteritis was diagnosed each time, and the symptoms resolved spontaneously within a few days. When he noticed a shortening of the interval between the attacks, he visited the hospital again. Upper endoscopy and colonoscopy performed at this hospital revealed no significant abnormal findings. He was then referred to our hospital under the suspicion of a small intestinal disease. Abdominal computed tomography revealed wall thickening and increased density of the mesenteric adipose tissue in the jejunum, which led us to suspect Crohn's disease. Oral double-balloon enteroscopy was performed; because this revealed only mild mucosal edema in the jejunum, Crohn's disease was considered to be highly improbable. Based on the patient's clinical course, we suspected familial Mediterranean fever. As the Livneh criteria for familial Mediterranean fever were satisfied, the patient was started on oral colchicine for the purpose of diagnostic treatment. A definitive diagnosis of familial Mediterranean fever was then made based on the detection of a mutation of the Mediterranean fever gene. A marked reduction in the frequency of attacks was observed in response to colchicine treatment.

**CONCLUSIONS:** Although Crohn's disease may be considered first in the differential diagnosis of young patients presenting with periodic fever, abdominal pain and diarrhea, the possibility of familial Mediterranean fever should also be borne in mind.

The NLRC4 inflammasome mediates the rapid release of proinflammatory cytokines in response to various microbial stimuli, but its role in the pathology of human diseases remains unknown. Two new studies now report gain-of-function mutations in the NLRC4 gene that cosegregate with distinct autoinflammatory syndromes in affected families.

**BACKGROUND:** NOD2 is the genetic cause of Blau syndrome, an autoinflammatory disease that manifests as coincident uveitis and arthritis. Since dysregulation of IL-1 signalling is considered a pathogenic mechanism in a number of related autoinflammatory conditions, we examined the extent to which unimpeded interleukin (IL)-1 signalling influences NOD2-dependent inflammation of the eye versus the joint.

**METHODS:** Mice deficient for IL-1R antagonist (IL-1Ra) were administered the NOD2 agonist muramyl dipeptide (MDP) by systemic (intraperitoneal) or local (intraocular and/or intra-articular) injections. NOD2-deficient mice received an intraocular injection of recombinant IL-1 $\beta$ . Uveitis was evaluated by intravital videomicroscopy and histopathology, and arthritis was assessed by near-infrared imaging and histopathology. Ocular levels of IL-1 $\alpha$ , IL-1 $\beta$  and IL-1Ra were quantified by enzyme-linked immunosorbent assay.

**RESULTS:** IL-1Ra deficiency did not render mice more responsive to systemic exposure of MDP. Despite the increased production of IL-1R agonists IL-1 $\alpha$  and IL-1 $\beta$  in response to intraocular injection of MDP, deficiency in IL-1Ra did not predispose mice to MDP-triggered uveitis, albeit intravascular cell rolling and adherence were exacerbated. NOD2 expression was dispensable for the potential of IL-1 to elicit uveitis. However, we find that IL-1Ra does play an important protective role in arthritis induced locally by MDP injection in the joint.

**CONCLUSIONS:** Our findings highlight the complexity of NOD2 activation and IL-1 signalling effects that can be compounded by local environmental factors of the target organ. These observations may impact how we understand the molecular mechanisms by which NOD2 influences inflammation of the eye versus joint, and consequently, treatment options for uveitis versus arthritis.

Correcting the expression of miRNA-155 represses PP2Ac and enhances the release of IL-2 in PBMCs of juvenile SLE patients.

MicroRNA-155 is involved in immune cell, differentiation, maturation and function. MiR-155 showed variable dysregulated expression in autoimmune diseases such as systemic lupus erythematosus (SLE) and rheumatoid arthritis (RA) patients. MiR-155 was previously confirmed to directly target CAMP response element binding protein (CREB), which was previously identified as a positive regulator of protein phosphatase 2A (PP2A). PP2A is a key negative regulator of interleukin-2, which is an important immune modulator and was previously shown to be decreased in SLE. In this study we aimed at investigating the regulation of PP2A by miR-155 and hence its role in juvenile SLE disease pathogenesis. MiR-155 showed significant downregulation in PBMCs from juvenile SLE and juvenile familial Mediterranean fever (FMF) and significant upregulation in PBMCs from juvenile idiopathic arthritis (JIA) patients. In SLE, miR-155 expression was negatively correlated with Systemic Lupus Erythematosus Disease Activity Index (SLEDAI) score and proteinuria and was positively correlated with white blood cell (WBC) count. The mRNA of the catalytic subunit of PP2A (PP2Ac) showed significant upregulation in PBMCs from SLE and FMF but not in JIA patients. Additionally, the relative expression of PP2Ac mRNA was positively correlated with SLEDAI score. Forced expression of miR-155 led to decreased relative expression of PP2Ac mRNA and increased IL-2 release in cultured-stimulated PBMCs. This study suggests for the first time the possible role of an miR-155-PP2Ac loop in regulating IL-2 release and identifies miR-155 as a potential therapeutic target in juvenile SLE disease through relieving IL-2 from the inhibitory role of PP2A.

Systemic autoinflammatory diseases are caused by abnormal activation of the cells that mediate innate immunity. In the past two decades, single-gene defects in different pathways, driving clinically distinct autoinflammatory syndromes, have been identified. Studies of these aberrant pathways have substantially advanced understanding of the cellular mechanisms that contribute to mounting effective and balanced innate immune responses. For example, mutations affecting the function of cytosolic immune sensors known as inflammasomes and the IL-1 signalling pathway can trigger excessive inflammation. A surge in discovery of new genes associated with autoinflammation has pointed to other mechanisms of disease linking innate immune responses to a number of basic cellular pathways, such as maintenance of protein homeostasis (proteostasis), protein misfolding and clearance, endoplasmic reticulum stress and mitochondrial stress, metabolic stress, autophagy and abnormalities in differentiation and development of myeloid cells. Although the spectrum of autoinflammatory diseases has been steadily expanding, a substantial number of patients remain undiagnosed. Next-generation sequencing technologies will be instrumental in finding disease-causing mutations in as yet uncharacterized diseases. As more patients are reported to have clinical features of autoinflammation and immunodeficiency or autoimmunity, the complex interactions between the innate and adaptive immune systems are unveiled.

Many advances in dermatology have been made in recent years. In the present review article, newly described disorders from the last six years are presented in detail. We divided these reports into different sections, including syndromes, autoinflammatory diseases, tumors, and unclassified disease. Syndromes included are "circumferential skin creases Kunze type" and "unusual type of pachyonychia congenita or a new syndrome"; autoinflammatory diseases include "chronic atypical neutrophilic dermatosis with lipodystrophy and elevated temperature (CANDLE) syndrome," "pyoderma gangrenosum, acne, and hidradenitis suppurativa (PASH) syndrome," and "pyogenic arthritis, pyoderma gangrenosum, acne, and hidradenitis suppurativa (PAPASH) syndrome"; tumors include "acquired reactive digital fibroma," "onychocytic matricoma and onychocytic carcinoma," "infundibulocystic nail bed squamous cell carcinoma," and "acral histiocytic nodules"; unclassified disorders include "saurian papulosis," "symmetrical acrokeratoderma," "confetti-like macular atrophy," and "skin spicules," "erythema papulosa semicircularis recidivans."

Rheumatology (Oxford). 2015 Nov;54(11):2119.

Rheumatology (Oxford). 2015 Nov;54(11):2118.

**OBJECTIVE:** The aim of this study was to analyse the role of circulating cleaved IL-1 $\beta$  in patients with FMF.

**METHODS:** We enrolled 20 patients with FMF (5 males and 15 females), 22 patients with RA (4 males and 18 females) and 22 healthy controls (6 males and 16 females). Serum levels of serum amyloid A (SAA) were measured by ELISA. We also determined whether IL-1 $\beta$  was present as the cleaved form (p17) in the sera of FMF patients by immunoblotting using anti-cleaved IL-1 $\beta$  antibody.

**RESULTS:** Although SAA concentrations were elevated in the sera, there was no significant difference in these concentrations between FMF patients and RA patients. Immunoblot analysis demonstrated that the cleaved form of IL-1 $\beta$  (p17) was present in sera from FMF patients during febrile attack periods, but not in healthy controls. Bands representing the cleaved form of IL-1 $\beta$  were not detected in serum from FMF patients at non-febrile attack periods or remission periods under colchicine treatment. The amounts of cleaved IL-1 $\beta$  (p17) were significantly higher in patients with FMF compared with those in patients with RA in the inflammatory phase.

**CONCLUSION:** The cleaved form of IL-1 $\beta$  is a valuable biomarker for monitoring disease activity and response to colchicine treatment in patients with FMF. It might be useful to discriminate FMF from other non-IL-1 $\beta$ -mediated inflammatory disorders.

**BACKGROUND:** Due to an increased frequency of vasculitis in FMF patients, many investigators have studied MEFV mutations in patients with HSP. The aim of the study is to investigate the frequency and clinical significance of MEFV mutations in Egyptian children with Henoch-Schonlein purpura (HSP). Investigating MEFV mutations in controls may help in estimating the prevalence of MEFV mutation carrier rate in Egyptian children.

**METHODS:** The study enrolled 90 individuals, sixty children with Henoch-Schonlein purpura (HSP), together with 30 sex-and age-matched apparently healthy controls. The entire study group was screened for 12 common MEFV mutations using a reverse hybridization assay of biotinylated PCR products.

**RESULTS:** Patients with HSP had a significantly higher frequency of MEFV mutations (61.7%), when compared to the apparently healthy control population (36.7%). V726A was the most frequent mutation with an allelic frequency of 10.8%. Ninety-one percent of patients with MEFV mutations were heterozygous for one mutation, while 8.1% had a compound heterozygous MEFV gene mutations. The mutation V726A, followed by E148Q, were the leading mutations, present in 16.6% and in 13.3% of controls.

**CONCLUSIONS:** MEFV mutations may be related to HSP susceptibility in children. The mutations were not associated with any clinical and laboratory manifestations. Screening for MEFV mutations in larger number of HSP children may be beneficial to evaluate any possible relationship between certain types of MEFV mutations and HSP, and compare the HSP MEFV mutations to the types of MEFV mutations associated with FMF.

Molecular regulation of cell fate in cerebral ischemia: role of the inflammasome and connected pathways.

Trendelenburg G(1).

Author information:

(1)Department of Neurology, University Medical Center Göttingen, Göttingen, Germany.

Analogous to Toll-like receptors, NOD-like receptors represent a class of pattern recognition receptors, which are cytosolic and constitute part of different inflammasomes. These large protein complexes are activated not only by different pathogens, but also by sterile inflammation or by specific metabolic conditions. Mutations can cause hereditary autoinflammatory systemic diseases, and inflammasome activation has been linked to many multifactorial diseases, such as diabetes or cardiovascular diseases. Increasing data also support an important role in different central nervous diseases such as stroke. Thus, the current knowledge of the functional role of this intracellular 'master switch' of inflammation is discussed with a focus on its role in ischemic stroke, neurodegeneration, and also with regard to the recent data which argues for a relevant role in other organs or biologic systems which influence stroke incidence or prognosis.

Vogt-Koyanagi-Harada disease (VKHD) is a multisystemic disorder characterized by granulomatous panuveitis variably combined with T cell-mediated neurologic and cutaneous manifestations. Early and aggressive treatment with systemic corticosteroids is the mainstay of treatment for VKHD. Additional use of immunosuppressants, intravenous immunoglobulins, and tumor necrosis factor-alpha inhibitors can help the most severely affected patients and work as corticosteroid-sparing agents. We report the case of a young woman with relapsing and multiresistant VKHD who demonstrated a stable remission of both uveitis and high-frequency hearing loss following rituximab intravenous administration (1 g. twice, 2 weeks apart, and 6 months later). A complete clinical response was observed 1 month since the first infusion, and no ocular relapses were recorded during the following year; in addition, audiometry showed a high-frequency hearing recovery in the right ear. Further observational studies are required to define the role of CD20 inhibition in the management of VKHD.

Exertional leg pain in familial Mediterranean fever: a manifestation of an underlying enthesopathy and a marker of more severe disease.

Eshed I(1), Rosman Y, Livneh A, Kedem R, Langevitz P, Ben-Zvi I, Lidar M.

Author information:

(1) Sheba Medical Center, Tel Hashomer, Israel.

**OBJECTIVE:** Exertional leg pain is a characteristic musculoskeletal manifestation of familial Mediterranean fever (FMF). We aimed to define the frequency and characteristics of exertional leg pain in a large cohort of FMF patients and to evaluate for additional signs and symptoms of spondyloarthritis (SpA) in this patient population.

**METHODS:** FMF patients were allocated into study or control groups based on the presence or absence of exertional leg pain. Randomly selected patients underwent magnetic resonance imaging (MRI) of the ankle as well as plain radiography of the sacroiliac joints.

**RESULTS:** The prevalence of exertional leg pain among the 170 FMF patients included in the study was 58.2%. Patients with exertional leg pain had significantly more joint attacks (74.7% versus 40.8%;  $P < 0.0001$ ), fever attacks (35.4% versus 15.5%;  $P = 0.004$ ), and pleuritis attacks (48.5% versus 29.6%;  $P = 0.013$ ) as well as more attacks per year. Elevations of inflammation markers were significantly more frequent among the study group (for the erythrocyte sedimentation rate, 44.4% of patients versus 21.1% of patients;  $P = 0.016$ ) (for the C-reactive protein level, 48.4% of patients versus 31.8% of patients;  $P = 0.013$ ), and M694V homozygosity was more prevalent among the study group (45.5% versus 21.1%;  $P = 0.001$ ). Signs compatible with enthesopathy on MRI were observed in 73.5% of patients in the study group and in 33.3% of patients in the control group ( $P = 0.046$ ). Definite SpA was diagnosed in 41.2% of the patients in the study group compared to none of the controls ( $P = 0.07$ ) (odds ratio 1.7 [95% confidence interval 1.2-2.3]).

**CONCLUSION:** Exertional leg pain is a common manifestation of FMF and is a marker of a more severe disease phenotype. Additionally, exertional leg pain is frequently associated with sacroiliitis and an underlying ankle enthesopathy and should therefore be considered a new feature of SpA.

Manipulating cytokine function with protein-based drugs has proven effective for treating a wide variety of autoimmune and autoinflammatory disorders. However, the limited ability of protein-based drugs to modulate intracellular targets, including many implicated by studies of the genetics and physiology of these diseases, and to coordinately neutralize redundant inflammatory cytokines, suggests an important and complementary role for small molecules in immunomodulatory drug development. The recent clinical approval of Janus kinase and phosphodiesterase inhibitors, along with emerging evidence from other compound classes, firmly establish small molecules as effective tools for modulating therapeutically relevant proteins that give rise to aberrant cytokine signaling or mediate its downstream consequences.

**OBJECTIVE:** The pathologic basis of systemic juvenile idiopathic arthritis (JIA) is a subject of some controversy, with evidence for both autoimmune and autoinflammatory etiologies. Several monogenic autoinflammatory disorders have been described, but thus far, systemic JIA has only been attributed to a mutation of MEFV in rare cases and has been weakly associated with the HLA class II locus. This study was undertaken to identify the cause of an autosomal-recessive form of systemic JIA.

**METHODS:** We studied 13 patients with systemic JIA from 5 consanguineous families, all from the southern region of Saudi Arabia. We used linkage analysis, homozygosity mapping, and whole-exome sequencing to identify the disease-associated gene and mutation.

**RESULTS:** Linkage analysis localized systemic JIA to a region on chromosome 13 with a maximum logarithm of odds score of 11.33, representing the strongest linkage identified to date for this disorder. Homozygosity mapping reduced the critical interval to a 1.02-Mb region defined proximally by rs9533338 and distally by rs9595049. Whole-exome sequencing identified a homoallelic missense mutation in LACC1, which encodes the enzyme laccase (multicopper oxidoreductase) domain-containing 1. The mutation was confirmed by Sanger sequencing and segregated with disease in all 5 families based on an autosomal-recessive pattern of inheritance and complete penetrance.

**CONCLUSION:** Our findings provide strong genetic evidence of an association of a mutation in LACC1 with systemic JIA in the families studied. Association of LACC1 with Crohn's disease and leprosy has been reported and justifies investigation of its role in autoinflammatory disorders.

The aim of this study is to assess the long-term effectiveness and safety of IL1Ra in Schnitzler syndrome (SchS). Between 2010 and 2012, we performed a nationwide survey among French internal medicine departments to identify SchS patients. We retrospectively analyzed the long-term efficacy and safety of IL1Ra and the outcome of patients that did not receive this treatment. Forty-two patients were included in the study, 29 of whom received IL1Ra. The mean age at disease onset was 59.9years. Disease manifestations included urticaria (100%), fever (76%), bone/joint pain (86%), bone lesions (76%), anemia (67%), and weight loss (60%). The monoclonal gammopathy was overwhelmingly IgM kappa (83%). The mean follow-up was 9.5years (range: 1.6-35). Two patients developed Waldenström's macroglobulinemia and one developed AA amyloidosis. All of the 29 patients who received IL1Ra responded dramatically. After a median follow-up of 36months (range: 2-79), the effectiveness remained unchanged. All patients remained on anti-IL-1 therapy. Twenty-four patients (83%) went into complete remission and five (17%) into partial remission. Three patients experienced grade 3-4 neutropenia. Six patients developed severe infections. No lymphoproliferative diseases occurred while on IL1Ra. When last seen, all patients without anakinra had an active disease with variable impact on their quality of life. Their median corticosteroids dosage was 6mg/d (range: 5-25). IL1Ra is effective in SchS, with a sharp corticosteroid-sparing effect. Treatment failures should lead to reconsider the diagnosis. Long-term follow-up revealed no loss of effectiveness and a favorable tolerance profile. The long-term effects on the risk of hemopathy remain unknown.

Upon detection of pathogen-associated molecular patterns, innate immune receptors

initiate inflammatory responses. These receptors include cytoplasmic NOD-like receptors (NLRs) whose stimulation recruits and proteolytically activates caspase-1 within the inflammasome, a multiprotein complex. Caspase-1 mediates the production of interleukin-1 family cytokines (IL1FCs), leading to fever and inflammatory cell death (pyroptosis). Mutations that constitutively activate these pathways underlie several autoinflammatory diseases with diverse clinical features. We describe a family with a previously unreported syndrome featuring neonatal-onset enterocolitis, periodic fever, and fatal or near-fatal episodes of autoinflammation. We show that the disease is caused by a de novo gain-of-function mutation in NLRC4 encoding a p.Val341Ala substitution in the HD1 domain of the protein that cosegregates with disease. Mutant NLRC4 causes constitutive IL1FC production and macrophage cell death. Infected macrophages from affected individuals are polarized toward pyroptosis and exhibit abnormal staining for inflammasome components. These findings identify and describe the cause of a life-threatening but treatable autoinflammatory disease that underscores the divergent roles of the NLRC4 inflammasome.

Inflammasomes are innate immune sensors that respond to pathogen- and damage-associated signals with caspase-1 activation, interleukin (IL)-1 $\beta$  and IL-18 secretion, and macrophage pyroptosis. The discovery that dominant gain-of-function mutations in NLRP3 cause the cryopyrin-associated periodic syndromes (CAPS) and trigger spontaneous inflammasome activation and IL-1 $\beta$  oversecretion led to successful treatment with IL-1-blocking agents. Herein we report a de novo missense mutation (c.1009A > T, encoding p.Thr337Ser) affecting the nucleotide-binding domain of the inflammasome component NLRC4 that causes early-onset recurrent fever flares and macrophage activation syndrome (MAS). Functional analyses demonstrated spontaneous inflammasome formation and production of the inflammasome-dependent cytokines IL-1 $\beta$  and IL-18, with the latter exceeding the levels seen in CAPS. The NLRC4 mutation caused constitutive caspase-1 cleavage in cells transduced with mutant NLRC4 and increased production of IL-18 in both patient-derived and mutant NLRC4-transduced macrophages. Thus, we describe a new monoallelic inflammasome defect that expands the monogenic autoinflammatory disease spectrum to include MAS and suggests new targets for

therapy.

Colchicine is the standard treatment in familial Mediterranean fever (FMF) patients. New treatment strategies are needed in FMF patients who were unresponsive to colchicine therapy or who had developed amyloidosis. The aim of this study was to present clinical-laboratory features and treatment responses of pediatric FMF patients that were treated with anti-IL-1 therapies. Files of patients who had been followed in our department with diagnosis of FMF were retrospectively evaluated. Patients that have been receiving anti-IL-1 therapies (anakinra or canakinumab) were included to the study. All patients were interpreted with respect to the demographic data, clinical and laboratory features of the disease, genetic analysis of MEFV mutations and treatment responses. Among 330 currently registered FMF patients, 13 patients were included to the study. Seven of them received anti-IL-1 therapy due to colchicine resistance and 6 due to FMF-related amyloidosis (1 of them with nephrotic

syndrome, 2 with chronic kidney disease, 3 with renal transplantation). In all treated patients, attacks completely disappeared or decreased in frequency; partial remission occurred in nephrotic syndrome patient; and their life quality improved. Anti-IL-1 therapies can be successfully used in colchicine-resistant FMF patients and patients with amyloidosis during childhood and adolescent period without major side effects.

TLR2 and TLR4 gene expression levels and associated factors during acute attack and attack-free periods in familial Mediterranean fever.

Karakose MZ(1), Yapali S, Salman E, Aksu K, Karakose S, Akarca US.

Author information:

(1)Department of Internal Medicine, Ege University Hospital, Izmir, Turkey.

The purpose of this clinical study was to determine if the expression of the TLR2 and/or TLR4 genes is involved in triggering the auto-inflammatory attacks in patients with familial Mediterranean fever (FMF). Thirty patients with FMF and 20 healthy control subjects were recruited. Comparisons were made in TLR2 and TLR4 gene expression levels during FMF attack episodes and attack-free periods, as well as with baseline levels in healthy control subjects. There was no significant difference in TLR2 and TLR4 gene expression between the attacks and attack-free periods in the entire group of FMF patients. However, among female patients, expression level of TLR4 gene was significantly higher during the attack than in the attack-free period (TLR2 Log  $2.04 \pm 0.14$  vs.  $2.52 \pm 0.10$ , respectively,  $P = 0.02$ ). There was not a significant difference between FMF patients and healthy subjects. The patients who had higher levels of TLR2 expression during the acute attack experienced their first attacks at an earlier age ( $r = -0.571$ ;  $P = 0.001$ ). The frequency of attacks, acute-phase response, MEFV mutations, and colchicine response were not associated with TLR2 and TLR4 levels. We conclude that changes in the expression of TLR2 and TLR4 genes do not appear to be involved in triggering FMF attacks. A higher level of TLR2 expression during acute attack may be related to the early onset of the disease. Further studies using specific cell populations such as neutrophils, monocytes, and

dendritic cells may be useful to explore any changes in the sensitivity of toll-like receptors to their agonists, such as lipopolysaccharides, in the onset of attacks.

Increased frequency of Mediterranean fever gene variants in multiple myeloma.

Celik S(1), Tangi F(2), Oktenli C(3).

Author information:

(1)Division of Oncology, GATA Haydarpasa Training Hospital, Istanbul, Turkey.

(2)Division of Internal Medicine, GATA Haydarpasa Training Hospital, Istanbul, Turkey.

(3)Department of Internal Medicine, Anadolu Medical Center, Kocaeli, Turkey.

High frequencies of inherited variants in the Mediterranean fever (MEFV) gene have been identified in patients with multiple myeloma (MM). The sample size of the present pilot study was small, therefore, the actual frequency of inherited variants in the MEFV gene could be investigated in patients with MM. Twenty-eight patients with MM and 65 healthy controls were included in the study. Six heterozygous and one homozygous (E148Q/E148Q) variant was identified in patients with MM. None of the patients had a family history compatible with familial Mediterranean fever. In the healthy control group, 11 heterozygous variants were identified. The difference in the overall frequency of the inherited variants in the MEFV gene between the MM patients and the controls was statistically significant ( $\chi^2=4.905$ ;  $P=0.027$ ). In conclusion, a high frequency of inherited variants in the MEFV gene was identified in patients with MM. Based on the current data, it is hypothesized that the MEFV gene is a cancer susceptibility gene. Additional evidence, such as familial aggregation, monozygotic versus dizygotic twin concordance, and tumors in genetically engineered model organisms, is required in order to support this hypothesis.

Pyoderma gangrenosum (PG) is an uncommon, distinctive cutaneous ulceration which is usually idiopathic, but may be associated with many systemic disorders. The etiopathogenesis of PG is still not well understood. PG is part of the spectrum of the neutrophilic dermatoses and it has been proposed as a prototype of cutaneous autoinflammatory disease. PG usually has a good outcome under immunosuppressive treatment. Although PG has been associated with several systemic diseases, it has rarely been reported in association with systemic lupus erythematosus (SLE). In this article we report five cases of SLE-related PG and review the literature. Our findings support the possible relationship between active SLE and PG, although the mechanism remains unclear. Clinical manifestations, used treatments and outcomes of SLE-related PG do not differ from the described for the general population.

**BACKGROUND:** Familial Mediterranean fever (FMF) is an autoinflammatory disease characterized by recurrent attacks of serositis, fever, and rash. Clinical and subclinical inflammatory processes may contribute to atherosclerosis in FMF patients, with mean platelet volume (MPV) as a potential indicator for atherosclerosis risk and neutrophil-to-lymphocyte ratio (NLR) as a marker for subclinical inflammation in these patients. In this study, we investigated whether MPV can be used as an indicator for atherosclerosis risk and if NLR is a marker for subclinical inflammation in FMF patients.

**MATERIAL AND METHODS:** The study consisted of 75 FMF patients in attack, 157 attack-free patients, and 77 healthy controls. White blood cell count neutrophil-to-lymphocyte ratio, platelet count, MPV, PDW C-reactive protein levels, and erythrocyte sedimentation rate were recorded.

**RESULTS:** There were no significant differences between attack, attack-free, and control groups in terms of mean MPV and PDW value. NLR value was higher in the attack group. NLR value was similar in attack-free and control groups.

**CONCLUSIONS:** We found that MPV and PDW values are similar in FMF patients and

healthy controls. NLR was higher in FMF patients in the attack period. Therefore, our results suggest that MPV and PDW values do not predict atherosclerosis risk in pediatric FMF patients, and NLR may be an indicator for attack period but not attack-free period.

Adult onset Still's disease (AOSD) is a rare inflammatory disorder characterized by hectic spiking fever, evanescent rash and joint involvement. Prognosis is highly variable upon disease course and specific involvements, ranging from benign and limited outcome to chronic destructive polyarthritides and/or life-threatening events in case of visceral complications or reactive hemophagocytic lymphohistiocytosis (RHL). AOSD remains a debatable entity at the frontiers of autoimmune diseases and autoinflammatory disorders. The pivotal role of macrophage cell activation leading to a typical Th1 cytokine storm is now well established in AOSD, and confirmed by the benefits using treatments targeting TNF- $\alpha$ , IL-1 $\beta$  or IL-6 in refractory patients. However, it remains difficult to determine predictive factors of outcome and to draw guidelines for patient management. Herein, reviewing literature and relying on our experience in a series of 8 refractory AOSD patients, we question nosology and postulate that different cytokine patterns could underlie contrasting clinical expressions, as well as responses to targeted therapies. We therefore propose to dichotomize AOSD according to its clinical presentation. On the one hand, 'systemic AOSD' patients, exhibiting the highest inflammation process driven by excessive IL-18, IL-1 $\beta$  and IL-6 production, would be at risk of life-threatening complications (such as multivisceral involvements and RHL), and would preferentially respond to IL-1 $\beta$  and IL-6 antagonists. On the other hand, 'rheumatic AOSD' patients, exhibiting pre-eminence of joint involvement driven by IL-8 and IFN- $\gamma$  production, would be at risk of articular destructions, and would preferentially respond to TNF- $\alpha$  blockers.

Blau syndrome (BS) and early onset sarcoidosis (EOS) are, respectively, the familial and sporadic forms of the pediatric granulomatous autoinflammatory disease, which belong to the group of monogenic autoinflammatory syndromes. Both

of these conditions are caused by mutations in the NOD2 gene, which encodes the cytosolic NOD2 protein, one of the pivotal molecules in the regulation of innate immunity, primarily expressed in the antigen-presenting cells. Clinical onset of BS and EOS is usually in the first years of life with noncaseating epithelioid granulomas mainly affecting joints, skin, and uveal tract, variably associated with heterogeneous systemic features. The dividing line between autoinflammatory and autoimmune mechanisms is probably not so clear-cut, and the relationship existing between BS or EOS and autoimmune phenomena remains unclear. There is no established therapy for the management of BS and EOS, and the main treatment aim is to prevent ocular manifestations entailing the risk of potential blindness and to avoid joint deformities. Nonsteroidal anti-inflammatory drugs, corticosteroids and immunosuppressive drugs, such as methotrexate or azathioprine, may be helpful; when patients are unresponsive to the combination of corticosteroids and immunosuppressant agents, the tumor necrosis factor- $\alpha$  inhibitor infliximab should be considered. Data on anti-interleukin-1 inhibition with anakinra and canakinumab is still limited and further corroboration is required. The aim of this paper is to describe BS and EOS, focusing on their genetic, clinical, and therapeutic issues, with the ultimate goal of increasing clinicians' awareness of both of these rare but serious disorders.

Interleukin-10 regulates the inflammasome-driven augmentation of inflammatory arthritis and joint destruction.

Greenhill CJ, Jones GW, Nowell MA, Newton Z, Harvey AK, Moideen AN, Collins FL, Bloom AC, Coll RC, Robertson AA, Cooper MA, Rosas M, Taylor PR, O'Neill LA, Humphreys IR, Williams AS, Jones SA.

**INTRODUCTION:** Activation of the inflammasome has been implicated in the pathology of various autoinflammatory and autoimmune diseases. While the NLRP3 inflammasome has been linked to arthritis progression, little is known about its synovial regulation or contribution to joint histopathology. Regulators of inflammation

activation, such as interleukin (IL)-10, may have the potential to limit the inflammasome-driven arthritic disease course and associated structural damage. Hence, we used IL-10-deficient (IL-10KO) mice to assess NLRP3 inflammasome-driven arthritic pathology.

**METHODS:** Antigen-induced arthritis (AIA) was established in IL-10KO mice and wild-type controls. Using histological and radiographic approaches together with quantitative real-time PCR of synovial mRNA studies, we explored the regulation of inflammasome components. These were combined with selective blocking agents and ex vivo investigative studies in osteoclast differentiation assays.

**RESULTS:** In AIA, IL-10KO mice display severe disease with increased histological and radiographic joint scores. Here, focal bone erosions were associated with increased tartrate-resistant acid phosphatase (TRAP)-positive cells and a localized expression of IL-1 $\beta$ . When compared to controls, IL-10KO synovium showed increased expression of Il1b, Il33 and NLRP3 inflammasome components. Synovial Nlrp3 and Casp1 expression further correlated with Acp5 (encoding TRAP), while neutralization of IL-10 receptor signaling in control mice caused increased expression of Nlrp3 and Casp1. In ex vivo osteoclast differentiation assays, addition of exogenous IL-10 or selective blockade of the NLRP3 inflammasome inhibited osteoclastogenesis.

**CONCLUSIONS:** These data provide a link between IL-10, synovial regulation of the NLRP3 inflammasome and the degree of bone erosions observed in inflammatory arthritis.

Three patients with familial Mediterranean fever: a possible underdiagnosed entity in Japan.

Yokota K(1), Fukuda M, Migita K, Tanaka E, Okamoto T, Kimura K.

Author information:

(1)Division of Nephrology, Iwakuni Medical Center, Japan.

Familial Mediterranean fever (FMF) is an autosomal recessive disorder

characterized by periodic fever and serosal inflammation. FMF is mostly reported in the Mediterranean region and is considered to be rare in Japan with estimated 292 cases. We treated three unrelated FMF patients in one year in a city with 144,000 residents. Two of the three patients were over 70 years old. FMF may therefore be underdiagnosed in Japan.

**OBJECTIVE:** The autoinflammatory hyperimmunoglobulinaemia D and periodic fever syndrome (HIDS) is characterized by recurrent episodes of fever and inflammation. As part of the mevalonate kinase deficiency spectrum, it is caused by MVK mutations, resulting in decreased mevalonate kinase activity in the isoprenoid pathway. Although IL-1 $\beta$  is considered a major cytokine in its pathogenesis, IL-1 blockade is not successful in a proportion of patients. We aimed to further characterize the pro-inflammatory cytokine profile of HIDS.

**METHODS:** Peripheral blood mononuclear cells from HIDS patients and healthy donors

were incubated with several stimuli. Cytokine concentrations were detected by ELISA. To analyse mRNA and protein expression, we performed quantitative RT-PCR and western blot, respectively.

**RESULTS:** We observed significant differences in cytokine production when cells were incubated with ligands for Toll-like receptor 2 (TLR2), TLR4 and nucleotide-binding oligomerization domain-containing 2 (NOD2). The increased ratio between active and inactive caspase-1 protein in HIDS patients could explain why these cells are more easily triggered to secrete IL-1 $\beta$ . This is apparently not regulated at the transcriptional level, since expression levels of caspase-1 and IL-1 $\beta$  mRNA were similar in patients and controls. Both anakinra and tocilizumab treatment resulted in decreased inflammation, both ex vivo as well as in vivo.

**CONCLUSION:** The increased cytokine secretion in HIDS is specific for TLR2, TLR4 and NOD2 ligation. Although IL-1 $\beta$  is important in the HIDS pathology, our data suggest it is a multicytokine disease. A more rigorous clinical trial is required to determine whether IL-6 receptor blockade may be considered in patients not responding to anakinra treatment.

Cytokines in immune-mediated inflammatory myopathies: cellular sources, multiple actions and therapeutic implications.

Moran EM(1), Mastaglia FL.

Author information:

(1)Institute for Immunology and Infectious Diseases (IIID), Murdoch University, Murdoch, WA, Australia.

The idiopathic inflammatory myopathies are a heterogeneous group of disorders characterised by diffuse muscle weakness and inflammation. A common

immunopathogenic mechanism is the cytokine-driven infiltration of immune cells into the muscle tissue. Recent studies have further dissected the inflammatory cell types and associated cytokines involved in the immune-mediated myopathies and other chronic inflammatory and autoimmune disorders. In this review we outline the current knowledge of cytokine expression profiles and cellular sources in the major forms of inflammatory myopathy and detail the known mechanistic functions of these cytokines in the context of inflammatory myositis. Furthermore, we discuss how the application of this knowledge may lead to new therapeutic strategies for the treatment of the inflammatory myopathies, in particular for cases resistant to conventional forms of therapy.

**BACKGROUND:** Familial Mediterranean Fever (FMF) is a hereditary autoinflammatory disease associated with subclinical inflammation, which includes atherosclerosis arising from endothelial inflammation, which in turn increases the risk of atrial or ventricular arrhythmias. Conduction abnormalities can be detected using the electrocardiographic (ECG) indices P and QT dispersion (Pdisp and QTdisp). Currently, it is unknown whether patients with FMF are more likely to have abnormalities of these ECG indices. Moreover, existing studies were conducted in countries with higher FMF prevalence. We therefore perform the first prospective study assessing Pdisp and QTdisp in adult FMF patients in Germany, where prevalence of FMF is low.

**METHOD:** Asymptomatic FMF patients (n=30) of Turkish ancestry living in Germany and age-matched healthy controls (n=37) were prospectively assessed using 12-lead ECG.

**RESULTS:** Patients and controls were comparable in gender and body mass index, and patients had higher erythrocyte sedimentation rate (ESR), C-reactive protein (CRP) and serum amyloid A (SAA) compared to controls (ESR:  $23.7 \pm 14.3$  vs.  $16.1 \pm 13.3$  mm/1(st)h,  $p=0.03$ , CRP:  $0.73 \pm 0.9$  vs.  $0.26 \pm 0.4$  g/dl,  $p=0.01$ , SAA:  $3.14 \pm 4.8$  vs.  $0.37 \pm 0.3$  mg/dl,  $p<0.01$ ). No statistically significant difference between patients and controls respectively, for Pdisp ( $43.7 \pm 11.9$  vs.  $47.1 \pm 11.2$  ms,  $p=0.23$ ), QTdisp ( $65.9 \pm 12.3$  vs.  $67.6 \pm 12.7$  ms,  $p=0.58$ ) or corrected QTdisp (cQTdisp:  $73.9 \pm 15.0$  vs.  $76.0 \pm 13.3$  ms,  $p=0.55$ ) was found. No correlation could be found between Pdisp or QTdisp or cQTdisp and any of the biochemical markers of inflammation.

**CONCLUSION:** FMF patients living in Germany show a Pdisp and QTdisp comparable to healthy controls, with no increased risk of atrial or ventricular arrhythmias indicated.

Introduction: mechanisms of tissue injury in autoimmune diseases.

Eilat D(1).

Author information:

(1)Department of Medicine, Hadassah University Hospital and The Hebrew University Faculty of Medicine, 91120, Jerusalem, Israel, eilatd@cc.huji.ac.il.

This issue of Seminars in Immunopathology is devoted to the most recent developments in our understanding of the mechanisms leading to tissue injury in autoimmune diseases. These include rheumatoid arthritis, systemic lupus erythematosus, type I diabetes, autoimmune liver diseases, inflammatory bowel diseases, autoimmune skin diseases, autoimmune uveitis, and autoinflammatory diseases. This impressive account of basic and clinical research in a wide spectrum of immunological disorders provides the reader with a comprehensive view of the common and unique features of these diverse conditions. It may also provide one with many new ideas for therapeutic intervention in the natural course of these autoimmune syndromes.

Behçet's disease (BD) is a multi-systemic disorder of unknown etiology characterized by relapsing oral-genital ulcers, uveitis, and involvement of the articular, gastrointestinal, neurologic, and vascular systems. Although the primum movens of this condition remains unknown, a tangled plot combining autoimmune and autoinflammatory pathways has been hypothesized to explain its start and recurrence. In-depth analysis of BD pathogenetic mechanisms, involving dysfunction of multiple proinflammatory molecules, has opened new modalities of treatment: different agents targeting interleukin-1 have been studied in recent years to manage the most difficult and multi-resistant cases of BD. Growing experience with anakinra, canakinumab and gevokizumab is discussed in this review, highlighting the relative efficacy of each drug upon the protean BD clinical manifestations. Safety and tolerability of interleukin-1 antagonists in different doses have been confirmed by numerous observational studies on both large and small cohorts of patients with BD. In particular, the potential for *Mycobacterium tuberculosis* reactivation and tuberculosis development appears to be significantly lower with interleukin-1 blockers compared to tumor necrosis factor- $\alpha$  inhibitors, thus increasing the beneficial profile of this approach.

Familial Mediterranean fever in Syrian children: phenotype-genotype correlation.

Jarjour RA(1), Al-Berrawi S.

Author information:

(1)Clinical Genetics Unit, Molecular Biology and Biotechnology Department, Atomic Energy Commission of Syria (AECS), P.O.Box 6091, Damascus, Syria, ascientific@aec.org.sy.

Familial Mediterranean fever (FMF) is an autosomal recessive disease characterized by recurrent attacks of serosal membranes. In this study, 103 unrelated Syrian children were included. Mutation screening of the MEditerranean

FeVer gene was performed for 12 mutations. Abdominal pain was observed in 91 (88.3 %) of the patients, fever in 82 (79.6 %), arthritis in 27 (26.2 %), pleuritis in 7 (6.7.5 %), rash and erysipelas-like erythema in 5 (4.8 %), myalgia in 5 (4.8 %), headache in 5 (4.8 %) and Henoch-Schonlein purpura in 1 (0.97 %). The most frequent mutation was M694V. In order to determine the association between M694V and clinical features of FMF, we compared the disease features between patients with and without this mutation. The presence of M694V was found to be associated with more severe course of FMF, earlier age of onset and more frequent arthritis in the Syrian children with FMF compared to other FMF patients who do not have this mutation.

There is a thriving interest in the field of hereditary autoinflammatory disorders (HAID), a gamut of heterogeneous conditions deriving from an aberrant orchestration of innate immunity, unified by the common feature of seemingly unprovoked inflammation, which might be systemic or occur in localized niches of the organism. Recurrent fever and episodic inflammation in the joints, serosal membranes, skin, gut, and other organs are the common denominator of HAID. Mutations in the inflammasome-related genes have been associated with different

HAID, showing the intimate link existing between interleukin-1 (IL-1)-structured inflammasome and their pathogenesis. Differential diagnosis of HAID can be challenging, as there are no universally accepted diagnostic protocols, and near half of patients may remain without any genetic abnormality identified. The use of IL-1-antagonists has been associated with beneficial effects in a large number of HAID associated with excessive IL-1 signalling, such as cryopyrin-associated periodic syndromes, familial Mediterranean fever, and deficiency of IL-1 receptor antagonist. This review will discuss about the key-clues of HAID which might guide for an early recognition and drive decisions for treatment.

**OBJECTIVE:** To examine the effect of rilonacept on the health-related quality of life (HRQoL) in patients with poorly controlled familial Mediterranean fever (FMF).

**METHODS:** As part of a randomized, double-blinded trial comparing rilonacept and placebo for the treatment of FMF, patients/parents completed the modified Child Health Questionnaire (CHQ) at baseline, and at the start and end of each of 4 treatment courses, 2 each with rilonacept and placebo.

**RESULTS:** Fourteen subjects were randomized; mean age was  $24.4 \pm 11.8$  years. At baseline the physical HRQoL score was significantly less ( $24.2 \pm 49.5$ ) but the psychosocial score was similar to the population norm ( $49.5 \pm 10.0$ ). There were significant improvements in most HRQoL concepts after rilonacept but not placebo. Significant differences between rilonacept and placebo were found in the physical ( $33.7 \pm 16.4$  versus  $23.7 \pm 14.5$ ,  $P = 0.021$ ) but not psychosocial scores ( $51.4 \pm 10.3$  versus  $49.8 \pm 12.4$ ,  $P = 0.42$ ). The physical HRQoL was significantly impacted by the treatment effect and patient global assessment.

**CONCLUSION:** Treatment with rilonacept had a beneficial effect on the physical HRQoL in patients with poorly controlled FMF and was also significantly related to the patient global assessment. This trial is registered with ClinicalTrials.gov Identifier NCT00582907.

Author information:

(1)Department of Rheumatology, Dokuz Eylul University School of Medicine, 35340,

Izmir, Turkey.

Herein, we reported our experience in colchicine-resistant familial Mediterranean fever (FMF) patients who are treated with anti-interleukin-1 (IL-1) drugs. A retrospective review of medical records of anti-IL-1 recipients was performed. The main clinical characteristics of these patients and the evolution after anti-IL-1 were recorded. There were 20 patients (11 male [M] and 9 female [F]). Despite regular colchicine treatment, median number of attacks per month and per year was 1 (1-4) and 12 (4-50), respectively. Twelve patients were receiving anakinra, and eight patients were treated with canakinumab. The number of monthly and yearly attacks after IL-1 treatment was significantly decreased after the biologic agent ( $p < 0.05$ ). One patient did not respond to the treatment, and one patient developed serious infection during anti-IL-1. We also observed a significant decrease in proteinuria in the amyloidosis complicated FMF patients. Anti-IL-1 targeting drugs seem safe and effective therapies in colchicine-resistant FMF.

Blau syndrome is a monogenic disease resulting from mutations in the pattern recognition receptor NOD2, and is phenotypically characterized by the triad of granulomatous polyarthritis, dermatitis and uveitis. This paper reviews briefly the classical clinical features of the disease, as well as more recently described extra-triad symptoms. From an ongoing prospective multicenter study, we provide new data on the natural history of Blau syndrome, focusing on functional status and visual outcome. We also present an update of the range of different NOD2 mutations found in Blau syndrome as well as recent data on morphologic and immunohistochemical characteristics of the Blau granuloma. Finally, emerging insights into pathogenic mechanisms including activation of NOD2 signal transduction, and potential biomarkers of disease activity are discussed.

**OBJECTIVES:** The NLRP3/ASC inflammasome drives host defence and autoinflammatory disorders by activating caspase-1 to trigger the secretion of mature interleukin (IL)-1 $\beta$ /IL-18, but its potential role in autoimmunity is speculative.

**METHODS:** We generated and phenotyped Nlrp3-deficient, Asc-deficient, Il-1r-deficient and Il-18-deficient C57BL/6-lpr/lpr mice, the latter being a mild model of spontaneous lupus-like autoimmunity.

**RESULTS:** While lack of IL-1R or IL-18 did not affect the C57BL/6-lpr/lpr phenotype, lack of NLRP3 or ASC triggered massive lymphoproliferation, lung T cell infiltrates and severe proliferative lupus nephritis within 6 months, which

were all absent in age-matched C57BL/6-lpr/lpr controls. Lack of NLRP3 or ASC increased dendritic cell and macrophage activation, the expression of numerous proinflammatory mediators, lymphocyte necrosis and the expansion of most T cell and B cell subsets. In contrast, plasma cells and autoantibody production were hardly affected. This unexpected immunosuppressive effect of NLRP3 and ASC may relate to their known role in SMAD2/3 phosphorylation during tumour growth factor (TGF)- $\beta$  receptor signalling, for example, Nlrp3-deficiency and Asc-deficiency significantly suppressed the expression of numerous TGF- $\beta$  target genes in C57BL/6-lpr/lpr mice and partially recapitulated the known autoimmune phenotype of Tgf- $\beta$ 1-deficient mice.

**CONCLUSIONS:** These data identify a novel non-canonical immunoregulatory function of NLRP3 and ASC in autoimmunity.

The innate immune system is involved in the pathophysiology of systemic autoinflammatory diseases (SAIDs), an enlarging group of disorders caused by dysregulated production of proinflammatory cytokines, such as interleukin-1 $\beta$  and tumor necrosis factor- $\alpha$ , in which autoreactive T-lymphocytes and autoantibodies are indeed absent. A widely deranged innate immunity leads to overactivity of proinflammatory cytokines and subsequent multisite inflammatory symptoms depicting various conditions, such as hereditary periodic fevers, granulomatous disorders, and pyogenic diseases, collectively described in this review. Further research should enhance our understanding of the genetics behind SAIDs, unearth triggers of inflammatory attacks, and result in improvement for their diagnosis and treatment.

Key teaching points • Synovitis-acne-pustulosis-hyperostosis-osteitis (SAPHO) syndrome is characterized by distinctive osteoarticular manifestations and a spectrum of neutrophilic dermatoses. • The most common dermatologic manifestations include palmoplantar pustulosis, acne conglobata, and acne fulminans. • SAPHO syndrome should be considered in patients presenting osteoarticular pain, particularly involving the anterior chest wall and/or spine, and neutrophilic skin lesions.

Prevalence of periodontal disease in patients with Familial Mediterranean Fever: a cohort study from central Turkey.

Bostancı V, Toker H, Senel S, Sahin S.

**OBJECTIVE:** The aim of this study was to compare the periodontal status in patients with Familial Mediterranean Fever (FMF) and in those without this disease.

**METHOD AND MATERIALS:** 84 subjects clinically diagnosed with FMF and 75 systemically healthy controls, matched by age and gender, were recruited. All FMF patients were on a regular daily colchicine treatment and during attack-free periods. Gingival Index (GI), Plaque Index (PI), probing pocket depth (PD), and clinical attachment level (CAL) were measured in all subjects. To evaluate periodontal disease further, patients were stratified into five groups. Education information and smoking habits were recorded.

**RESULTS:** The FMF patients and healthy controls were comparable for age, gender, and smoking status ( $P>.05$ ). The FMF patients had significantly higher PI and GI values and lower PD and CAL values than those of the control group ( $P<.05$ ). However, there was no significant difference among all groups in terms of periodontal disease severity ( $P>.05$ ). In the FMF-severe periodontitis group, higher PI and GI values were seen ( $P<.05$ ). However, there was no significant difference between the FMF-severe periodontitis group and the controls with severe periodontitis regarding the PD and CAL values ( $P>.05$ ).

**CONCLUSION:** Patients with FMF using colchicine did not manifest higher attachment loss compared to age- and sex-matched systemically healthy controls.

Colchicine levels in chronic kidney diseases and kidney transplant recipients using tacrolimus.

Amanova A(1), Kendi Celebi Z, Bakar F, Caglayan MG, Keven K.

Author information:

(1)Department of Internal Medicine, Ankara University School of Medicine, Ankara, Turkey.

**BACKGROUND:** Tacrolimus is a CYP3A4 inhibitor and can alter colchicine metabolism. In this study, we aimed to evaluate plasma colchicine levels in different stages of kidney disease as well as in kidney transplant (KTx) recipients using tacrolimus.

**METHOD:** This study included six familial Mediterranean fever (FMF) patients with normal glomerular filtration rate (GFR) as controls, three patients with low GFR, six FMF patients on hemodialysis (HD), and six FMF patients who were KTx recipients using tacrolimus. After a three-d washout period, plasma colchicine levels were measured at 0 (pre-dose), one, two, four, eight, and 24 h post-dose of 1 mg oral colchicine. Area under the curve 0-24 h (AUC<sub>0-24</sub>) and maximum concentration (C<sub>max</sub>) were evaluated and compared between the groups.

**RESULTS:** Colchicine AUC<sub>0-24</sub> was six-fold higher in HD ( $p < 0.001$ ) and three-fold higher in KTx recipients ( $p < 0.001$ ) when compared to the control. The low GFR group had mildly higher AUC<sub>0-24</sub> than the control group. C<sub>max</sub> levels were also higher in HD ( $p = 0.011$ ) and KTx recipient ( $p = 0.06$ ) groups and mildly elevated in low GFR patients in comparison with controls.

**CONCLUSION:** Colchicine AUC<sub>0-24</sub> and C<sub>max</sub> were significantly increased in HD patients and KTx recipients using tacrolimus. Therefore, dose adjustments are needed to avoid toxicity in both circumstances.

The skin is an immune organ that contains innate and acquired immune systems and thus is able to respond to exogenous stimuli producing large amount of proinflammatory cytokines including IL-1 and IL-1 family members. The role of the epidermal IL-1 is not limited to initiation of local inflammatory responses, but also to induction of systemic inflammation. However, association of persistent release of IL-1 family members from severe skin inflammatory diseases such as psoriasis, epidermolysis bullosa, atopic dermatitis, blistering diseases and desmoglein-1 deficiency syndrome with diseases in systemic organs have not been so far assessed. Here, we showed the occurrence of severe systemic cardiovascular diseases and metabolic abnormalities including aberrant vascular wall remodeling with aortic stenosis, cardiomegaly, impaired limb and tail circulation, fatty tissue loss and systemic amyloid deposition in multiple organs with liver and kidney dysfunction in mouse models with severe dermatitis caused by persistent release of IL-1s from the skin. These morbid conditions were ameliorated by simultaneous administration of anti-IL-1 $\alpha$  and IL-1 $\beta$  antibodies. These findings may explain the morbid association of arteriosclerosis, heart involvement,

amyloidosis and cachexia in severe systemic skin diseases and systemic autoinflammatory diseases, and support the value of anti-IL-1 therapy for systemic inflammatory diseases.

Development of positive antinuclear antibodies and rheumatoid factor in systemic juvenile idiopathic arthritis points toward an autoimmune phenotype later in the disease course.

Hügler B(1), Hinze C(2), Lainka E(3), Fischer N(1), Haas JP(1).

Author information:

(1)German Center for Pediatric and Adolescent Rheumatology, Gehfeldstrasse 24, 82467 Garmisch-Partenkirchen, Germany.

(2)German Center for Pediatric and Adolescent Rheumatology, Gehfeldstrasse 24, 82467 Garmisch-Partenkirchen, Germany ; Department of Pediatric Rheumatology and

Immunology, University Children's Hospital Münster, Münster, Germany.  
(3)Department of Pediatric Rheumatology, University Duisburg-Essen, Children's Hospital, Essen, Germany.

**BACKGROUND:** Systemic juvenile idiopathic arthritis (sJIA) is commonly considered an autoinflammatory disease. However, sJIA patients may develop aggressive arthritis without systemic inflammation later in the disease, resembling an autoimmune phenotype similar to other subtypes of JIA. The objective of this study was to determine whether antinuclear antibodies (ANA) and rheumatoid factor (RF) will develop in patients with sJIA over the course of the disease.

**FINDINGS:** A single center sample of sJIA patients with follow-up of more than one year was obtained. A retrospective chart survey was used to extract demographic and clinical data as well as presence and titers of ANA and RF at diagnosis and during follow-up. 32 patients were included in the study, with a median age of 4.2 years and median follow-up of 6.0 years. 8/32 patients had ANA titers  $\geq 1:80$  at diagnosis, with 22/32 patients showing rising ANA titers with titers  $\geq 1:80$  at last follow-up ( $p = 0.001$ ). 10/32 patients had a positive RF at least once during follow-up, compared to 0/32 at diagnosis ( $p = 0.001$ ). In 5/10 patients, positive RF was documented at least twice, more than twelve weeks apart. Patients treated with TNF antagonists were not significantly more likely to develop positive ANA titers ( $p = 0.425$ ) or positive RF ( $p = 0.703$ ).

**CONCLUSIONS:** Patients with sJIA developed increased ANA titers and positive RF over the course of the disease, independent of treatment with TNF antagonists. This might point towards an autoimmune, rather than an autoinflammatory phenotype later in the course of sJIA.

**OBJECTIVE:** The study aim was to determine treatment persistence rates and to identify causes of discontinuation in psoriatic arthritis (PsA) and ankylosing spondylitis (AS) patients in clinical practice.

**METHODS:** Patients treated with adalimumab (ADA), etanercept (ETA), or infliximab (INF) were retrospectively included. Treatment persistence rates were analyzed by means of a stepwise logistic regression. Differences between therapy duration were assessed by means of an analysis of variance model (ANOVA), while a chi-square test was used to evaluate relationships between therapies and causes of treatment discontinuation and the administration of concomitant disease-modifying antirheumatic drugs (DMARDs) among therapies and types of disease considering completed courses of therapy versus courses that were discontinued.

**RESULTS:** 268 patients received a total of 353 anti-TNF treatment courses (97 ADA, 180 ETA, and 76 INF). Comparison among therapies showed significant difference regarding the treatment persistence rates due to the contrast between ETA and INF ( $P = 0.0062$ ). We observed that 84.7% of patients were still responding after 6 months of follow-up. Comparison among diseases showed that there were significant differences between PsA and AS ( $P = 0.0073$ ) and PsA and PsA with predominant axial involvement ( $P = 0.0467$ ) in terms of duration of the therapy, while there were no significant differences with regard to the persistence rate.

**CONCLUSIONS:** In this cohort, anti-TNF- $\alpha$  therapy was associated with high drug persistence rates. As in rheumatoid arthritis, switching to another anti-TNF- $\alpha$  agent can be an effective option when, during the treatment of AS or PsA, therapy is suspended because of inefficacy or an adverse event. Combination therapy with DMARDs was associated with a better persistence rate.

Innate immune sensing of nucleic acids provides resistance against viral infection and is important in the aetiology of autoimmune diseases. AGS (Aicardi-Goutières syndrome) is a monogenic autoinflammatory disorder mimicking in utero viral infection of the brain. Phenotypically and immunologically, it also exhibits similarities to SLE (systemic lupus erythematosis). Three of the six genes identified to date encode components of the ribonuclease H2 complex. As all six encode enzymes involved in nucleic acid metabolism, it is thought that pathogenesis involves the accumulation of nucleic acids to stimulate an inappropriate innate immune response. Given that AGS is a monogenic disorder with a defined molecular basis, we use it as a model for common autoimmune disease to investigate cellular processes and molecular pathways responsible for nucleic-acid-mediated autoimmunity. These investigations have also provided fundamental insights into the biological roles of the RNase H2 endonuclease enzyme. In the present article, we describe how human RNase H2 and its role in AGS were first identified, and give an overview of subsequent structural, biochemical, cellular and developmental studies of this enzyme. These investigations have culminated in establishing this enzyme as a key genome-surveillance enzyme required for mammalian genome stability.

Cutaneous necrotizing vasculitis as a manifestation of familial Mediterranean fever.

Komatsu S(1), Honma M, Igawa S, Tsuji H, Ishida-Yamamoto A, Migita K, Ida H, Iizuka H.

Author information:

(1)Department of Dermatology, Asahikawa Medical University, Asahikawa, Japan.

Familial Mediterranean Fever (FMF) is a hereditary autoinflammatory disease, which is characterized by recurrent and paroxysmal fever, peritonitis, arthritis, myalgia, and skin rashes. Although various skin lesions such as "erysipelas-like erythema", urticaria, nonspecific purpura, and subcutaneous nodules have been described, cutaneous vasculitis is rare. We report a Japanese case of sporadic FMF accompanied by cutaneous arteritis at the time of febrile attacks of FMF. Gene analysis revealed M694I mutation in a single allele of the MEFV gene, and oral colchicine successfully controlled both periodic fever and subcutaneous nodules of arteritis. Cutaneous necrotizing vasculitis repeatedly emerging with febrile attacks should be included among the skin manifestations of FMF.

Immigrant health, our health.

Hemminki K(1).

Author information:

This final chapter reviews the main conclusions reached by the Special Issue articles in the areas of EUNAM (EU and North African Migrants: Health and Health

Systems) activities, covering well-being, health status, disease panorama and use of health services of immigrants to the EU. The reviewed chapters show that immigrants are a vulnerable population experiencing, in some aspects, discrimination and hardship similar to the socially weakest national population groups. Immigration has changed the disease spectrum, particularly in infectious diseases and recessive conditions such as sickle cell disease and familial Mediterranean fever. Importantly, health questions of immigrants cannot be separated from those of any human health issues. An imminent new immigrant question for the EU will be the massive internal migration. Although the overall disease spectrum may not be vastly different between EU countries, the internal migrants will be exposed to lifestyle-dependent ill health and diseases probably in a similar way as did migrants from outside Europe. Migrant health research requires dedicated funding, which needs to come from central EU sources because multiple nationalities are involved. This funding should be able to project the course of health from the country of origin to the country of destination and back again, which was one of guidelines in the funding that initiated EUNAM.

Endemic diseases are caused by environmental and genetic factors. While in this

special issue several chapters deal with environmental factors, including infections, the present focus is on genetic causes of disease clustering due to inbreeding and recessive disease mechanisms. Consanguinity is implying sharing of genetic heritage because of marriage between close relatives originating from a common ancestor. With limited natural selection, recessive genes may become more frequent in an inbred compared with an outbred population. Consanguinity is common in North Africa (NA), and the estimates range from 40 to 49% of all marriages in Tunisia and 29-33% in Morocco. As a consequence, recessive disorders are common in the NA region, and we give some examples. Thalassaemia and sickle cell disease/anaemia constitute the most common inherited recessive disorders globally and they are common in NA, but with immigration they have spread to Europe and to other parts of the world. Another example is familial Mediterranean fever, which is common in the Eastern Mediterranean area. With immigration from that area to Sweden, it has become the most common hereditary autoinflammatory disease in that country, and there is no evidence that any native Swede would have been diagnosed with this disease. The examples discussed in this chapter show that the historic movement of populations and current immigration are influencing the concept of 'endemic' disease.

Protein prenylation is a post-translational modification whereby non-sterol isoprenoid lipid chains are added, thereby modifying the molecular partners with which proteins interact. The autoinflammatory disease mevalonate kinase deficiency (MKD) is characterized by a severe reduction in protein prenylation. A major class of proteins that are affected are small GTPases, including Rac1 and RhoA. It is not clear how protein prenylation of small GTPases relates to GTP hydrolysis activity and downstream signaling. Here, we investigated the contribution of RhoA prenylation to the biochemical pathways that underlie MKD-associated IL-1 $\beta$  hypersecretion using human cell cultures, Rac1 and RhoA protein variants, and pharmacological inhibitors. We found that when unprenylated, the GTP-bound levels of RhoA decrease, causing a reduction in GTPase activity and increased protein kinase B (PKB) phosphorylation. Cells expressing unprenylated RhoA produce increased levels of interleukin 1 $\beta$  mRNA. Of other phenotypic cellular changes seen in MKD, increased mitochondrial potential and mitochondrial elongation, only mitochondrial elongation was observed. Finally, we show that pharmacological inactivation of RhoA boosts Rac1 activity, a small GTPase whose activity was earlier implied in MKD pathogenesis. Together, our data show that RhoA plays a pivotal role in MKD pathogenesis through Rac1/PKB signaling toward interleukin 1 $\beta$  production and elucidate the effects of protein prenylation in monocytes.

Hypovitaminosis D in children with familial Mediterranean fever.

Yilmaz R(1), Karaaslan E, Ozer S, Sonmezgoz E, Kazanci NO, Cakan N, Akbas A.

Author information:

(1). drresul@hotmail.com.

**PURPOSE:** Vitamin D deficiency or insufficiency plays a role in the initiation and perpetuation of certain autoimmune diseases. The purpose of this study was to measure the vitamin D status of children with Familial Mediterranean Fever (FMF) and compare it to their healthy peers.

**METHODS:** A total of 50 FMF patients and 49 healthy children were enrolled in this prospective study. Vitamin D levels were measured via HPLC. Demographic data, FMF symptom severity scores and the levels of other disease activity markers were retrieved from our hospital database.

**RESULTS:** The mean age and gender balance of patients and controls were similar, being  $8.4 \pm 3.8$  years and 19 male patients, and  $9.1 \pm 3.0$  years and 25 male controls, respectively. The mean 25(-OH) vitamin D3 levels were  $15.94 \pm 9.66$  µg/L in FMF patients and  $41.22 \pm 21.31$  µg/L in controls. Vitamin D levels were normal in 12% of FMF patients, insufficient in 62% and deficient in 26%. No vitamin D deficiency was evident in any control subject; 30% had insufficient and 70% had normal vitamin D levels. Plasma vitamin D3 levels were similar in all patients despite varying FMF symptom severity scores.

**CONCLUSIONS:** Vitamin D deficiency is frequent in children with FMF but is not associated with disease severity score.

Acute pericarditis as the first manifestation of familial Mediterranean fever: a possible relationship with idiopathic recurrent pericarditis.

Yoshioka K(1), Furumitsu Y, Sano T, Miyamoto T, Agematsu K.

Author information:

(1)Department of Internal Medicine, Social Welfare Foundation Shitennoji Hospital, Japan.

A 56-year-old man was admitted to our hospital due to periodic episodes of acute pericarditis. These episodes occurred monthly along with a high fever and elevation of the C-reactive protein (CRP) level. The patient became afebrile and his CRP level decreased following the administration of a non-steroidal anti-inflammatory drug. A mutation analysis revealed the heterozygote of the familial Mediterranean fever (FMF) gene (E84K, G304R). This finding confirmed our diagnosis, and we treated the patient with colchicine. He responded to treatment and has been visiting our hospital without disease recurrence. FMF should be included in the differential diagnosis of repeated episodes of pericarditis.

Genetic defects in cytolysis in macrophage activation syndrome.

Zhang M(1), Behrens EM, Atkinson TP, Shakoory B, Grom AA, Cron RQ.

Author information:

(1)University of Alabama at Birmingham, 1825 University Blvd., Shelby 306, Birmingham, AL, 35294, USA, [mzhang@ped.s.uab.edu](mailto:mzhang@ped.s.uab.edu).

Macrophage activation syndrome (MAS), typically presenting beyond the first year of life, is an often lethal cousin of familial hemophagocytic lymphohistiocytosis (fHLH). Defects in natural killer (NK) cell and CD8 T cell cytotoxicity result in a pro-inflammatory cytokine storm, cytopenia, coagulopathy, and multi-organ system dysfunction. MAS can occur in association with infections (herpes viruses), cancer (leukemia), immune deficient states (post-transplantation), and in autoimmune (systemic lupus erythematosus) and autoinflammatory conditions (systemic juvenile idiopathic arthritis). The distinction between fHLH, the result of homozygous defects in cytolytic pathway genes, and MAS is becoming blurred with the identification of single or multiple mutations in the same cytolytic pathway genes in patients with later onset MAS. Here, we review the literature and present novel cytolytic pathway gene mutations identified in children with MAS. We study the inhibitory effect of one these novel mutations on NK cell function to suggest a direct link between fHLH and MAS.

(1)Department of Internal Medicine, Dongguk University Ilsan Hospital, 27 Donggung-ro, Ilsandong-gu, Goyang 410-773, Korea.

Familial Mediterranean fever (FMF) is an autosomal recessive disease characterized by recurrent episodes of fever and serosal, synovial, or cutaneous inflammation, caused by a dysfunction of pyrin as a result of mutation within the MEFV gene. It occurs mainly among Mediterranean and Middle Eastern populations, including Jews, Arabs, and Turks. However, FMF cases have been reported outside the Mediterranean and Middle Eastern countries in recent years. Although FMF has been relatively rare in Korea until now, proper recognition of FMF might lead to more frequent diagnoses of FMF. We experienced an interesting case, a 31-year-old Korean man who presented with recurrent abdominal pain with fever and urticarial eruption for 10 years. DNA analysis showed complex mutations (p.Leu110Pro, p.Glu148Gln) in the MEFV gene. To date, three cases have been reported, and this case of FMF with skin conditions is the first case in Korea.

**OBJECTIVES:** Cryopyrin-associated periodic syndromes (CAPS) are a group of chronic, relapsing autoinflammatory disorders which may be complicated by systemic AA amyloidosis. The aim of our study was to evaluate serum amyloid protein A (SAA) level in CAPS patients treated with Interleukin-1beta (IL-1 $\beta$ ) antagonist and to correlate its level with treatment response.

**METHODS:** All patients of CAPS Italian Register treated with IL-1 $\beta$  inhibitor were enrolled. SAA levels before starting therapy, and at last visit were evaluated. Patients were then divided in complete responders and partial responders.

**RESULTS:** Twenty-five patients were enrolled. SAA level before starting therapy was increased (median 118.5 mg/L, IQR 96.4-252.8; normal value <6.4 mg/L), while at last visit SAA was significantly reduced (median 4.3 mg/L, IQR 2.3-12.7) (p<0.001). However 12 patients still presented SAA levels beyond normal range,

10/25 patients (40%) showed a complete response to treatment. Conversely, 15 patients presented only a partial response, of which 12 for increased SAA value and 3 for increased CRP value. Patients with partial response had SAA values significantly higher than patients with complete response (median 12.6 mg/L; IQR 8.3-20.0 vs. 2.7 mg/L; IQR 1.6-4.1,  $p < 0.001$ ).

**CONCLUSIONS:** Our results confirm the long term efficacy of anti IL-1 $\beta$  treatment in CAPS and the decrease of SAA levels; however 48% of patients still presented SAA elevation despite treatment. The real risk of these patients in developing amyloidosis is not clear but the persistent increase of SAA needs a close follow-up.

A standardized clinical and radiological follow-up of patients with chronic non-bacterial osteomyelitis treated with pamidronate.

Hofmann C(1), Wurm M, Schwarz T, Neubauer H, Beer M, Girschick H, Morbach H.

Author information:

(1)Pediatric Rheumatology and Osteology, Children's Hospital, University of Wurzburg, Germany. hofmann\_c5@ukw.de.

**OBJECTIVES:** Chronic non-bacterial osteomyelitis (CNO) is an autoinflammatory disorder of the skeletal system. Treatment with NSAIDs is generally effective in the majority of patients, however, a sizeable proportion of patients have persistent disease and subsequent treatment strategies are required. The aim of this study was to characterise the clinical and radiological disease course in CNO patients treated with the bisphosphonate pamidronate (PAM).

**METHODS:** Eight CNO patients refractory to NSAIDs, glucocorticoids and sulfasalazine were treated with 6 cycles of PAM in four-weekly intervals. The disease course was assessed by clinical examination and whole-body (WB) MRI at standardised time points during the treatment phase and in a 6 months follow-up.

**RESULTS:** Seven patients were in complete clinical remission after 6 applications of PAM. WB MRIs showed regression of inflammatory lesions in 7 patients with complete remission in only one patient and partial remission in 6 patients. One

patient developed radiological progression despite a marked improvement of clinical symptoms. In the follow-up after PAM therapy, 3 patients developed MRI confirmed relapse. Additional applications of PAM induced a sustained clinical remission and partial radiological response in two of them. Mild temporary adverse effects were noted in 5 patients.

**CONCLUSIONS:** Our study highlights that PAM is effective in controlling clinical symptoms (e.g. pain) in CNO patients. However, subclinical bone inflammation was still detectable by MRI in most of the patients and disease progression was noticed in some patients after cessation of PAM.

**CONTEXT:** The natural progression of metabolic abnormalities among patients with inherited autoinflammation is unclear.

**OBJECTIVE:** The objective of the study was to assess the cardiometabolic risk of participants with familial Mediterranean fever (FMF).

**DESIGN AND SETTING:** This study included nationwide cross-sectional and

longitudinal cohorts.

**PARTICIPANTS:** The prevalence of components of the metabolic syndrome at age 17 years was assessed from the medical database of the Israeli Defense Force from 1973 through 1997. Included were 745 males with FMF, 902 healthy male siblings, and a control group of 787,714 participants. A prospective follow-up study traced the incidence of components of the metabolic syndrome to age 45 years among 57 FMF and 1568 control army personnel participants.

**INTERVENTIONS:** Body mass index (BMI) and blood pressure (BP) were measured at age 17 years (cross-sectional); lifestyle, anthropometric, and biochemical data were periodically recorded from age 25 years.

**MAIN OUTCOME MEASURES:** Abnormal BMI or BP (age 17 y) and Adult Treatment Panel III criteria of the metabolic syndrome were measured.

**RESULTS:** In multivariable regression analysis adjusted for known confounders of obesity, FMF participants had an odds ratio of 0.65 for the occurrence of overweight [95% confidence interval (CI) 0.44-0.96,  $P = .03$ ] and 0.66 (95% CI 0.48-0.92,  $P = .012$ ) for hypertension-range BP; their siblings tended to obesity (odds ratio 1.48; 95% CI 1.04-2.11,  $P = .008$ ). In the follow-up arm, a multivariable analysis adjusted for age, birth year, BMI, education, socioeconomic status, ethnicity, and physical activity yielded hazard ratios of 0.32 (95% CI 0.10-0.82,  $P = .002$ ) for incident obesity, 0.49 (95% CI 0.25-0.95,  $P = .037$ ) for incident triglycerides 150 mg/dL or greater, 0.56 (95% CI 0.31-0.98,  $P = .048$ ) for low-density lipoprotein cholesterol 130 mg/dL or greater, and 2.14 (1.368-3.359,  $P = .001$ ) for high-density lipoprotein cholesterol less than 40 mg/dL for FMF participants compared with controls. Incident elevated BP was lower among FMF participants (hazard ratio 0.49; 95% CI 0.23-1.00,  $P = .05$ ), whereas dysglycemia incidence was comparable.

**CONCLUSIONS:** FMF is associated with lower rates of most components of the metabolic syndrome compared with normal subjects, unlike other inflammatory conditions.

(4)Department of Biotechnological and Applied Clinical Sciences, University of L'Aquila, L'Aquila, Italy.

**BACKGROUND:** This study aims to investigate the inflammasome response in peripheral blood mononuclear cells (PBMCs) and the expression of inflammasome components in bone biopsies from patients with chronic recurrent multifocal osteomyelitis (CRMO).

**METHODS:** The expression of inflammasome components mRNAs was evaluated in PBMCs isolated from 15 CRMO patients and 13 healthy controls by quantitative real-time PCR. The Interleukin (IL)-1 $\beta$  released in the medium of PBMC cultures after treatment with lipopolysaccharides (LPS) alone or LPS and ATP was measured by ELISA. Immunohistochemical staining for Apoptosis-associated Speck-like protein (ASC), caspase-1 (CASP-1), Nod-like receptor protein-3 (NLRP3) and IL-1 $\beta$  expression was performed in bone biopsies from CRMO patients.

**RESULTS:** mRNA levels of ASC, CASP-1 and IL-1 $\beta$  were significantly higher in freshly isolated PBMCs from CRMO patients in active disease than in healthy controls. CASP-1 and IL-1 $\beta$  transcript levels were significantly higher also in PBMCs from CRMO patients in remission compared to healthy controls. PBMCs from CRMO patients in active disease stimulated in vitro with LPS showed a significant increase in IL-1 $\beta$  release compared to healthy control cells. Immunohistochemistry staining of bone tissue revealed the expression of inflammasome components in CRMO osteoclasts.

**CONCLUSIONS:** Our data suggest that an abnormal regulation of IL-1 $\beta$  axis may be involved in CRMO pathogenesis.

Behçet's disease (BD) is universally recognized as a multisystemic inflammatory disease of unknown etiology with chronic course and unpredictable exacerbations: its clinical spectrum varies from pure vasculitic manifestations with thrombotic complications to protean inflammatory involvement of multiple organs and tissues. Treatment has been revolutionized by the progressed knowledge in the pathogenetic mechanisms of BD, involving dysfunction and oversecretion of multiple proinflammatory molecules, chiefly tumor necrosis factor- (TNF-)  $\alpha$ , interleukin- (IL-)  $1\beta$ , and IL-6. However, although biological treatment with anti-TNF- $\alpha$  agents has been largely demonstrated to be effective in BD, not all patients are definite responders, and this beneficial response might drop off over time.

Therefore, additional therapies for a subset of refractory patients with BD are inevitably needed. Different agents targeting various cytokines and their receptors or cell surface molecules have been studied: the IL-1 receptor has been targeted by anakinra, the IL-1 by canakinumab and gevokizumab, the IL-6 receptor by tocilizumab, the IL12/23 receptor by ustekinumab, and the B-lymphocyte antigen CD-20 by rituximab. The aim of this review is to summarize all current experiences and the most recent evidence regarding these novel approaches with biological drugs other than TNF- $\alpha$  blockers in BD, providing a valuable addition to the actually available therapeutic armamentarium.

Clinical and radiological dissociation of anti-TNF plus methotrexate treatment in early rheumatoid arthritis in routine care: results from the ABRAB study.

Juhász P, Mester A, Biró AJ, Héjj G, Poór G(1).

Author information:

(1)National Institute of Rheumatology and Physiotherapy, Budapest, Hungary.  
poor.gyula@orfi.hu.

**BACKGROUND:** Rheumatoid arthritis (RA) is a chronic autoinflammatory joint disease which leads to the destruction of joints and disability of the patients.

Anti-tumour necrosis factor (anti-TNF) drugs can halt radiological progression better than conventional DMARDs even in clinical non-responders.

**METHODS:** The efficacy of anti-TNF plus methotrexate (MTX) treatment versus MTX monotherapy on clinical and radiological outcomes were compared in early rheumatoid arthritis (RA) patients in clinical practice by retrospective analysis of an observational cohort. 49 early RA patients (group A) on first-line MTX monotherapy and 35 early RA patients (group B) on anti-TNF plus MTX treatment were selected from an observational cohort and evaluated retrospectively focusing on their first twelve months of treatment. Data on disease activity (DAS28) and functional status (HAQ-DI) were collected three monthly. One-yearly radiological progression was calculated according to the van der Heijde modified Sharp method

(vdHS). Clinical non-responder patients in both groups were selectively investigated from a radiological point of view.

**RESULTS:** Disease activity was decreased and functional status was improved significantly in both groups. One-yearly radiological progression was significantly lower in group B than in group A. The percentage of patients showing radiological non-progression or rapid radiological progression demonstrated a significant advantage for group B patients. In addition non-responder patients in group B showed similar radiological results as responders, while a similar phenomenon was not observed in patients in group A.

**CONCLUSIONS:** Clinical efficacy within our study was similar for tight-controlled MTX monotherapy as well as for combination treatment with anti-TNF and MTX. However MTX monotherapy was accompanied by more rapid radiological progression and less radiological non-progression. Anti-TNF plus MTX decreased radiological progression even in clinical non-responders supporting the advantage of anti-TNF plus MTX combination in dissociating clinical and radiological effects.

(4)Department of Internal Medicine, Section of Nephrology, School of Medicine, Turgut Ozal University, Alparslan Türkes Cad. No: 57, Emek, 06510, Ankara, Turkey.

**BACKGROUND:** The most common and pernicious complication of Familial Mediterranean fever (FMF) is renal amyloidosis, usually affecting the kidneys, leading to end-stage renal failure. FMF-related renal amyloidosis needed to be diagnosed early. Optimal colchicine dose is effective in preventing and reversing renal amyloidosis. Galectin-3, profibrotic mediator, has regulatory functions in inflammation, fibrosis and tumorigenesis. Galectin-3 is a strong prognostic marker for heart failure. Galectin-3 plays role in diabetic nephropathy and chronic kidney disease. The aim of the study is to investigate whether galectin-3 is related to proteinuria and amyloidosis in FMF.

**METHODS:** Seventy-five FMF patients who have no exclusion criteria and healthy controls (n = 36) were included. Serum galectin-3 was measured and morning spot urine was collected for determination of the protein/creatinine ratio (PCR).

**RESULTS:** Serum Galectin-3 levels were significantly higher in FMF patients than the control group [969.66 (3825) pg/mL vs. 238 (921) pg/mL, respectively;  $P < 0.001$ ]. We classified into two groups: Group1 (n = 48) had FMF patients with proteinuria, Group2 (n = 27) had FMF patients without proteinuria. Group1 had higher levels of galectin-3 than Group2 [1106(3812) pg/mL vs. 867.3(1433) pg/mL,  $P < 0.001$ ]. Galectin-3 levels were correlated with PCR in whole group and FMF group ( $r = 0.785$ ,  $P < 0.001$  and  $r = 0.803$ ,  $P < 0.001$ ). In ROC curve, best cutoff value = 581.50 pg/mL was used to detect proteinuria (sensitivity = 91.7 %, specificity = 71.4 %, AUC = 0.879) and optimal cutoff value = 1458.00 pg/mL was an indicator of nephrotic-range proteinuric (sensitivity = 100 %, specificity = 92.1 %, AUC = 0.983).

**CONCLUSION:** Galectin-3 is associated with proteinuria and renal amyloidosis in FMF. Galectin-3 may play role in pathogenesis of amyloidosis.

SHP-1 and IL-1 $\alpha$  conspire to provoke neutrophilic dermatoses.

Lukens JR, Kanneganti TD.

Neutrophilic dermatoses are a spectrum of autoinflammatory skin disorders that are characterized by extensive infiltration of neutrophils into the epidermis and dermis. The underlining biological pathways that are responsible for this

heterogeneous group of cutaneous diseases have remained elusive. However, recent work from our laboratory and other groups has shown that missense mutations in Ptpn6, which encodes for the non-receptor protein tyrosine phosphatase Src homology region 2 (SH2) domain-containing phosphatase-1 (SHP-1), results in a skin disease with many of the major histopathological and clinical features that encompass neutrophilic dermatoses in humans. In particular, we found that loss-of-function mutation in Ptpn6 results in unremitting footpad swelling, suppurative inflammation, and neutrophilia. Dysregulated wound healing responses were discovered to contribute to chronic inflammatory skin disease in SHP-1 defective mice and genetic abrogation of interleukin-1 receptor (IL-1R) protected mice from cutaneous inflammation, suggesting that IL-1-mediated events potentiate disease. Surprisingly, inflammasome activation and IL-1 $\beta$ -mediated events were dispensable for Ptpn6(sp1n) -mediated footpad disease. Instead, RIP1-mediated regulation of IL-1 $\alpha$  was identified to be the major driver of inflammation and tissue damage.

Nat Rev Rheumatol. 2014 Aug;10(8):445.

Rheumatoid arthritis is a chronic autoinflammatory disease that affects 1-2% of the world's population and is characterized by widespread joint inflammation. Interleukin-1 is an important mediator of cartilage destruction in rheumatic diseases, but our understanding of the upstream mechanisms leading to production of interleukin-1 $\beta$  in rheumatoid arthritis is limited by the absence of suitable mouse models of the disease in which inflammasomes contribute to pathology. Myeloid-cell-specific deletion of the rheumatoid arthritis susceptibility gene A20/Tnfrsf3 in mice (A20(myel-KO) mice) triggers a spontaneous erosive polyarthritis that resembles rheumatoid arthritis in patients. Rheumatoid arthritis in A20(myel-KO) mice is not rescued by deletion of tumour necrosis factor receptor 1 (ref. 2). Here we show, however, that it crucially relies on the Nlrp3 inflammasome and interleukin-1 receptor signalling. Macrophages lacking A20 have increased basal and lipopolysaccharide-induced expression levels of the inflammasome adaptor Nlrp3 and proIL-1 $\beta$ . As a result, A20-deficiency in macrophages significantly enhances Nlrp3 inflammasome-mediated caspase-1 activation, pyroptosis and interleukin-1 $\beta$  secretion by soluble and crystalline Nlrp3 stimuli. In contrast, activation of the Nlrp4 and AIM2 inflammasomes is not altered. Importantly, increased Nlrp3 inflammasome activation contributes to the pathology of rheumatoid arthritis in vivo, because deletion of Nlrp3, caspase-1 and the interleukin-1 receptor markedly protects against

rheumatoid-arthritis-associated inflammation and cartilage destruction in A20(myel-KO) mice. These results reveal A20 as a novel negative regulator of Nlrp3 inflammasome activation, and describe A20(myel-KO) mice as the first experimental model to study the role of inflammasomes in the pathology of rheumatoid arthritis.

Hepatitis-B vaccine (HBVv) can prevent HBV-infection and associated liver diseases. However, concerns regarding its safety, particularly among patients with autoimmune diseases (i.e. SLE) were raised. Moreover, the aluminum adjuvant in HBVv was related to immune mediated adverse events. Therefore, we examined the effects of immunization with HBVv or alum on SLE-like disease in a murine model. NZBWF1 mice were immunized with HBVv (Engerix), or aluminum hydroxide (alum) or phosphate buffered saline (PBS) at 8 and 12 weeks of age. Mice were followed for weight, autoantibodies titers, blood counts, proteinuria, kidney histology, neurocognitive functions (novel object recognition, staircase, Y-maze and the forced swimming tests) and brain histology. Immunization with HBVv induced acceleration of kidney disease manifested by high anti-dsDNA antibodies ( $p < 0.01$ ), early onset of proteinuria ( $p < 0.05$ ), histological damage and deposition of HBs antigen in the kidney. Mice immunized with HBVv and/or alum had decreased cells counts mainly of the red cell lineage ( $p < 0.001$ ), memory deficits ( $p < 0.01$ ), and increased activated microglia in different areas of the brain compare with mice immunized with PBS. Anxiety-like behavior was more pronounced among mice immunized with alum. In conclusion, herein we report that immunization with the HBVv aggravated kidney disease in an animal model of SLE. Immunization with either HBVv or alum affected blood counts, neurocognitive functions and brain gliosis. Our data support the concept that different component of vaccines may be linked with immune and autoimmune mediated adverse events.

**PURPOSE:** We report on the endovascular management of hemorrhage with stent-graft due to a misplaced central venous catheter in the vertebral artery (VA) during percutaneous internal jugular vein catheterization in a child.

**METHODS:** A 16-year-old female was presented with the diagnosis of familial Mediterranean fever related chronic renal insufficiency. An attempt was made to place a central venous catheter via the right internal jugular vein without image guidance and the patient experienced dyspnea and pain at the catheter insertion site. Computerized tomography (CT) showed hemorrhage in the cervical region and upper mediastinum, also reformatted images showed that the catheter was passing through the proximal part of the VA and terminating in the right mediastinum. The catheter was removed during manual compression under angio-fluoroscopic monitoring and ongoing extravasation was observed. A stent-graft was placed to the bleeding site of the VA.

**RESULTS:** Angiography immediately after the stent-graft placement revealed complete disappearance of extravasation and patency of vertebral and subclavian arteries.

**CONCLUSION:** Central venous catheterization (CVC) is not a risk-free procedure and arterial injuries are in a wide spectrum from a simple puncture to rupture of the artery. Inadvertent VA cannulation is a rare and serious complication necessitating prompt diagnosis and early treatment. If an arterial injury with a large-caliber catheter occurs, endovascular treatment with stent-graft seems to be a safe and effective option in terms of achieving hemostasis and preserving arterial patency. Recent findings suggest that endovascular management of inadvertent cervical arterial injury secondary to CVC seems to be the safest strategy.

Proline-serine-threonine phosphatase interacting protein 1 (PSTPIP1) is an adaptor protein associated with the cytoskeleton that is mainly expressed in hematopoietic cells. Mutations in PSTPIP1 cause the rare autoinflammatory disease called pyogenic arthritis, pyoderma gangrenosum, and acne. We carried out this study to further our knowledge on PSTPIP1 function in T cells, particularly in relation to the phosphatase lymphoid phosphatase (LYP), which is involved in several autoimmune diseases. LYP-PSTPIP1 binding occurs through the C-terminal homology domain of LYP and the F-BAR domain of PSTPIP1. PSTPIP1 inhibits T-cell activation upon T-cell receptor (TCR) and CD28 engagement, regardless of CD2 costimulation. This function of PSTPIP1 depends on the presence of an intact SH3 domain rather than on the F-BAR domain, indicating that ligands of the F-BAR domain, such as the PEST phosphatases LYP and PTP-PEST, are not critical for its negative regulatory role in TCR signaling. Additionally, PSTPIP1 mutations that cause the pyogenic arthritis, pyoderma gangrenosum and acne syndrome do not affect PSTPIP1 function in T-cell activation through the TCR.

OBJECTIVE: To evaluate genetic, demographic and clinical features in patients

with cryopyrin-associated periodic syndrome (CAPS) from the Eurofever Registry, with a focus on genotype-phenotype correlations and predictive disease severity markers.

**METHODS:** A web-based registry retrospectively collected data on patients with CAPS. Experts in the disease independently validated all cases. Patients carrying NLRP3 variants and germline-mutation-negative patients were included.

**RESULTS:** 136 patients were analysed. The median age at disease onset was 9 months, and the median duration of follow-up was 15 years. Skin rash, musculoskeletal involvement and fever were the most prevalent features. Neurological involvement (including severe complications) was noted in 40% and 12% of the patients, respectively, with ophthalmological involvement in 71%, and neurosensory hearing loss in 42%. 133 patients carried a heterozygous, germline mutation, and 3 patients were mutation-negative (despite complete NLRP3 gene screening). Thirty-one different NLRP3 mutations were recorded; 7 accounted for 78% of the patients, whereas 24 rare variants were found in 27 cases. The latter were significantly associated with early disease onset, neurological complications (including severe complications) and severe musculoskeletal involvement. The T348M variant was associated with early disease onset, chronic course and hearing loss. Neurological involvement was less strongly associated with V198M, E311 K and A439 V alleles. Early onset was predictive of severe neurological complications and hearing loss.

**CONCLUSIONS:** Patients carrying rare NLRP3 variants are at risk of severe CAPS; onset before the age of 6 months is associated with more severe neurological involvement and hearing loss. These findings may have an impact on treatment decisions.

Mutations in the B30.2 domain of pyrin and the risk of ankylosing spondylitis in the Chinese Han population: a case-control study.

He C(1), Li J(1), Xu W(1).

Author information:

(1)Department of Orthopedics, Changhai Hospital Affiliated to the Second Military Medical University, 168 Changhai Road, Shanghai 200433, People's Republic of China.

Ankylosing spondylitis (AS) and familial Mediterranean fever (FMF) are a common autoimmune disease and a classic autoinflammatory disease, respectively. Mediterranean fever (MEFV) encodes the pyrin protein and is the causal disease gene in FMF. This protein is an important regulator of innate immunity and may play a key role in the development of AS. To identify the mutations in the B30.2 domain of pyrin and to uncover the relationships between these mutations and AS risk in the Chinese Han population, we extracted genomic DNA from the peripheral blood of 200 AS patients and 200 matched controls and performed polymerase chain reactions (PCRs) and direct sequencing on those samples. Statistical analysis indicated that only Met694Val (rs61752717) in the B30.2 domain of pyrin could affect the risk of AS ( $P = 0.042$ ; odds ratio [OR] = 5.103; 95% confidence interval [CI] = 1.111-23.437 for the model of Met (M) vs. Val (V),  $P = 0.040$ ; OR = 5.211; 95% CI = 1.127-24.091 for the model of MM vs. MV+VV). Moreover, M694V is significantly associated with a higher level of erythrocyte sedimentation rate (ESR) and C-reactive protein (CRP) in AS patients. Our results are the first to suggest that the M694V allele of the pyrin was associated with AS risk in the Chinese Han population and that this mutation may be associated with the inflammatory response in the development of AS.

CANDLE syndrome: a recently described autoinflammatory syndrome.

Tüfekçi Ö(1), Bengoa Ş, Karapinar TH, Ataseven EB, İrken G, Ören H.

Author information:

(1)Department of Pediatric Hematology, Faculty of Medicine, Dokuz Eylül University, Balçova, İzmir, Turkey.

CANDLE syndrome (chronic atypical neutrophilic dermatosis with lipodystrophy and elevated temperature) is a recently described autoinflammatory syndrome characterized by early onset, recurrent fever, skin lesions, and multisystemic inflammatory manifestations. Most of the patients have been shown to have mutation in PSMB8 gene. Herein, we report a 2-year-old patient with young onset recurrent fever, atypical facies, widespread skin lesions, generalized lymphadenopathy, hepatosplenomegaly, joint contractures, hypertriglyceridemia, lipodystrophy, and autoimmune hemolytic anemia. Clinical features together with the skin biopsy findings were consistent with the CANDLE syndrome. The pathogenesis and treatment of this syndrome have not been fully understood. Increased awareness of this recently described syndrome may lead to recognition of new cases and better understanding of its pathogenesis which in turn may help for development of an effective treatment.

**BACKGROUND:** The study of autoinflammatory diseases has uncovered mechanisms underlying cytokine dysregulation and inflammation.

**METHODS:** We analyzed the DNA of an index patient with early-onset systemic inflammation, cutaneous vasculopathy, and pulmonary inflammation. We sequenced a candidate gene, TMEM173, encoding the stimulator of interferon genes (STING), in this patient and in five unrelated children with similar clinical phenotypes.

Four children were evaluated clinically and immunologically. With the STING ligand cyclic guanosine monophosphate-adenosine monophosphate (cGAMP), we stimulated peripheral-blood mononuclear cells and fibroblasts from patients and controls, as well as commercially obtained endothelial cells, and then assayed transcription of IFNB1, the gene encoding interferon- $\beta$ , in the stimulated cells.

We analyzed IFNB1 reporter levels in HEK293T cells cotransfected with mutant or nonmutant STING constructs. Mutant STING leads to increased phosphorylation of signal transducer and activator of transcription 1 (STAT1), so we tested the effect of Janus kinase (JAK) inhibitors on STAT1 phosphorylation in lymphocytes from the affected children and controls.

**RESULTS:** We identified three mutations in exon 5 of TMEM173 in the six patients. Elevated transcription of IFNB1 and other gene targets of STING in peripheral-blood mononuclear cells from the patients indicated constitutive activation of the pathway that cannot be further up-regulated with stimulation. On stimulation with cGAMP, fibroblasts from the patients showed increased transcription of IFNB1 but not of the genes encoding interleukin-1 (IL1), interleukin-6 (IL6), or tumor necrosis factor (TNF). HEK293T cells transfected with mutant constructs show elevated IFNB1 reporter levels. STING is expressed in endothelial cells, and exposure of these cells to cGAMP resulted in endothelial activation and apoptosis. Constitutive up-regulation of phosphorylated STAT1 in patients' lymphocytes was reduced by JAK inhibitors.

**CONCLUSIONS:** STING-associated vasculopathy with onset in infancy (SAVI) is an autoinflammatory disease caused by gain-of-function mutations in TMEM173. (Funded by the Intramural Research Program of the National Institute of Arthritis and Musculoskeletal and Skin Diseases; ClinicalTrials.gov number, NCT00059748.).

In order to clarify the inflammatory mechanism underlying familial Mediterranean fever (FMF), we aimed to evaluate the ex vivo cytokine profile of FMF patients during acute attacks and attack-free periods, and compare it with that of healthy controls. The study included 34 FMF patients, of whom 9 were studied during attack and remission and 24 healthy controls. Cytokine levels were evaluated by Luminex technology in serum and supernatants of PBMC (Peripheral Blood Mononuclear Cells) cultures with and without 24h stimulation of monocytes by LPS and T lymphocytes by anti-CD3/CD28 beads. Levels of IL-6 and TNF- $\alpha$  were higher in unstimulated and LPS-stimulated PBMC supernatants of FMF patients in crises compared to controls. In response to LPS stimulation, higher levels of IL-1 $\beta$  and IL-1 $\alpha$  were found in PBMC supernatants of patients during crises compared to those in remission and to controls. IFN- $\gamma$  and IL-4 levels were the lowest in unstimulated and anti-CD3/CD28 stimulated PBMCs supernatants of patients during crises compared to remission and controls. The Th17 cytokines IL-17 and IL-22 were respectively higher in anti-CD3/CD28 stimulated PBMC supernatants of FMF patients during and between crises compared to controls. Amongst cytokines tested in serum, only IL-6 and TNF $\alpha$  were enhanced in FMF patients. The ex vivo study represents an interesting approach to evaluate cytokines' involvement in FMF. Our results suggest an ongoing subclinical inflammation and define an elevated

inflammatory cytokine signature, distinctly for M694V homozygous patients. The absence of spontaneous IL-1 $\beta$  release by PBMCs reflects no constitutive activation of the inflammasome in FMF physiopathology.

While autoimmunity as cause of disease is well-established, other categories of immune-mediated diseases that are not produced by targeting of self-antigens by antibodies is in the process of being described. These so-called autoinflammatory diseases arise when an inappropriate activation of antigen-independent mechanisms occurs. Autoinflammatory diseases course with recurrent attacks of fever and multisystemic inflammation; however, the skin may also be affected by a variety of inflammatory manifestations that often alert the clinician about the presence of an autoinflammatory disease. Recognizing the cutaneous features of these syndromes will aid for prompt diagnosis and early treatment that is key for the quality of life and survival of the affected patients. In this paper, we focus on the skin manifestations of autoinflammatory diseases in children, which is the usual period of appearing of the first symptoms and signs.

Use of microarrays in the clinical practice of pediatric rheumatology: the future is now?

Punaro M(1).

Author information:

(1)Texas Scottish Rite Hospital, University of Texas Southwestern Medical Center, Dallas, Texas, USA.

**PURPOSE OF REVIEW:** Systems immunology is an integrative approach that leverages high throughput technologies as well as mathematical and computational tools to investigate complex immunologic diseases by looking at the state of a system on a comprehensive scale. Gene expression profiling, also known as transcriptomics, measures the expression level of mRNAs (transcripts) in a given cell population at a specific time. Over the past decade, several major gene expression discoveries have been made in pediatric rheumatology, most notably the alpha interferon signature of systemic lupus erythematosus and the interleukin-1 signature in systemic onset juvenile idiopathic arthritis. This article reviews these discoveries, their clinical implications and the recent associated literature.

**RECENT FINDINGS:** Interferon- $\alpha$  has been exploited as a therapeutic target in lupus. Interleukin-1 blockade has been utilized to treat systemic onset juvenile idiopathic arthritis and related autoinflammatory diseases.

**SUMMARY:** Current gene expression studies extend our understanding of the disease pathogenesis of lupus and systemic onset juvenile idiopathic arthritis as well as related conditions. This knowledge has translated to the bedside with implications for clinical practice and direct therapeutic targeting.

Colchicine is frequently used in the treatment of familial Mediterranean fever (FMF). First symptoms of colchicine intoxication are gastrointestinal disturbances, such as abdominal cramps, diarrhea, pancytopenia and so on. Herein, we report a female FMF patient with pancytopenia and hemophagocytic lymphohistiocytosis (HLH), following colchicine intoxication for committing suicide. To our knowledge, this is the first reported case of a patient with HLH associated with colchicine intoxication.

**OBJECTIVE:** Familial Mediterranean fever (FMF) is an autoinflammatory, autosomal recessive, inherited disease characterized by recurrent self-limiting attacks of serosal surfaces. The imbalance of oxidants/antioxidants may play a role in such attacks. In this study, we aimed to evaluate the relationship between serum paraoxonase (PON1) activity, PON1 phenotype, and other parameters in patients with FMF and healthy controls.

**METHODS:** A total of 120 FMF patients with an attack-free period (AFP) and 65 healthy subjects were included in this study. The serum PON1 activity, stimulated paraoxonase (SPON) activity, PON1 phenotype (representing Q192R polymorphism; QQ, QR, RR), arylesterase activity, total oxidant status (TOS), total antioxidant capacity (TAC), oxidative stress index (OSI), advanced oxidative protein products (AOPP), total thiols (TTL), and ischemia-modified albumin (IMA) and cystatin-c (CYS-C) levels were measured.

**RESULTS:** For the QQ phenotype, the median TTL and AOPP levels of the control group were 264.50 (57.75) mol/L and 21.26 (21.17) mmol/L, respectively, whereas the median TTL, AOPP levels of the patients were 309.00 (47.00) mol/L and 12.98 (6.96) mmol/L, respectively. There was a statistically significant difference between the patients and controls with the QQ phenotype in terms of TTL and AOPP ( $p < 0.001$  and  $p = 0.004$ , respectively). However, there were no statistically significant differences between the QQ and QR+RR phenotypes with respect to TAC, TOS, OSI, or the other parameters.

**CONCLUSIONS:** The FMF patients with AFP had higher TTL and lower AOPP levels than the controls. However, other oxidant and antioxidant parameters were similar among the patients during AFP and the controls.

Inflammasomes are macromolecular complexes that mediate inflammatory and cell death responses to pathogens and cellular stress signals. Dysregulated inflammasome activation is associated with autoinflammatory syndromes and several common diseases. During inflammasome assembly, oligomerized cytosolic pattern recognition receptors recruit procaspase-1 and procaspase-8 via the adaptor protein ASC. Inflammasome assembly is mediated by pyrin domains (PYDs) and caspase recruitment domains, which are protein interaction domains of the death

fold superfamily. However, the molecular details of their interactions are poorly understood. We have studied the interaction between ASC and pyrin PYDs that mediates ASC recruitment to the pyrin inflammasome, which is implicated in the pathogenesis of familial Mediterranean fever. We demonstrate that both the ASC and pyrin PYDs have multifaceted binding modes, involving three sites on pyrin PYD and two sites on ASC PYD. Molecular docking of pyrin-ASC PYD complexes showed that pyrin PYD can simultaneously interact with up to three ASC PYDs. Furthermore, ASC PYD can self-associate and interact with pyrin, consistent with previous reports that pyrin promotes ASC clustering to form a proinflammatory complex. Finally, the effects of familial Mediterranean fever-associated mutations, R42W and A89T, on structural and functional properties of pyrin PYD were investigated. The R42W mutation had a significant effect on structure and increased stability. Although the R42W mutant exhibited reduced interaction with ASC, it also bound less to the pyrin B-box domain responsible for autoinhibition and hence may be constitutively active. Our data give new insights into the binding modes of PYDs and inflammasome architecture.

Co-existence of familial Mediterranean fever and multiple sclerosis in two patients.

Ceylan G, Erten S, Ercan K.

**ABSTRACT** Two female patients, aged 23 and 25 years-old diagnosed with Familial Mediterranean fever (FMF) were presented with ataxia and headache. Multiple sclerosis plaques were detected in their spinal and cranial MRI and diagnosis of multiple sclerosis was established. Genetic analysis demonstrated M694 V mutation (one homozygous and the other heterozygous) in both of the patients. Although it is quite rare, coexistence of familial Mediterranean fever and multiple sclerosis should be kept in the mind.

Autoimmunity versus autoinflammation--friend or foe?

"Autoimmunity" is a designation dependent on the conventional immunological issue of self/non-self discrimination. Identification of novel target autoantigens is still an important issue ongoing in classical tissue-specific autoimmune bullous diseases and autoimmune connective tissue diseases. In contrast, synchronized with the paradigm shift of the fundamental aspect of immunity to danger sensing/signaling, distinct collagen-like diseases have been defined by the genetic mutations causing dysregulated innate immunity/inflammation and have been designated as "autoinflammatory" diseases. Due to the clinical and etiological similarities, the concept of autoinflammatory diseases has expanded to include non-hereditary collagen-like diseases, tissue-specific chronic idiopathic inflammatory diseases and metabolic diseases. On the other hand, various genetic causes of autoimmune diseases have been identified and the border of these two pathophysiology is becoming obscure. Instead, a variable mixture of both autoimmunity and autoinflammation can cause each inflammatory phenotype with a variable level of antigen specificity

Capsular Polysaccharide A (CPSA), a polymer of a four-sugar repeating unit that coats the surface of the mammalian symbiont *Bacteroides fragilis*, has therapeutic potential in animal models of Multiple Sclerosis and other autoinflammatory diseases. Genetic studies have demonstrated that CPSA biosynthesis is dependent primarily on a single gene cluster within the *B. fragilis* genome. However, the precise functions of the individual glycosyltransferases encoded by this cluster have not been identified. In this report each of these glycosyltransferases (WcfQ, WcfP, and WcfN) have been expressed and tested for their function in vitro. Using a reverse phase high performance liquid chromatography (HPLC) assay, WcfQ and WcfP were found to transfer galactose from uridine diphosphate (UDP)-linked galactose (Gal) to N-acetyl-4-amino-6-deoxy-galactosamine (AADGal) linked to a fluorescent mimic of bactoprenyl diphosphate, the native isoprenoid anchor for bacterial polysaccharide biosynthesis. The incorporation of galactose to form a bactoprenyl-linked disaccharide was confirmed by radiolabel incorporation and mass spectrometry (MS) of purified product. Using varying concentrations of UDP-Gal and enzyme, WcfQ was found to be the most effective protein at transferring galactose, and is the most likely candidate for in vivo incorporation of the sugar. WcfQ also cooperated in the presence of three preceding biosynthetic enzymes to form an isoprenoid-linked disaccharide in a single-pot reaction. This work represents a critical step in understanding the biosynthetic pathway responsible for the formation of CPSA, an unusual and potentially therapeutic biopolymer.

Assessment of renal involvement in patients with familial Mediterranean fever: a clinical study from Ardabil, Iran.

Bashardoust B(1), Maleki N.

Author information:

(1)Department of Internal Medicine, Imam Khomeini Hospital, Ardabil University of Medical Sciences, Ardabil, Iran.

**BACKGROUND AND AIM:** Familial Mediterranean fever (FMF) is an autosomal recessive disease characterised by recurrent episodes of painful inflammation in the abdomen, chest or joints. The association between FMF and non-amyloid glomerulopathies are unusual. In this study, we describe our experiences and observations about renal involvement in patients with FMF.

**METHODS:** A total of 108 patients with FMF was enrolled in the study. Twelve patients with FMF were referred to the Nephrology Service, for evaluation and assessment of the degree of renal involvement. All the 12 patients underwent percutaneous ultrasound-guided renal biopsies and genetic analysis.

**RESULTS:** On microscopic examination of the kidney specimens, six patients were found to have amyloidosis, five focal segmental glomerulosclerosis and one patient membranoproliferative glomerulonephritis. It seems that in patients with FMF and renal amyloidosis, the response to treatment with colchicine is excellent, but in patients with FMF and focal segmental glomerulosclerosis, the response to treatment with colchicine is poor. We present an evidence-based algorithm, constructed based on literature review, to aid decision making in management of renal involvement in patients with FMF.

**CONCLUSION:** The results of our study suggest that in patients with FMF and renal involvement, non-amyloid renal lesions should be considered in the differential diagnosis in addition to amyloidosis.

**BACKGROUND:** Familial Mediterranean Fever (FMF), characterized by recurrent fever and inflammation of serous membranes, is an autosomal recessive disease caused by mutations in the Mediterranean fever (MEFV) gene. Around 296 mutations have been reported to date.

**METHODS:** Two two-generation Turkish families with a total of four members

diagnosed with FMF clinically were screened with DNA sequencing performed on exon 2 and exon 10 of the MEFV genes. Then, complete exome sequencing analysis of MEFV gene was done for four patients in whom novel mutation was detected.

RESULTS: A novel single base Guanine (G) insertion mutation in the coding region of MEFV gene, named c.2330dupG (p.Gln778Serfs\*4 or Q778SfsX4) resulting in a mutated Pyrin/Marenostrin protein was identified.

CONCLUSIONS: This is the first report of a new mutation in exon 10 of the MEFV gene in two Turkish families. This novel pattern of insertion mutation may provide important information for further studies on FMF pathogenesis.

Colchicine failure in familial Mediterranean fever and potential alternatives: embarking on the anakinra trial.

Ben-Zvi I, Livneh A.

Familial Mediterranean fever (FMF) is a genetic auto-inflammatory disease characterized by spontaneous short attacks of fever, elevated acute-phase reactants, and serositis. Approximately 5%-10% of FMF patients do not respond to colchicine treatment and another 5% are intolerant to colchicine because of side effects. Recently, following the discovery of the inflammasome and recognition of the importance of interleukin-1beta (IL-1beta) as the major cytokine involved in the pathogenesis of FMF, IL-1beta blockade has been suggested and tried sporadically to treat FMF, with good results. To date, case reports and small case series involving colchicine-resistant FMF patients and showing high efficacy of IL-1beta blockade have been reported. At the Israel Center for FMF at the Sheba Medical Center the first double-blind randomized placebo-controlled trial of anakinra in FMF patients who are resistant or intolerant to colchicines is underway. In this report we discuss the mechanism of colchicine resistance in FMF patients, the data in the literature on IL1beta blockade in these patients, and the anakinra trial inclusion criteria and study protocol.

**PURPOSE:** To examine functional capacity and muscle strength in children and youth with familial Mediterranean fever (FMF) as compared with controls, and to assess whether these factors influence quality of life (QOL) in FMF.

**METHODS:** A total of 100 subjects with FMF and 55 control subjects (8-18 years old) without known health issues were enrolled in the study. The 6-Minute Walk Test (6MWT) was used to evaluate functional capacity. Quadriceps strength was measured with a hand-held dynamometer. Quality of life was evaluated with the Pediatric Quality of Life Inventory 4.0 (PedsQL 4.0).

**RESULTS:** Significant differences were found between subjects with FMF and controls in the 6MWT and strength test. PedsQL scores of subjects with FMF were

significantly lower than the scores of the controls. The 6MWT and quadriceps strength were weakly correlated with the PedsQL.

CONCLUSION: Subjects with FMF displayed lower functional capacity and QOL than peers who are healthy. Decreased functional capacity was correlated with decreased QOL in those with FMF.

Autoinflammatory diseases are characterized by the presence of chronic or recurrent systemic inflammation secondary to abnormal activation of innate immunity pathways. Many of these diseases have been found to have mutations in the genes within these pathways. Due to their rarity, non-specific symptoms and the very recent genetic and phenotypic identification and recognition, a delay in diagnosis is common. Nevertheless, some specific clinical features should help the clinician to make the diagnosis. The purpose of this article is to provide a brief clinical description of these conditions and to present clinical flow-charts useful for a correct diagnosis of children with suspected autoinflammatory syndromes.

MEFV gene polymorphisms and TNFRSF1A mutation in patients with inflammatory myopathy with abundant macrophages.

Fujikawa K(1), Migita K, Shigemitsu Y, Umeda M, Nonaka F, Tamai M, Nakamura H, Mizokami A, Tsukada T, Origuchi T, Yonemitsu N, Yasunami M, Kawakami A, Eguchi K.

Author information:

(1)Department of Rheumatology, Japan Community Health Care Organization, Isahaya General Hospital, Isahaya, Japan.

Inflammatory myopathy with abundant macrophages (IMAM) has recently been proposed as a new clinical condition. Although IMAM shares certain similarities with other inflammatory myopathies, the mechanisms responsible for this condition remain unknown. Patients with familial Mediterranean fever (FMF) and tumour necrosis factor receptor-associated periodic syndrome (TRAPS) also often develop myalgia. We therefore investigated the polymorphisms or mutations of MEFV and TNFRSF1A genes in patients with IMAM to identify their potential role in this condition. We analysed the clinical features of nine patients with IMAM and sequenced exons of the MEFV and TNFRSF1A genes. The patients with IMAM had clinical symptoms such as myalgia, muscle weakness, erythema, fever and arthralgia. Although none of the patients were diagnosed with FMF or TRAPS, seven demonstrated MEFV polymorphisms (G304R, R202R, E148Q, E148Q-L110P and P369S-R408Q), and one demonstrated a TNFRSF1A mutation (C43R). These results suggest that MEFV gene polymorphisms and TNFRSF1A mutation are susceptibility and modifier genes in IMAM.

Assessment of thyroid disorders and autoimmunity in patients with rheumatic diseases.

Acay A, Ulu MS, Ahsen A, Eroglu S, Ozuguz U, Yuksel S, Acarturk G(1).

Author information:

(1)Department of Internal Medicine, Afyon Kocatepe University Faculty of Medicine, Address: Afyon Kocatepe Universitesi, Tıp Fakultesi, İç Hastalıkları AD, 03200, Afyonkarahisar, Turkey. drakifacay@gmail.com.

We investigated whether there was a significant increase in thyroid autoimmunity, and disorders in patients with rheumatic diseases (RDs). We enrolled 201 patients with RDs (41 with ankylosing spondylitis, 15 with systemic lupus erythematosus, 80 with rheumatoid arthritis [RA], 65 with familial Mediterranean fever), and 122 healthy controls. Serum levels of thyroid-stimulating hormone (TSH), free triiodothyronine (fT3), free thyroxine (fT4), C-reactive protein, and thyroid autoantibodies (anti-thyroglobulin and anti-thyroid peroxidase) were measured in all participants. There were no significant differences between the ages of the patients and controls. The mean TSH values of the patients with RDs and the controls were  $3.1 \pm 2.68$  mIU/L and  $1.9 \pm 0.83$  mIU/L, respectively ( $P = 0.004$ ). The mean fT4 value of the patients with RDs was  $1.43 \pm 0.67$  ng/dL whereas that of the controls was  $1.58 \pm 0.68$  ng/dL ( $P < 0.001$ ). Subclinical hypothyroidism was detected in 24 patients with RDs. Thyroid antibodies were detected in 16 of 201 (8%) patients with RDs. Three of these patients had subclinical hypothyroidism, while the others were euthyroid. Thyroid autoantibodies were significantly higher in patients with RDs ( $P < 0.001$ ). Additionally, thyroid disorders were observed more frequently in patients with RDs than in the healthy controls. Based on our findings, we recommend that thyroid function tests should better be included in the clinical evaluation of patients with RDs.

Autoinflammatory disorders are a group of Mendelian disorders characterized by seemingly unprovoked inflammatory bouts without high-titer autoantibodies or antigen-specific T-cells and are probably due to defects in the innate immunity. We here report on a 4-year-old Arabic boy with the clinical presentation of an autoinflammatory disorder, namely Pyogenic Arthritis, Pyoderma Gangrenosum and Acne (PAPA) syndrome. The presentation includes abscess formation after immunization and recurrent mono-articular acute arthritis in various joints that responded favourably to systemic glucocorticosteroids, albeit without acne or pyoderma gangrenosum. The mutation analysis of the boy identified a novel de novo mutation in PSTPIP1, the gene responsible for PAPA syndrome. We recommend that the diagnosis of PAPA syndrome should be entertained in the differential diagnosis of patients with recurrent sterile pyogenic arthritis prior to the development of pyoderma gangrenosum or acne in order to initiate a timely management of the disorder.

BACKGROUND: Familial Mediterranean fever (FMF) is autosomal recessive disease

that affects people from Mediterranean region, Europe and Japan. Its gene (Mediterranean fever [MEFV]) has more than 100 mostly non-sense mutations.

**OBJECTIVES:** The objective of the following study is to provide some phenotype-genotype correlates in FMF by categorizing the Egyptian FMF cases from Delta governorates after analysis of the four most common mutations of MEFV gene (M680I, M694I, M694V, V726A).

**SUBJECTS AND METHODS:** Clinically, suspected FMF cases using Tel-Hashomer criteria were enrolled in the study. Cases were referred to Mansoura University Children's Hospital that serves most of the most middle Delta governorates, in the period from 2006 to 2011. Subjects included 282 males and 144 females, mean age of onset  $9.3 \pm 2.2$  years. All cases were analyzed for these mutations using amplification refractory mutation system based on the polymerase chain reaction technique. Five FMF patients agreed to undergo renal biopsy to check for development of amyloidosis. Analysis of data was carried out using SPSS (SPSS, Inc., Chicago, IL, USA).

**RESULTS:** Mutation was found in 521 out of 852 studies alleles, the most frequent is M694V (35.4%) followed by M694I, V726A and M680I. 11 cases were homozygous; 7 M694V, 3 M680I and only one M694I case. Severe abdominal pain occurred in 31 (7.28%) but severe arthritis in 103 cases (24.2%). Strong association was found between arthritis and homozygous mutant compared with single and double heterozygous (72.7% vs. 33.3% and 20.24%,  $P < 0.001$ ). Four amyloid cases were M694V positive.

**CONCLUSION:** M694V allele is the most common among Egyptian FMF especially those with amyloidosis. We recommend routine check for amyloidosis in FMF cases to statistically validate this link.

Following activation, the cytoplasmic pattern recognition receptor nucleotide-binding oligomerization domain-containing protein 1 (NOD1) interacts with its adaptor protein receptor-interacting protein 2 (RIP2) to propagate immune signaling and initiate a proinflammatory immune response. This interaction is mediated by the caspase recruitment domain (CARD) of both proteins.

Polymorphisms in immune proteins can affect receptor function and predispose individuals to specific autoinflammatory disorders. In this report, we show that mutations in helix 2 of the CARD of NOD1 disrupted receptor function but did not interfere with RIP2 interaction. In particular, N43S, a rare polymorphism, resulted in receptor dysfunction despite retaining normal cellular localization, protein folding, and an ability to interact with RIP2. Mutation of Asn-43 resulted in an increased tendency to form dimers, which we propose is the source of this dysfunction. We also demonstrate that mutation of Lys-443 and Tyr-474 in

RIP2 disrupted the interaction with NOD1. Mapping the key residues involved in the interaction between NOD1 and RIP2 to the known structures of CARD complexes revealed the likely involvement of both type I and type III interfaces in the NOD1-RIP2 complex. Overall we demonstrate that the NOD1-RIP2 signaling axis is more complex than previously assumed, that simple engagement of RIP2 is insufficient to mediate signaling, and that the interaction between NOD1 and RIP2 constitutes multiple CARD-CARD interfaces.

Autoinflammatory disorders (AIDs) are a novel class of diseases elicited by mutations in genes regulating the homeostasis of innate immune complexes, named inflammasomes, which lead to uncontrolled oversecretion of the proinflammatory cytokine interleukin-1 $\beta$ . Protean inflammatory symptoms are variably associated with periodic fever, depicting multiple specific conditions. Childhood is usually the lifetime in which most hereditary AIDs start, though still a relevant number of patients may experience a delayed disease onset and receive a definite diagnosis during adulthood. As a major referral laboratory for patients with recurrent fevers, we have tested samples from 787 patients in the period

September 2007-March 2014, with a total of 1,328 AID-related genes evaluated and a gene/patient ratio of 1.69. In this report, we describe our experience in the clinical approach to AIDs, highlight the most striking differences between child and adult-onset AIDs, and shed an eye-opening insight into their diagnostic process.

Assembly of the NLRP3 inflammasome activates caspase-1 and mediates the processing and release of the leaderless cytokine IL-1 $\beta$  and thereby serves a central role in the inflammatory response and in diverse human diseases. Here we found that upon activation of caspase-1, oligomeric NLRP3 inflammasome particles were released from macrophages. Recombinant oligomeric protein particles composed of the adaptor ASC or the p.D303N mutant form of NLRP3 associated with cryopyrin-associated periodic syndromes (CAPS) stimulated further activation of caspase-1 extracellularly, as well as intracellularly after phagocytosis by surrounding macrophages. We found oligomeric ASC particles in the serum of patients with active CAPS but not in that of patients with other inherited autoinflammatory diseases. Our findings support a model whereby the NLRP3 inflammasome, acting as an extracellular oligomeric complex, amplifies the inflammatory response.

We report a 2-year-old girl with tumor necrosis factor receptor-associated periodic syndrome (TRAPS) who is the youngest proband diagnosed in Japan. Recurrent fever had started at her 6 months of age, and she had the familial

history of recurrent fever, suggesting underlying genetic disorder, in her father and grandfather. Careful clinical observation of characteristics of fever with disease course and the familial history of recurrent fever may lead to diagnosis of TRAPS in early infancy.

Familial Mediterranean Fever (FMF) is a hereditary autoinflammatory disorder caused by mutations in the MEFV gene. Carrier rates are known to be particularly high among Sephardic Jews, Turks, Armenians and Arab populations. Our literature survey regarding FMF and MEFV mutations in Georgia revealed a lack of existing studies. We applied multiplex PCR and reverse-hybridization teststrips (FMF StripAssay) to simultaneously analyze twelve common MEFV mutations in DNA samples from dried blood on filter cards, which had been obtained from 202 unselected newborns at various hospitals in Tbilisi, Georgia. We found 30 samples to be heterozygous and one to be compound heterozygous or carrier of a complex allele (two mutations in cis). The carrier rate of MEFV mutations (15.3%) was remarkable. The most frequently observed variants were E148Q (15x), M680I G/C (5x) and M694V (4x). Five other MEFV mutations were found at lower prevalence (V726A, A744S, R761H: 2x each; P369S, F479L: 1x each). Based on these new findings, the awareness for FMF and the availability of appropriate testing should be further promoted in Georgia.

We report the cases of two sisters born of parents who were first-degree cousins, who started recurrent fever with lymph node and digestive tract involvement at the age of 2 years. There was no mutation of the familial Mediterranean fever gene and a diagnosis of partial mevalonate kinase (MVK) deficiency was made. However, immunoglobulin (Ig) D and A levels were normal. Elevated mevalonic acid in the patients' urine during an episode and MVK gene analysis provided the diagnosis. Clinical remission was obtained under anti-TNF-alpha treatment with etanercept. These observations and those of several previously reported patients, particularly in French and Dutch series, illustrate the importance of considering the diagnosis in a child with early-onset auto-inflammatory syndrome even in the absence of hyper-IgD or -IgA.

Tumor necrosis factor receptor-associated periodic syndrome (TRAPS), formerly known as familial Hibernian fever, is the most common autosomal dominant autoinflammatory disease, resulting from mutations in the TNFRSF1A gene, encoding the 55-kD tumor necrosis factor receptor. The pathophysiologic mechanism of TRAPS remains ambiguous and only partially explained. The onset age of the syndrome is variable and the clinical scenery is characterized by recurrent episodes of high-grade fever that typically lasts 1-3 weeks, associated with migrating myalgia, pseudocellulitis, diffuse abdominal pain, appendicitis-like findings, ocular inflammatory signs, and risk of long-term amyloidosis. Fever episodes are responsive to high-dose corticosteroids, but different classes of drugs have been reported to be ineffective. The use of etanercept is unable to control systemic inflammation, while interleukin-1 blockade has been shown as effective in the control of disease activity in many patients reported so far.

**OBJECTIVE:** To compare clinical manifestations and activity of Behçet syndrome (BS) in the United States versus Turkey using validated outcome measures.

**METHODS:** Consecutive patients with BS from the US National Institutes of Health (NIH), New York University, and the University of Istanbul were evaluated.

Disease activity was measured using the Behçet's Syndrome Activity Scale (BSAS) and the Behçet's Disease Current Activity Form (BDCAF) with quality of life measured by the Behçet Disease Quality of Life (BDQOL) form. One-way ANOVA, t-tests, and multivariate regression analyses were performed.

**RESULTS:** Mean age did not differ between sites; however, more women were seen in the United States versus in Turkey ( $p < 0.001$ ), and disease duration was longer in the United States ( $p = 0.02$ ). Organ manifestations were similar for oral and genital ulcers, skin disease, arthralgia, eye disease, and thrombosis. However, more gastrointestinal ( $p < 0.001$ ) and neurologic disease ( $p = 0.003$ ) was seen in the United States. BSAS and BDCAF scores were worse in the United States compared to Turkey ( $p = 0.013$  and  $< 0.001$ , respectively). Worse mean BDQOL scores were observed at the NIH compared to Istanbul (not significant). Multivariable regression models showed worse scores in ethnically atypical patients for BSAS and BDCAF ( $p = 0.04$  and  $p = 0.001$ ), American patients for BDCAF ( $p = 0.01$ ), older age for BDCAF ( $p = 0.005$ ), and women for BDQOL ( $p = 0.01$ ).

**CONCLUSION:** Demographic and clinical manifestations of BS differ between sites with higher disease activity in the United States compared to Turkey. Referral patterns, age, sex, ethnicity, and country of origin may be important in these differences. These observations raise the question of whether pathogenic mechanisms differ in Turkish and American patients.

In the present study, 1000 patients with clinical suspicion of FMF were retrospectively reviewed to determine the spectrum of MEFV gene mutations by using DNA sequence analysis between September, 2008 and April, 2012. Sixteen different mutations and 55 different genotypes were detected in 618 of 1000 patients. Among 16 different mutations, R202Q (21.35%) was the most frequently observed mutation; followed by E148Q (8.85%), M694V (7.95%), M680I (2.40%), V726A (1.85%), M694I (0.95%), A744S (0.80%), R761H (0.55%), P283L (0.35%), K695R (0.20%), E230K (0.15%), L110P (0.10%), I247V (0.05%), G196W (0.05%) and G304R (0.05%). In the present study, a novel missense mutation (I247V) and a silent variant (G150G) were identified in the MEFV gene. On the other hand, P238L, G632A and G304R mutations are the first cases reported from Turkey. Our results indicated that MEFV mutations are highly heterogeneous in our study population as in other regions of Turkey and mutation screening techniques such as PCR-RFLP, amplification refractory mutation system or reverse hybridization do not adequately detect uncommon or novel mutations. Therefore, it was proven that sequence analysis of the MEFV gene could be useful for detection of rare or unknown mutations.

Familial Mediterranean fever (FMF) is the most common inherited autoinflammatory disease in the world. The long-term effects of subclinical inflammation in FMF are not well recognized. Some studies have suggested that FMF is associated with cardiac autonomic dysfunction in adult FMF patients. The objective of this study was to investigate the cardiac autonomic functions in pediatric FMF patients by using several autonomic tests. Thirty-five patients with FMF and 35 healthy controls were enrolled in this cross-sectional study. Demographic data, disease-specific data, and orthostatic symptoms were recorded. In all participants, 12-lead electrocardiography (ECG), 24 h ambulatory electrocardiographic monitoring, transthoracic echocardiography, treadmill exercise test, and head upright tilt-table (HUTT) test were performed. The heart rate recovery (HRR) indices of the two groups were similar. Also, chronotropic response was similar in both groups. The time-domain parameters of heart rate variability (HRV) were similar in both groups, except mean RR ( $p = 0.024$ ). Frequencies of ventricular and supraventricular ectopic stimuli were similar in both groups. There were no statistically significant differences between the groups in average QT and average corrected QT interval length, average QT interval dispersion, and average QT corrected dispersion. There was no significant difference between the two groups regarding the ratio of clinical dysautonomic reactions on HUTT. However, we observed a significantly higher rate of dysautonomic reactions on HUTT in patients with exertional leg pain than that

in patients without ( $p = 0.013$ ). When the fractal dimension of time curves were compared, FMF patients exhibited significantly lower diastolic blood pressure parameters than controls in response to HUTT. Cardiovascular autonomic dysfunction in children with FMF is not prominent. Particularly, patients with exertional leg pain are more prone to have dysautonomic features. Further studies are needed to elucidate the exact mechanisms leading to impaired cardiac autonomic functions in FMF.

Familial Mediterranean fever (FMF) is an autosomal recessive disease characterized by recurrent attacks of fever, peritonitis, pleuritis, arthritis, or erysipelas-like skin lesion. FMF is the most common periodic febrile syndrome affecting more than 150,000 people worldwide. The majority of patients develop FMF before the age of 20. FMF may cause amyloidosis, which mainly affects the kidneys but may also be accumulated in other organs such as the heart, gastrointestinal tract, and reproductive organs. FMF being a systemic disorder with a risk for amyloidosis, affecting patients in their childbearing years, and with its lifelong colchicine therapy raises concern about its effect on the reproductive system. In this article, we review the impact of FMF and its treatment to the reproductive system of male and female patients, pregnancy, and lactation.

Cytosolic inflammasome complexes mediated by a pattern recognition receptor (PRR) defend against pathogen infection by activating caspase 1. Pyrin, a candidate PRR, can bind to the inflammasome adaptor ASC to form a caspase 1-activating complex. Mutations in the Pyrin-encoding gene, MEFV, cause a human autoinflammatory disease known as familial Mediterranean fever. Despite important roles in immunity and disease, the physiological function of Pyrin remains unknown. Here we show that Pyrin mediates caspase 1 inflammasome activation in response to Rho-glucosylation activity of cytotoxin TcdB, a major virulence factor of *Clostridium difficile*, which causes most cases of nosocomial diarrhoea. The glucosyltransferase-inactive TcdB mutant loses the inflammasome-stimulating activity. Other Rho-inactivating toxins, including FIC-domain

adenylyltransferases (*Vibrio parahaemolyticus* VopS and *Histophilus somni* IbpA) and *Clostridium botulinum* ADP-ribosylating C3 toxin, can also biochemically activate the Pyrin inflammasome in their enzymatic activity-dependent manner. These toxins all target the Rho subfamily and modify a switch-I residue. We further demonstrate that *Burkholderia cenocepacia* inactivates RHOA by deamidating Asn 41, also in the switch-I region, and thereby triggers Pyrin inflammasome activation, both of which require the bacterial type VI secretion system (T6SS). Loss of the Pyrin inflammasome causes elevated intra-macrophage growth of *B. cenocepacia* and diminished lung inflammation in mice. Thus, Pyrin functions to sense pathogen modification and inactivation of Rho GTPases, representing a new paradigm in mammalian innate immunity.

Ocul Immunol Inflamm. 2015;23(6):467.

**PURPOSE:** The aim of the present study was to evaluate retinal and choroidal thicknesses in children with familial Mediterranean fever (FMF).

**METHODS:** Thirty patients with FMF and 28 healthy controls were included in the study. The thicknesses of the retina and choroid of each subject's right eye were measured at the fovea and horizontal nasal and temporal quadrants at 500-µm intervals to 1500 µm from the foveal center using spectral-domain optic coherence tomography.

**RESULTS:** Retinal and choroidal thicknesses at the fovea did not differ between groups ( $p = 0.32$  and  $p = 0.39$ , respectively). Horizontal nasal and temporal retinal and choroidal thickness measurements at 500-µm intervals to a distance of

1500 µm from the foveal center were also similar between the groups (all  $p > 0.05$ ).

CONCLUSIONS: The retinal and choroidal thicknesses of children with FMF do not differ from those of age- and sex-matched healthy controls.

**OBJECTIVES:** Secondary amyloidosis is the most important complication of FMF and endothelial function is more severely impaired. Elevated asymmetric dimethyl arginine (ADMA) may mediate the excess cardiovascular disease (CVD) risk of this group. We aimed to compare endothelial function characteristics, including ADMA, in patients with FMF-related amyloidosis and primary glomerulopathies and to define risk factors for a CVD event.

**METHODS:** We undertook a cross-sectional study with prospective follow-up

including consecutive patients with FMF-related amyloidosis (n = 98) or other non-diabetic glomerulopathies (n = 102). All patients had nephrotic-range proteinuria and normal glomerular filtration rate. Flow-mediated dilatation (FMD) was assessed and ADMA levels, CRP and pentraxin 3 (PTX3) were determined. Patients were followed for cardiovascular events.

**RESULTS:** Amyloidosis patients secondary to FMF showed higher levels of ADMA, CRP and PTX3 and lower FMD as compared with patients with other glomerulopathies. Cardiovascular events (n = 54) were registered during 3 years of follow-up. Increased ADMA levels and lower FMD were observed in patients with cardiovascular risk in both groups, but especially in individuals with amyloidosis.

**CONCLUSION:** Patients with FMF-related amyloidosis have increased CVD event risk, probably related to the high ADMA levels, elevated inflammatory markers and decreased FMD measures observed in these patients.

**OBJECTIVE:** To study efficacy and safety of escalating doses of canakinumab, a fully human anti-IL-1 $\beta$  monoclonal antibody in the severe cryopyrin-associated periodic syndrome, neonatal-onset multisystem inflammatory disease (NOMID).

**METHODS:** 6 patients were enrolled in this 24-month, open-label phase I/II study. All underwent anakinra withdrawal. The initial subcutaneous canakinumab dose was 150 mg (or 2 mg/kg in patients  $\leq 40$  kg) or 300 mg (or 4 mg/kg) with escalation up to 600 mg (or 8 mg/kg) every 4 weeks. Full remission was remission of patient-reported clinical components and measures of systemic inflammation and CNS inflammation. Hearing, vision and safety were assessed. Primary endpoint was full remission at month 6.

**RESULTS:** All patients flared after anakinra withdrawal, and symptoms and serum inflammatory markers improved with canakinumab. All patients required dose escalation to the maximum dose. At month 6, none had full remission, although 4/6 achieved inflammatory remission, based on disease activity diary scores and normal C-reactive proteins. None had CNS remission; 5/6 due to persistent CNS leucocytosis. At the last study visit, 5/6 patients achieved inflammatory remission and 4/6 had continued CNS leucocytosis. Visual acuity and field were stable in all patients, progressive hearing loss occurred in 1/10 ears. Adverse events (AEs) were rare. One serious AE (abscess due to a methicillin-resistant *Staphylococcus aureus* infection) occurred.

**CONCLUSIONS:** Canakinumab at the studied doses improves symptoms and serum inflammatory features of NOMID, although low-grade CNS leukocytosis in four patients and headaches in one additional patient persisted. Whether further dose intensifications are beneficial in these cases remains to be assessed.

Erratum in

Clin Exp Immunol. 2015 Jul;181(1):188.

Pyoderma gangrenosum (PG) and Sweet's syndrome (SS) are two inflammatory skin diseases presenting with painful ulcers and erythematous plaques, respectively; both disorders have a debilitating clinical behaviour and PG is potentially life-threatening. Recently, PG and SS have been included among the autoinflammatory diseases, which are characterized by recurrent episodes of sterile inflammation, without circulating autoantibodies and autoreactive T cells. However, an autoinflammatory pattern clearly supporting this inclusion has never been demonstrated. We studied 16 patients with PG, six with SS and six controls, evaluating, using a sandwich-based protein antibody array method, the expression profile of inflammatory effector molecules in PG, SS and normal skin. The expressions of interleukin (IL)-1 beta and its receptor I were significantly higher in PG ( $P = 0.0001$  for both) and SS ( $P = 0.004$ - $0.040$ ) than in controls. In PG, chemokines such as IL-8 ( $P = 0.0001$ ), chemokine (C-X-C motif) ligand (CXCL) 1/2/3 ( $P = 0.002$ ), CXCL 16 ( $P = 0.003$ ) and regulated upon activation normal T cell expressed and secreted (RANTES) ( $P = 0.005$ ) were over-expressed. In SS, IL-8 ( $P = 0.018$ ), CXCL 1/2/3 ( $P = 0.006$ ) and CXCL 16 ( $P = 0.036$ ) but not RANTES were over-expressed, suggesting that chemokine-mediated signals are lower than in PG. Fas/Fas ligand and CD40/CD40 ligand systems were over-expressed in PG ( $P = 0.0001$  for Fas,  $P = 0.009$  for Fas ligand,  $P = 0.012$  for CD40,  $P = 0.0001$  for CD40

ligand), contributing to tissue damage and inflammation, while their role seems to be less significant in SS. Over-expression of cytokines/chemokines and molecules amplifying the inflammatory network supports the view that PG and SS are autoinflammatory diseases. The differences in expression profile of inflammatory effectors between these two disorders may explain the stronger local aggressiveness in PG than SS.

Pyoderma gangrenosum: pathogenetic oriented treatment approaches.

Wollina U(1), Tchernev G.

Author information:

(1)Department of Dermatology and Allergology, Academic Teaching Hospital Dresden-Friedrichstadt, Friedrichstrasse 41, 01067, Dresden, Germany, wollina-uw@khdf.de.

Pyoderma gangrenosum (PG) shows features of autoimmune and autoinflammatory disorders. Genetic defects which affect the inflammasome, and in particular the NLRP3 zone, can cause an abnormal secretion of interleukin 1 (IL-1). IL-1 may be involved in clinical manifestation of certain (genetic) forms of PG. IL-1 receptor antagonists reduce the activity of IL-1 $\alpha$  and IL-1 $\beta$ . Mutations in the PSTPIP1 gene have been identified in patients with pyogenic arthritis, pyoderma gangrenosum and acne syndrome. In patients with a pyoderma gangrenosum, acne, and suppurative hidradenitis syndrome these mutations cannot be found and the effect of IL-1 inhibition is questionable. Another upcoming opportunity is targeted therapy by tumor necrosis factor- $\alpha$  inhibitors in steroid-resistant patients. This review has been focused on (1) the modern pathogenetic concepts, (2) the currently accepted criteria for differentiating the disease, (3) the target therapy and (4) valuable advice to the clinicians regarding a number of

medicaments capable of aggravating or inducing the PG.

IL36RN mutation causing generalized pustular psoriasis in a Palestinian patient.

Renert-Yuval Y(1), Horev L, Babay S, Tams S, Ramot Y, Zlotogorski A, Molho-Pessach V.

Author information:

(1)Department of Dermatology, Hadassah-Hebrew University Medical Center, Jerusalem, Israel.

Deficiency of interleukin-36 (IL-36) receptor antagonist (DITRA; OMIM 614204) is a rare autoinflammatory disorder characterized by periodic fever associated with a generalized erythematous and pustular skin rash. A 6-year-old Arab-Palestinian boy presented with a history of periodic fever and unremitting, erythematous, scaly skin rash accompanied by widespread pustules that had been present since the age of one month. The patient's skin lesions were compatible with generalized pustular psoriasis. Sequence analysis revealed a homozygous nonsense mutation, c.28C>T (p.Arg10X) in the IL36RN gene. The patient improved with oral methotrexate in combination with oral and topical corticosteroids. The molecular basis for DITRA has only recently been identified, and the mutation spectrum for this disorder in many populations is still obscure. This paper reports the presence of the c.28C>T mutation in an Arab-Palestinian patient and thus represents the first description of this mutation in a non-Japanese subject.

**OBJECTIVE:** Autoinflammatory disorders are caused by a primary dysfunction of the innate immune system. Among these disorders are hereditary recurrent fevers, which are characterized by recurrent episodes of fever and inflammatory manifestations affecting multiple tissues. Hereditary recurrent fevers often lack objective diagnostic criteria, thereby hampering the identification of disease-causing genes. This study was undertaken to identify a gene responsible for hereditary recurrent fevers.

**METHODS:** Copy number variations and point mutations were sought by array-comparative genomic hybridization and polymerase chain reaction sequencing, respectively. Serum cytokine levels were measured using Luminex technology. The effect of TNFRSF11A molecular defects on NF- $\kappa$ B signaling in cells expressing wild-type and mutated forms of the receptor was evaluated by luciferase assay.

**RESULTS:** A patient with multiple congenital anomalies and hereditary recurrent fever was found to carry a de novo heterozygous complex chromosomal rearrangement encompassing a duplication of TNFRSF11A, a gene known to regulate fever in rodents. We also identified a heterozygous frameshift mutation (p.Met416Cysfs\*110) in TNFRSF11A in a mother and daughter with isolated hereditary recurrent fever. This mutation was associated with increased secretion of several inflammatory cytokines (tumor necrosis factor  $\alpha$  [TNF $\alpha$ ], interleukin-18 [IL-18], IL-1 receptor antagonist, interferon- $\gamma$ ) and altered the biologic effects of the receptor on NF- $\kappa$ B signaling. The disease in the patients described herein exhibits striking clinical similarities to TNF receptor-associated periodic syndrome, another hereditary recurrent fever involving a gene of the same family (TNFRSF1A).

**CONCLUSION:** The involvement of TNFRSF11A in hereditary recurrent fever highlights the key role of this receptor in innate immunity. The present results also suggest that TNFRSF11A screening could serve as a new diagnostic test for autoinflammatory disorders.

Decreased interleukin 27 expression is associated with active uveitis in Behçet's disease.

Wang C, Tian Y, Ye Z, Kijlstra A, Zhou Y, Yang P.

**INSTRUCTION:** Interleukin 27 (IL-27) is an important regulator of the proinflammatory T-cell response. In this study, we investigated its role in the pathogenesis of Behçet's disease (BD).

**METHODS:** IL-27 mRNA in peripheral blood mononuclear cells (PBMCs) was examined by

performing RT-PCRs. Cytokine levels in sera or supernatants of PBMCs, naïve CD4(+) T cells, dendritic cells (DCs) and DC/T cells were determined by enzyme-linked immunosorbent assay. We used RNA interference in naïve CD4(+) T cells to study the role of interferon regulatory factor 8 (IRF8) in the inhibitory effect of IL-27 on Th17 cell differentiation. Flow cytometry was used to evaluate the frequency of IL-17- and interferon  $\gamma$ -producing T cells.

**RESULTS:** The expression of IL-27p28 mRNA by PBMCs and IL-27 in the sera and supernatants of cultured PBMCs were markedly decreased in patients with active BD. A higher frequency of IL-17-producing CD4(+) T (Th17) cells and increased IL-17 production under Th17 polarizing conditions were observed in patients with active BD. IL-27 significantly inhibited Th17 cell differentiation.

Downregulation of IRF8 by RNA interference abrogated the suppressive effect of IL-27 on Th17 differentiation. IL-27 inhibited the production of IL-1 $\beta$ , IL-6 and IL-23, but promoted IL-10 production, by DCs. IL-27-treated DCs inhibited both the Th1 and Th17 cell responses.

**CONCLUSIONS:** The results of the present study suggest that a decreased IL-27 expression is associated with disease activity in BD patients. Low IL-27 expression may result in a higher Th1 and Th17 cell response and thereby promote the autoinflammatory reaction observed in BD. Manipulation of IL-27 may offer a new treatment modality for this disease.

**OBJECTIVE:** Familial Mediterranean fever (FMF) is an autosomal recessive autoimmune disease, presenting with the attacks of fever and inflammation of serous membranes. One of the leading causes of death in autoimmune rheumatologic diseases is cardiovascular events. The purpose of this study is to evaluate the effects of FMF on the autonomic nerve and cardiovascular systems by measuring the indices of heart rate variability (HRV).

**MATERIAL AND METHODS:** Thirty FMF patients and the same number of healthy volunteers were enrolled to the study. Standard deviation of all R-R intervals (SDNN), the square root of the sum of the square of the differences between successive R-R intervals (RMSSD), standard deviation of 5-minute mean values of R-R interval (SDANN), low frequency (LF), and high frequency (HF) were measured.

**RESULTS:** Time domain indices (SDNN, SDANN, and RMSSD) were:  $124.67 \pm 40.79$ ,  $129.87 \pm 36.43$  ( $p=0.605$ );  $11.43 \pm 38.41$ ,  $11.23 \pm 38.98$  ( $p=0.984$ ); and  $33.43 \pm 17.39$ ,  $38.17 \pm 12.8$  ( $p=0.235$ ) for FMF patients and controls, respectively, and similar in both groups. Frequency domain indices (HF, LF, and LF/HF) were:  $290.41 \pm 290.25$ ,  $322.20 \pm 222.54$  ( $p=0.639$ );  $596.16 \pm 334.07$ ,  $805.80 \pm 471.00$  ( $p=0.051$ ); and  $3.57 \pm 2.57$ ,  $3.05 \pm 1.40$  ( $p=0.338$ ) for FMF patients and controls, respectively, and similar in both groups.

**CONCLUSION:** The HRV parameters were similar in both groups. However, studies including larger populations and using different methods are required to clarify if autonomic dysfunction exists in patients with FMF.

Dong, Chuncheon, Korea 200-702. swsuh@hallym.ac.kr.

Colchicine has been discovered to inhibit many inflammatory processes such as gout, familial Mediterranean fever, pericarditis and Behcet disease. Other than these beneficial anti-inflammatory effects, colchicine blocks microtubule-assisted axonal transport, which results in the selective loss of dentate granule cells of the hippocampus. The mechanism of the colchicine-induced dentate granule cell death and depletion of mossy fiber terminals still remains unclear. In the present study, we hypothesized that colchicine-induced dentate granule cell death may be caused by accumulation of labile intracellular zinc. 10  $\mu\text{g kg}^{-1}$  of colchicine was injected into the adult rat hippocampus and then brain sections were evaluated at 1 day or 1 week later. Neuronal cell death was evaluated by H&E staining or Fluoro-Jade B. Zinc accumulation and vesicular zinc were detected by N-(6-methoxy-8-quinolyl)-para-toluene sulfonamide (TSQ) staining. To test whether an extracellular zinc chelator can prevent this process, CaEDTA was injected into the hippocampus over a 5 min period with colchicine. To test whether other microtubule toxins also produce similar effects as colchicine, vincristine was injected into the hippocampus. The present study found that colchicine injection induced intracellular zinc accumulation in the dentate granule cells and depleted vesicular zinc from mossy fiber terminals. Injection of a zinc chelator, CaEDTA, did not block the zinc accumulation and neuronal death. Vincristine also produced intracellular zinc accumulation and neuronal death. These results suggest that colchicine-induced dentate granule cell death is caused by blocking axonal zinc flow and accumulation of intracellular labile zinc.

First report of keratitis in familial cold autoinflammatory syndrome.

Espandar L(1), Boehlke CS(2), Kelly MP(2).

Author information:

(1)Duke University Eye Center, Durham, N.C.. Electronic address: ladan.espandar@duke.edu.

(2)Duke University Eye Center, Durham, N.C.

**OBJECTIVE:** To report corneal manifestations of familial cold autoinflammatory syndrome (FCAS) for the first time.

**DESIGN:** small case series

**PARTICIPANTS:** Medical records of three members of a single family were reviewed after obtaining institutional review board (IRB) approval and informed consent.

**METHODS:** All three members presented with a long history of maculopapular rash after cold exposure starting in childhood associated with nausea, low-grade fever, fatigue and arthralgia that lasted less than 24 hours. Their ocular manifestations consisted of ocular pain, photophobia and keratitis with subsequent stromal haziness.

**RESULTS:** Patients underwent systemic therapy with canakinumab (Ilaris). They responded very well to repeated injections of Ilaris without side effects.

**CONCLUSIONS:** FCAS causes lifelong debilitating effects that restrict patients' daily activities. Ilaris is an FDA-approved treatment for this condition and that typically results in dramatic improvement in clinical and laboratory measures of inflammation, and is well tolerated. Our report is the first small case series of FCAS with keratitis that responded to Ilaris beautifully.

(1)Department of Paediatrics, Level 12, NUHS Tower Block, 1E Kent Ridge Road, Singapore 119228. [pei\\_ling\\_ooi@nuhs.edu.sg](mailto:pei_ling_ooi@nuhs.edu.sg).

Paediatric rheumatology is an exciting field exploding with new knowledge of autoimmune and autoinflammatory conditions and how to treat them. It is, however,

a relatively new subspecialisation in Asia. There is thus a great need to educate the public and medical community about paediatric rheumatic diseases so that children with such conditions are given the highest possibility of achieving normal function in their daily lives.

MEFV mutations in Egyptian children with systemic-onset juvenile idiopathic arthritis.

Lotfy HM(1), Kandil ME, Issac MS, Salah S, Ismail NA, Abdel Mawla MA.

Author information:

(1)Department of Pediatrics, Faculty of Medicine, Cairo University, Cairo, Egypt.

**BACKGROUND AND OBJECTIVES:** Systemic-onset juvenile idiopathic arthritis (SoJIA) is a chronic auto-inflammatory disease of childhood, with a complex genetic trait, which is characterized by arthritis associated with systemic manifestations. Familial Mediterranean fever (FMF) is another auto-inflammatory disorder that is monogenic. There are speculations as to whether Mediterranean fever (MEFV) mutations are among the genetic determinants of SoJIA. Our aim was to explore the frequency and clinical significance of MEFV mutations in Egyptian SoJIA patients. A group of healthy children were assigned to the control group in an attempt to estimate the carrier rate of MEFV mutations in Egypt.

**METHODS:** Eighty-four children were recruited in this study; 54 children, age (mean  $\pm$  standard deviation;  $8.31 \pm 2.85$  years), diagnosed as having SoJIA with no typical symptoms of FMF; 30 healthy age- and gender-matched children served as the control group. All recruited children were screened for 12 common MEFV mutations using a reverse hybridization assay of biotinylated PCR products.

**RESULTS:** SoJIA patients had a significantly higher frequency of MEFV mutations (66.7 %) than in the healthy control population (16.7 %). V726A was the leading mutation in SoJIA patients, with an allelic frequency of 15.74 %, followed by E148Q, with an allelic frequency of 7.4 %. Children who were carriers of MEFV mutations had an 18 times higher risk of developing SoJIA than wild-type carriers

[odds ratio 18.0 (95 % CI 5-69),  $P < 0.01$ ]. E148Q was the leading mutation, present in 13.3 % of healthy controls.

CONCLUSION: These findings suggest that MEFV mutations may be responsible for auto-inflammatory diseases other than FMF, and patients with SoJIA, especially those with a positive family history of FMF or SoJIA, should be screened for MEFV mutations in countries where FMF is frequent.

**AIM:** The aim of this study is to analyze possible autonomic nerve system alterations and assess the efficacy of heart rate variability (HRV) analysis in anticipation of cardiovascular risks in pediatric patients with familial Mediterranean fever (FMF).

**METHOD:** In this study, cardiac autonomic functions were investigated in children with FMF by analyzing HRV and its other probable cardiac effects by echocardiography. We studied 70 pediatric patients with FMF and 50 healthy controls.

**RESULTS:** The time-domain parameters of HRV were compared between the FMF and control groups. SDNN (standard deviation of all NN intervals) was significantly decreased in patients with FMF as compared to control subjects. The other time-domain parameters of HRV and the frequency-domain parameters of HRV were similar in both groups. Frequency-dependent HRV parameters were similar in both groups, as were conventional echocardiographic parameters.

**CONCLUSION:** HRV is a convenient and reliable technique for evaluation of autonomic functions. There are only a few studies on the assessment of autonomic functions by means of HRV in adult FMF patients but not in pediatric patients. Further studies are required to assess whether there is autonomic dysfunction in children with FMF.

Autoimmune and autoinflammatory mechanisms in uveitis.

Lee RW(1), Nicholson LB, Sen HN, Chan CC, Wei L, Nussenblatt RB, Dick AD.

Author information:

(1)National Institute for Health Research Biomedical Research Centre at Moorfields Eye Hospital NHS Foundation Trust and UCL Institute of Ophthalmology, University Hospitals Bristol NHS, Foundation Trust, and University of Bristol, Bristol, UK.

The eye, as currently viewed, is neither immunologically ignorant nor sequestered from the systemic environment. The eye utilises distinct immunoregulatory mechanisms to preserve tissue and cellular function in the face of immune-mediated insult; clinically, inflammation following such an insult is termed uveitis. The intra-ocular inflammation in uveitis may be clinically obvious as a result of infection (e.g. toxoplasma, herpes), but in the main infection, if any, remains covert. We now recognise that healthy tissues including the retina have regulatory mechanisms imparted by control of myeloid cells through receptors (e.g. CD200R) and soluble inhibitory factors (e.g. alpha-MSH), regulation of the blood retinal barrier, and active immune surveillance. Once homeostasis has been disrupted and inflammation ensues, the mechanisms to regulate inflammation, including T cell apoptosis, generation of Treg cells, and myeloid cell suppression in situ, are less successful. Why inflammation becomes persistent remains unknown, but extrapolating from animal models, possibilities include differential trafficking of T cells from the retina, residency of CD8(+) T cells, and alterations of myeloid cell phenotype and function. Translating lessons learned from animal models to humans has been helped by system biology approaches and informatics, which suggest that diseased animals and people share similar changes in T cell phenotypes and monocyte function to date. Together the data infer a possible cryptic infectious drive in uveitis that unlocks and drives persistent autoimmune responses, or promotes further innate immune responses. Thus there may be many mechanisms in common with those observed in autoinflammatory disorders.

Recent studies have offered a glimpse into the sophisticated mechanisms by which inflammasomes respond to danger and promote secretion of interleukin (IL)-1 $\beta$  and IL-18. Activation of caspases 1 and 11 in canonical and noncanonical inflammasomes, respectively, also protects against infection by triggering pyroptosis, a proinflammatory and lytic mode of cell death. The therapeutic potential of inhibiting these proinflammatory caspases in infectious and autoimmune diseases is raised by the successful deployment of anti-IL-1 therapies to control autoinflammatory diseases associated with aberrant inflammasome signaling. This Review summarizes recent insights into inflammasome biology and discusses the questions that remain in the field.

The intestinal epithelium is equipped with sensing receptor mechanisms that interact with luminal microorganisms and nutrients to regulate barrier function and gut immune responses, thereby maintaining intestinal homeostasis. Herein, we clarify the role of the extracellular calcium-sensing receptor (CaSR) using intestinal epithelium-specific *Casr*(-/-) mice. Epithelial CaSR deficiency diminished intestinal barrier function, altered microbiota composition, and skewed immune responses towards proinflammatory. Consequently, *Casr*(-/-) mice were significantly more prone to chemically induced intestinal inflammation resulting in colitis. Accordingly, CaSR represents a potential therapeutic target for autoinflammatory disorders, including inflammatory bowel diseases.

Familial Mediterranean fever (FMF) is an autosomal recessive disorder and is the most frequent of the periodic febrile inflammatory syndromes. The pathogenesis of the disease is not completely understood, even though the FMF gene has been identified. Oxidative stress and inflammation may play a role in the pathogenesis of FMF. We investigated gene polymorphisms of the antioxidative enzymes, glutathione peroxidase (GPX) and paraoxonase (PON) in FMF patients, and possible associations with FMF pathogenesis. Sixty FMF patients during an attack-free period and 51 healthy children as the control group were included in our study. PON1 Q/R192 and GPX1 Pro197Leu gene polymorphisms were assayed. Blood urea nitrogen, creatinine and serum lipid profile were also measured. PON1 Q/R192 genotype distribution was 52% QQ, 46% QR and 2% RR in the FMF group and 45% QQ, 45% QR and 10% RR in the control group ( $P>0.05$ ). GPX1 Pro197Leu genotype distribution was 28% PP, 57% PL, 15% LL in the FMF group and 18% PP, 53% PL, 29% LL in the control group ( $P>0.05$ ). Blood urea nitrogen, serum creatinine, lipid levels, and the distribution of PON1 Q/R192 and GPX1 Pro197Leu genotypes were similar in the two groups. We conclude that the PON1 Q/R192 and GPX1 Pro197Leu gene polymorphisms are not important risk factors in the development of FMF. However, larger studies are warranted to validate these conclusions.

Author information:

(1)Department of Immunology, St. Jude Children's Research Hospital, MS #351, 262 Danny Thomas Place, Suite E7004, Memphis, TN, 38105-2794, USA.

In recent years, non-communicable chronic diseases that are potentiated by sterile inflammation have replaced infectious diseases as the major threat to human health. Sterile inflammation that results from aberrant tissue damage plays pivotal roles in the pathogenesis of numerous acute and chronic inflammatory diseases including atherosclerosis, type 2 diabetes, cancer, obesity, and multiple neurodegenerative diseases. The cellular events and molecular signaling pathways that govern sterile inflammation currently remain poorly defined; however, emerging data suggest central roles for IL-1 in driving autoimmune and inflammatory disease pathogenesis. Improved characterization of the immunological pathways that contribute to sterile inflammation are desperately needed to develop effective therapeutics to treat these devastating diseases. In this review, we discuss recent advances in our understanding of how IL-1 is regulated in response to tissue damage. In particular, we highlight recent studies that

describe novel roles for conventional cell death molecules in the regulation of IL-1 $\beta$  production.

Overlap syndrome between Familial Mediterranean fever and tumor necrosis factor receptor-associated periodic syndrome in a lupus patient.

Nonaka F(1), Migita K, Iwasaki K, Shimizu T, Kawakami A, Yasunami M, Eguchi K.

Author information:

(1)Department of Rheumatology, Sasebo City General Hospital.

Autoinflammatory diseases represent an expanding spectrum of genetic and non-genetic inflammatory diseases characterized by recurrent episodes of fever and systemic inflammation, affecting joints, skin and serosal surfaces. Familial Mediterranean fever (FMF) is the most common autosomal recessive hereditary autoinflammatory disease. Tumor necrosis factor receptor-associated periodic syndrome (TRAPS) is an autosomal dominant hereditary autoinflammatory disease. They share some clinical manifestations such as a periodic fever and skin rash. We present here the association of FMF with TRAPS in a systemic lupus erythematosus (SLE) patient. A 54-year-old SLE patient with recurrent attacks of fever, arthritis, and skin rashes was referred to our hospital. She had been diagnosed with lupus nephritis at 19 years old. Her lupus nephritis was controlled by steroid treatments; however, since childhood she has suffered from recurrent episodes of periodic fever, abdominal pain, arthritis, and erythematous skin rashes. An initial diagnosis of FMF was suspected based on the genetic analysis, showing the compound heterozygous L110P/E148Q mutations in the MEFV gene that is responsible for FMF. Her symptoms responded to colchicine, but the febrile attacks were not completely resolved. Therefore, genetic testing for TRAPS was performed. The results revealed a heterozygous T61I mutation in the TNFRSF1A gene that encodes tumor necrosis factor- $\alpha$  receptor and is responsible for TRAPS. The patient was diagnosed with overlapping FMF and TRAPS, in addition to SLE. This is the first report of SLE associated with both FMF and TRAPS.

Enhancing crossover trial design for rare diseases: limiting ineffective exposure and increasing study power by enabling patient choice to escape early.

Huang B(1), Giannini EH(2), Lovell DJ(2), Ding L(2), Liu Y(2), Hashkes PJ(3).

Author information:

(1)Cincinnati Children's Hospital Medical Center, Cincinnati, OH 45229, USA.

Electronic address: bin.huang@cchmc.org.

(2)Cincinnati Children's Hospital Medical Center, Cincinnati, OH 45229, USA.

(3)Shaare Zedek Medical Center, POB 3235, Jerusalem 91031, Israel.

**BACKGROUND:** Addressing the two most important considerations in designing clinical trials, i.e. maximizing study power and minimizing patient exposure to ineffective treatment, is particularly challenging for trials of rare diseases. The familial Mediterranean fever (FMF) rilonacept trial (Hashkes et al., Ann Intern Med 2012;157:533-41) demonstrates a novel crossover design by enabling patient choice to early escape for rare disease.

**PURPOSE:** To investigate the effect on study power, exposure to the ineffective treatment arm and dropout rate by implementing early escape to crossover design, and to propose a Bayesian modeling approach.

**METHOD:** Based on the FMF trial data, simulation studies compared study power and dropout rate among three types of designs for crossover trial: traditional without early escape, early escape per-patient-choice, and early escape per-protocol.

**RESULTS:** The early escape per patient choice or per protocol design achieved  $0.89 \pm 0.12$  and  $0.78 \pm 0.20$  of the study efficiency when compared to the traditional crossover design assuming no dropout. Early escape per patient choice compared to early escape per protocol improved power by  $1.29 \pm 0.26$ , and reduced the dropout rate by 8-29%, but with greater patient exposure to the less effective treatment arm.

**CONCLUSIONS:** The results of the FMF trial and simulation studies suggest that

allowing early escape in crossover trial enhanced the design by minimizing patient's exposure to the ineffective treatment arm while maintaining a reasonable study power, which is particularly important for rare disease trials. Choice between the two types of early escape presents tradeoff between study power and exposure to ineffective treatment.

Development of thyroglobulin antibodies after GVAX immunotherapy is associated with prolonged survival.

De Remigis A(1), de Gruijl TD, Uram JN, Tzou SC, Iwama S, Talor MV, Armstrong TD, Santeagoets SJ, Slovin SF, Zheng L, Laheru DA, Jaffee EM, Gerritsen WR, van den Eertwegh AJ, Le DT, Caturegli P.

Author information:

(1)Department of Pathology, Johns Hopkins University, Baltimore, MD.

Cancer immunotherapy induces a variety of autoinflammatory responses, including those against the thyroid gland, which can be exploited to predict clinical outcomes. Considering the paucity of information about thyroid autoimmunity in patients receiving cancer vaccines, we designed our study to assess the development of thyroglobulin antibodies (TgAbs) in patients treated with GVAX (vaccine made of a tumor cell type transfected with GM-CSF) and/or ipilimumab and correlated seroconversion with survival. Using both in house and commercial ELISA assays, we measured TgAbs in patients with pancreatic (No. = 53), prostate (No. = 35) or colon (No. = 8) cancer, before and after treatment with GVAX only (No. = 34), GVAX plus ipilimumab (No. = 42) or ipilimumab (No. = 20), and correlated their levels with patient's survival, disease status and T-cell surface markers. Antibodies to thyroperoxidase, myeloperoxidase, proteinase 3, insulin and actin were also measured. TgAbs specifically developed after GVAX, independent of the underlying cancer (81% in prostate, 75% colon cancer and 76% pancreatic cancer) and co-administration of ipilimumab (75% in GVAX only and 78%

in GVAX plus ipilimumab). This TgAbs seroconversion could be detected mainly by the in house assay, suggesting that the thyroglobulin epitopes recognized by the antibodies induced by GVAX are different from the epitopes seen in the classic form of Hashimoto thyroiditis. Notably, TgAbs seroconversion was associated with significantly prolonged survival ( $p = 0.01$  for pancreas and  $p = 0.005$  for prostate cancer). In conclusion, GVAX immunotherapy induces the appearance of TgAbs that recognize a unique antigenic repertoire and associate with prolonged survival.

Service of Immunology and Rheumatology, Hospital de Pediatría Garrahan, Buenos Aires, Argentina, University College London Institute of Child Health and Department of Paediatric Rheumatology, Great Ormond Street Hospital NHS Foundation Trust, London, UK.

During the past 15 years, a growing number of monogenic inflammatory diseases have been described and their respective responsible genes identified. The proteins encoded by these genes are involved in the regulatory pathways of

inflammation and are mostly expressed in cells of the innate immune system. Diagnosis remains clinical, with genetic confirmation where feasible. Although a group of patients exhibit episodic systemic inflammation (periodic fevers), these disorders are mediated by continuous overproduction and release of pro-inflammatory mediators, such as IL-1 and IL-6, and TNF and are best considered as autoinflammatory diseases rather than periodic fevers. Treatment with biologic agents that block these cytokines, particularly IL-1, has proved to be dramatically effective in some patients. Still, in many cases of autoinflammation no genetic abnormalities are detected and treatment remains suboptimal, raising the question of novel pathogenic mutations in unexplored genes and pathways.

**OBJECTIVE:** Chronic inflammation plays a key role in the development of atherosclerosis. Early progression of atherosclerosis has been reported in patients with RA. Cryopyrin-associated periodic syndromes (CAPS) are autosomal dominant autoinflammatory disorders caused by heterozygous NLRP3 gene mutations. Chronic infantile neurological cutaneous and articular (CINCA) syndrome is the most severe form of CAPS and patients display early onset of rash, fever, uveitis and joint manifestations. However, there has been no previous report on atherosclerosis in patients with CAPS. The objective of this study is to assess the development of atherosclerosis in patients with CINCA syndrome.

**METHODS:** Intima-media thickness (IMT) of the carotid arteries, stiffness parameter  $\beta$ , ankle brachial index (ABI) and pressure wave velocity (PWV) were evaluated by ultrasonography in 3 patients with CINCA syndrome [mean age 9.0 years (S.D. 5.3)] and 19 age-matched healthy controls [9.3 years (S.D. 4.3)].

**RESULTS:** The levels of carotid IMT, stiffness parameter  $\beta$  and PWV in CINCA syndrome patients were significantly higher than those in healthy controls [0.51 mm (S.D. 0.05) vs 0.44 (0.04),  $P = 0.0021$ ; 6.1 (S.D. 1.7) vs 3.9 (1.0),  $P = 0.0018$ ; 1203 cm/s (S.D. 328) vs 855 (114),  $P = 0.017$ , respectively].

**CONCLUSION:** Patients with CINCA syndrome showed signs of atherosclerosis from their early childhood. The results of this study emphasize the importance of chronic inflammation in the development of atherosclerosis. Further analysis on atherosclerosis in young patients with CINCA syndrome may provide more insights into the pathogenesis of cardiovascular disease.

Most of the autoinflammatory diseases (AID) are orphan diseases with recurrent episodes of systemic inflammation. Fever and exanthema are leading features. Given the ongoing elucidation of pathogenic causes and hence therapeutic approaches, we provided a review of the current literature of AID.

**BACKGROUND:** All aspects of aetiopathogenesis of recurrent aphthous stomatitis (RAS) have not been elucidated. RAS and Behçet's disease (BD) have clinical and immunological characteristics in common. Although T17 cytokines and alpha-enolase have been shown to play effective roles in BD and many other autoinflammatory diseases recently, their roles in RAS have not been studied extensively. In the present study, we investigated levels of several Th1, Th2 and Th17 pathways related cytokines and alpha-enolase to elucidate pathogenesis of RAS and to obtain data about possible treatment alternatives for the condition.

**METHODS:** Serum interleukin-1, interleukin-13, interleukin-17, interleukin-18, interferon gamma and alpha-enolase levels in 24 patients with RAS, 30 patients with BD and 20 healthy controls were measured.

**RESULTS:** Serum interleukin-1, interleukin-13, interleukin-17, interleukin-18, interferon gamma and alpha-enolase levels were higher in patients with RAS and patients with BD than in healthy controls ( $P < 0.005$ ).

**CONCLUSION:** Like Th1 and Th2 cells, Th17 cells were found to be effective in pathogenesis of RAS. In addition, alpha-enolase, the levels of which were high, may play an important role in etio-pathogenesis of RAS. Further studies to be designed in the light of these findings are required to shed light on pathogenesis and treatment of the condition.

Familial mediterranean Fever: diagnosing as early as 3 months of age.

Keskindemirci G(1), Aktay Ayaz N(1), Aldemir E(1), Aydoğmuş C(1), Aydoğan G(1), Kavuncuoğlu S(1).

Author information:

Familial Mediterranean Fever is an autosomal recessive disease. Major symptoms of disease are recurrent fever accompanied by serositis attacks. The disease is usually diagnosed before 20 years of age. Symptoms related to FMF are noted when children become more verbal, usually after 2 years of age. In this case report, the youngest patient with the diagnosis of FMF is presented. She was consulted to pediatric rheumatology for the high acute phase response and fever. It was learned that her mother had recurrent swelling of her ankle joints. Mutation analysis was performed and two homozygous mutations (M694V and R202Q) were identified. She was diagnosed as FMF at 3 months of age and colchicine was started. She responded to colchicine. Her uncontrolled acute phase response declined gradually. This case was reported to point out the importance of early remembrance of autoinflammatory diseases even at very early ages especially at endemic countries.

Familial Mediterranean fever: genotype-phenotype correlations in Japanese patients.

Migita K, Agematsu K, Yazaki M, Nonaka F, Nakamura A, Toma T, Kishida D, Uehara R, Nakamura Y, Jiuchi Y, Masumoto J, Furukawa H, Ida H, Terai C, Nakashima Y, Kawakami A, Nakamura T, Eguchi K, Yasunami M, Yachie A.

Familial Mediterranean fever (FMF) is an autoinflammatory disease caused by MEditerranean FeVer gene (MEFV) mutations. In Japan, patients with FMF have been previously reported, including a mild or incomplete form. Several factors are presumed to contribute to the variable penetrance and to the phenotypic variability of FMF. We conducted the current study to investigate the correlation of variable clinical presentations and MEFV genotypic distributions in Japanese FMF patients. We analyzed demographic, clinical, and genetic data for 311 FMF patients enrolled in the study. Clinically, we classified FMF into 2 phenotypes: 1) the "typical" form of FMF, and 2) the "atypical" form of FMF according to the Tel Hashomer criteria. Patients with the typical FMF phenotype had a higher frequency of febrile episodes, a shorter duration of febrile attacks, more frequent thoracic pain, abdominal pain, a family history of FMF, and MEFV exon 10 mutations. Conversely, patients with the atypical FMF phenotype had a lower frequency of fever episodes and more frequent arthritis in atypical distribution, myalgia, and MEFV exon 3 mutations. Multivariate analysis showed that the variable associated with typical FMF presentation was the presence of MEFV exon 10 mutations. Typical FMF phenotype frequencies were decreased in patients carrying 2 or a single low-penetrance mutations compared with those carrying 2 or a single high-penetrance mutations (M694I), with an opposite trend for the atypical FMF phenotype. In addition, patients having more than 2 MEFV mutations had a younger disease onset and a higher prevalence of thoracic pain than those carrying a single or no mutations. Thus, MEFV exon 10 mutations are associated with the more typical FMF phenotype. In contrast, more than half of the Japanese FMF patients without MEFV exon 10 mutations presented with an atypical FMF phenotype, indicating that Japanese FMF patients tend to be divided into 2 phenotypes by a variation of MEFV mutations.

Hemophagocytic lymphohistiocytosis (HLH) is a life-threatening hyperinflammatory syndrome and not an independent disease. HLH represents the extreme end of a severe uncontrolled hyperinflammatory reaction that can occur in many underlying conditions. Genetic forms of HLHs are due to defects in transport, processing and function of cytotoxic granules in natural killer cells and cytotoxic T lymphocytes, and are not restricted to manifestation in childhood. Acquired forms of HLH are encountered in infections, autoinflammatory and autoimmune diseases, malignancies, acquired immune deficiency. Functional tests allow for differentiation between genetic and acquired HLH. Treatment aims at suppressing hypercytokinemia and eliminating activated and infected cells. It includes immunomodulatory and immunosuppressive agents, cytostatics, T-cell and cytokine antibodies. In genetic HLH cure can only be achieved with hematopoietic stem cell transplantation. Reduced-intensity conditioning regimens have considerably improved survival.

Adaptor protein complex 1 (AP-1) is an evolutionary conserved heterotetramer that promotes vesicular trafficking between the trans-Golgi network and the endosomes. The knockout of most murine AP-1 complex subunits is embryonically lethal, so the identification of human disease-associated alleles has the unique potential to deliver insights into gene function. Here, we report two founder mutations (c.11T>G [p.Phe4Cys] and c.97C>T [p.Arg33Trp]) in AP1S3, the gene encoding AP-1 complex subunit  $\sigma$ 1C, in 15 unrelated individuals with a severe autoinflammatory skin disorder known as pustular psoriasis. Because the variants are predicted to destabilize the 3D structure of the AP-1 complex, we generated AP1S3-knockdown

cell lines to investigate the consequences of AP-1 deficiency in skin keratinocytes. We found that AP1S3 silencing disrupted the endosomal translocation of the innate pattern-recognition receptor TLR-3 (Toll-like receptor 3) and resulted in a marked inhibition of downstream signaling. These findings identify pustular psoriasis as an autoinflammatory phenotype caused by defects in vesicular trafficking and demonstrate a requirement of AP-1 for Toll-like receptor homeostasis.

1. Familial Mediterranean fever (FMF) is considered an autosomal recessive disorder, associated with a single gene named Mediterranean fever (MEFV). The aim of this study was to perform genotyping and haplotyping analysis of the multidrug resistance (ATP-binding cassette, subfamily B, member 1 - ABCB1) gene in FMF patients. 2. Three ABCB1 gene polymorphisms (C1236T, G2677T/A and C3435T) were analyzed in 309 FMF patients and 250 healthy control subjects. All subjects were genotyped by PCR-restriction fragment length polymorphism analysis, and statistical analysis was performed using the Arlequin 3.1.1 and SPSS 16.0 software packages. 3. The CT genotype frequency of the C3435T polymorphism ( $p = 0.003$ ), the CT-GT-CT (C1236T-G2677T/A-C3435T) triple genotype ( $p = 0.001$ ) and the

C-G (C1236T-G2677T/A) haplotype ( $p = 0.030$ ) were more common in the FMF patients. The CT-GG-CC triple genotype and T-G-C, C-T-T and T-G-T haplotypes (C1236T-G2677T/A-C3435T) were higher in the control subjects ( $p = 0.011$ ,  $0.001$ ,  $0.009$  and  $0.000$ , respectively). The CT-GG binary genotype and C-T and T-G haplotypes for C1236T-G2677T/A polymorphisms may have a high degree of protective effect against FMF ( $p = 0.0005$ ,  $0.002$  and  $0.000$ , respectively). 4. Our study showed that genotypes and haplotypes of ABCB1 gene polymorphisms may affect patients' FMF susceptibility.

Rag2-deficient IL-1 Receptor Antagonist-deficient Mice Are a Novel Colitis Model in Which Innate Lymphoid Cell-derived IL-17 Is Involved in the Pathogenesis.

Akitsu A(1), Kakuta S, Saijo S, Iwakura Y.

Author information:

(1)Center for Experimental Medicine and Systems Biology, The Institute of Medical Science, The University of Tokyo, 4-6-1, Shirokanedai, Minato-ku, Tokyo 108-8639, Japan.

Il1rn(-/-) mice spontaneously develop arthritis and aortitis by an autoimmune mechanism and also develop dermatitis by an autoinflammatory mechanism. Here, we show that Rag2(-/-)Il1rn(-/-) mice develop spontaneous colitis with high mortality, making a contrast to the suppression of arthritis in these mice. Enhanced IL-17A expression in group 3 innate lymphoid cells (ILC3s) was observed in the colon of Rag2(-/-)Il1rn(-/-) mice. IL-17A-deficiency prolonged the survival of Rag2(-/-)Il1rn(-/-) mice, suggesting a pathogenic role of this cytokine in the development of intestinal inflammation. Although IL-17A-producing T cells were increased in Il1rn(-/-) mice, these mice did not develop colitis, because CD4(+)Foxp3(+) regulatory T cell population was also expanded. Thus, excess IL-1 signaling and IL-1-induced IL-17A from ILC3s cause colitis in Rag2(-/-)Il1rn(-/-) mice in which Treg cells are absent. These observations suggest that the balance between IL-17A-producing cells and Treg cells is important to keep the immune homeostasis of the colon.

Neutrophilic dermatoses (ND) are inflammatory skin conditions characterized by a sterile infiltrate of normal polymorphonuclear leukocytes. The main clinical forms of ND include Sweet syndrome, pyoderma gangrenosum, erythema elevatum diutinum, subcorneal pustular dermatosis, and their atypical or transitional forms. ND are often idiopathic, but they may be associated with myeloid hematologic malignancies (Sweet syndrome), inflammatory bowel disease or rheumatoid arthritis (pyoderma gangrenosum), and monoclonal gammopathies (erythema elevatum diutinum, subcorneal pustular dermatosis). The possible infiltration of internal organs with neutrophils during the setting of ND underlies the concept of a neutrophilic systemic disease. ND may be seen as a polygenic autoinflammatory syndrome due to their frequent association with other autoinflammatory disorders (monogenic or polygenic) and the recent published efficacy of interleukin-1 blocking therapies in their management.

1600 7th Avenue South, CPP 210, Birmingham, AL, 35233-1711 USA.

Systemic juvenile idiopathic arthritis (JIA) is an autoinflammatory condition that is distinct from other forms of childhood arthritis. Recently, biologic agents that specifically inhibit the cytokines interleukin (IL)-1 and IL-6 have demonstrated remarkable clinical effectiveness and confirmed the importance of these cytokines in the disease process. Future studies are likely to optimize the care of children with systemic arthritis and further elucidate the disease pathogenesis.

Turkey. [fatos.yalcinkaya@medicine.ankara.edu.tr](mailto:fatos.yalcinkaya@medicine.ankara.edu.tr).

**OBJECTIVES:** The aims of this study were to explore whether the demographic and clinical features of paediatric familial Mediterranean fever (FMF) patients with different colchicine response vary or not and to determine whether colchicine response can be predicted in FMF patients.

**METHODS:** Files of patients who have been on colchicine therapy for at least 6 months were retrospectively evaluated. Patients were divided into two groups: group I included patients with no attacks after colchicine and group II comprised patients with ongoing attacks. Thereafter group II was further divided into two groups according to the reduction rate of attack frequency: group IIA (>50%) and group IIB ( $\leq$ 50%).

**RESULTS:** The study group comprised 221 FMF patients (116 females, 105 males). There were 131 patients in group I and 90 patients in group II (54 in group IIA and 36 in group IIB). Leg pain and M694V homozygosity were more frequent in group II ( $P < 0.05$ ). Final colchicine doses, disease severity scores and number of patients with elevated acute phase reactant levels (attack-free period) were significantly higher and colchicine compliance was lower in group II when compared with group I ( $P < 0.05$ ). Erysipelas-like erythema (ELE), leg pain and protracted arthritis/protracted febrile myalgia/vasculitis were more frequently detected in group IIB ( $P < 0.05$ ).

**CONCLUSION:** Colchicine response is excellent in the majority of FMF patients, however, colchicine unresponsiveness cannot be predicted easily at onset. More rarely encountered clinical findings such as ELE, leg pain and protracted complaints and M694V homozygosity may be a clue for less colchicine response.

Endoscopic photoconversion reveals unexpectedly broad leukocyte trafficking to and from the gut.

Morton AM(1), Sefik E, Upadhyay R, Weissleder R, Benoist C, Mathis D.

Author information:

(1)Division of Immunology, Department of Microbiology and Immunobiology, Harvard Medical School, Boston, MA 02115.

Given mounting evidence of the importance of gut-microbiota/immune-cell interactions in immune homeostasis and responsiveness, surprisingly little is known about leukocyte movements to, and especially from, the gut. We address this topic in a minimally perturbant manner using Kaede transgenic mice, which universally express a photoconvertible fluorescent reporter. Transcutaneous exposure of the cervical lymph nodes to violet light permitted punctual tagging of immune cells specifically therein, and subsequent monitoring of their immigration to the intestine; endoscopic flashing of the descending colon allowed specific labeling of intestinal leukocytes and tracking of their emigration. Our data reveal an unexpectedly broad movement of leukocyte subsets to and from the gut at steady state, encompassing all lymphoid and myeloid populations examined. Nonetheless, different subsets showed different trafficking proclivities (e.g., regulatory T cells were more restrained than conventional T cells in their exodus from the cervical lymph nodes). The novel endoscopic approach enabled us to evidence gut-derived Th17 cells in the spleens of K/BxN mice at the onset of their genetically determined arthritis, thereby furnishing a critical mechanistic link between the intestinal microbiota, namely segmented filamentous bacteria, and an extraintestinal autoinflammatory disease.

Familial Mediterranean fever (FMF) is characterized by recurrent inflammation of serosal and synovial membranes. Despite the fact that it is a genetic disease, environmental factors, including infections, are shown to be triggering factors associated with the precipitation of attacks in FMF. Antimicrobial peptides (AMPs) are components of innate immunity which exert antimicrobial activity against many microorganisms. Human AMPs; cathelicidin (LL37) and defensins have immunomodulatory properties and are involved in the pathogenesis of many inflammatory disorders. Hence, we investigated serum AMPs in 23 newly diagnosed FMF patients. Blood samples were obtained at baseline, 6 months after initiation of colchicine and during an attack. Twenty-four healthy individuals constituted the control group. The concentrations of LL37, alpha-1, beta-1 and beta-2 defensins were determined by ELISA. Serum AMPs did not change during attacks and did not correlate with acute phase reactants. However, serum LL37 and defensins were found to be remarkably higher in FMF patients compared to healthy individuals both at baseline and 6 months after initiation of colchicine therapy which suggest that AMPs might have a role in the pathogenesis of FMF.

Vitamin D levels and effects of vitamin D replacement in children with periodic fever, aphthous stomatitis, pharyngitis, and cervical adenitis (PFAPA) syndrome.

Stagi S(1), Bertini F(2), Rigante D(3), Falcini F(2).

Author information:

- (3)Institute of Pediatrics, Università Cattolica Sacro Cuore, Rome, Italy.

**BACKGROUND:** The periodic fever, aphthous stomatitis, pharyngitis and cervical adenitis (PFAPA) syndrome is an autoinflammatory disease characterized by regularly recurrent fever episodes due to seemingly unprovoked inflammation.

**OBJECTIVE:** To assess serum 25-hydroxyvitamin D [25(OH)D] concentrations in children with PFAPA syndrome and evaluate longitudinally the effect of wintertime vitamin D supplementation on the disease course.

**STUDY DESIGN:** We have evaluated 25 Italian patients (19 males, 6 females, aged 2.4-5.3 years), fulfilling the Euro-Fever PFAPA criteria. For each patient, we recorded demographic and anthropometric data, clinical manifestations, serum calcium, phosphate, and 25(OH)D. After 400 IU vitamin D supplementation during wintertime, clinical and auxological characteristics, calcium, phosphate, and 25(OH)D levels were re-evaluated. Data were compared with a sex- and age-matched control group.

**RESULTS:** PFAPA patients showed reduced 25(OH)D levels than controls ( $p<0.0001$ ). Regarding the effect of seasons on vitamin D, winter 25(OH)D levels were significantly reduced than summer ones ( $p<0.005$ ). Moreover, these levels were significantly lower than in healthy controls ( $p<0.005$ ), and correlated with both fever episodes ( $p<0.005$ ) and C-reactive protein values ( $p<0.005$ ). After vitamin D supplementation, PFAPA patients showed a significantly decreased number of febrile episodes and modification of their characteristics (mean duration of fever episodes,  $p<0.05$ ; number of febrile episodes per year  $p<0.005$ ).

**CONCLUSIONS:** Deficient and insufficient vitamin D serum levels were found in most children with PFAPA syndrome, and hypovitaminosis D might be a significant risk factor for PFAPA flares. However, vitamin D supplementation seems to significantly reduce the typical PFAPA episodes and their duration, supporting the role of vitamin D as an immune-regulatory factor in this syndrome.

Diagnostic validity of colchicine in patients with Familial Mediterranean fever.

Ozaltin F(1), Bilginer Y, Gülhan B, Bajin I, Erdogan O, Hayran M, Yılmaz E, Ozen S.

Author information:

(1)Departments of Pediatric Nephrology and Rheumatology, Hacettepe University Faculty of Medicine, 06100, Sıhhiye, Ankara, Turkey, fozaltin@hacettepe.edu.tr.

Although response to colchicine has been proposed as one of the diagnostic criteria in patients with Familial Mediterranean fever (FMF), the validity of this response has not been validated. The aim of this study was to assess the efficacy of the response to colchicine and to evaluate the extent of the effect of placebo. A double-blind randomized placebo-controlled trial with a cross-over design was conducted. The frequency of FMF attacks, the disease score, physical examination, and acute phase reactants were assessed at 0, 3, and 6 months. Blood samples were collected for complete blood count (CBC), erythrocyte sedimentation rate (ESR), levels of serum C-reactive protein (CRP) and serum amyloid A (SAA), and MEFV mutation analysis in 79 patients with a preliminary diagnosis of FMF. Patients were randomly allocated to receive either drug A or drug B in a double-blind fashion. The designated drug was switched at 3 months. Patients taking colchicine had less frequent FMF attacks (median 0) and lower FMF disease score (median 0) when compared to those on placebo (median 1 and 3, respectively) ( $p = 0.002$  and  $p = 0.007$ , respectively). In genetically confirmed FMF patients, median attack number and median disease score was 0 under colchicine treatment, whereas these parameters were significantly higher in the placebo group (median 2 and 8, respectively) ( $p = 0.007$  and  $p = 0.02$ , respectively) suggesting that colchicine is more effective than placebo in reducing attacks and disease score. Positive and negative predictive values were 70.2 and 37.5 %, respectively. During the placebo period, patients had less FMF attacks when compared to that of the pre-study period (median 2 vs 6, respectively) ( $p < 0.001$ ). The high false positive rate raises concerns for considering the colchicine response test as diagnostic for FMF. The role of placebo on the attacks of periodic fever syndromes needs to be further investigated.

[Anakinra treatment in Schnitzler syndrome - results of the first retrospective multicenter study in six patients from the Czech Republic].

[Article in Czech]

Szturz P, Sedivá A, Zurek M, Adam Z, Stork J, Cermáková Z, Steyerová P, Vokáčová A, Hrbek J, Sýkora M, Spička I, Mechl Z, Mayer J.

**BACKGROUND:** Schnitzler syndrome is a very rare, acquired, autoinflammatory disease of mostly adult onset with characteristic combination of chronic recurrent urticaria and monoclonal immunoglobulin M or G gammopathy predisposing the patients to malignant lymphoproliferation. In this work, we analyzed the results of bio-logical therapy with anakinra on a national level aiming to supply data for effective pharmaco-economic estimates, lay the grounds of nationwide patient registry, raise awareness among professional public and optimize provided health care.

**PATIENTS AND METHODS:** The retrospective study (10/2006-9/2013) included six males with definite Schnitzler syndrome verified by the new Strasbourg criteria. All patients were pretreated with antihistamines, nonsteroidal antiinflammatory drugs and glucocorticoids. Four patients underwent two or more treatment lines including intravenous bisphosphonates, 2-chlorodeoxyadenosine (cladribine), interferon $\alpha$ , PUVA photochemotherapy, cyclosporine A, thalidomide, bortezomib, chlorambucil, cyclophosphamide, colchicine and methotrexate. Anakinra monotherapy was initiated in standard dosing (100 mg subcutaneously daily).

**RESULTS:** Complete and partial remissions were achieved in five (83%) and one patients (17%), respectively. Complete remission was characterized by urticaria and pain regression (within hours), normalization of inflammatory markers (with--in days) and bone metabolism improvement assessed by the markers of osteoblastic osteoformation and osteoclastic osteoresorption in one case (within weeks). With normalized inflammatory markers (including interleukin6 and interleukin18), arthralgia and sporadic exacerbations of urticaria and fevers persist in the patient in partial remission with proven Q703K polymorphism in NLRP3 gene. The median treatment followup was 30.5 months ( $37.2 \pm 31.2$  (n = 6)). The dosing interval was prolonged in one case of complete remission to 48 hours.

No serious adverse reactions occurred during anakinra application.

**CONCLUSION:** In Schnitzler syndrome, anakinra represents an effective, verified and safe medication with potentially longterm administration not compromising its original efficacy and subjective tolerance. Anakinra, blocking autonomous inflammatory reaction of the organism via interleukin1 pathway, is a generally accepted first line treatment that should be made available in standard dosing for all Schnitzler patients.

Chronic recurrent multifocal osteomyelitis: typical patterns of bone involvement in whole-body bone scintigraphy.

Acikgoz G(1), Averill LW.

Author information:

(1)Department of Medical Imaging, Nemours/Alfred I. duPont Hospital for Children, Wilmington, Delaware, USA.

Chronic recurrent multifocal osteomyelitis (CRMO) is an autoinflammatory bone disease of unknown etiology. It affects children and adolescents predominantly and occurs mostly in the female population. It is characterized by the insidious onset of pain and swelling, with a fluctuating clinical course of relapses and remissions. Typically, several bones are affected, either synchronously or metachronously, and bilateral involvement is common. CRMO most commonly affects the metaphysis of long bones, especially the tibia, femur, and clavicle. The spine, pelvis, ribs, sternum, and mandible may also be affected. Although lesions are mostly multiple, patients may present with a single symptomatic focus. Radiographic findings may be negative early in the course of the disease. Bone scintigraphy is useful in determining the presence of abnormality and the extent of disease. The imaging and clinical features of CRMO overlap with those of infectious osteomyelitis, bone malignancy, and inflammatory arthritis. Nonetheless, CRMO can be confidently diagnosed with the recognition of typical imaging patterns in the appropriate clinical setting. This article reviews imaging findings with special emphasis on bone scintigraphy and specific disease

sites.

Waldenstrom disease is a rare hematologic disorder characterized by lymphoplasmacytic proliferation associated with the production of monoclonal IgM. Visceral injuries are described but some are rare (lung), others never reported (cardiac). We report for information and discussion a case representing these particular situations, considering that these attacks were revealing. It is a 63 year old man who was admitted to the emergency room in an array of tamponade, with edema at the front and four members. Clinical and radiological examinations were objectified bilateral pleural effusion, ascite and pericarditis. The biological exploration showed pancytopenia, serum proteins 120 g/L and a monoclonal peak migrant beta2 globulin electrophoresis which is made by monoclonal immunoglobulin M (IgM kappa). The bone marrow confirmed the diagnosis of the Waldenström disease. This is a mode of revelation never described before. Considering this case, it would be wise to think of a Waldenström disease before any polyserositis.

Anakinra treatment in patients with gout and type 2 diabetes.

Vitale A(1), Cantarini L, Rigante D, Bardelli M, Galeazzi M.

Author information:

(1)Research Center of Systemic Autoimmune and Autoinflammatory Diseases and Behçet's Disease Clinic, University of Siena, Siena, Italy.

We report three Caucasian patients affected by gout and type 2 diabetes, who were treated with the recombinant nonglycosylated human interleukin-1 receptor antagonist anakinra (100 mg/day subcutaneously) after an unsatisfactory or incomplete response to urate-lowering therapy, colchicine, nonsteroidal anti-inflammatory drugs, and prednisone. The remarkable clinical improvement in joint symptoms within 24 h and in glycemic control during a 6-month period gives anakinra a potential therapeutic role in the management of gout and type 2 diabetes. When anakinra was discontinued, a gout attack occurred within 3-25 days in all three patients. The contribution of anakinra in the treatment of such syndromes is encouraging, but requires further studies to establish its long-term efficacy.

Paradoxical mucocutaneous flare in a case of Behçet's disease treated with tocilizumab.

Cantarini L(1), Lopalco G, Vitale A, Coladonato L, Rigante D, Lucherini OM, Lapadula G, Iannone F.

Author information:

(1)Research Center of Systemic Autoimmune and Autoinflammatory Diseases, Rheumatology Unit, Policlinico Le Scotte, University of Siena, Siena, Italy, cantariniluca@hotmail.com.

We report on a patient with a long-standing history of recurrent oral aphthosis and pseudofolliculitis, diagnosed with Behçet's disease (BD), previously treated with high-dose prednisone, colchicine, cyclosporine, cyclophosphamide and methotrexate, all of which were partially effective. Treatment with the chimeric mouse-human anti-tumour necrosis factor (TNF)- $\alpha$  monoclonal antibody infliximab brought about the resolution of mucocutaneous lesions for a period of 6 years. After an oral and articular BD relapse, the anti-interleukin-6 agent tocilizumab was started in association with high-dose prednisone. Unexpectedly, the patient experienced a paradoxical mucocutaneous flare following tocilizumab administration, which worsened after the second infusion. Tocilizumab was then discontinued, and total recovery was achieved after the patient was started on the fully human anti-TNF- $\alpha$  monoclonal antibody golimumab in association with colchicine and methylprednisolone.

TH17 cells are increased in the peripheral blood of patients with SAPHO syndrome.

Firinu D(1), Barca MP, Lorrai MM, Perra S, Cabras S, Muggianu E, Di Martino ML, Manconi PE, Del Giacco SR.

Author information:

(1)Unit of Internal Medicine, Allergy and Clinical Immunology, Department of Medical Sciences "M. Aresu", University of Cagliari , Monserrato , Italy .

To assess whether the immune derangement previously observed in SAPHO syndrome could be linked to variations in blood TH1, TH2 or TH17 lymphocytes frequency. Seven SAPHO patients with a protracted course of the disease were studied ex-vivo for intracellular cytokines production by means of flow-cytometry and compared with matched groups of Psoriatic Arthritis patients and healthy controls. The Kruskal-Wallis test on the median of the three categories showed that there is a significant association between the TH17 levels and the category (p value = 0.02474). The mean and variance for the proportion of IL-17 producing CD4+ cells were compared between groups showing significant differences between SAPHO versus PsA subgroup (p = 0.05) and SAPHO versus healthy controls (p = 0.008). Interestingly, activation of TH17 axis, but not of TH1 and TH2, has been found, and can be observed both in patients with different activity of the disease or treated with different drugs. The TH17 increase in peripheral blood of our SAPHO subjects resembles the one recently found in patients with different AIDs. Novel therapeutic options in these patients may therefore include IL-17 blockade.

Clinical evaluation of R202Q alteration of MEFV genes in Turkish children.

Comak E(1), Akman S, Koyun M, Dogan CS, Gokceoglu AU, Arikan Y, Keser I.

Author information:

(1)Department of Pediatric Nephrology and Rheumatology, School of Medicine, Akdeniz University, 07070, Antalya, Turkey, elif\_comak@hotmail.com.

To date, over 200 alterations have been reported in Mediterranean fever (MEFV) genes, but it is not clear whether all these alterations are disease-causing mutations. This study aims to evaluate the clinical features of the children with R202Q alteration. The medical records of children with R202Q alteration were reviewed retrospectively. A total of 225 children, with 113 males, were included. Fifty-five patients were heterozygous, 30 patients were homozygous for R202Q, and 140 patients were compound heterozygous. Classical familial Mediterranean fever (FMF) phenotype was present in 113 patients: 2 heterozygous and 7 homozygous R202Q, 46 double homozygous R202Q and M694V, and 58 compound heterozygous. The main clinical characteristics of the patients were abdominal pain in 71.5 %, fever in 37.7 %, arthralgia/myalgia in 30.2 %, arthritis in 10.2 %, chest pain in 14.6 % and erysipelas-like erythema in 13.3 %. The frequency of abdominal pain was significantly lower in patients with homozygous R202Q alteration ( $p = 0.021$ ), whereas patients with heterozygous R202Q mutations, though not statistically significant, had a higher frequency of arthralgia/myalgia (40.0 %,  $p = 0.05$ ). R202Q alteration of the MEFV gene leads to symptoms consistent with FMF in some cases. This alteration may be associated with a mild phenotype and shows phenotypic differences other than the common MEFV mutations.

(4)The M.I.N.D. Institute, University of California Davis, Davis, California, United States of America; Department of Pediatrics University of California Davis, Davis, California, United States of America.

**BACKGROUND:** Increased rates of autoinflammatory and autoimmune disorders have been observed in female premutation carriers of CGG repeat expansion alleles of between 55-200 repeats in the fragile X mental retardation 1 (FMR1) gene. To determine whether an abnormal immune profile was present at a cellular level that may predispose female carriers to autoinflammatory conditions, we investigated dynamic cytokine production following stimulation of blood cells. In addition, splenocyte responses were examined in an FMR1 CGG knock-in mouse model of the fragile X premutation.

**METHODS:** Human monocyte and peripheral blood leukocytes (PBLs) were isolated from the blood of 36 female FMR1 premutation carriers and 15 age-matched controls. Cells were cultured with media alone, LPS or PHA. In the animal model, splenocytes were isolated from 32 CGG knock-in mice and 32 wild type littermates. Splenocytes were cultured with media alone or LPS or PMA/Ionomycin. Concentrations of cytokines (GM-CSF, IL-1 $\beta$ , IL-6, IL-10, IL-13, IL-17, IFN $\gamma$ , TNF $\alpha$ , and MCP-1) were determined from the supernatants of cellular cultures via Luminex multiplex assay. Additionally, phenotypic cellular markers were assessed on cells isolated from human subjects via flow cytometry.

**RESULTS:** We found decreases in cytokine production in human premutation carriers as well as in the FMR1 knock-in mice when compared with controls. Levels of cytokines were found to be associated with CGG repeat length in both human and mouse. Furthermore, T cells from human premutation carriers showed decreases in cell surface markers of activation when compared with controls.

**CONCLUSIONS:** In this study, FMR1 CGG repeat expansions are associated with decreased immune responses and immune dysregulation in both humans and mice. Deficits in immune responses in female premutation carriers may lead to increased susceptibility to autoimmunity and further research is warranted to determine the link between FMR1 CGG repeat lengths and onset of autoinflammatory conditions.

Neonatal hepatitis as first manifestation of hyperimmunoglobulinemia d syndrome.

von Linstow ML(1), Rosenfeldt V(1).

Author information:

(1)Department of Paediatrics, Hvidovre University Hospital, Kettegaard Alle 30, 2650 Hvidovre, Denmark.

Hyper IgD syndrome (HIDS) is a rare metabolic autoinflammatory syndrome characterised by recurrent febrile episodes, accompanied by various inflammatory symptoms. We present a case of severe HIDS in a young girl, whose symptoms started in the neonatal period with hepatomegaly, hepatitis, thrombocytopenia, and conjugated hyperbilirubinemia. From the age of five months, the child had recurrent febrile episodes, stomatitis, adenitis, and persistent hepatomegaly. The diagnosis of HIDS was established when she was three years and eight months old. This case report suggests that HIDS should be included in the differential diagnosis of neonatal hepatitis and conjugated hyperbilirubinemia.

Ultrasonographic assessment reveals detailed distribution of synovial inflammation in Blau syndrome.

Ikeda K, Kambe N, Takei S, Nakano T, Inoue Y, Tomiita M, Oyake N, Satoh T, Yamatou T, Kubota T, Okafuji I, Kanazawa N, Nishikomori R, Shimojo N, Matsue H, Nakajima H.

**INTRODUCTION:** Arthritis is the most frequent manifestation of Blau syndrome, an autoinflammatory disorder caused by the genetic mutation of NOD2. However, detailed information on arthritis in Blau syndrome on which the therapeutic strategy should be based on is lacking. This multi-center study aimed to accurately characterize the articular manifestation of Blau syndrome and also to

demonstrate the utility of musculoskeletal ultrasound in Blau syndrome.

**METHODS:** Patients who had been diagnosed with Blau syndrome by genetic analysis of NOD2 were recruited. A total of 102 synovial sites in 40 joints were assessed semiquantitatively by ultrasound for gray-scale synovitis and synovial power Doppler (PD) signal.

**RESULTS:** In total, 10 patients whose age ranged from 10 months to 37 years enrolled in this study. Although only 4 joints (0.8%) were tender on physical examination, 81 joints (16.9%) were clinically swollen. Moreover, 240 (50.0%), and 124 (25.8%) joints showed gray-scale (GS) synovitis and synovial PD signal on ultrasound, respectively. Importantly, GS synovitis was present in 168 out of 399 non-swollen joints, in which 61 also exhibited synovial PD signal. Among 40 joint regions, the ankle, the wrist, and the proximal interphalangeal joints were the most frequently and severely affected joints. Comparisons between different synovial tissues demonstrated a significantly higher proportion of the joints with tenosynovitis as compared with that with intra-articular synovitis (41.5% versus 27.9%,  $P < 0.0001$ ). In respect of age and treatment, synovial PD signals were minimal in the youngest patient and in the oldest two patients, and were relatively mild in patients receiving treatment with methotrexate plus TNF antagonists. In two patients who underwent the second ultrasound examination, total PD scores markedly decreased after initiating the treatment with a tumor necrosis factor (TNF) antagonist.

**CONCLUSIONS:** The detailed information on synovial inflammation obtained by ultrasound confirms the dissociation between pain and inflammation and the frequently involved joint regions and synovial tissue in the arthritis of Blau syndrome. Our data also demonstrate that ultrasonography can be a potent tool in monitoring the activity of synovial inflammation and in investigating the pathophysiology of arthritis in this rare but archetypical autoinflammatory condition.

The relationship between familial Mediterranean fever gene (MEFV) mutations and clinical and radiologic parameters in multiple sclerosis patients.

Terzi M(1), Taskın E, Unal Akdemir N, Bağcı H, Onar M.

Author information:

(1)1Department of Neurology, Ondokuz Mayıs University Faculty of Medicine ,  
Samsun , Turkey.

**OBJECTIVE:** Central nervous system (CNS) involvement in patients with familial Mediterranean fever (FMF) is considerably rare. Patients with FMF may exhibit clinical and radiologic symptoms similar to multiple sclerosis (MS). However, the impact of the Familial Mediterranean Fever Gene (MEFV) mutations on the clinical course of MS is not fully understood as yet.

**METHODS:** In our study, we investigated the presence of probable MEFV mutations in patients diagnosed with definite MS and the association of these mutations with the clinical course, radiologic characteristics and disability status of the individuals. A total of 105 patients diagnosed with definite MS according to the McDonald criteria and a control group of 112 non-symptomatic individuals were included in the study.

**RESULTS:** Thirty-seven patients (35.2%) had MEFV gene mutations; three were compound heterozygotes (M694V/E148Q; M694V/V726A; P369S/E148Q) and one was homozygous for P369S. No statistically significant differences were found among patients with MS and healthy individuals with respect to existing mutations. In addition, we did not observe a statistically significant relationship between MEFV mutations and the gender of the patients, oligoclonal band (OCB) positivity, Expanded Disability Status Scale (EDSS), disease onset age, clinical presentation, affected neurologic systems, existence of spinal lesions, response to immunomodulatory treatment, time to reach EDSS scores of 3 and 6, the number of attacks and the average number of lesions on a brain MRI.

**CONCLUSION:** Our results indicate that MEFV gene mutations do not affect the neurologic prognosis in patients with MS. However, additional research studies involving more patients with MS and clinical forms are warranted to confirm our results.

Periodic fevers in adult Greeks: clinical and molecular presentation.

Karatsourakis TP(1), Oikonomaki KN, Tzioufas AG, Moutsopoulos HM.

Author information:

(1)Department of Pathophysiology, School of Medicine, University of Athens, Athens 11527, Greece. karatsourakis@yahoo.gr.

**OBJECTIVES:** Hereditary periodic fever syndromes (HPFS) are rare diseases characterised by recurrent, self-limited episodes of fever and localised inflammation, which arise from monogenic defects. In the present study we describe the clinical features, laboratory parameters and genetic profile of adult patients.

**METHODS:** Samples examined between May 2010 and December 2012 at the laboratory of genetic molecular diagnosis of the department of Pathophysiology of School of Medicine, National University of Athens.

**RESULTS:** Of the MEFV gene variants the most frequent genotype was the E148Q heterozygosity, with patients presenting with the typical clinical picture, two

patients were positive for the pR92Q/c.362G>A mutation in heterozygosity. The testing for the Hyper IgD Syndrome was positive for the pV377I/c.1129 G>A heterozygosity in a patient with the corresponding typical picture and the testing for the CAPS syndromes was positive for a new mutation, pR170H/c.509G>A in heterozygosity, in a case with less typical clinical features.

CONCLUSIONS: Availability of genetic testing in everyday clinical practice can provide valuable information regarding the clinical diversity, geographic distribution and genetic characteristics of these rare disease in all age groups.

Tumor necrosis factor receptor-associated periodic syndrome as a model linking autophagy and inflammation in protein aggregation diseases.

Bachetti T(1), Ceccherini I.

Author information:

(1)U.O.C. Genetica Medica, Istituto Giannina Gaslini, Via Gerolamo Gaslini, 5-16147, Genoa, Italy.

Autophagy prevents cellular damage by eliminating insoluble aggregates of mutant misfolded proteins, which accumulate under different pathological conditions. Downregulation of autophagy enhances the inflammatory response and thus represents a possible common pathogenic event underlying a number of autoinflammatory syndromes, such as tumor necrosis factor (TNF) receptor-associated periodic syndrome (TRAPS). The pathogenesis of other monogenic or complex disorders that display symptoms of excessive inflammation also involve the autophagy pathway. Studies have shown that TRAPS-associated TNFRSF1A mutations induce cytoplasmic retention of the TNFR1 receptor, defective TNF-induced apoptosis, and production of reactive oxygen species (ROS). Furthermore, autophagy impairment may account for the pathogenic effects of TNFRSF1A mutations, thus inducing inflammation in TRAPS. In this review, we summarize the molecular interactions and functional links between autophagy with regard to nuclear factor-kappa B activation, ROS production, and apoptosis.

Furthermore, we propose a complex interplay of these pathways as a model to explain the relationship between mutant protein misfolding and inflammation in genetically determined and aggregation-prone diseases. Accordingly, autophagy function should be investigated in all diseases showing an inflammatory component, and for which the molecular pathogenesis is still unclear.

Non-response to colchicine in familial Mediterranean fever should be identified accurately.

Melikoglu MA(1), Senel K(2).

Author information:

(1)Departments of Rheumatology, Faculty of Medicine, Ataturk University, Erzurum, Turkey.

(2)Physical Medicine and Rehabilitation, Faculty of Medicine, Ataturk University, Erzurum, Turkey.

AIM: Colchicine prophylaxis is the single most important factor in ameliorating familial Mediterranean fever (FMF) for the prevention of both attacks and secondary amyloidosis. The aim of the present study was to evaluate the exact proportion of those patients who do not respond to colchicine and to characterize their demographic, sociodemographic and clinical aspects.

METHODS: One hundred and eight patients with FMF were included in our study. The demographic (age, gender), socioeconomic (education level, employment status, economic income level) and clinical features (age at onset of FMF, age at FMF diagnosis, family history of FMF, mean duration of colchicine use and mean daily colchicine dose) of the patients were evaluated. The patients unresponsive to colchicine therapy, according to their statements, were recorded. Also with another question, patients' routine colchicine-consuming habits were elucidated in a self-answering format. 'Non-responders' were defined as patients who experienced FMF attacks at a frequency greater than once every 3 months despite treatment with 2 mg colchicine daily. Data were analyzed with the chi-square test

and Fisher's exact test.

**RESULTS:** There were 50 female and 58 male patients with a mean age of  $42.4 \pm 11.3$  years. The mean age at FMF onset and at FMF diagnosis were  $14.3 \pm 10.5$  and  $19.1 \pm 12.9$  years, respectively. Sixteen percent of the patients defined themselves as 'suffering from attacks in spite of regular colchicine'. Irregular colchicine usage was determined in 11% of the patients who were considered as 'unresponsive to colchicine therapy' according to their statements. In spite of regular colchicine regimen, attacks were present in 5% of the patients in our study. Although there was no difference in demographic and clinical aspects, patients with irregular colchicine usage were found to be from lower socioeconomic backgrounds, had less education and more unemployment ( $P < 0.001$ ).

**CONCLUSION:** Regular colchicine usage anamnesis may be misleading in the first evaluation and this risk seems to be higher in patients from lower socioeconomic background. Routine colchicine-consuming habits should be detailed in patients with FMF before claiming its failure.

(4)Department of Internal Medicine, Division of Rheumatology, Gulhane School of Medicine, Ankara, Turkey.

**OBJECTIVE:** Cardiovascular diseases (CVD) are very common in the general population. Atherosclerosis is the main pathogenesis. Familial Mediterranean fever (FMF) is an autosomal recessive disease. The gene causing FMF, designated MEFV, encodes a protein called pyrin or marenostrin that is expressed mainly in myeloid bone marrow precursors, neutrophils and monocytes. We herein aimed to determine the prevalence of MEFV mutations (all exon 2, 10 mutations) in patients with early coronary heart disease (early CHD) and coronary heart disease (CHD) with multiple risk factors and among the healthy subjects as controls.

**METHODS:** A total of 197 patients and 119 healthy subjects were recruited and enrolled into three groups in terms of inclusion criteria. Ninety-one patients diagnosed with early CHD enrolled into group one (men < 45 years of age, women < 40 years of age), 106 patients with CHD (men > 50 years of age) to group two and 119 healthy controls enrolled into group three. None of patients was diagnosed with FMF. The diagnosis of CHD was established on electrocardiographic changes, echocardiography and coronary angiography.

**RESULTS:** Thirty-eight patients (41.8%) with early CHD, 17 patients (16%) with CHD and 24 healthy controls (20.2%) carried at least one mutated MEFV allele. Young patients with CHD have different risk factor profiles, clinical presentations and prognoses than older patients. Young patients with CHD usually have multiple risk factors.

**CONCLUSION:** This study suggests that MEFV mutations in early CHD patients had significantly increased in contrast to CHD patients and healthy controls.

Neutrophil-lymphocyte ratio in patients with familial Mediterranean fever.

Celikbilek M(1), Dogan S, Akyol L, Borekci E, Zararsiz G, Kozan M, Gunaydin I.

Author information:

(1)Department of Gastroenterology, Bozok University Medical School, Yozgat, Turkey.

**BACKGROUND:** Blood neutrophil-to-lymphocyte (N/L) ratio is an indicator of the overall inflammatory status of the body, and an alteration in N/L ratio may be found in patients with familial Mediterranean fever (FMF). The aim of this study was to investigate the interrelationship between N/L ratio and FMF.

**METHODS:** One hundred and fifteen patients and controls were enrolled in the study. The cases in the study were categorized as FMF with attack, FMF with attack-free period, and controls. The neutrophil and lymphocyte counts were recorded, and the N/L ratio was calculated from these parameters. All patients were diagnosed according to Tel Hashomer criteria.

**RESULTS:** A total of 79 FMF patients were included in the study and all subjects were receiving colchicine treatment at the time. The serum N/L ratios of active patients were significantly higher than those of attack-free FMF patients and controls ( $P < 0.001$ ). The optimum N/L ratio cut-off point for active FMF was 2.63 with sensitivity, specificity, positive predictive value, and negative predictive value of 0.62 (0.41-0.80), 0.85 (0.72-0.93), 0.67 (0.44-0.85), and 0.82 (0.69-0.91), respectively. The overall accuracy of the N/L ratio in determination of FMF patients during attack was 71%.

**CONCLUSION:** Our results demonstrate that N/L ratio is higher in patients with active FMF compared with FMF patients in remission and controls, and a cut-off value of 2.63 can be used to identify patients with active FMF.

Comment in

Mol Ther. 2014 May;22(5):899-900.

The adoptive transfer of regulatory T cells (Tregs) offers a promising strategy to combat pathologies that are characterized by aberrant immune activation, including graft rejection and autoinflammatory diseases. Expression of a chimeric antigen receptor (CAR) gene in Tregs redirects them to the site of autoimmune activity, thereby increasing their suppressive efficiency while avoiding systemic immunosuppression. Since carcinoembryonic antigen (CEA) has been shown to be overexpressed in both human colitis and colorectal cancer, we treated CEA-transgenic mice that were induced to develop colitis with CEA-specific CAR Tregs. Two disease models were employed: T-cell-transfer colitis as well as the azoxymethane-dextran sodium sulfate model for colitis-associated colorectal cancer. Systemically administered CEA-specific (but not control) CAR Tregs accumulated in the colons of diseased mice. In both model systems, CEA-specific CAR Tregs suppressed the severity of colitis compared to control Tregs. Moreover, in the azoxymethane-dextran sodium sulfate model, CEA-specific CAR Tregs significantly decreased the subsequent colorectal tumor burden. Our data demonstrate that CEA-specific CAR Tregs exhibit a promising potential in ameliorating ulcerative colitis and in hindering colorectal cancer development. Collectively, this study provides a proof of concept for the therapeutic potential of CAR Tregs in colitis patients as well as in other autoimmune inflammatory disorders.

Partial clinical response to anakinra in severe palmoplantar pustular psoriasis.

Tauber M(1), Viguier M, Alimova E, Petit A, Lioté F, Smahi A, Bachelez H.

Author information:

(1)Université Paris Diderot-Sorbonne, Paris Cité, Department of Dermatology, Hôpital Saint-Louis, APHP, 1 avenue Claude-Vellefaux, 75475 Cedex 10, Paris, France; Laboratory of genetics of autoinflammatory diseases, Université Paris Diderot-Sorbonne, Paris Cité, Institut Imagine, Hôpital Necker-Enfants Malades, Paris, France.

**BACKGROUND:** Palmoplantar pustular psoriasis is a clinical psoriasis variant characterised by a high impact on quality of life and poor response to biologics approved for plaque type psoriasis. The recombinant interleukin-1 (IL-1) receptor antagonist anakinra has been recently used for the treatment of isolated refractory cases of generalised pustular psoriasis with contrasted results.

**OBJECTIVES:** To report the clinical response in two patients treated with anakinra as salvage therapy in two patients with severe palmoplantar pustular psoriasis refractory to currently available antipsoriatic systemic therapies.

**METHODS:** Anakinra was given subcutaneously at the daily dose of 100 mg, and clinical response was evaluated using the palmoplantar psoriasis area and severity index (PPPASI).

**RESULTS:** Only partial and transient responses were observed in both patients, who had to stop anakinra due to lack of efficacy and to side effects.

**CONCLUSION:** Anakinra appears to provide only partial clinical improvement in refractory palmoplantar pustular psoriasis. Prospective clinical studies on larger populations are warranted to investigate more accurately both efficacy and safety of IL-1-inhibiting strategies in pustular psoriasis.

Familial Mediterranean fever (FMF) is characterized by recurrent attacks of fever

and inflammation in the peritoneum, synovium, or pleura, accompanied by pain. It is an autosomal recessive disease caused by mutations in the MEFV (MEditerranean FeVer) gene. Patients with similar genotypes exhibit phenotypic diversity. As a result, the variations in different genes could be responsible for the clinical findings of this disease. In previous studies genes encoding Angiotensin-Converting Enzyme (ACE) and IL-4 (Interleukin-4) were found to be associated with rheumatologic and autoimmune diseases. In the present study we hypothesized whether ACE I/D or IL-4 70 bp variable tandem repeats (VNTR) genes are associated with FMF and its clinical findings in Turkish patients. Genomic DNA obtained from 670 persons (339 patients with FMF and 331 healthy controls) was used in the study. Genotypes for an ACE gene I/D polymorphism and IL-4 gene 70 bp VNTR were determined by polymerase chain reaction with specific primers. To our knowledge, this is the first study examining ACE gene I/D polymorphism and IL-4 gene 70 bp VNTR polymorphism in FMF patients. As a result, there was a statistically significant difference between the groups with respect to genotype distribution ( $p < 0.001$ ). According to our results, ACE gene DD genotype was associated with an increased risk in FMF [ $p < 0.001$ ; OR (95%): 7.715 (4.503-13.22)]. When we examined ACE genotype frequencies according to the clinical characteristics, we found a statistically significant association between DD+ID genotype and fever ( $p = 0.04$ ). In addition IL-4 gene P1P1 genotype was associated with FMF ( $p < 0.001$ ). We propose that D allele or DD genotype of ACE gene and P1 allele or P1P1 genotype of IL-4 gene may be important molecular markers for susceptibility of FMF.

Periodic fever, aphthous stomatitis, pharyngitis and cervical adenopathy syndrome is associated with activation of GM-CSF and burst-like expression of IL-8 in peripheral blood.

Ling E(1), Israeli M, Klein T, Amir J, Harel L.

Author information:

(1)Pediatrics Department B, Saban Pediatric Medical Center , Beer Sheva , Israel.

**INTRODUCTION:** Periodic fever, aphthous stomatitis, pharyngitis and cervical adenopathy (PFAPA) is an autoinflammatory syndrome characterized by periodic fever with aphthous stomatitis, cervical lymphadenopathy, myalgia, and abdominal pain. Peripheral blood concentrations of selected cytokines of PFAPA patients during and between febrile episodes were analyzed in a search for PFAPA-specific molecular signature.

**METHODS:** 23 children with PFAPA (age  $6.07 \pm 2.94$  years, range 5-9 years) and three control children with severe oropharyngeal infections (age  $6.2 \pm 7.95$  years, range 1-17 years) participated in the study. Peripheral blood concentrations of IL-1 $\beta$ , IL-2, IL-4, IL-5, IL-6, IL-8, IL-10, IFN- $\gamma$ , GM-CSF, TNF- $\alpha$  were measured using Luminex technology.

**RESULTS:** PFAPA febrile episodes were characterized by detection of GM-CSF -  $134.07 \pm 315.5$  pg/mL; significant ( $P < 0.001$ ), compared to baseline and controls, elevation of concentrations of IL-8 ( $3193.7 \pm 2508$  pg/mL vs.  $100.36 \pm 119.$  pg/mL vs.  $2.04 \pm 4.08$  pg/mL, respectively), IL-6 ( $1355.38 \pm 2026.53$  pg/mL vs.  $28.8 \pm 44.2$  pg/mL and  $27.13 \pm 26.42$  pg/mL, respectively). IL-1 $\beta$  was detected only in febrile and afebrile PFAPA patients ( $922.8 \pm 1639$  pg/mL vs.  $10.98 \pm 19.4$  pg/ml,  $P < 0.002$ , respectively), but not in controls. Peripheral blood concentration of TNF $\alpha$  did not differ significantly between study groups. IL-2, IL-4, IL-5, and IL-10 were negligible in all study subjects.

**DISCUSSION:** PFAPA febrile episodes are characterized by activation of GM-CSF and IL-8 with Th1 skewing. We propose a molecular mechanism governing this phenomenon.

The prevalence of Familial Mediterranean Fever common gene mutations in patients with simple febrile seizures.

Ozen F(1), Kocak N, Kelekci S, Yildirim IH, Hacimuto G, Ozdemir O.

Author information:

(1)Department of Medical Genetics, Medeniyet University, Goztepe Training and Research Hospital, Turkey. dr.fozen@hotmail.com.

**BACKGROUND:** Febrile seizures (FS) represent the most common form of childhood seizures that occurs in 2-5 % of the children younger than 6 years. There have been many recent reports on the molecular genetic and pathogenesis of FC. It has been recognized that there is significant genetic component for susceptibility of FC with different reported mutation. FEB1, FEB2, FEB4, SCNA1, SCNA2, GABRG2 and IL-1 $\beta$  are related to with febrile convulsions (FCs). Interleukin 1 $\beta$  (IL-1 $\beta$ ) is a cytokine that contributes to febrile inflammatory responses. There are conflicting results on increasing this cytokine in serum during FC.

**AIM:** The determine the association between mutations of MEFV gene product pyrine and febrile seizures.

**PATIENTS AND METHODS:** The study was carried out on 104 children that were diagnosed as FS and 96 healthy children. MEFV gene mutations were detected and analyzed with PyroMark Q24. PCR was performed using the PyroMark PCR Kit and pyrosequencing reaction was conducted on instrument instructions.

**RESULTS:** M694V is the most common mutation in our patient group and we found a significant association between MEFV gene mutations and FSs. Of 104 patients, 68 were heterozygotes for any mutation and 10 patients were compound. 17.7% of control group were heterozygotes for any studied mutation. Statistical analyses showed that there was strongly significant statistical difference between results obtained from FS and control group ( $X = 46.20$ ,  $p < 0.0001$ ).

**CONCLUSIONS:** MEFV gene mutations, especially M694V mutation, are positively associated with FSs.

Mutations in TNFRSF1A encoding TNF receptor 1 (TNFR1) cause the autosomal dominant TNF receptor-associated periodic syndrome (TRAPS): a systemic autoinflammatory disorder. Misfolding, intracellular aggregation, and ligand-independent signaling by mutant TNFR1 are central to disease pathophysiology. Our aim was to understand the extent of signaling pathway perturbation in TRAPS. A prototypic mutant TNFR1 (C33Y), and wild-type TNFR1 (WT), were expressed at near physiological levels in an SK-Hep-1 cell model. TNFR1-associated signaling pathway intermediates were examined in this model, and in PBMCs from C33Y TRAPS patients and healthy controls. In C33Y-TNFR1-expressing SK-Hep-1 cells and TRAPS patients' PBMCs, a subtle, constitutive upregulation of a wide spectrum of signaling intermediates and their phosphorylated forms was observed; these were associated with a proinflammatory/antiapoptotic phenotype. In TRAPS patients' PBMCs, this upregulation of proinflammatory signaling pathways was observed irrespective of concurrent treatment with glucocorticoids, anakinra or etanercept, and the absence of overt clinical symptoms at the time that the blood samples were taken. This study reveals the pleiotropic effect of a TRAPS-associated mutant form of TNFR1 on inflammatory signaling pathways (a proinflammatory signalome), which is consistent with the variable and limited efficacy of cytokine-blocking therapies in TRAPS. It highlights new potential target pathways for therapeutic intervention.

Treatment of hereditary autoinflammatory diseases.

Ter Haar NM(1), Frenkel J.

Author information:

(1)aDepartment of Pediatric Rheumatology bDepartment of General Pediatrics,  
University Medical Center Utrecht, Utrecht, The Netherlands.

Erratum in

Curr Opin Rheumatol. 2014 Jul;26(4):458.

**PURPOSE OF REVIEW:** The purpose of this review is to summarize recent advances in the treatment of the hereditary autoinflammatory diseases, focusing on Familial Mediterranean fever (FMF), tumor necrosis factor receptor-associated periodic syndrome (TRAPS), cryopyrin-associated periodic syndromes (CAPS) and mevalonate kinase deficiency (MKD). We discuss recently published studies and their implications for current patient care and future clinical research.

**RECENT FINDINGS:** Interleukin (IL)-1 blockade is effective in most autoinflammatory conditions. Younger patients require a higher dose per kg of body weight. In FMF, colchicine remains the treatment of choice. Single daily dosing appears adequate. When colchicine fails, IL-1 blockade is effective. In CAPS, the beneficial effect of IL-1 blockade is sustained, and side-effects are limited. There is no evidence that one IL-1 blocker is superior to the other. In TRAPS and MKD, IL-1 blockade appears effective. Some patients have sufficient suppression of inflammatory symptoms with NSAIDs or corticosteroids.

**SUMMARY:** Apart from CAPS and FMF, therapy of autoinflammatory diseases is based on small and retrospective studies. IL-1 blockade appears effective, but larger prospective trials are needed, especially in MKD, TRAPS and colchicine-resistant FMF patients.

Familial Mediterranean fever (FMF) is a genetic autoinflammatory disorder that usually develops before 20 years of age and is characterized by periodic fever with serositis and arthritis. Both FMF and rheumatoid arthritis (RA) involve arthritis; however, their coexistence is rare. We describe two RA patients with an MEFV mutation in exon 2, who were diagnosed with FMF at an age of over 50 years. We also discuss the possibility that MEFV mutations could modulate RA disease activity.

Clin Rheumatol. 2016 Feb;35(2):551-2.

Serum amyloid-A (SAA) is an acute phase protein, synthesized by the liver and previously investigated as a marker of disease activity in many rheumatologic disorders. Its significance in Behçet's disease (BD), a chronic inflammatory disorder at the crossroad between autoimmune and autoinflammatory syndromes, is still unraveled. Our aim was to assess the role of SAA levels as a potential marker of disease activity in patients with BD. According to our findings, the occurrence of oral aphthosis, neurological impairment, and ocular disease is significantly associated with SAA serum levels higher than 30, 50, and 150 mg/L, respectively. We also suggest that increased SAA levels might identify a thrombotic risk in BD with previous or concurrent vascular involvement.

Primary immunodeficiency disorders in Iran: update and new insights from the third report of the national registry.

Aghamohammadi A, Mohammadinejad P, Abolhassani H, Mirminachi B, Movahedi M, Gharagozlou M, Parvaneh N, Zeiaee V, Mirsaeed-Ghazi B, Chavoushzadeh Z, Mahdavian A, Mansouri M, Yousefzadegan S, Sharifi B, Zandieh F, Hedayat E, Nadjafi A, Sherkat R, Shakerian B, Sadeghi-Shabestari M, Hosseini RF, Jabbari-Azad F, Ahanchian H, Behmanesh F, Zandkarimi M, Shirkani A, Cheraghi T, Fayezi A, Mohammadzadeh I, Amin R, Aleyasin S, Moghtaderi M, Ghaffari J, Arshi S, Javahertrash N, Nabavi M, Bermanian MH, Shafiei A, Kalantari N, Ahmadiafshar A, Khazaei HA, Atarod L, Rezaei N.

**BACKGROUND:** Primary immunodeficiency disorders (PID) are a group of heterogeneous disorders mainly characterized by severe and recurrent infections and increased susceptibility to malignancies, lymphoproliferative and autoimmune conditions. National registries of PID disorders provide epidemiological data and increase the awareness of medical personnel as well as health care providers.

**METHODS:** This study presents the demographic data and clinical manifestations of Iranian PID patients who were diagnosed from March 2006 till the March of 2013 and were registered in Iranian PID Registry (IPIDR) after its second report of 2006.

**RESULTS:** A total number of 731 new PID patients (455 male and 276 female) from 14

medical centers were enrolled in the current study. Predominantly antibody deficiencies were the most common subcategory of PID (32.3 %) and were followed by combined immunodeficiencies (22.3 %), congenital defects of phagocyte number, function, or both (17.4 %), well-defined syndromes with immunodeficiency (17.2 %), autoinflammatory disorders (5.2 %), diseases of immune dysregulation (2.6 %), defects in innate immunity (1.6 %), and complement deficiencies (1.4 %). Severe combined immunodeficiency was the most common disorder (21.1 %). Other prevalent disorders were common variable immunodeficiency (14.9 %), hyper IgE syndrome (7.7 %), and selective IgA deficiency (7.5 %).

**CONCLUSIONS:** Registration of Iranian PID patients increased the awareness of medical community of Iran and developed diagnostic and therapeutic techniques across more parts of the country. Further efforts must be taken by increasing the coverage of IPIDR via electronically registration and gradual referral system in order to provide better estimation of PID in Iran and reduce the number of undiagnosed cases.

First described in 1971, adult-onset Still's disease (AOSD) is a rare multisystemic disorder considered as a complex (multigenic) autoinflammatory syndrome. A genetic background would confer susceptibility to the development of autoinflammatory reactions to environmental triggers. Macrophage and neutrophil activation is a hallmark of AOSD which can lead to a reactive hemophagocytic lymphohistiocytosis. As in the latter disease, the cytotoxic function of natural killer cells is decreased in patients with active AOSD. IL-18 and IL-1 $\beta$ , two proinflammatory cytokines processed through the inflammasome machinery, are key factors in the pathogenesis of AOSD; they cause IL-6 and Th1 cytokine secretion as well as NK cell dysregulation leading to macrophage activation. The clinico-biological picture of AOSD usually includes high spiking fever with joint symptoms, evanescent skin rash, sore throat, striking neutrophilic leukocytosis, hyperferritinemia with collapsed glycosylated ferritin (<20%), and abnormal liver function tests. According to the clinical presentation of the disease at diagnosis, two AOSD phenotypes may be distinguished: i) a highly symptomatic, systemic and feverish one, which would evolve into a systemic (mono- or polycyclic) pattern; ii) a more indolent one with arthritis in the foreground and poor systemic symptomatology, which would evolve into a chronic articular pattern. Steroid- and methotrexate-refractory AOSD cases benefit now from recent insights into autoinflammatory disorders: anakinra seems to be an efficient, well tolerated, steroid-sparing treatment in systemic patterns; tocilizumab seems efficient in AOSD with active arthritis and systemic symptoms while TNF $\alpha$ -blockers could be interesting in chronic polyarticular refractory AOSD.

Gene. 2015 Mar 15;559(1):99-101.

Hyperimmunoglobulinemia D and periodic fever syndrome (HIDS; MIM# 260920) is a rare recessively-inherited autoinflammatory condition caused by mutations in the MVK gene, which encodes for mevalonate kinase, an essential enzyme in the isoprenoid pathway. HIDS is clinically characterized by recurrent episodes of fever and inflammation. Here we report on the case of a 2 year-old Portuguese boy with recurrent episodes of fever, malaise, massive cervical lymphadenopathy and hepatosplenomegaly since the age of 12 months. Rash, arthralgia, abdominal pain and diarrhea were also seen occasionally. During attacks a vigorous acute-phase response was detected, including elevated erythrocyte sedimentation rate, C-reactive protein, serum amyloid A and leukocytosis. Clinical and laboratory improvement was seen between attacks. Despite normal serum IgD level, HIDS was clinically suspected. Mutational MVK analysis revealed the homozygous genotype with the novel p.Arg277Gly (p.R277G) mutation, while the healthy non-consanguineous parents were heterozygous. Short nonsteroidal anti-inflammatory drugs and corticosteroid courses were given during attacks with poor benefits, whereas anakinra showed positive responses only at high doses. The p.R277G mutation here described is a novel missense MVK mutation, and it has been detected in this case with a severe HIDS phenotype. Further studies are needed to evaluate a co-relation genotype, enzyme activity and phenotype, and to define the best therapeutic strategies.

Drug-induced toxic myopathy is a complication of familial Mediterranean fever in patients who receive colchicine, especially when combined with cyclosporine. Protracted febrile myalgia syndrome is a severe form of familial Mediterranean fever. A 34-year-old man who had familial Mediterranean fever for > 15 years developed kidney failure because of secondary amyloidosis. He received living-unrelated-donor kidney transplant that functioned normally. He was on colchicine prophylaxis that was continued after transplant, and he received immuno-suppression induction with antithymocyte globulin and maintenance with prednisolone, mycophenolate mofetil, and cyclosporine. After 2 months, he presented with severe myopathy and elevated creatine kinase. Muscle biopsy showed evidence of drug-induced toxic myopathy, most likely caused by cyclosporine in combination with colchicine. Cyclosporine was replaced with sirolimus and colchicine was stopped. Symptoms partially improved and creatine kinase decreased to normal. The prednisolone dosage was reduced gradually to 5 mg daily. At 8 months after transplant, he was readmitted because of severe arthralgia, prolonged fever, pleuritic chest pain, diffuse abdominal pain, purpuric rash, macroscopic hematuria, proteinuria, and diarrhea. The C-reactive protein and erythrocyte sedimentation rate were elevated. The clinical diagnosis was recurrent familial Mediterranean fever presenting as protracted febrile myalgia syndrome. Despite the history of toxic myopathy, he was restarted on colchicine

(0.5 mg, twice daily), and colchicine was well tolerated. There was marked improvement of most symptoms within several days. Follow-up 5 years later showed normal kidney graft function and no familial Mediterranean fever activity on colchicine prophylaxis. In summary, familial Mediterranean fever reactivation and protracted febrile myalgia syndrome after kidney transplant may be treated with colchicine and modulation of immunosuppressive therapy.

Gout is the most common autoinflammatory arthritis characterized by elevated

serum urate and recurrent attacks of intra-articular crystal deposition of monosodium urate (MSU) in tissues. The pathogenesis of gout has not been fully determined, although certain genetic factors are involved in the development of gout. Accumulated data suggested that MSU crystal-induced inflammation is a paradigm of innate immunity. As Toll-like receptors (TLRs) are the underlying mechanisms of the innate immune response, the present study aimed to investigate whether TLR2 polymorphisms are associated with gout. Two single-nucleotide polymorphisms (Arg677Trp and Arg753Gln, rs5743708) in TLR2 were genotyped by polymerase chain reaction-restriction fragment length polymorphism and the -196 to -174 del polymorphism was investigated using the allele-specific polymerase chain reaction in 431 individuals (215 patients with gout and 216 healthy controls). TLR2 Arg677Trp and Arg753Gln genotyping indicated that all the positive samples were of the wild-type genotype. No significant differences in genotype ( $\chi^2=1.686$ ,  $P=0.430$ ) and allele ( $\chi^2=1.430$ ,  $P=0.232$ ) frequencies of the -196 to -174 del polymorphism between the patients with gout and the control groups was observed. Our results suggested that the TLR2 Arg677Trp, Arg753Gln and the -196 to -174 del polymorphisms were not associated with susceptibility to primary gouty arthritis.

Recommendations related to ocular, mucosal and cutaneous involvement of Behçet's disease (BD) are mainly evidence-based, but in cases of vascular, neurological and gastrointestinal involvement there are no guidelines to define the best

treatment strategy. We report three adult patients with BD, who received an interleukin-1 $\beta$  inhibitor by subcutaneous injections, canakinumab (at the dosage of 150 mg every 6 weeks), after failure shown by corticosteroids and different combinations of immunosuppressant agents. The prompt and sustained clinical efficacy demonstrated by canakinumab as a monotherapy supports the opportunity of using this specific anti-interleukin-1 $\beta$  agent as a valid therapeutic option for resistant or refractory BD. Open trials and observational studies should be performed to test canakinumab efficacy on a larger number of patients. The most appropriate dosage and intervals between administrations should be decided according to the individual patient, severity or recurrence of clinical manifestations and major organ involvement.

AIMS: This study aimed to investigate sleep patterns, sleep disturbances and possible factors that are associated with sleep disturbances among children with familial Mediterranean fever (FMF).

PATIENTS AND METHODS: Fifty-one patients with FMF and 84 age- and sex-matched healthy controls were enrolled in the study. The patients who had an attack during the last 2 weeks were not included. Demographic data, FMF symptoms, disease duration, dose of colchicine, disease severity score, number of attacks

in the last year, MEFV mutation and serum C-reactive protein (CRP) levels were recorded for each patient. A Children's Sleep Habits Questionnaire was performed.

**RESULTS:** The total sleep scores of the patients with FMF were significantly higher than the control group. Total sleep durations were similar between FMF patients and controls. Children with FMF had significantly higher scores regarding sleep-onset delay, sleep anxiety, night wakings and sleep-disordered breathing when compared to healthy controls. There was a significant positive correlation between number of attacks in the last year and sleep onset delay, night wakings and sleep disordered-breathing. Disease severity score and CRP levels were not associated with any of the subscale scores. The patients with exertional leg pain had significantly higher total sleep scores than the ones without. Furthermore, patients with exertional leg pain had significantly higher subscale scores regarding sleep onset delay, parasomnias and sleep-disordered breathing.

**CONCLUSION:** This study showed for the first time that children with FMF had more sleep disturbances than their healthy peers. Higher numbers of attacks and exertional leg pain were associated with poor sleep quality. In conclusion, this study underlines the need to assess and manage sleep problems in children with FMF.

of Medicine, 3-1-1 Asahi, Matsumoto, 390-8621, Japan.

Periodic fever, aphthous stomatitis, pharyngitis, and cervical adenitis (PFAPA) syndrome is the most commonly encountered autoinflammatory disease in children, but its pathogenesis and diagnostic biomarkers are unknown. In this study, we examined the utility of CD64, a member of the Fc $\gamma$  receptors, expressions on neutrophils and monocytes in diagnosing patients with PFAPA, along with other autoinflammatory diseases exhibiting periodic fever, and bacterial infections. Although CD64 was expressed at a similar level in the attack-free period of PFAPA and in controls, CD64 expressions on both neutrophils and monocytes were dramatically increased during attacks. Serum IFN- $\gamma$  also increased in some PFAPA patients during flares, suggesting the involvement of T cell activation. Our findings demonstrate that remarkable CD64 expression during PFAPA flares serves as a potential biomarker for the diagnosis. We also suspect that IFN- $\gamma$ , possibly from retention of activated T cells in peripheral tissues, increases CD64 synthesis in such cases.

Urticaria--an allergologic, dermatologic or multidisciplinary disease?

Leru P.

Urticaria is a frequent disease, with complex etiopathogeny, raising important problems in clinical practice. The life-time prevalence for any subtype of urticaria is about 20%. Urticaria and/or angioedema is a heterogeneous group of diseases that result from a large variety of underlining causes, are elicited by a great diversity of factors and present clinically in a high variable way. In the past few decades an increasing understanding of the pathomechanisms involved in urticaria has highlighted the heterogeneity of different subtypes. According to the clinical picture and associated signs and symptoms, urticaria can be a simple, self-limited disease or a very complicated and debilitating one.

Urticaria is frequently caused by allergic reactions, but there are also many nonallergic causes. The majority cases of chronic urticaria have unknown (idiopathic) causes, with about 30-40% possibly having an autoimmune substrate.

An autoimmune subset of chronic spontaneous urticaria is increasingly being recognized internationally, based on laboratory and clinical evidence that accrued over the last 20 years. Urticarial rash may be part of clinical picture of autoinflammatory diseases, a group of rare disorders of the innate immune system, mediated by Interleukin-1. Since urticaria is an early and prominent symptom of a complex clinical picture, the awareness of these disorders may help the diagnostic in early stages and prevent severe long-term complications. Management of urticaria is based on recommendations of EAACI/GA2LEN/EDF/WAO Guideline published in 2009 and updated during the 4th International Consensus Meeting on Urticaria (Berlin, November 2012).

Primary immunodeficiencies are intrinsic defects in the immune system that result in a predisposition to infection and are frequently accompanied by a propensity to autoimmunity and/or immunodysregulation. Primary immunodeficiencies can be divided into innate immunodeficiencies, phagocytic deficiencies, complement deficiencies, disorders of T cells and B cells (combined immunodeficiencies), antibody deficiencies and immunodeficiencies associated with syndromes. Diseases of immune dysregulation and autoinflammatory disorder are many times also included although the immunodeficiency in these disorders are often secondary to the autoimmunity or immune dysregulation and/or secondary immunosuppression used to control these disorders. Congenital primary immunodeficiencies typically manifest early in life although delayed onset are increasingly recognized. The

early diagnosis of congenital immunodeficiencies is essential for optimal management and improved outcomes. In this International Consensus (ICON) document, we provide the salient features of the most common congenital immunodeficiencies.

Tumor necrosis factor receptor-associated periodic syndrome managed with the couple canakinumab-alendronate.

Lopalco G(1), Rigante D, Vitale A, Frediani B, Iannone F, Cantarini L.

Author information:

(1)Interdisciplinary Department of Medicine, Rheumatology Unit, Policlinico of Bari, Bari, Italy.

Management of tumor necrosis factor receptor-associated periodic syndrome (TRAPS) is puzzling, and therapeutic choices can be complicated, due to both wide genetic heterogeneity and protean clinical phenotype. We report on a 35-year-old female who was diagnosed with TRAPS, after finding the V95M mutation on the TNFRSF1A gene; who was treated in order with etanercept, anakinra, and canakinumab (150 mg/every 8 weeks by subcutaneous injection, then increased to 150 mg every 4 weeks); and who started therapy with oral alendronate (70 mg/weekly) to control her osteoporosis. Alendronate combined with canakinumab led to the optimal clinical control of all TRAPS manifestations and normalization of inflammatory markers. Further studies should be performed to clarify bisphosphonates' role in the scenery of autoinflammatory disorders.

Colchicine (COL), an alkaloid derived from plants, has been used to treat gout, pseudogout and familial Mediterranean fever for several decades. The purpose of this study was to investigate the in vivo effect of COL on rat cytochrome P450 enzymes (CYP1A2, CYP2C9, CYP2C19 and CYP2D6) to assess its potential to interact with co-administered drugs. This was a randomized, double-blind, two-way crossover study with a 4-week washout period between the phases. Rats received COL via an irrigation stomach needle at a dose of 0.4 mg/kg once daily for consecutive 10 days. On the eleventh day, a cocktail solution at a dose of 4 ml/kg, which contained phenacetin (15.0 mg/kg), tolbutamide (3.0 mg/kg), omeprazole (15.0 mg/kg) and dextromethorphan (15.0mg/kg), was oral administered to all rats. Then 0.3 ml blood samples were collected at a set of time-points. The plasma concentrations of probe drugs were simultaneously determined by

HPLC-MS/MS. Pharmacokinetic parameters simulated by DAS software were used for the evaluation of COL on the activities of rat CYP1A2, CYP2C9, CYP2C19 and CYP2D6 enzymes. Our study showed that COL administration induced CYP2C9 activity, causing a significant decrease in AUC(0-infinity) ( $P < 0.01$ ) and  $t_{1/2}$  ( $P < 0.05$ ) of tolbutamide, and a distinct increase in CL ( $P < 0.01$ ). Many pharmacokinetic parameters of dextromethorphan in COL-treated rats were affected significantly, which indicated that the metabolism of dextromethorphan in these treatment groups was evidently slowed down. However, there was no significant influence of pharmacokinetic parameters of phenacetin and omeprazole in COL-treated rats. The results from the present in vivo study suggested that COL showed no effects on rat CYP1A2 and CYP2C19, however, it demonstrated potential inductive effects on CYP2C9 and inhibitory effects on CYP2D6. Therefore, caution is needed when COL is co-administered with drugs metabolized by CYP2C9 or CYP2D6, which may result in altered plasma concentrations of these drugs and relevant drug-drug interactions.

During the past years, significant progress in the understanding of the complexity, regulation, and relevance of innate immune responses underlying several inflammatory conditions with neutrophilic skin involvement has been made. These diseases belong to the novel class of autoinflammatory diseases, and several are caused by mutations in genes regulating the function of innate immune complexes, termed inflammasomes, leading to enhanced secretion of the proinflammatory cytokine IL-1 $\beta$ . Consequently, targeting of IL-1 $\beta$  has proven successful in the treatment of these diseases, and the identification of related

pathogenic mechanisms in other more common skin diseases characterized by autoinflammation and neutrophilic tissue damage also provides extended opportunities for therapy by interfering with IL-1 signaling.

Amyloid A amyloidosis in a Japanese patient with familial Mediterranean fever associated with homozygosity for the pyrin variant M694I/M694I.

Nakamura T(1), Migita K, Ando Y, Takaoka H, Suzushima H, Shiraishi N.

Author information:

(1)Section of Internal Medicine and Rheumatology, Kumamoto Shinto General Hospital , Japan.

Familial Mediterranean fever (FMF) is an autoinflammatory disease common in eastern Mediterranean populations. The most severe complication is the development of secondary amyloid A (AA) amyloidosis. A 51-year-old Japanese male who had been suffering from periodic fever since in his twenties was referred to our hospital for proteinuria. Histological findings from renal biopsy revealed the deposition of AA amyloid fibrils, suggesting that renal dysfunction was due to AA amyloidosis. Gene analysis of the patient and his mother showed that both were homozygous for the M694I mutation in the MEFV gene. His mother was also a carrier of the SAA1.3 allele, which is not only a univariate predictor of survival but also a risk factor for the association of AA amyloidosis with rheumatoid arthritis in Japanese patients, and the SAA1-13T allele in the 13T/C polymorphism on the 5'-flanking region of the SAA1 gene. The patient was also a carrier of the SAA-13T allele. Colchicine resulted in not only an amelioration of the acute febrile attacks of FMF inflammation, but also an improvement in kidney dysfunction due to AA amyloidosis.

**Introduction.** Familial Mediterranean fever (FMF) is an auto-inflammatory disease characterized by attacks of fever and polyserositis. FMF is often associated with other autoimmune diseases such as rheumatoid arthritis, polyarteritis nodosa (PAN), and Behcet. Uveitis is an inflammatory process caused by underlying infectious and inflammatory disorders. This study investigates the probable relationship between idiopathic uveitis and FMF. **Methods.** Patients with idiopathic uveitis were analyzed for the 12 most common MEFV mutations (P369S, F479L, M680I(G/C), M680I(G/A), I692del, M694V, M694I, K695R, V726A, A744S, R761H, E148Q) by a reverse hybridization assay (FMF StripAssay, Vienna lab, Vienna, Austria). **Results.** 12 patients with idiopathic uveitis were enrolled in this study. 10 of them were female. The youngest patient was a 7-year-old child and the oldest was 57. The most common complaints of patients were blurred vision and then eye redness. One patient was heterozygous for R761H. Genetic analysis of the 12 most common MEFV mutations in the patients with idiopathic uveitis did not have any positive results. **Conclusion.** According to the analysis of the 12 most common MEFV gene mutations, FMF is not an underlying cause of idiopathic uveitis. On the other hand, uveitis merely could not be the first presentation of FMF.

## Fibromyalgia in patients with other rheumatic diseases: prevalence and relationship with disease activity.

Haliloglu S(1), Carlioglu A, Akdeniz D, Karaaslan Y, Kosar A.

### Author information:

(1)Department of Physical Medicine and Rehabilitation, Erzurum Regional Research and Training Hospital, 25240, Erzurum, Turkey, sema@haliloglu.org.

Fibromyalgia (FM) is a syndrome characterized by chronic widespread pain and the presence of specific tender points. The prevalence of FM has been estimated at 2-7 % of the general global population. The presence of FM in several rheumatic diseases with a structural pathology has been reported as 11-30 %. The objectives of this study were to determine the prevalence of FM and to evaluate the possible relationship between FM existence and disease activity among rheumatic diseases. The study group included 835 patients--197 rheumatoid arthritis (RA), 67 systemic lupus erythematosus (SLE), 119 ankylosing spondylitis (AS), 238 osteoarthritis (OA), 14 familial Mediterranean fever (FMF), 53 Behçet's disease (BD), 71 gout, 25 Sjögren's syndrome (SS), 20 vasculitis, 29 polymyalgia rheumatica (PMR), and two polymyositis (PM)--with or without FM. Recorded information included age, gender, laboratory parameters, presence of fatigue, and disease activity indexes. The prevalence of FM in patients with rheumatologic diseases was found to be 6.6 % for RA, 13.4 % for SLE, 12.6 % for AS, 10.1 % for OA, 5.7 % for BD, 7.1 % for FMF, 12 % for SS, 25 % for vasculitis, 1.4 % for gout, and 6.9 % for PMR. One out of two patients with PM was diagnosed with FM. Some rheumatologic cases (AS, OA) with FM were observed mostly in female patients ( $p = 0.000$ ). Also, there were significant correlations between disease activity indexes and Fibromyalgia Impact Questionnaire scores for most rheumatologic patients (RA, AS, OA, and BD) ( $p < 0.05$ ; respectively,  $r = 0.6, 0.95, 0.887, \text{ and } 1$ ). Concomitant FM is a common clinical problem in rheumatologic diseases, and its recognition is important for the optimal management of these diseases. Increased pain, physical limitations, and fatigue may be interpreted as increased activity of these diseases, and a common treatment option is the prescription of higher doses of biologic agents or corticosteroids. Considerations of the FM component in the management of rheumatologic diseases increase the likelihood of the success of the treatment.

[A case of colchicine-responsive Mollaret's meningitis with MEFV gene mutation].

[Article in Japanese]

Kinohshita T(1), Matsushima A, Satoh S, Hoshi K, Kishida D, Yahikozawa H.

Author information:

(1)Department of Neurology, Nagano Red-cross Hospital.

A 66-year-old woman was admitted to our hospital with recurrent meningitis. She presented with 10 episodes of meningitis in 10 months. Examination of cerebrospinal fluid demonstrated pleocytosis, with neutrophils dominant at the early stage, and lymphocytes dominant at the late stage. Mollaret cells were found and the level of IL-6 was increased in cerebrospinal fluid. Several antibiotics and antiviral agents failed to prevent relapse. However, colchicine therapy successfully prevented the recurrence of meningitis. Genetic testing for familial Mediterranean fever (FMF) showed a mutation in the MEFV gene. It is difficult to diagnose the cause of Mollaret's meningitis in some patients. FMF, neuro-Behçet's disease, and neuro-Sweet disease should be included in the differential diagnosis of recurrent meningitis. In addition, colchicine therapy can prevent the relapse of meningitis in such cases.

Turkey .

**BACKGROUND:** Coagulation abnormalities have been reported in familial Mediterranean fever (FMF) patients with amyloidosis and nephrotic syndrome; but there is not enough data about the continuity of the thrombogenic activity in FMF patients in clinical remission. The purpose of this study was to assess thrombin activatable fibrinolysis inhibitor (TAFI) levels and its relationship with fibrinolytic activity and also evaluate relationships between mutations and clinical signs in attack-free patients without amyloidosis.

**METHODS:** Seventy-nine FMF patients and 40 healthy adults were included. The study group was divided into five groups as follows: first group, homozygote M694V; second group, homozygote M680I; third group, M694V in one allele, the other allele have other mutations or not; fourth group, other mutations; and fifth group, no mutation.

**RESULTS:** Serum TAFI levels were significantly increased in patients compared with healthy individuals ( $116.64 \pm 21.8$  vs.  $78.48 \pm 19.7$   $\mu\text{g/mL}$ ,  $p < 0.001$ ) and a positive correlation was detected between TAFI antigen level and erythrocyte sedimentation rate and C-reactive protein levels ( $r = 0.247$ ,  $p = 0.029$  and  $r = 0.252$ ,  $p = 0.032$ , respectively). Mean fibrinogen and TAFI levels were significantly higher in Group 1 than the other groups ( $p = 0.04$  and  $p = 0.001$ , respectively) and in Group 3 it was higher than Groups 2, 4 and 5 ( $p = 0.04$  and  $p = 0.001$ , respectively).

**CONCLUSIONS:** High level of TAFI antigen in attack-free period of FMF disease shows ongoing subclinical inflammation and hypercoagulability. Clinicians should be careful about thrombosis even in patients at clinical remission. Also, genetic tests must be considered to predict clinical outcome and to reduce complications of FMF disease.

Familial Mediterranean Fever (FMF) is a hereditary autoinflammatory disorder characterised by acute attacks of fever and serosal inflammation. FMF primarily affects Jewish, Armenian, Turkish, and Arab populations. The disease is accompanied by a marked decrease in quality of life due to the effects of attacks and subclinical inflammation in the attack-free periods. Untreated or inadequately treated patients run the risk of amyloidosis, which is an important cause of morbidity and mortality. In this review, the current information available on FMF is summarised.

Evaluation of arterial stiffness with plasma GGT levels and pulse wave velocity

measurement in patients with FMF.

Yılmaz F(1), Ulu S(1), Akıcı Ö(2), Ahsen A(1), Demir K(1), Yüksel Ş(1).

Author information:

(2)Department of Cardiology, Afyon Kocatepe University Faculty of Medicine, Afyonkarahisar, Turkey.

**OBJECTIVE:** Pulse wave velocity (PWV) is a non-invasive technique used to evaluate the arterial elasticity, which is an early indicator of atherosclerosis. Lately, gamma glutamyl transferase (GGT) is considered a determiner of arterial stiffness (AS). In this study, we aimed to evaluate the relationship between GGT levels and AS with PWV in patients with Familial Mediterranean fever (FMF).

**MATERIAL AND METHODS:** The study was conducted with 60 patients with FMF and 40 controls. Genetic analysis of the patients were performed. AS was assessed by PWV and, after the measurement of PWV, the presence of AS was determined.

**RESULTS:** Mean PWV values and AS frequency were significantly higher in patients with FMF compared with the control group ( $p<0.001$  and  $p=0.004$ , respectively). Mean GGT levels of FMF patients were higher than in the control group but the difference was not statistically different. In the correlation analysis, PWV and AS were positively correlated with FMF ( $r=0.349$ ,  $p<0.001$ ;  $r=0.435$ ,  $p<0.001$ , respectively). FMF duration and FMF were associated with GGT ( $r=0.300$ ,  $p=0.02$ ;  $r=0.199$ ,  $p=0.047$ , respectively).

**CONCLUSION:** Increased PWV values in FMF patients may indicate arterial stiffness. These patients may be followed closely with PWV as an early indicator of atherosclerosis. Therefore, the cardiovascular risk can be determined in the early stages of disease and it may be possible to take necessary precautions.

Author information:

(1)Department of Pediatrics, Hacettepe University Faculty of Medicine, , Ankara, Turkey.

**BACKGROUND:** Colchicine is the main treatment for familial Mediterranean fever (FMF). However, biological agents and other treatments are available for patients who are unable to receive optimal treatment.

**OBJECTIVE:** To develop outcome criteria that define response to treatment.

**METHODS:** Two rounds of Delphi exercise were followed by a consensus conference enabling the definition of the criteria to be employed. Data for patients with FMF responding and resistant to their treatment were obtained from the FMF Arthritis Vasculitis and Orphan disease Research in paediatric rheumatology (FAVOR) website. The suggested criteria were analysed and validated in this patient cohort. Sensitivity/specificity measures and the ability of the score to discriminate between patients with active and inactive disease via the best cut-off score were calculated by a receiver operating characteristic analysis.

**RESULTS:** Compliance with the maximum dose of the drug was considered essential for evaluation of the patients. Seven criteria were suggested in the consensus conference. The performance of each criterion, in differentiating between resistant and responsive patients, was tested. The final set of criteria was defined as at least 50% improvement in five of six criteria, without worsening in any one defined response to treatment with a very high sensitivity and specificity. The items of this FMF50 included: 1. Percentage change in the frequency of attacks with the treatment. 2. Percentage change in the duration of attacks with the treatment. 3. Patients/parents' global assessment of disease severity (10 cm visual analogue scale (VAS)). 4. Physicians' global assessment of

disease severity (10 cm VAS). 5. Percentage change in arthritis attacks with the treatment. 6. Percentage change in C-reactive protein, erythrocyte sedimentation rate or serum amyloid A level with the treatment.

CONCLUSIONS: The FMF50 produced is a user-friendly measurement tool to guide physicians and can be used in clinical trials.

Are MEFV mutations susceptibility factors in enthesitis-related arthritis patients in the eastern Mediterranean?

Gülhan B(1), Akkuş A, Özçakar L, Beşbaş N, Ozen S.

Author information:

(1)Hacettepe University, İhsan Doğramacı Children's Hospital, Department of Pediatric Nephrology and Rheumatology, Ankara, Turke. boragulhan@yahoo.comy.

OBJECTIVES: Enthesitis-related arthritis (ERA), is a complex genetic disease.

Although HLA-B27 is well established, it does not explain all the genetic load in ERA. Familial Mediterranean fever (FMF), caused by mutations in the MEFV gene, is a frequent autoinflammatory disorder in the eastern Mediterranean.

METHODS: We investigated the clinical and imaging features of 53 ERA patients, as well as the frequency of MEFV gene mutations in those who were HLA-B27 negative.

RESULTS: The mean age of the patients was  $13.3 \pm 2.2$  years and 49 were boys.

Peripheral arthritis was present in all and sacroileitis in 26 patients.

Ultrasonography showed enthesitis in 6 patients of the tendons, whereas these were assessed to be normal by physical examination. Forty patients (75.5%) were positive for HLA-B27. MEFV analysis was performed for patients who were HLA-B27 negative. One patient refused MEFV analysis. 9 patients carried MEFV mutations: 2 patients were homozygous for M694V (both patients were subsequently started colchicine along with ERA treatment), 5 patients were heterozygous for M694V mutation, 1 patient was heterozygous for E148Q, and 1 patient was heterozygous for K695R mutation. None of the patients had features suggesting FMF at diagnosis of ERA; 1 patient subsequently developed typical FMF attacks.

CONCLUSIONS: Our findings suggest that MEFV mutations may represent a

susceptibility factor for ERA in the populations of the eastern Mediterranean.

Vnitr Lek. 2014 Jan;60(1):17-9.

Familial Mediterranean fever (FMF) is the most prevalent genetically determined autoinflammatory disease. FMF significantly decreases the quality of life and limits life expectancy due to the development of amyloidosis in affected individuals. Prevalence of FMF is highest in the south-eastern Mediterraneans. In other parts of the world, its occurrence is often restricted to high-risk ethnic groups. In Central Europe, experience with FMF is scarce to none, as in the case of Slovakia, where no cases have been reported, so far. Herein we report the first five patients (3 adults and 2 children, 4 native Slovaks) in whom the diagnosis of FMF could be confirmed in Slovakia. Our experience demonstrates that FMF does occur in low-risk populations in Central Europe. Due to low prevalence and lack of experience, FMF diagnosis may be significantly delayed (4.5-30 years) and undiagnosed cases are to be expected in our population.

Familiar Mediterranean fever (FMF) is a well defined autosomal recessive disease occurring mostly in Mediterranean regions. Here we present the experience from one center from Czech Republic, where we follow 4 families with patients with genetically proven FMF. Three out of these 4 families cluster to one limited region in Moravia, in the heart of Europe, without any linkage to Mediterranean

origin. Furthermore, majority of these patients are heterozygots presenting with well defined typical clinical symptoms. Potential pseudodominant inheritance and/or epigenetic and environmental factors might influence clinical presentation of the disease.

IgG4-related disease (IgG4-RD) are a group of autoinflammatory diseases often presenting as tumor-like lesions because of their infiltrative or mass forming behavior. They are characterized by a typical histology consisting of storiform fibrosis, high numbers of infiltrating IgG4-positive plasma cells, obliterative phlebitis, and a moderate presence of eosinophilic cells. Serum IgG4 levels can be elevated. We present a case of a 57 year-old male patient with immobilizing lower back pain, fever, and night sweats. We diagnosed IgG4-related periaortitis using serum IgG4 levels, abdominal ultrasound, PET/CT, and histology. We successfully treated the patient with glucocorticoids (GC) and azathioprine. Periaortitis is a rare presentation of IgG4-RD and therefore noteworthy. It has to be considered in patients with a retroperitoneal mass.

Modified regimen of etanercept for tumor necrosis factor receptor associated periodic syndrome (TRAPS) like illness.

Dhanrajani A(1), Khubchandani RP.

Author information:

(1)Pediatric Rheumatology Clinic, Jaslok Hospital and Research Center, Mumbai, Maharashtra, India. Correspondence to: Dr RP Khubchandani, Consultant Pediatrician, Jaslok Hospital and Breach Candy Hospital, Mumbai, Maharashtra, India. rajukhubchandani@yahoo.co.in.

**BACKGROUND:** TRAPS, an autosomal dominant autoinflammatory disorder occurs due to mutations of the TNFRSF1A gene. Mutation negative TRAPS (TRAPS like illness) is also known. Anti TNF molecules (etanercept) is the mainstay of therapy.

**CASE CHARACTERISTICS:** A 11-year-old boy with a 5 year clinical profile indicative of a TRAPS like illness and with negative mutation studies is described. He has been followed up for nearly 2 years after starting etanercept.

**OUTCOME:** He had sustained response to etanercept which has subsequently been titrated (0.4 mg/kg subcutaneously every 23-24 days) to keep him symptom free.

**MESSAGE:** Mutation negative cases of TRAPS can be diagnosed with a high index of suspicion. Treatment with etanercept is expensive but possibly intervals between doses could be titrated to reduce cost.

Interleukin 6 blockade for hyperimmunoglobulin D and periodic fever syndrome.

Shendi HM(1), Devlin LA, Edgar JD.

Author information:

(1)From the Royal Victoria Hospital, Belfast, United Kingdom.

Hyperimmunoglobulin D and periodic fever syndrome (HIDS) is a rare, autoinflammatory condition caused by mutations in the mevalonate kinase gene. There is no standard treatment for HIDS, and randomized controlled trials are lacking. Corticosteroids, colchicine, nonsteroidal anti-inflammatory drugs, statins, and cyclosporine are of limited efficacy in controlling this condition. Recent case reports suggest that most patients respond to etanercept or anakinra. Interleukin 6 blockade in HIDS has not been described. We report the case of a 13-year-old girl with HIDS, who failed to respond to colchicine, corticosteroids, etanercept, and anakinra but was successfully treated with the anti-IL-6 monoclonal antibody, tocilizumab.

Clin Infect Dis. 2014 Jul 15;59(2):iii.

Autophagy. 2014 Jun;10(6):1141-2.

Patients with chronic granulomatous disease (CGD) have a mutated NADPH complex resulting in defective production of reactive oxygen species; these patients can develop severe colitis and are highly susceptible to invasive fungal infection. In NADPH oxidase-deficient mice, autophagy is defective but inflammasome activation is present despite lack of reactive oxygen species production. However, whether these processes are mutually regulated in CGD and whether defective autophagy is clinically relevant in patients with CGD is unknown. Here, we demonstrate that macrophages from CGD mice and blood monocytes from CGD patients display minimal recruitment of microtubule-associated protein 1 light chain 3 (LC3) to phagosomes. This defect in autophagy results in increased IL-1 $\beta$  release. Blocking IL-1 with the receptor antagonist (anakinra) decreases neutrophil recruitment and T helper 17 responses and protects CGD mice from colitis and also from invasive aspergillosis. In addition to decreased inflammasome activation, anakinra restored autophagy in CGD mice in vivo, with increased Aspergillus-induced LC3 recruitment and increased expression of autophagy genes. Anakinra also increased Aspergillus-induced LC3 recruitment from 23% to 51% ( $P < 0.01$ ) in vitro in monocytes from CGD patients. The clinical relevance of these findings was assessed by treating CGD patients who had severe colitis with IL-1 receptor blockade using anakinra. Anakinra treatment resulted in a rapid and sustained improvement in colitis. Thus, inflammation in CGD is due to IL-1-dependent mechanisms, such as decreased autophagy and increased inflammasome activation, which are linked pathological conditions in CGD that can be restored by IL-1 receptor blockade.

**OBJECTIVES:** To assess the presence, prevalence and clinical characteristics of primary headaches in pediatric patients with chronic rheumatic diseases such as juvenile idiopathic arthritis (JIA) and familial Mediterranean fever (FMF), and to analyze the common pathophysiological mechanisms.

**STUDY DESIGN:** In this noncontrolled, cross-sectional study, a semi-structured 53 item headache questionnaire was administered to subjects with FMF and JIA, and interviewed a total sample size of 601 patients younger than 16 years of age. The questionnaires were then analyzed according to the International Headache Society's diagnostic criteria.

**RESULTS:** Children with FMF (n=378) and JIA (n=223) were studied. Each group was then divided into two subgroups according to whether the subjects reported headache or not. 29.5% of subjects with FMF reported having migraine, 37.6% probable migraine and 32.9% tension type headache (TTH). In JIA group 28.2% were diagnosed with migraine; 41.2% with probable migraine and 30.6% with TTH. No significant difference was found between all subjects with (n=258) and without

(n=343) headache for variables such as living in a crowded family ( $p=0.95$ ), being the first child in the family ( $p=0.63$ ), academic achievement of the child ( $p=0.63$ ), high education level (higher than high school) of the mother ( $p=0.52$ ) and father ( $p=0.46$ ). The presence of systemic disease was reported not to be effecting the daily life at the time of evaluation by 90.2% of the children with headache and 91.0% of the children without headache ( $p=0.94$ ). 81.4% of the children reported their headaches were not aggravating with the exacerbation periods of their systemic disease. Family history of hypertension was reported higher by the subjects with headache (13.5% with headache and 4.0% without headache  $p=0.001$ ). Diabetes mellitus was also reported higher (5.8% with headache; 0.5% without headache;  $p=0.006$ ). Family history of headache was reported in 28.2% of the patients with headache whereas it was 17.4% of the patients without headache ( $p<0.001$ ). Family history of headache was reported in 28.2% of the FMF subjects with headache whereas it was 17.4% of the patients without headache ( $p<0.001$ ). For JIA patients a positive family history for headache was obtained in 25.9% of children with headache notably in migraineurs (81.8%).

**CONCLUSION:** Patients with JIA and FMF should be asked specifically about accompanying primary headaches particularly migraine headaches as they may be additional disabilities for these patients.

Anti-dsDNA antibodies as a classification criterion and a diagnostic marker for systemic lupus erythematosus: critical remarks.

Rekvig OP(1).

Author information:

(1)RNA and Molecular Pathology Research Group, Department of Medical Biology, Faculty of Health Sciences, University of Tromsø, Tromsø, Norway.

Antibodies to mammalian dsDNA have, for decades, been linked to systemic lupus erythematosus (SLE) and particularly to its most serious complication, lupus nephritis. This canonical view derives from studies on its strong association with disease. The dogma was particularly settled when the antibody was included in the classification criteria for SLE that developed during the 1970s, most prominently in the 1982 American College of Rheumatology (ACR), and recently in The Systemic Lupus International Collaborating Clinics (SLICC) classification criteria. There are several problems to be discussed before the anti-dsDNA antibody can be accepted without further distinction as a criterion to classify SLE. Old and contemporary knowledge make it clear that an anti-dsDNA antibody is not a unifying term. It embraces antibodies with a wide spectrum of fine molecular specificities, antibodies that are produced transiently in context of infections and persistently in the context of true autoimmunity, and also includes anti-dsDNA antibodies that have the potential to bind chromatin (accessible DNA structures) and not (specificity for DNA structures that are embedded in chromatin and therefore inaccessible for the antibodies). This critical review summarizes this knowledge and questions whether or not an anti-dsDNA antibody, as simply that, can be used to classify SLE.

Coexistence of two rare genetic disorders: Kartagener syndrome and familial Mediterranean fever.

Çetin D(1), Genç Çetin B, Şentürk T, Şahin Çildağ S, Yılmaz Akdam İ.

Author information:

(1)Division of Rheumatology, Department of Internal Medicine, Adnan Menderes University Faculty of Medicine , Aydın , Turkey.

Primary ciliary dyskinesia (PCD) is a rare disease, predominantly inherited as an autosomal recessive, with ciliary dysfunction leading to impaired mucociliary clearance, chronic airway infection and inflammation. Situs inversus totalis occurs in ~50 % of PCD patients and it is known as Kartagener syndrome. Familial Mediterranean fever (FMF) is an autosomal recessive disease characterized by recurrent attacks of fever and peritonitis, pleuritis, arthritis, or erysipelas-like skin disease. FMF is caused by mutations in the MEFV gene which is located on chromosome 16p13.3. p.M680I, p.M694 V, p.M694I, p.V726A on exon 10 and p.E148Q on exon 2 are the most common mutations among FMF patients and these constitute 85 % of all. Homozygosity of R202Q polymorphism is strongly associated with FMF. We would like to present a case of Kartagener syndrome accompanied by FMF with R202Q polymorphism. Our case is the first in the literature indicating the accidental coexistence of FMF and Kartagener syndrome.

Protracted febrile myalgia syndrome (PFMS) is a very rare but severe manifestation of familial Mediterranean fever (FMF) which is characterized by severe debilitating pain in large muscle groups that may last for several weeks. Colchicine is ineffective and treatment is largely supportive. Demonstration of crucial role of interleukin-1 (IL-1) in the pathogenesis of FMF has increased the use of IL-1 blockers in colchicine resistant or intolerant patients. Herein, we

reported successful use of an IL-1 inhibitor, anakinra, in treatment of two patients with PFMS.

Mevalonate kinase deficiency in two sisters with therapeutic response to anakinra: case report and review of the literature.

Campanilho-Marques R(1), Brogan PA.

Author information:

(1)Rheumatology Department, Lisbon Academic Medical Centre, Lisbon, Portugal, raquelpcmarques@gmail.com.

Mevalonate kinase deficiency (MKD) is a rare, hereditary autoinflammatory condition characterized by recurrent inflammatory episodes. Depending on the residual mevalonate kinase activity, the clinical spectrum ranges from a relatively mild periodic fever syndrome to a lethal metabolic disease. Data on therapeutic options for MKD are currently limited and rely generally on case reports and small series. Recent reports show promising results with anakinra and etanercept to treat the attacks. We report two sisters treated with good, but partial response, to continuous daily anakinra (interleukin-1 receptor antagonist).

Muckle-Wells syndrome (MWS) is a rare hereditary autoinflammatory disorder characterized by recurrent urticaria-like skin rashes, arthralgias, conjunctivitis, hypoacusia, and risk of reactive AA amyloidosis due to the progressive accumulation of amyloid fibrils in different organs. Its genetic defect lies in mutations in the NLRP3 gene, encoding the cryopyrin protein, and resulting in interleukin (IL)-1 $\beta$  oversecretion. Renal involvement, in terms of proteinuria or renal insufficiency, can be observed in up to 25% of patients. Herein, we describe our experience with two Caucasian patients, father and son, aged 52 and 26 years, respectively, heterozygous for both V198M and R260W NLRP3 mutations who had AA amyloid deposits on renal biopsy. The fully human monoclonal antibody canakinumab, providing selective and prolonged IL-1 $\beta$  blockade, was administered in both patients every 60 days over a period of 18 months. This treatment allowed to obtain amazing results: a rapid disappearance of any clinical symptoms, the stable normalization of serum amyloid-A and, furthermore,

a marked improvement of glomerular filtration rate and proteinuria with no adverse events. Our data, though limited to only two patients, emphasize that therapeutic intervention with canakinumab, suppressing both inflammation and IL-1 $\beta$ -mediated manifestations, can contribute to improve kidney function in MWS with overt renal amyloidosis.

Inflammasome, an intracellular inflammatory machinery, has been reported to be involved in a variety of chronic degenerative diseases such as atherosclerosis, autoinflammatory diseases and Alzheimer's disease. The present study hypothesized that the formation and activation of inflammasomes associated with apoptosis associated speck-like protein (ASC) are an important initiating mechanism resulting in obesity-associated podocyte injury and consequent glomerular sclerosis. To test this hypothesis, Asc gene knockout (Asc(-/-)), wild type (Asc(+/+)) and intrarenal Asc shRNA-transfected wild type (Asc shRNA) mice were fed a high fat diet (HFD) or normal diet (ND) for 12 weeks to produce obesity and associated glomerular injury. Western blot and RT-PCR analyses demonstrated that

renal tissue Asc expression was lacking in Asc(-/-) mice or substantially reduced in Asc shRNA transfected mice compared to Asc(+/+) mice. Confocal microscopic and co-immunoprecipitation analysis showed that the HFD enhanced the formation of inflammasome associated with Asc in podocytes as shown by colocalization of Asc with Nod-like receptor protein 3 (Nalp3). This inflammasome complex aggregation was not observed in Asc(-/-) and local Asc shRNA-transfected mice. The caspase-1 activity, IL-1 $\beta$  production and glomerular damage index (GDI) were also significantly attenuated in Asc(-/-) and Asc shRNA-transfected mice fed the HFD. This decreased GDI in Asc(-/-) and Asc shRNA transfected mice on the HFD was accompanied by attenuated proteinuria, albuminuria, foot process effacement of podocytes and loss of podocyte slit diaphragm molecules. In conclusion, activation and formation of inflammasomes in podocytes are importantly implicated in the development of obesity-associated glomerular injury.

International periodic fever, aphthous stomatitis, pharyngitis, cervical adenitis syndrome cohort: description of distinct phenotypes in 301 patients.

Hofer M, Pillet P, Cochard MM, Berg S, Krol P, Kone-Paut I, Rigante D, Hentgen V, Anton J, Brik R, Neven B, Touitou I, Kaiser D, Duquesne A, Wouters C, Gattorno M.

**OBJECTIVES:** The aims of this study were to describe the clinical features of periodic fever, aphthous stomatitis, pharyngitis and cervical adenitis (PFAPA) and identify distinct phenotypes in a large cohort of patients from different countries.

**METHODS:** We established a web-based multicentre cohort through an international collaboration within the periodic fevers working party of the Pediatric Rheumatology European Society (PReS). The inclusion criterion was a diagnosis of PFAPA given by an experienced paediatric rheumatologist participating in an international working group on periodic fever syndromes.

**RESULTS:** Of the 301 patients included from the 15 centres, 271 had pharyngitis,

236 cervical adenitis, 171 oral aphthosis and 132 with all three clinical features. A total of 228 patients presented with additional symptoms (131 gastrointestinal symptoms, 86 arthralgias and/or myalgias, 36 skin rashes, 8 neurological symptoms). Thirty-one patients had disease onset after 5 years and they reported more additional symptoms. A positive family history for recurrent fever or recurrent tonsillitis was found in 81 patients (26.9%). Genetic testing for monogenic periodic fever syndromes was performed on 111 patients, who reported fewer occurrences of oral aphthosis or additional symptoms. Twenty-four patients reported symptoms (oral aphthosis and malaise) outside the flares. The CRP was >50 mg/l in the majority (131/190) of the patients tested during the fever.

**CONCLUSION:** We describe the largest cohort of PFAPA patients presented so far. We confirm that PFAPA may present with varied clinical manifestations and we show the limitations of the commonly used diagnostic criteria. Based on detailed analysis of this cohort, a consensus definition of PFAPA with better-defined criteria should be proposed.

The risk of venous thromboembolism in patients with multiple sclerosis: the Clinical Practice Research Datalink.

Peeters PJ(1), Bazelier MT, Uitdehaag BM, Leufkens HG, De Bruin ML, de Vries F.

Author information:

(1)Utrecht Institute of Pharmaceutical Sciences, Utrecht University, Utrecht, The Netherlands.

**BACKGROUND:** In patients with multiple sclerosis (MS), disability and autoinflammatory processes may result in an increased risk of venous thromboembolism (VTE) **OBJECTIVE:** To evaluate the risk of VTE associated with MS. **METHODS:** We conducted an observational-cohort study within the Clinical Practice Research Datalink (1987-2009) linked to the National Registry of Hospitalizations (1997-2008). At the time of MS diagnosis, a comparison cohort (N = 33 370) without a recorded MS diagnosis during the study period was matched (6:1) to the

MS cohort (n = 5566) by birth year, sex, and practice. Subjects were followed from the index date until the occurrence of VTE, end of data collection, migration, or death, whichever came first. Cox proportional-hazards models were used to derive adjusted hazard ratios and 95% confidence intervals for VTE associated with MS and VTE risk factors within the MS cohort. Time-dependent adjustments were made for age, comorbidity, and medication use.

RESULTS: Compared with the comparison cohort, a 2.6-fold increased risk of VTE was observed for MS patients (adjusted hazard ratio 2.56, 95% confidence interval 2.06-3.20). A prior VTE event, varicose veins, obesity, and major trauma were found to be associated with an increased risk of VTE within the MS population. Moreover, the risk of VTE was increased in MS patients with recent records indicating immobility, spasticity, glucocorticoid use, or disability.

CONCLUSIONS: Patients with MS had an increased risk of VTE. Furthermore, our results provide evidence that this association is, at least in part, mediated through an increased prevalence of VTE risk factors in MS patients.

Genetics of proteasome diseases.

Gomes AV(1).

Author information:

(1)Department of Neurobiology, Physiology, and Behavior, University of California, Davis, CA 95616, USA ; Department of Physiology and Membrane Biology, University of California, Davis, CA 95616, USA.

The proteasome is a large, multiple subunit complex that is capable of degrading most intracellular proteins. Polymorphisms in proteasome subunits are associated with cardiovascular diseases, diabetes, neurological diseases, and cancer. One polymorphism in the proteasome gene PSMA6 (-8C/G) is associated with three different diseases: type 2 diabetes, myocardial infarction, and coronary artery

disease. One type of proteasome, the immunoproteasome, which contains inducible catalytic subunits, is adapted to generate peptides for antigen presentation. It has recently been shown that mutations and polymorphisms in the immunoproteasome catalytic subunit PSMB8 are associated with several inflammatory and autoinflammatory diseases including Nakajo-Nishimura syndrome, CANDLE syndrome, and intestinal M. tuberculosis infection. This comprehensive review describes the disease-related polymorphisms in proteasome genes associated with human diseases and the physiological modulation of proteasome function by these polymorphisms. Given the large number of subunits and the central importance of the proteasome in human physiology as well as the fast pace of detection of proteasome polymorphisms associated with human diseases, it is likely that other polymorphisms in proteasome genes associated with diseases will be detected in the near future. While disease-associated polymorphisms are now readily discovered, the challenge will be to use this genetic information for clinical benefit.

Quality of life measures and psychiatric symptoms in adolescents with systemic lupus erythematosus and familial Mediterranean fever.

Düzçeker Y, Kanbur NÖ, Demirkaya E, Derman O, Moorthy LN, Ozen S.

**PURPOSE:** To describe the relation between global Quality of Life (QL) and psychiatric symptoms in adolescents with systemic lupus erythematosus (SLE) and familial Mediterranean fever (FMF), and to analyze the perceptions of parents and adolescents.

**METHODS:** This study included 51 adolescents diagnosed with SLE (n=25) and FMF (n=26), and 51 healthy adolescents. The Health Related QL (HRQL) of SLE patients was rated by parents and adolescents using the Simple Measurement of Impact of Lupus Erythematosus in Youngsters© (SMILEY©). The global QL of FMF patients and healthy adolescents was rated by the response given to the first question of the SMILEY© by each parent and adolescent. All participants completed the Brief Symptom Inventory (BSI), which measures psychiatric symptoms.

**RESULTS:** In total, 92.3% with FMF, 56% with SLE and 76.5% of healthy adolescents reported their global QL as good and very good using the first question of the SMILEY©. The global QL perceptions of adolescents and their parents did not correlate (FMF,  $p=0.94$ ; SLE,  $p=0.16$ ). SLE patients had the highest rate of depression (54.2%), whereas hostility was detected among 54.9% of healthy adolescents. Significant relations were detected between BSI and SMILEY© scores.

**CONCLUSION:** The global QL perceptions of adolescents with FMF were better than those of healthy adolescents, which may be explained by their perceived relief of anguish they suffer during their short-lived attacks. The global QL perceptions of adolescents with SLE were the worst, most probably due to the chronic course resulting in an awareness of limitations and intense treatment. Adolescents with SLE had similar psychopathological symptom scores when compared with FMF patients and healthy adolescents. This could be explained by developing resilience. Differences in the perception of adolescents versus their parents regarding global QL emphasized the importance of adolescent-specific interviews for chronic illnesses and multidisciplinary follow-up with adolescent medicine.

Periodic fever in MVK deficiency: a patient initially diagnosed with incomplete Kawasaki disease.

Thors VS(1), Vastert SJ, Wulffraat N, van Royen A, Frenkel J, de Sain-van der Velden M, de Koning TJ.

Author information:

(1)Departments of General Pediatrics.

Mevalonate kinase deficiency (MKD) is a rare autosomal recessive disorder causing 1 of 2 phenotypes, hyperimmunoglobulin D syndrome and mevalonic aciduria, presenting with recurrent fever episodes, often starting in infancy, and sometimes evoked by stress or vaccinations. This autoinflammatory disease is caused by mutations encoding the mevalonate kinase (MVK) gene and is classified in the group of periodic fever syndromes. There is often a considerable delay in the diagnosis among pediatric patients with recurrent episodes of fever. We present a case of an 8-week-old girl with fever of unknown origin and a marked systemic inflammatory response. After excluding infections, a tentative diagnosis of incomplete Kawasaki syndrome was made, based on the finding of dilated coronary arteries on cardiac ultrasound and fever, and she was treated accordingly. However, the episodes of fever recurred, and alternative diagnoses were considered, which eventually led to the finding of increased excretion of mevalonic acid in urine. The diagnosis of MKD was confirmed by mutation analysis of the MVK gene. This case shows that the initial presentation of MKD can be indistinguishable from incomplete Kawasaki syndrome. When fever recurs in Kawasaki syndrome, other (auto-)inflammatory diseases must be ruled out to avoid inappropriate diagnostic procedures, ineffective interventions, and treatment

delay.

Familial mediterranean fever (FMF) is an autosomal recessive autoinflammatory disorder (MIM# 249100), particularly common in populations of Mediterranean extraction. MEFV gene, responsible for FMF, encoding pyrin has recently been mapped to chromosome 16p13.3. In the present study, 3,341 unrelated patients with the suspicion of FMF in south-east part of Turkey between the years 2009 and 2013 were enrolled and genomic sequences of exon 2 and exon 10 of the MEFV gene were scanned for mutations by direct sequencing. We identified 43 different type of mutations and 9 of them were novel. DNA was amplified by PCR and subjected to direct sequencing for the detection of MEFV gene mutations. Among the 3,341 patients, 1,598 (47.8 %) were males and 1,743 (52.1 %) were females. The mutations were heterozygous in 806 (62.3 %), compound heterozygous in 188 (14.5 %), homozygous in 281 (21.8 %) and mutations had complex genotype in 17 (1.32 %) patients. No mutation was detected in 2,051 (61.4 %) patients. The most frequent mutations were M694V, E148Q, M680I(G/C) and V726A. We could not find any significant differences between the two common mutations according to the gender. Molecular diagnosis of MEFV is a useful tool in clinical practice, thus a future study relating to genotype/phenotype correlation of FMF in more and larger group in Turkish population involving the whole MEFV gene mutations is necessary.

(7)AID-NET Autoinflammatory Disorders (AID) in Children: Genetics, Disease Mechanisms, Diagnostic Markers and Therapeutic Targets, Essen, Germany.

AIM: To determine the prevalence of anxiety and depression among patients with familial Mediterranean fever (FMF) living in Germany or Turkey a prospective study was conducted.

METHODS: Forty FMF patients living in Turkey (T), 40 FMF patients living in Germany (G) and 40 healthy controls living in Germany (C) were included. Patients and controls were of Turkish ancestry. G were compared to T and C. The Hospital Anxiety and Depression Scale (HADS) was used with a cut-off of  $\geq 8$  for each subdomain score (HADS-A, HADS-D).

RESULTS: Baseline characteristics of G were comparable to T and C except for age (T: 30.5 years, G: 35.2 years, C: 34.6 years; T vs. G  $P = 0.045$ ), duration of disease (T: 14.4 years, G: 24;  $P < 0.001$ ), C-reactive protein (T: 0.78 mg/dL, G: 0.78 mg/dL, C: 0.35 mg/dL; G vs. C  $P = 0.03$ ). Prevalence of anxiety was higher in G compared to C (T: 65%, G: 52.5%, C: 22.5%; G vs. C  $P < 0.05$ ). No difference was

found for the prevalence of depression (T: 30%, G: 35%, C: 20%). The association between FMF and anxiety in subjects living in Germany persisted after adjusting for age and gender in a regression analysis and was robust to an adjustment for coexisting depression. Anxiety and depression did not correlate with FMF disease severity assessed with the Pras score.

CONCLUSION: Anxiety, but not depression is more common among FMF patients living in Germany compared to healthy controls. No significant difference could be found between FMF patients living in Germany or Turkey concerning the prevalence of anxiety or depression.

SHARPIN is a key regulator of NFkB and integrin signaling. Mice lacking Sharpin develop a phenotype known as chronic proliferative dermatitis (CPDM), typified by progressive epidermal hyperplasia, apoptosis of keratinocytes, cutaneous and systemic eosinophilic inflammation, and hypoplasia of secondary lymphoid organs.

Rag1(-/-) mice, which lack mature B and T cells, were crossed with Sharpin(-/-) mice to examine the role of lymphocytes in CPDM. Although inflammation in the lungs, liver, and joints was reduced in these double mutant mice, dermatitis was not reduced in the absence of functional lymphocytes, suggesting that lymphocytes are not primary drivers of the inflammation in the skin. Type 2 cytokine expression is increased in CPDM. In an attempt to reduce this aspect of the phenotype, Il4ra(-/-) mice, unresponsive to both IL4 and IL13, were crossed with Sharpin(-/-) mice. Double homozygous Sharpin(-/-) , Il4ra(-/-) mice developed an exacerbated granulocytic dermatitis, acute system inflammation, as well as hepatic necrosis and mineralization. High expression of CHI3L4, normally seen in CPDM skin, was abolished in Sharpin(-/-) , Il4ra(-/-) double mutant mice indicating the crucial role of IL4 and IL13 in the expression of this protein. Cutaneous eosinophilia persisted in Sharpin(-/-) , Il4ra(-/-) mice, although expression of Il5 mRNA was reduced and the expression of Ccl11 and Ccl24 was completely abolished. TSLP and IL33 were both increased in the skin of Sharpin(-/-) mice and this was maintained in Sharpin(-/-) , Il4ra(-/-) mice suggesting a role for TSLP and IL33 in the eosinophilic dermatitis in SHARPIN-deficient mice. These studies indicate that cutaneous inflammation in SHARPIN-deficient mice is autoinflammatory in nature developing independently of B and T lymphocytes, while the systemic inflammation seen in CPDM has a strong lymphocyte-dependent component. Both the cutaneous and systemic inflammation is enhanced by loss of IL4 and IL13 signaling indicating that these cytokines normally play an anti-inflammatory role in SHARPIN-deficient mice.

Relapsing polychondritis is a rare and potentially fatal autoimmune disease of unknown etiology, characterized by inflammation and destruction of different cartilaginous structures, including the ear, nose, larynx, trachea, bronchi, peripheral joints, eye, heart and skin, with high risk of misdiagnosis. The spectrum of clinical presentations is protean and may vary from intermittent episodes of painful and disfiguring auricular and nasal chondritis or polyarthritis to severe progressive multi-organ damage. A laryngotracheobronchial involvement appears in nearly half of patients and is complicated by local obstructions, which may be life-threatening. A highly medical specialized approach is required for diagnosis of relapsing polychondritis. This review comprehensively examines the literature related to the clinical sceneries of the disease and focuses on both diagnostic tools used in clinical studies and recent findings related to its etiopathogenesis.

In recent years, it has become increasingly clear that the term Juvenile Idiopathic Arthritis (JIA) comprises not one disease but several. Moreover, recent studies strongly suggest that some of these clinico-pathophysiologic entities appear to cross current diagnostic categories. The ultimate goal of the JIA classification is to facilitate development of better, more specific therapy for different forms of disease through improved understanding of pathophysiology. The past two decades have witnessed significant advances in treatment and improved outcomes for many children with chronic arthritis. However, understanding of the basic biologic processes underlying these diseases remains far from complete. As a result, even the best biologic agents of today represent "halfway technologies". Because they do not treat fundamental biologic processes, they are inherently expensive, need to be given for a long time in order to ameliorate the adverse effects of chronic inflammation, and do not cure the disease. Pediatric rheumatology is now entering an era in which diagnostic categories may need to change to keep up with discovery. A more precise, biologically based classification is likely to contribute to development of more specific and improved treatments for the various forms of childhood arthritis. In this review, we discuss how genetic, gene expression, and immunologic findings have begun to influence how these diseases are understood and classified.

The coexistence of rheumatoid arthritis (RA) and familial Mediterranean fever (FMF) has been rarely seen in case reports in the literature. Herein, we wanted to present a patient who had been followed up and treated as RA, but on investigation we concluded that he really had FMF and its joint complaints associated with sacroiliitis. Recovery was achieved by etanercept administered as if he was an RA patient.

Autoinflammatory diseases.

Rubartelli A(1).

Author information:

(1)Cell Biology Unit, IRCCS AOU San Martino IST, 16132 Genova, Italy. Electronic address: anna.rubartelli@hsanmartino.it.

Autoinflammatory diseases represent an expanding spectrum of genetic and non-genetic inflammatory diseases characterized by recurrent episodes of fever and systemic inflammation affecting the eyes, joints, skin, and serosal surfaces. Thus, these syndromes are recognized as disorders of innate immunity. Confirming this view, most autoinflammatory diseases are uniquely responsive to IL-1 $\beta$  blockade. Although many autoinflammatory diseases have a genetic cause,

increasing evidence indicates that the degree of cell stress concurs to the severity of the disease phenotype. In this mini-review, I will discuss the recent advances on pathogenesis, pathophysiology and therapeutic approaches in autoinflammatory syndromes.

Cytokine networking of innate immunity cells: a potential target of therapy.

Striz I, Brabcova E(1), Kolesar L(1), Sekerkova A(1).

Author information:

(1)\*Department of Clinical and Transplant Immunology, Institute for Clinical and Experimental Medicine, Videnska 1958/9 Prague, Czech Republic.

Innate immune cells, particularly macrophages and epithelial cells, play a key role in multiple layers of immune responses. Alarmins and pro-inflammatory cytokines from the IL (interleukin)-1 and TNF (tumour necrosis factor) families initiate the cascade of events by inducing chemokine release from bystander cells and by the up-regulation of adhesion molecules required for transendothelial trafficking of immune cells. Furthermore, innate cytokines produced by dendritic cells, macrophages, epithelial cells and innate lymphoid cells seem to play a critical role in polarization of helper T-cell cytokine profiles into specific subsets of Th1/Th2/Th17 effector cells or regulatory T-cells. Lastly, the innate immune system down-regulates effector mechanisms and restores homeostasis in injured tissue via cytokines from the IL-10 and TGF (transforming growth factor) families mainly released from macrophages, preferentially the M2 subset, which have a capacity to induce regulatory T-cells, inhibit the production of pro-inflammatory cytokines and induce healing of the tissue by regulating extracellular matrix protein deposition and angiogenesis. Cytokines produced by innate immune cells represent an attractive target for therapeutic intervention, and multiple molecules are currently being tested clinically in patients with inflammatory bowel disease, rheumatoid arthritis, systemic diseases,

autoinflammatory syndromes, fibrosing processes or malignancies. In addition to the already widely used blockers of TNF $\alpha$  and the tested inhibitors of IL-1 and IL-6, multiple therapeutic molecules are currently in clinical trials targeting TNF-related molecules [APRIL (a proliferation-inducing ligand) and BAFF (B-cell-activating factor belonging to the TNF family)], chemokine receptors, IL-17, TGF $\beta$  and other cytokines.

Increased Notch pathway activation in Behçet's disease.

Qi J(1), Yang Y, Hou S, Qiao Y, Wang Q, Yu H, Zhang Q, Cai T, Kijlstra A, Yang P.

Author information:

(1)First Affiliated Hospital of Chongqing Medical University, Chongqing Key Laboratory of Ophthalmology, and Chongqing Eye Institute, Chongqing 400016, China. peizengycmu@126.com.

**OBJECTIVE:** Behçet's disease (BD) is a refractory inflammatory disorder with unknown causes. Since the Notch pathway is critically involved in the immune response, the present study was undertaken to investigate the role of this pathway in BD.

**METHODS:** Hes-1, Notch 1-4, Jagged-1, DLL-1 and DLL-4 expression, frequency of IFN- $\gamma$  and IL-17 expressing Th cells, Notch intracellular domain (NICD), phosphorylation of signal transducer and activator of transcription 3 (STAT3) and the production of IFN- $\gamma$  and IL-17 were examined by real-time PCR, flow cytometry and ELISA. Notch blockade was performed using the  $\gamma$ -secretase inhibitor N-[N-(3,5-difluorophenacetyl)-1-alanyl]-S-phenylglycine t-butyl ester (DAPT). Transfection with miR-23b mimics and inhibitor was used to examine the effect of miR-23b on Notch pathway activation.

**RESULTS:** Active BD patients showed an increased activation of the Notch pathway in association with a higher Th17 response. Notch blockade preferentially inhibited Th17 responses. The effect of Notch blockade on the Th17 response was associated with a lower level of STAT3 phosphorylation. miR-23b was significantly

decreased in CD4(+) T cells from active BD patients. CD4(+) T cells transfected with miR-23b showed a reduced expression of NICD and a reduced frequency of IL-17- and IFN- $\gamma$ -expressing T cells.

**CONCLUSION:** The present study suggests that an increased activation of the Notch pathway may contribute to the pathogenesis of BD. Decreased expression of miR-23b may be involved in activation of the Notch pathway in BD. Manipulation of the Notch pathway may offer a novel therapeutic approach for BD.

Early-onset sarcoidosis caused by a rare CARD15/NOD2 de novo mutation and responsive to infliximab: a case report with long-term follow-up and review of the literature.

La Torre F(1), Lapadula G, Cantarini L, Lucherini OM, Iannone F.

Author information:

(1)Department of Pediatrics, Antonio Perrino Hospital, Brindisi, Italy, latorre\_francesco@virgilio.it.

Granulomatous autoinflammatory diseases are monogenic syndromes caused by mutations in the region encoding for the nucleotide-binding domain region of the NOD2/CARD15 gene with subsequent dysregulation of the inflammatory response and formation of noncaseous granulomas. They include Blau syndrome (BS) and early-onset sarcoidosis (EOS); both are clinically and genetically indistinguishable between them and they are the familial (autosomal dominantly inherited) and sporadic forms of the same disease, respectively. We describe a case of EOS, misdiagnosed for 30 years such as "juvenile rheumatoid arthritis" before and "classic sarcoidosis" later. In our patient, we found a new de novo mutation (E383G) in NOD2 that has been reported only in a family of Japanese patients with BS. After long-term follow-up (42 months), infliximab maintained good efficacy and safety without any sign of disease relapse and side effects.

**AIM:** Familial Mediterranean fever (FMF) is an autosomal recessive autoinflammatory disease characterised by recurrent episodes of fever and polyserositis. To date, insufficient data regarding the prevalence of functional gastrointestinal disorders such as irritable bowel syndrome (IBS) and functional dyspepsia (FD) have been reported in patients with FMF. This study aimed to determine the prevalence of functional gastrointestinal disorders in patients with FMF.

**METHODS:** This study included 122 patients with FMF and a control group of 122 healthy volunteers who were similar with respect to age and sex. Clinical data were collected and gastrointestinal complaints were evaluated according to the Rome III criteria.

**RESULTS:** IBS was found in 18% of the patients and 10.7% of the controls ( $P > 0.05$ ). Dyspepsia was reported in 37.7% of the patients and 35.2% of the

controls. Constipation was significantly higher in the control group (15.6% vs. 7.4%,  $P = 0.045$ ), whereas diarrhoea was reported significantly more often in patients with FMF ( $P = 0.001$ ).

CONCLUSIONS: IBS and dyspepsia were not increased in patients with FMF, whereas diarrhoea was more frequently reported.

MEFV gene mutations and cardiac phenotype in children with familial Mediterranean fever: a cohort study.

Salah S, Hegazy R(1), Ammar R, Sheba H, Abdelrahman L.

Author information:

(1)Department of Pediatrics, Faculty of Medicine, Cairo University, Giza, Egypt.  
r\_hegazy@hotmail.com.

**BACKGROUND:** Familial Mediterranean fever (FMF) is the most common autoinflammatory disorder in the world. It is characterized by recurrent febrile inflammatory attacks of serosal and synovial membranes. MEFV gene mutations are responsible for the disease and its protein product, pyrin or marenostrin, plays an essential role in the regulation of the inflammatory reactions. Although the disease may carry a potential for cardiovascular disorders because of sustained inflammation during its course, the spectrum of cardiac involvement in children with FMF has not been well studied. We aimed at defining the frequency and spectrum of cardiac affection in children with FMF. The correlation between these affections and MEFV gene mutations was searched for to establish the relationship between cardiac phenotype and the patient's genotype in FMF.

**METHODS:** The present work is a cohort study including 55 patients with the clinical diagnosis of FMF based on the Tel-Hashomere criteria, confirmed by genetic analysis showing homozygous or compound heterozygous mutation of MEFV genes. Fifty age- and sex-matched normal children were included as controls. The

entire study group underwent detailed cardiac examination, 12-lead ECG and echocardiography. All data was statistically analysed using SPSS version-15.

RESULTS: Patients had an average age of 8.5+/-4.2 years; with an average disease duration of 2.1+/-2.2 years; 28 were males. All controls showed no MEVF gene mutations. The most frequent gene mutation of the studied cases was E148Q mutation seen in 34% of cases and the most frequent compound mutation was E148Q/V726A seen in 16.6% of cases. Echocardiographic examination revealed pericardial effusion in nine patients. Twelve had aortic regurgitation; nine had mitral regurgitation and six had pulmonary regurgitation. The most common mutation associated with pericardial effusion was E148Q/V726A in 5/9 of cases. Valvular involvement were significantly more common in FMF patients with gene mutations. Also cardiac involvement was more common in patients with positive consanguinity. However, these cardiac manifestations showed no correlation to age, family history of FMF, or response to therapy or laboratory data.

CONCLUSIONS: In our cohort of children with FMF, cardiac involvement appears to be common. Pericardial effusions are significantly related to presence of mutation types E48Q, P 369S, V726A. These associations may warrant genetic screening of children with FMF to detect cardiac risk.

Brief Report: whole-exome sequencing revealing somatic NLRP3 mosaicism in a patient with chronic infantile neurologic, cutaneous, articular syndrome.

Omoyinmi E(1), Melo Gomes S, Standing A, Rowczenio DM, Eleftheriou D, Klein N, Aróstegui JI, Lachmann HJ, Hawkins PN, Brogan PA.

Author information:

(1)University College London, London, UK.

OBJECTIVE: To identify the genetic cause of chronic infantile neurologic, cutaneous, articular syndrome (CINCA syndrome) using whole-exome sequencing in a child who had typical clinical features but who was NLRP3 mutation negative based on conventional Sanger sequencing.

**METHODS:** We performed whole-exome sequencing on DNA from peripheral blood, using Illumina TruSeq Exome capture and the HiSeq sequencing platform. Exome data were analyzed in the Galaxy Web-based suite. Whole-exome sequencing findings were confirmed by massively parallel sequencing.

**RESULTS:** Analysis of variants in known autoinflammatory genes led to the identification of the pathogenic p.F556L NLRP3 missense mutation in 17.7% of Illumina reads (25 of 141). No new candidate genes were identified. Massively parallel sequencing of DNA from peripheral blood (performed in duplicate) unequivocally confirmed the presence of this mutation in 14.5% of alleles. Reexamination of the original Sanger chromatograms revealed a small peak at nucleotide position c.1698 corresponding to the mutated allele. This had initially been regarded as background noise, but in retrospect is completely consistent with somatic mosaicism for the p.F556L NLRP3 mutation in this child with CINCA syndrome.

**CONCLUSION:** This is the first description of somatic NLRP3 mosaicism detected using whole-exome sequencing in a "mutation-negative" patient with CINCA syndrome. Our findings suggest that whole-exome sequencing could be an important diagnostic tool for detecting somatic mosaicism, as well as for the discovery of novel causative gene mutations, in patients with clinical features of cryopyrin-associated periodic syndromes who are NLRP3 mutation negative by conventional sequencing. This approach could also be applicable to patients with other autosomal-dominant autoinflammatory diseases characterized by gain-of-function mutations who are mutation negative by conventional Sanger sequencing.

Preliminary evidence demonstrating that adding 0.5 mg of colchicine per day to statin and antiplatelet therapy reduced the risk of acute coronary events in patients with stable coronary artery disease has raised the hope that it may prove effective for the long-term secondary prevention of cardiovascular disease. The ability of colchicine to suppress blood levels of inflammatory mediators and prevent cholesterol-crystal-induced neutrophil-mediated inflammation implicated in the progression and instability of atherosclerosis adds plausibility to this clinical observation. Early intestinal intolerance in some patients is well recognized, but clinical experience gained over more than half a century with the continuous use of colchicine for the prevention of neutrophil-mediated inflammation in patients with familial Mediterranean fever and gout indicates that low-dose long-term therapy is safe. Nonetheless, before colchicine can be recommended for the secondary prevention of cardiovascular disease, further studies are required to confirm its safety and efficacy in a broad range of patients with coronary disease, and to determine whether doses of colchicine less

than 0.5 mg/day might be effective and even better tolerated. Trials exploring the role of colchicine in the treatment of patients with acute coronary syndromes would also be of special interest but may require the use of doses higher than those used for long-term secondary prevention.

Familial Mediterranean fever (FMF) is the most prevalent monogenic autoinflammatory disease, mainly affecting ethnic groups living at Mediterranean basin. FMF is characterized by recurrent, self-limited episodes of fever and serositis. The diagnosis is difficult in the presence of atypical signs, which may result in significant delay in initiating treatment. As autoinflammatory diseases may have overlapping symptoms, strict diagnostic criteria are essential. Since the discovery that mutations in the gene MEFV underlie FMF, molecular genetic testing has been used as a diagnostic adjunct, especially in atypical cases. However, despite progress in the understanding of FMF disease mechanisms during the past 15 years; the diagnosis is still based on clinical criteria. Several sets of diagnostic criteria have been proposed and used. Existing diagnostic criteria should be modified to include genetic data, and need to be more widely validated.

IL-1 blockade in autoinflammatory syndromes.

Jesus AA(1), Goldbach-Mansky R.

Author information:

(1)Translational Autoinflammatory Disease Section, National Institute of Arthritis, Musculoskeletal and Skin Diseases (NIAMS), National Institutes of Health, Bethesda, Maryland 20982; email: goldbacr@mail.nih.gov.

Monogenic autoinflammatory syndromes present with excessive systemic inflammation including fever, rashes, arthritis, and organ-specific inflammation and are caused by defects in single genes encoding proteins that regulate innate inflammatory pathways. Pathogenic variants in two interleukin-1 (IL-1)-regulating genes, NLRP3 and IL1RN, cause two severe and early-onset autoinflammatory syndromes, CAPS (cryopyrin associated periodic syndromes) and DIRA (deficiency of IL-1 receptor antagonist). The discovery of the mutations that cause CAPS and DIRA led to clinical and basic research that uncovered the key role of IL-1 in an extended spectrum of immune dysregulatory conditions. NLRP3 encodes cryopyrin, an intracellular "molecular sensor" that forms a multimolecular platform, the NLRP3 inflammasome, which links "danger recognition" to the activation of the proinflammatory cytokine IL-1 $\beta$ . The success and safety profile of drugs targeting IL-1 in the treatment of CAPS and DIRA have encouraged their wider use in other autoinflammatory syndromes including the classic hereditary periodic fever syndromes (familial Mediterranean fever, TNF receptor-associated periodic syndrome, and hyperimmunoglobulinemia D with periodic fever syndrome) and additional immune dysregulatory conditions that are not genetically well defined, including Still's, Behcet's, and Schnitzler diseases. The fact that the accumulation of metabolic substrates such as monosodium urate, ceramide, cholesterol, and glucose can trigger the NLRP3 inflammasome connects metabolic stress to IL-1 $\beta$ -mediated inflammation and provides a rationale for therapeutically targeting IL-1 in prevalent diseases such as gout, diabetes mellitus, and coronary artery disease.

Blood. 2014 Apr 24;123(17):2597-9.

PSTPIP1 is a cytoskeletal adaptor and F-BAR protein that has been implicated in autoinflammatory disease, most notably in the PAPA syndrome: pyogenic sterile arthritis, pyoderma gangrenosum, and acne. However, the mechanism by which PSTPIP1 regulates the actin cytoskeleton and contributes to disease pathogenesis remains elusive. Here, we show that endogenous PSTPIP1 negatively regulates macrophage podosome organization and matrix degradation. We identify a novel PSTPIP1-R405C mutation in a patient presenting with aggressive pyoderma gangrenosum. Identification of this mutation reveals that PSTPIP1 regulates the balance of podosomes and filopodia in macrophages. The PSTPIP1-R405C mutation is in the SRC homology 3 (SH3) domain and impairs Wiskott-Aldrich syndrome protein (WASP) binding, but it does not affect interaction with protein-tyrosine phosphatase (PTP)-PEST. Accordingly, WASP inhibition reverses the elevated F-actin content, filopodia formation, and matrix degradation induced by PSTPIP1-R405C. Our results uncover a novel role for PSTPIP1 and WASP in orchestrating different types of actin-based protrusions. Our findings implicate the cytoskeletal regulatory functions of PSTPIP1 in the pathogenesis of pyoderma gangrenosum and suggest that the cytoskeleton is a rational target for therapeutic intervention in autoinflammatory disease.

Interleukins (IL)-17A and -22 are involved in the patho-genesis of psoriasis. Cathelicidin LL37 serves as not only antimicrobial peptide but also as autoinflammatory mediator. 1,25-Dihydroxyvitamin D3 analogues, such as calcipotriol, are used as topical treatment for psoriasis. However, the effect of calcipotriol on the mRNA expression/production of human cathelicidin antimicrobial protein (hCAP18) and LL37 peptide by IL-17A/IL-22-stimulated keratinocytes remains controversial. To evaluate the modulatory action of calcipotriol on the production of hCAP18 and LL37, we analysed hCAP18 mRNA expression and hCAP18/LL37 peptide production in IL-17A/IL-22-stimulated cultured human keratinocytes by real-time qPCR, ELISA, western blotting, and immunocytochemical staining. By western blotting, hCAP18 protein was detected in keratinocytes cultured for 72 h with IL-17/IL-22. Calcipotriol increased hCAP18 mRNA expression in IL-17/IL-22-stimulated keratinocytes. However, LL37 peptide in the culture supernatants was reduced by calcipotriol. Immunostaining revealed that the overproduced LL37 resides within the cells. LL37 promotes psoriasis via interaction with extracellular DNA, but may suppress psoriasis by interfering cytosolic DNA.

Decreased vitamin D levels in children with familial Mediterranean fever.

Anık A(1), Catlı G, Makay B, Abacı A, Küme T, Unsal E, Böber E.

Author information:

(1)Department of Pediatric Endocrinology, Dokuz Eylul University Hospital, Izmir, Turkey.

**OBJECTIVES:** To determine the frequency of vitamin D deficiency in children with familial Mediterranean fever (FMF) and to investigate the factors associated with low vitamin D status.

**DESIGN AND METHODS:** Forty-four patients with FMF and 39 age- and sex-matched healthy controls were enrolled in this study. Demographic data, FMF symptoms, disease duration, time to delay for diagnosis, duration of follow-up, disease severity score, MEFV gene mutation, cumulative colchicine dose, compliance to treatment and serum C-reactive protein levels were recorded for each patient. Serum 25-hydroxyvitamin D levels were measured by an original commercial kit based on chemiluminescent microparticle immunoassay (CMIA).

**RESULTS:** The serum 25-hydroxyvitamin D levels were significantly lower in FMF patients than the healthy controls ( $12.9 \pm 3.6$  and  $16.3 \pm 5.5$  ng/mL, respectively,  $P = 0.001$ ). Vitamin D levels were similar in patients homozygous for M694V and other genotypes ( $11.8 \pm 3.7$  and  $13.2 \pm 3.6$  ng/mL, respectively,  $P = 0.21$ ). Stepwise multiple linear regression analysis confirmed that the cumulative colchicine dose was the strongest independent variable correlating with vitamin D levels ( $r(2) = 0.194$ ,  $P = 0.001$ ).

**CONCLUSION:** Our results suggest that serum 25-hydroxyvitamin D levels are decreased in children with FMF. Cumulative colchicine dose appears to negatively affect vitamin D levels. The role of colchicine on vitamin D metabolism needs to be elicited.

Absence of autoantibodies against oral and vascular-related cell lines in the sera of patients with Behcet's disease.

Ataollahi M(1), Gharesi-Fard B(1), Aflaki E(2).

Author information:

(1)Immunology Department, Center of Shiraz University of Medical Sciences, Iran.

(2)Rheumatology Department, Center of Shiraz University of Medical Sciences. Iran.

**BACKGROUND:** Behcet's disease (BD) is an autoinflammatory disease with unclear pathogenesis. The oral and vascular tissue are the main target organs in BD. The role of humoral immunity in pathogenesis of oral and vascular lesions in BD patients has not been well studied. Therefore, the aim of this study was to investigate the presence of autoantibodies in the sera of BD patients using oral and vascular tissue related cell lines.

**METHODS:** Proteins from oral (KB, HGF-1) and vascular (HUVEC) related cell lines as well as C2C12 (a muscle myoblast cell line) were extracted as representatives of oral and vascular tissue antigens and the presence of autoantibodies in BD's sera were investigated using high throughput two dimensional electrophoresis (2DE) and immunoblotting techniques. Sera of other autoimmune diseases (RA and SLE) and normal individuals were used as controls.

**RESULTS:** After silver staining of 2DE gels, 2831, 2195, 1732, and 1839 spots were detectable in the proteome map of HUVEC, KB, HGF-1, and C2C12 cell lines, respectively. The majority of spots were in the pH range of 5 - 8 and the molecular weight range of 14 - 66 Kd. The immunoreactivity of BD, RA, SLE, and normal sera were not different with separated proteins of the cell lines.

**CONCLUSIONS:** According to our results, it seems that humoral immunity is not significantly involved in BD pathogenesis. Therefore, investigation of the role of cellular immunity, especially TH1 and TH17 cells and their cytokine profiles, in the pathogenesis of BD is recommended for future studies.

Colchicine-free remission in familial Mediterranean fever: featuring a unique subset of the disease-a case control study.

Ben-Zvi I(1), Krichely-Vachdi T, Feld O, Lidar M, Kivity S, Livneh A.

Author information:

(1)Department of Medicine F and the Rheumatology unit, Sheba Medical Center, Tel-Hashomer, Israel. Ilan.Benzvi@sheba.health.gov.il.

**BACKGROUND:** To demonstrate and clinically, genetically and demographically characterize familial Mediterranean fever (FMF) patients, maintaining remission despite colchicine abstinence.

**METHODS:** FMF patients were screened for an endurance of prolonged remission ( $\geq 3$  years), despite refraining from colchicine. Clinical, demographic and genetic parameters were collected. Data were compared with those of consecutive control FMF subjects, coming to the clinic for their periodic follow up examination.

**RESULTS:** Of 1000 patients screened over 5 years, 33 manifested colchicine-free remission. The mean duration of the remission period was  $12.6 \pm 8.1$  years.

Patients in the remission group had milder severity of FMF, compared to the control group (22 vs. 11 patients with mild disease, respectively,  $p=0.003$ ) and a longer diagnosis delay ( $21 \pm 15.7$  vs.  $13.4 \pm 13.5$  years, respectively,  $p=0.04$ ).

Patients experiencing remission suffered mostly of abdominal attacks, low rate of attacks in other sites and low rate of chronic and non-attack manifestations.

When the disease resumed activity, it responded well to colchicine, despite using a lower dose, as compared to the control subjects ( $p<0.001$ ). None of the patients in this group was homozygous for the M694V mutation ( $p=0.0008$ ).

**CONCLUSIONS:** Prolonged colchicine-free remission defines a rare and milder form of FMF with unique clinical, demographic, and molecular characteristics.

Chronic recurrent multifocal osteomyelitis (CRMO) is a human autoinflammatory

disorder that primarily affects bone. Missense mutation (L98P) of proline-serine-threonine phosphatase-interacting protein 2 (Pstpip2) in mice leads to a disease that is phenotypically similar to CRMO called chronic multifocal osteomyelitis (cmo). Here we show that deficiency of IL-1RI in cmo mice resulted in a significant reduction in the time to onset of disease as well as the degree of bone pathology. Additionally, the proinflammatory cytokine IL-1 $\beta$ , but not IL-1 $\alpha$ , played a critical role in the pathology observed in cmo mice. In contrast, disease in cmo mice was found to be independent of the nucleotide-binding domain, leucine-rich repeat-containing family, pyrin domain-containing 3 (NLRP3) inflammasome as well as caspase-1. Neutrophils, but not bone marrow-derived macrophages, from cmo mice secreted increased IL-1 $\beta$  in response to ATP, silica, and *Pseudomonas aeruginosa* compared with neutrophils from WT mice. This aberrant neutrophil response was sensitive to inhibition by serine protease inhibitors. These results demonstrate an inflammasome-independent role for IL-1 $\beta$  in disease progression of cmo and implicate neutrophils and neutrophil serine proteases in disease pathogenesis. These data provide a rationale for directly targeting IL-1RI or IL-1 $\beta$  as a therapeutic strategy in CRMO.

Critical role for inflammasome-independent IL-1 $\beta$  production in osteomyelitis.

Lukens JR(1), Gross JM, Calabrese C, Iwakura Y, Lamkanfi M, Vogel P, Kanneganti TD.

Author information:

(1)Department of Immunology, Small Animal Imaging Core, and Animal Resources Center and the Veterinary Pathology Core, St. Jude Children's Research Hospital, Memphis, TN 38105.

The immune system plays an important role in the pathophysiology of many acute and chronic bone disorders, but the specific inflammatory networks that regulate

individual bone disorders remain to be elucidated. Here, we characterized the osteoimmunological underpinnings of osteolytic bone disease in *Pstpip2(cmo)* mice. These mice carry a homozygous L98P missense mutation in the Pombe Cdc15 homology family phosphatase PSTPIP2 that is responsible for the development of a persistent autoinflammatory disease resembling chronic recurrent multifocal osteomyelitis in humans. We found that improper regulation of IL-1 $\beta$  production resulted in secondary induction of inflammatory cytokines, inflammatory cell infiltration in the bone, and unremitting bone inflammation. Aberrant IL1 $\beta$  expression precedes the development of osteolytic damage in young *Pstpip2(cmo)* mice, and genetic deletion of *Il1r* and *Il1 $\beta$* , but not *Il1 $\alpha$* , rescued osteolytic bone disease in mutant mice. Intriguingly, caspase-1 and nucleotide-binding oligomerization domain (NOD)-like receptor family, pyrin domain containing 3 activation in the inflammasome complex were dispensable for *Pstpip2(cmo)*-mediated bone disease. Thus, our findings establish a critical role for inflammasome-independent production of IL-1 $\beta$  in osteolytic bone disease and identify PSTPIP2 as a negative regulator of caspase-1-autonomous IL-1 $\beta$  production.

**OBJECTIVE:** To analyze the clinical manifestations and response to treatment in a cohort of adult patients presenting with recurrent inflammatory attacks and carrying low-penetrance TNFRSF1A variants, as well as to provide data on their long-term follow-up.

**METHODS:** We performed a retrospective chart review of 36 patients carrying low-penetrance TNFRSF1A variants. Moreover, 60 genetically negative patients treated for recurrent inflammatory attacks and 13 patients with structural TNFRSF1A mutations were also analyzed. Detailed demographic and clinical data were collected at the time of molecular screening and at each follow-up visit. Treatments and markers of inflammation were also assessed.

**RESULTS:** Individuals with low-penetrance TNFRSF1A variants have a lower family history for inflammatory attacks and present with a later disease onset compared with patients with structural mutations, but do not differ, in this respect, with genetically negative individuals. Moreover, low-penetrance variants are less frequently associated with a chronic disease course, with clinical manifestations such as abdominal pain and myalgia, and with amyloidosis. A distinctive clinical feature is a higher rate of pericarditis. Interestingly, mutation-negative patients were found to present with a significant history of recurrent pharyngitis during childhood. Patients with low-penetrance variants are mostly managed with short courses of steroids or non-steroidal anti-inflammatory drugs on attacks. Although the need for a biological treatment is significantly lower compared with patients with structural mutations, still approximately 20% of individuals with recurrent inflammatory attacks carrying low-penetrance variants ultimately require these therapies.

**CONCLUSIONS:** Our study confirms that low-penetrance TNFRSF1A variants can be associated with an autoinflammatory phenotype. Although a chronic disease course is rarely observed, some patients ultimately benefit from a biological treatment.

Author information:

(1)Department of Pulmonary Medicine and Clinical Immunology, Dokkyo University School of Medicine, Tochigi, Japan.

Familial Mediterranean fever (FMF) is characterized by repeated episodes of fever, peritonitis, pleuritis, and synovitis. We describe here 3 Japanese patients (a mother and 2 children) in whom FMF was diagnosed on analysis of MEFV. A 40-year-old woman presented with fever and abdominal pain. The patient had had these symptoms on and off since childhood and consulted many hospitals. A

38-year-old man had abdominal pain and fever since the age of 30 years. A 59-year-old woman had had episodes of fever, abdominal pain, and chest pain for more than 20 years. MEFV gene analysis showed compound heterozygosity for L110P, E148Q, and M694I in all three patients. In Japanese patients with FMF, this mode of autosomal true dominant inheritance has not yet been reported. FMF is difficult to diagnose unless it is included in the differential diagnosis by physicians. We hope that our valuable experience will promote increased awareness and understanding of FMF.

Author information:

(1)Department of Medical Genetics, School of Medicine, Kırıkkale University, 71450, Kirikkale, Turkey, dsayin@yahoo.com.

In this study we have retrospectively analysed the mutation spectrum of the 351 Familial Mediterranean fever patients referred to Kırıkkale University Faculty of Medicine, Department of Medical Genetics Laboratory over a period of 5 years and compared them with Turkey's mean. We have found 11 different mutations, including rare mutations such as F479L, K695R, M680I(G/A) and 45 different genotypes showing the heterogeneity of MEFV mutations in Central Anatolia. The most three prevalent mutations were M694V (14.8%), E148Q (7.1%) and M680I(G/C) (4.1%) in accordance with the literature. We have also investigated R202Q in our routine molecular diagnosis. Mutation causing R202Q (c.605G > A) change was described as a frequent polymorphism and G allele was found in linkage disequilibrium (LD) with M694V. There are limited number of studies investigating R202Q, some of them implicate that its homozygote state is disease causing. We showed the high frequency of R202Q (23.7%) with and without M694V in all the groups analysed and its high LD rate with M694V in the diagnosed group. Our study is reflecting the mutational heterogeneity of MEFV and summarize mutational spectrum of Turkey's geographical regions and overall Turkey.

Interleukin (IL)-23 is a heterodimeric cytokine composed of a distinct p19 subunit and a p40 subunit, which it shares with IL-12. The dermatology and rheumatology communities have long surmised that anti-IL-12/23p40 antibodies

suppress autoinflammatory disease owing to their effect on IL-12. The aim of this review is to bring to light new data from murine and human studies demonstrating that in fact IL-23 and its resulting Th17 pathway mediate the inflammatory cascade that induces psoriatic plaque formation. Evidence derives from lesional immunohistochemical analyses, genetic studies, and research in other autoimmune diseases. Although current IL-12/23p40 inhibitors have shown good efficacy and safety, data regarding the functional role of IL-12 in immune defense suggest that preserving this cytokine would be beneficial. To date, evidence from mouse models and preliminary data in human beings show that specifically targeting IL-23p19 may be a safer but equally efficacious treatment option.

Spectrum of primary immunodeficiency disorders in Sri Lanka.

de Silva NR(1), Gunawardena S, Rathnayake D, Wickramasingha GD.

Author information:

(1)Department of Immunology, Medical Research Institute, Colombo 08, Sri Lanka.  
nilhanrajivadesilva@yahoo.com.

**BACKGROUND:** While primary immunodeficiencies (PID) has been recognized in the west for decades, recognition has been delayed in the third world. This study attempts to detail the spectrum of PID, the therapy provided, and constraints in the diagnosis and treatment in a middle income country such as Sri Lanka.

**METHODS:** Nine hundred and forty two patients with recurrent infections and features suggestive of immune deficiency, referred from the entire country in a 4 year period, to the sole immunology unit in Sri Lanka were included. The following tests were performed. Full blood counts, serum Immunoglobulin and complement C3 and C4 levels, functional antibody levels, enumeration of lymphocyte subsets, in vitro and in vivo T cell functional assays,, nitroblue tetrazolium assay to diagnose chronic granulomatous disease, hair shaft assay to

diagnose Griscelli syndrome. Sequencing of the common gamma chain to identify x linked severe combined immune deficiency, and X linked agammaglobulinemia was confirmed by assaying for Btk mutations by single sequence conformation polymorphism. HIV/AIDS was excluded in all patients.

RESULTS: Seventy three patients were diagnosed with a primary immune deficiency. The majority (60.27%) had antibody deficiency. Common variable immune deficiency was the commonest (28.76%), followed by X linked agammaglobulinemia (XLA) (20.54%). Five patients had possible hyper IgM syndrome. Ten patients had severe combined immune deficiency (SCID), including 2 with x linked SCID, in addition to DiGeorge syndrome (2), ataxia telangiectasia (6), autosomal dominant hyper IgE syndrome (2), chronic granulomatous disease (4), leucocyte adhesion deficiency type 1 (2) and Griscelli syndrome (3). Patients with autoinflammatory, innate immune and complement defects could not be identified due to lack of facilities.

CONCLUSIONS: Antibody deficiency is the commonest PID, as in the west. IgA deficiency is rare. Autoinflammatory diseases, innate immune and complement deficiencies could not be identified due to lack of diagnostic facilities. Lack of awareness of PID among adult physicians result in delay in treatment of adult patients. While treatment of antibody deficiencies provided in state hospitals has extended life expectancy, there is no treatment available for severe T cell defects.

[Psoriasis: how the epithelium influences the immune response: keratinocytes, dendritic cells and T lymphocytes].

[Article in French]

Nicolas JF.

Psoriasis is an autoinflammatory skin disease mediated by interactions between keratinocytes, dendritic cells and T lymphocytes, which create a vicious circle of cell activation and lead to the development and persistence of skin lesions. Inflammatory cytokines produced by these three cell types, especially TNF $\alpha$ , IL-23

and IL-17, are central to the disease and are the targets of new, highly effective immunobiological therapies. Advances in the pathophysiology and treatment of psoriasis have applications far beyond the skin disease itself. Indeed, psoriasis serves as a model for studies of the mechanisms of chronic inflammation such as rheumatoid arthritis, Crohn's disease, atherosclerosis and type 2 diabetes, and for developing new targeted therapies for autoinflammatory diseases.

**INTRODUCTION:** Dermatitis herpetiformis (DH) seems to be a chronic immune-mediated inflammatory disease of partially known origin. In light of its known biological functions and its involvement in tissue pathology in other disease states, particularly in nickel-induced allergic contact dermatitis coexisting with DH, it would appear that the central and peripheral response by neutrophils and their mediators (e.g. neutrophil elastase - NE) in DH may be partially mediated by interleukin-6 (IL-6). The aim of the study was to assess the role of IL -6 in DH lesions by examining the relationships between IL -6/NE cutaneous expression and

levels of serum anti-nonapeptides of gliadin (npG) IgA, anti-tissue transglutaminase (tTG) immunoglobulin A (IgA), anti-epidermal transglutaminase (eTG) IgA in DH.

**MATERIAL AND METHODS:** In total, 24 DH patients having IgA cutaneous deposition were studied. Immunohistochemistry on paraffin-embedded sections with quantitative digital morphometry was used to measure the intensity of IL -6 and NE cutaneous expressions. Levels of serum anti-npG IgA, anti-tTG IgA and anti-eTG IgA were evaluated with ELISA.

**RESULTS:** We found no statistically significant correlation between the NE and IL -6 expression intensities. Our results revealed also a lack of correlations between NE/IL -6 expressions and levels of anti-npG IgA, anti-tTG IgA, anti-eTG IgA in DH. However, the IL -6 expression level was significantly lower than that of NE.

**CONCLUSIONS:** The lack of correlations suggested no substantial interactions between IL -6, NE, IgA/npG, IgA/tTG or IgA/eTG in DH. Presented results might indicate the heterogenetic nature of DH pathogenesis suggesting further that both autoimmune and autoinflammatory phenomena may be involved in DH cutaneous pathology.

Schnitzler's syndrome is an autoinflammatory disorder characterized by the association of a monoclonal IgM (or IgG) gammopathy, a chronic urticarial rash,

and signs and symptoms of systemic inflammation, including fever, arthralgias and bone pain. It was first described in 1972. This review summarizes the clinical features, efficacy of therapies, and follow-up data of the 281 cases that have been reported to date. Also, the results of skin histology, bone imaging, laboratory investigations, and studies of the pathogenesis will be discussed, including the pivotal role of interleukin-1 beta in this disorder.

How the cells triggers the induction of innate immune genes in response to nucleic acids derived from microbes, such as DNA viruses, intracellular bacteria, and parasites, or self DNA, has not been elucidated fully. We have previously shown that an endoplasmic reticulum (ER)-associated multiple transmembrane protein, so-called STING (stimulator of interferon genes), functions as an essential molecules for triggering DNA-mediated gene induction. STING may directly associate with stimulatory ligands, which include DNA, as well as with cyclic dinucleotides (CDNs), which are secreted by intracellular bacteria. After DNA or CDN stimulation, STING traffics with kinase TBK1 in an autophagic signaling complex, from ER to perinuclear endosomal compartments harboring IRF3 and NF- $\kappa$ B. STING may involve in autoinflammatory disease manifested by aberrant self-DNA. Understanding of STING function may conceivably lead to the development of potent adjuvants for vaccine development or conversely therapeutics that could control inflammation aggravated disease.

No appreciable decrease in fertility in Behçet's syndrome.

Uzunaslán D(1), Saygin C, Hatemi G, Tascilar K, Yazici H.

Author information:

(1)Cerrahpasa Tip Fakultesi, Ic Hastaliklari Anabilim Dali, Romatoloji Bilim Dali, Fatih, Istanbul 34098, Turkey. gulenhatemi@yahoo.com.

**OBJECTIVES:** Behçet's syndrome (BS) follows an active course during the childbearing years in both men and women. We formally surveyed the infertility rate and the effect of drugs and types of organ involvement on fertility in BS.

**METHODS:** We compared fertility among BS patients with and without major organ involvement with those with FMF, AS and healthy controls. A structured interview was performed and the medical records of the patients were reviewed to confirm the sites of involvement and drugs they used during their entire follow-up.

**RESULTS:** The number of female patients who were not able to ever conceive, who were not able to conceive before or after disease onset or who were able to conceive late or only with assisted reproductive technology was not increased among the BS group. The same was true for the male patients to successfully achieve a conception and/or father a child. The average number of children, miscarriages, terminations and ectopic pregnancies were similar among the groups. Infertility was more common in BS patients with major organ involvement who used cyclophosphamide (CYC) compared with those who did not ( $P = 0.009$ ).

**CONCLUSION:** Infertility is not appreciably increased among BS patients attending a dedicated outpatient clinic. Major organ involvement does not increase the risk of infertility and CYC is the only drug that seems to compromise fertility in BS.

**OBJECTIVE:** The primary aim of this study was to investigate the prevalence of amyloidosis and its related factors in a large number of FMF patients.

**METHODS:** Fifteen centres from the different geographical regions of Turkey were included in the study. Detailed demographic and medical data based on a structured questionnaire and medical records were collected. The diagnosis of amyloidosis was based on histological proof of congophilic fibrillar deposits in tissue biopsy specimens.

**RESULTS:** There were 2246 FMF patients. The male/female ratio was 0.87 (1049/1197). The mean age of the patients was 34.5 years (S.D. 11.9). Peritonitis was the most frequent clinical finding and it was present in 94.6% of patients. Genetic testing was available in 1719 patients (76.5%). The most frequently observed genotype was homozygous M694V mutation, which was present in 413 (24%) patients. Amyloidosis was present in 193 patients (8.6%). Male sex, arthritis, delay in diagnosis, M694V genotype, patients with end-stage renal disease (ESRD) and family history of amyloidosis and ESRD were significantly more prevalent in patients with amyloidosis compared with the amyloidosis-negative subjects. Patients with homozygous M694V mutations had a 6-fold higher risk of amyloidosis compared with the other genotypes (95% CI 4.29, 8.7,  $P < 0.001$ ).

**CONCLUSION:** In this nationwide study we found that 8.6% of our FMF patients had amyloidosis and homozygosity for M694V was the most common mutation in these patients. The latter finding confirms the association of homozygous M694V mutation with amyloidosis in Turkish FMF patients.

Familial Mediterranean fever (FMF) is a hereditary disease characterized by brief, recurring and self-limited episodes of fever and pain with inflammation, of one or several serous (peritoneum, pleura, pericardium, synovial or vaginal tunic of the testicle). Amyloidosis is its more important complication and the principal reason of death in the cases in which it appears. Diagnosis is based on the clinic and is confirmed by genetic tests. The treatment with Colchicine (0,02-0,03 mg/kg/day) prevents the recurrence of FMF attacks and the development of secondary (AA) amyloidosis. We report a case of a 13-year-old child in which FMF was diagnosed after several coincidental episodes with fever, pericarditis and cardiac tamponade. The genetic confirmation showed an autosomal dominant inheritance that is less frequent than the recessive form, in this disease.

Muckle-Wells treatment with anakinra.

Eungdamrong J(1), Boyd KP, Meehan SA, Latkowski JA.

Author information:

(1)New York University School of Medicine.

A 35-year-old man initially was referred for management of recalcitrant urticaria. Owing to his long history of arthritis and sensorineural hearing loss, genetic testing was performed. The test showed a D305N heterozygous mutation in the NLRP3 gene, which is consistent with the diagnosis of Muckle-Wells syndrome. We discussed the rationales behind the use of the interleukin-1 antagonist anakinra in this autoinflammatory disorder.

**OBJECTIVE:** Fever of unknown origin (FUO) can be caused by many diseases, and varies depending on region and time period. Research on FUO in Japan has been limited to single medical institution or region, and no nationwide study has been conducted. We identified diseases that should be considered and useful diagnostic testing in patients with FUO.

**DESIGN:** A nationwide retrospective study.

**SETTING:** 17 hospitals affiliated with the Japanese Society of Hospital General

Medicine.

**PARTICIPANTS:** This study included patients  $\geq 18$  years diagnosed with 'classical fever of unknown origin' (axillary temperature  $\geq 38^{\circ}\text{C}$  at least twice over a  $\geq 3$ -week period without elucidation of a cause at three outpatient visits or during 3 days of hospitalisation) between January and December 2011.

**RESULTS:** A total of 121 patients with FUO were enrolled. The median age was 59 years (range 19-94 years). Causative diseases were infectious disease in 28 patients (23.1%), non-infectious inflammatory disease in 37 (30.6%), malignancy in 13 (10.7%), other in 15 (12.4%) and unknown in 28 (23.1%). The median interval from fever onset to evaluation at each hospital was 28 days. The longest time required for diagnosis involved a case of familial Mediterranean fever. Tests performed included blood cultures in 86.8%, serum procalcitonin in 43.8% and positron emission tomography in 29.8% of patients.

**CONCLUSIONS:** With the widespread use of CT, FUO due to deep-seated abscess or solid tumour is decreasing markedly. Owing to the influence of the ageing population, polymyalgia rheumatica was the most frequent cause (9 patients). Four patients had FUO associated with HIV/AIDS, an important cause of FUO in Japan. In a relatively small number of cases, cause remained unclear. This may have been due to bias inherent in a retrospective study. This study identified diseases that should be considered in the differential diagnosis of FUO.

Weekly oral alendronate in mevalonate kinase deficiency.

Cantarini L(1), Vitale A, Magnotti F, Lucherini OM, Caso F, Frediani B, Galeazzi M, Rigante D.

Author information:

(1)Interdepartmental Research Center of Systemic Autoimmune and Autoinflammatory Diseases, Rheumatology Unit, Policlinico Le Scotte, University of Siena, Siena, Italy. cantariniluca@hotmail.com.

**BACKGROUND:** Mevalonate kinase deficiency (MKD) is caused by mutations in the MVK

gene, encoding the second enzyme of mevalonate pathway, which results in subsequent shortage of downstream compounds, and starts in childhood with febrile attacks, skin, joint, and gastrointestinal symptoms, sometimes induced by vaccinations.

**METHODS:** For a history of early-onset corticosteroid-induced reduction of bone mineral density in a 14-year-old boy with MKD, who also had presented three bone fractures, we administered weekly oral alendronate, a drug widely used in the management of osteoporosis and other high bone turnover diseases, which blocks mevalonate and halts the prenylation process.

**RESULTS:** All of the patient's MKD clinical and laboratory abnormalities were resolved after starting alendronate treatment.

**CONCLUSIONS:** This observation appears enigmatic, since alendronate should reinforce the metabolic block characterizing MKD, but is crucial because of the ultimate improvement shown by this patient. The anti-inflammatory properties of bisphosphonates are a new question for debate among physicians across various specialties, and requires further biochemical and clinical investigation.

Autoinflammatory bone disorders with special focus on chronic recurrent multifocal osteomyelitis (CRMO).

Hedrich CM(1), Hofmann SR, Pablik J, Morbach H, Girschick HJ.

Author information:

(1)Division of Pediatric Rheumatology and Immunology, Children's Hospital Dresden, University Medical Center Carl Gustav Carus, TU Dresden, Dresden, Germany. Christian.hedrich@uniklinikum-dresden.de.

Sterile bone inflammation is the hallmark of autoinflammatory bone disorders, including chronic nonbacterial osteomyelitis (CNO) with its most severe form chronic recurrent multifocal osteomyelitis (CRMO). Autoinflammatory osteopathies are the result of a dysregulated innate immune system, resulting in immune cell infiltration of the bone and subsequent osteoclast differentiation and

activation. Interestingly, autoinflammatory bone disorders are associated with inflammation of the skin and/or the intestine. In several monogenic autoinflammatory bone disorders mutations in disease-causing genes have been reported. However, regardless of recent developments, the molecular pathogenesis of CNO/CRMO remains unclear. Here, we discuss the clinical presentation and molecular pathophysiology of human autoinflammatory osteopathies and animal models with special focus on CNO/CRMO. Treatment options in monogenic autoinflammatory bone disorders and CRMO will be illustrated.

Defects in mitochondrial clearance predispose human monocytes to interleukin-1 $\beta$  hypersecretion.

van der Burgh R(1), Nijhuis L, Pervolaraki K, Compeer EB, Jongeneel LH, van Gijn M, Coffier PJ, Murphy MP, Mastroberardino PG, Frenkel J, Boes M.

Author information:

(1)From the Department of Pediatric Immunology and Infectious Diseases, University Medical Center Utrecht, Wilhelmina Children's Hospital, 3584 EA Utrecht, The Netherlands.

Most hereditary periodic fever syndromes are mediated by deregulated IL-1 $\beta$  secretion. The generation of mature IL-1 $\beta$  requires two signals: one that induces synthesis of inflammasome components and substrates and a second that activates inflammasomes. The mechanisms that mediate autoinflammation in mevalonate kinase deficiency, a periodic fever disease characterized by a block in isoprenoid biosynthesis, are poorly understood. In studying the effects of isoprenoid shortage on IL-1  $\beta$  generation, we identified a new inflammasome activation signal that originates from defects in autophagy. We find that hypersecretion of IL-1 $\beta$  and IL-18 requires reactive oxygen species and is associated with an oxidized redox status of monocytes but not lymphocytes. IL-1 $\beta$  hypersecretion by monocytes involves decreased mitochondrial stability, release of mitochondrial content into

the cytosol and attenuated autophagosomal degradation. Defective autophagy, as established by ATG7 knockdown, results in prolonged cytosolic retention of damaged mitochondria and increased IL-1 $\beta$  secretion. Finally, activation of autophagy in healthy but not mevalonate kinase deficiency patient cells reduces IL-1 $\beta$  secretion. Together, these results indicate that defective autophagy can prime monocytes for mitochondria-mediated NLRP3 inflammasome activation, thereby contributing to hypersecretion of IL-1 $\beta$  in mevalonate kinase deficiency.

Complexities in the relationship between infection and autoimmunity.

Root-Bernstein R(1), Fairweather D.

Author information:

(1)Department of Physiology, Michigan State University, 2174 Biomedical and Physical Sciences Building, East Lansing, MI, 48824, USA.

The possible role of infections in driving autoimmune disease (AD) has long been debated. Many theories have emerged including release of hidden antigens, epitope spread, anti-idiotypes, molecular mimicry, the adjuvant effect, antigenic complementarity, or simply that AD could be a direct consequence of activation or subversion of the immune response by microbes. A number of issues are not adequately addressed by current theories, including why animal models of AD require adjuvants containing microbial peptides in addition to self tissue to induce disease, and why ADs occur more often in one sex than the other. Reviews published in the past 3 years have focused on the role of the innate immune response in driving AD and the possible role of persistent infections in altering immune responses. Overall, recent evidence suggests that microbes activating specific innate immune responses are critical, while antigenic cross-reactivity may perpetuate immune responses leading to chronic autoinflammatory disease.

Efficacy and safety of canakinumab therapy in paediatric patients with cryopyrin-associated periodic syndrome: a single-centre, real-world experience.

Russo RA(1), Melo-Gomes S, Lachmann HJ, Wynne K, Rajput K, Eleftheriou D, Edelsten C, Hawkins PN, Brogan PA.

Author information:

(1)Department of Rheumatology, UCL Institute of Child Health, 30 Guilford Street, London WC1N 1EH, UK. p.brogan@ucl.ac.uk.

**OBJECTIVE:** The aim of this study was to determine the short- and long-term efficacy and safety of 8-weekly canakinumab therapy in children with cryopyrin-associated periodic syndromes (CAPS) in routine clinical practice.

**METHODS:** A single-centre observational study was performed. Patients were assessed every 8 weeks at a dedicated clinic. Standardized assessments were the 10-domains DAS for CAPS, acute phase reactants (APRs), physician's global assessment of disease activity, Child Health Assessment Questionnaire (CHAQ) and Child Health Questionnaire Parent Form 28 (CHQPF-28). The primary endpoint was clinical improvement, defined as a reduction of DAS score 8 weeks after commencing therapy. Secondary endpoints included sustained clinical improvement in APRs, relapses, CHAQ score and CHQPF-28 score.

**RESULTS:** Ten children with CAPS [eight Muckle-Wells syndrome (MWS), two chronic infantile cutaneous neurological articular (CINCA); median age 6.3 years] received 8-weekly canakinumab treatments at 2-8.7 mg/kg for a median of 21 months (range 12-31 months). Nine of 10 patients improved after the first dose: baseline median DAS of 7.5/20 decreased to 3.5/20 at 8 weeks ( $P = 0.04$ ). This clinical improvement was sustained at a median follow-up of 21 months (range 12-31 months). Children with CINCA required higher doses of canakinumab than those with MWS. CHAQ and CHQ scores indicated improvement in functioning and health-related quality of life (HRQoL). Treatment was well tolerated, with no injection site reactions and no serious infections.

**CONCLUSION:** Canakinumab, although costly, is a safe and effective treatment for CAPS in children, leading to sustained improvement in disease activity,

serological markers, functional ability and HRQoL.

# Ophthalmic manifestations in familial Mediterranean fever: a case series of 6 patients.

Yazici A(1), Ozdal P, Yuksekkaya P, Elgin U, Teke MY, Sari E.

## Author information:

(1)Department of Ophthalmology, Balikesir University Faculty of Medicine, Balikesir - Turkey.

**PURPOSE:** To describe the ocular involvement of patients with familial Mediterranean fever (FMF) followed in a tertiary referral center.

**METHODS:** The data of 6 patients with FMF were retrospectively reviewed. Detailed ophthalmologic examinations, type of inflammation, course of the disease, number of recurrences, treatment regimens, complications, and comorbid ocular or systemic diseases were noted.

**RESULTS:** The mean age  $\pm$  SD at diagnosis was  $29.3 \pm 19.3$  (4-53) years. A total of 66.7% of the patients were male and 66.7% of the patients had bilateral disease. The anatomical distribution of the ophthalmic involvement was as follows: posterior uveitis in 2 (33.3%), anterior uveitis in 2 (33.3%), posterior scleritis in 1 (16.7%), and intermediate uveitis in 1 (16.7%) patient. The course was recurrent in 50% of the patients. Final visual acuities were favorable except in the patients with chronic course uveitis. Cystoid macula edema, epiretinal membrane, retinal ischemia, cataract, glaucoma, and band keratopathy were complications noted in the follow-up period. Both cataract and glaucoma patients (50%) needed a surgical intervention. In 33.3% of patients, Behçet disease was present as a concurrent disease. In patients with posterior uveitis and the patient with intermediate uveitis (50%), systemic immunosuppression was required.

**CONCLUSIONS:** There was a male and bilateral involvement predominance. The course of the inflammation was recurrent in half of the patients. Since ocular involvement in FMF is very rare, it should be considered as diagnosis of exclusion.

[Self-medication to treat pain in attacks of familial Mediterranean fever: aiming to find a new approach to pain management].

[Article in German]

Giese A(1), Ornek A, Kurucay M, Kilic L, Şendur SN, Münker A, Puchstein C, Lainka E, Wittkowski H, Henning BF.

Author information:

(1)Medizinische Klinik I, St. Josef-Hospital Bochum, Ruhr-Universität Bochum, Gudrunstr. 56, 44791, Bochum, Deutschland, arnd.giese@rub.de.

**BACKGROUND:** Familial Mediterranean fever (FMF) is an autoinflammatory disease characterized by bouts of fever and serositis. Morbidity caused by bouts as well as self-medication were assessed among patients of Turkish ancestry living in Germany (D) or Turkey (T) in order to evaluate current analgetic concepts from a patient's perspective.

**MATERIAL AND METHODS:** D and T were asked about the 3 months preceding the interview.

**RESULTS:** A total of 40 D and 40 T were included; 35/40 D and 40/40 T were on colchicine. In the last 3 months, 61.3 % had  $\geq 1$  bout and suffered from peritonitis (87.8 %), fever (61.2 %), myalgia (45 %), pleuritis (42.8 %), arthralgia (36.7 %), and cephalgia (32.6 %). Of the patients, 65.3 % were bedridden during bouts, 61.2 % sought the attention of a physician, 53.1 % were unable to work or attend school, and 38.8 % were hospitalized. The following drugs were taken: NSAIDs (45.6 %), NSAIDs and paracetamol (42.6 %), and combinations of NSAIDs with other analgesics. NSAIDs (58.6 %) and paracetamol (20.7 %) were considered the most potent substances.

**CONCLUSION:** FMF inflicts substantial morbidity. Patients most commonly rely on NSAIDs and paracetamol to relieve symptoms of FMF bouts.

Development of Kawasaki disease in a patient with PFAPA.

Ninomiya T(1), Takada H, Nagatomo Y, Nanishi E, Nagata H, Yamamura K, Doi T, Ikeda K, Hara T.

Author information:

(1)Department of Pediatrics, Graduate School of Medical Sciences, Kyushu University, Fukuoka, Japan.

Periodic fever, aphthous stomatitis, pharyngitis and cervical adenitis syndrome (PFAPA) is one of the autoinflammatory diseases of unknown etiology characterized by regularly recurrent fever episodes with attacks lasting 3-6 days every 3-8 weeks associated with at least one of the three cardinal clinical signs: aphthous stomatitis, pharyngitis, and cervical adenitis. Kawasaki disease (KD) is an acute, self-limited systemic vasculitis that occurs predominantly in infants and young children. In most KD patients, i.v. immunoglobulin leads to a rapid amelioration of clinical symptoms and significantly decreases the risk of coronary artery aneurysms. Although the etiology of KD is still unknown, it was reported that innate immunity was activated in the patients. Described herein is a patient with PFAPA who developed KD. This is the first report of KD development in a PFAPA patient. The association between KD and PFAPA may represent a genetic predisposition to dysregulated innate immune response.

Interleukin-32 $\gamma$  suppresses allergic airway inflammation in mouse models of asthma.

Bang BR(1), Kwon HS, Kim SH, Yoon SY, Choi JD, Hong GH, Park S, Kim TB, Moon HB, Cho YS.

Author information:

(1)1 Asan Institute for Life Science, Seoul, Korea.

Asthma is a chronic airway inflammatory disease typically associated with T helper cell type 2 (Th2) cytokines. IL-32, first reported as an inducer of tumor necrosis factor (TNF)- $\alpha$ , is an inflammatory cytokine involved in various autoinflammatory diseases, viral infection, and cancer-related inflammation. However, the role of IL-32 $\gamma$  in asthma has not been clearly elucidated. In this study, the levels of IL-32 $\gamma$  in sputum from patients with asthma were measured by ELISA, and IL-32 $\gamma$  function was investigated in murine models of asthma with human IL-32 $\gamma$ -overexpressed transgenic (IL-32 $\gamma$  TG) mice. The therapeutic effect of recombinant IL-32 $\gamma$  (rIL-32 $\gamma$ ) on allergic inflammation was also evaluated through bronchoalveolar lavage fluid analysis and histopathologic examinations. Sputum IL-32 $\gamma$  levels from patients with asthma were lower than those from healthy control subjects. In an acute mouse model of asthma, IL-32 $\gamma$  TG mice exhibited significantly reduced airway inflammation compared with that in wild-type mice. The production of Th1 cytokines, such as TNF- $\alpha$  and IFN- $\gamma$ , and Th2 cytokines, such as IL-4, IL-5, and IL-13, was decreased in the lungs of IL-32 $\gamma$ TG mice. On the contrary, the expression of IL-10 and IL-10-producing CD11b(+) monocytic cells was significantly increased in the lungs of ovalbumin-sensitized IL-32 $\gamma$  TG mice. In addition, rIL-32 $\gamma$  treatment revealed a suppressive effect on the airway inflammation in a chronic mouse model of asthma. The results of this study suggest that IL-32 $\gamma$  may have a preventive role in the development of allergic airway inflammation and could be a potential novel therapeutic target for bronchial asthma.

: Familial cold autoinflammatory syndrome, Muckle-Wells syndrome (MWS), and chronic, infantile, neurological, cutaneous and articular (CINCA) syndrome are dominantly inherited autoinflammatory diseases associated to gain-of-function NLRP3 mutations and included in the cryopyrin-associated periodic syndromes (CAPS). A variable degree of somatic NLRP3 mosaicism has been detected in  $\approx 35\%$  of patients with CINCA. However, no data are currently available regarding the relevance of this mechanism in other CAPS phenotypes. **OBJECTIVE:** To evaluate somatic NLRP3 mosaicism as the disease-causing mechanism in patients with clinical CAPS phenotypes other than CINCA and NLRP3 mutation-negative. **METHODS:** NLRP3 analyses were performed by Sanger sequencing and by massively parallel sequencing. Apoptosis-associated Speck-like protein containing a CARD (ASC)-dependent nuclear factor kappa-light chain-enhancer of activated B cells (NF- $\kappa$ B) activation and transfection-induced THP-1 cell death assays determined

the functional consequences of the detected variants.

**RESULTS:** A variable degree (5.5-34.9%) of somatic NLRP3 mosaicism was detected in 12.5% of enrolled patients, all of them with a MWS phenotype. Six different missense variants, three novel (p.D303A, p.K355T and p.L411F), were identified. Bioinformatics and functional analyses confirmed that they were disease-causing, gain-of-function NLRP3 mutations. All patients treated with anti-interleukin1 drugs showed long-lasting positive responses.

**CONCLUSIONS:** We herein show somatic NLRP3 mosaicism underlying MWS, probably representing a shared genetic mechanism in CAPS not restricted to CINCA syndrome. The data here described allowed definitive diagnoses of these patients, which had serious implications for gaining access to anti-interleukin 1 treatments under legal indication and for genetic counselling. The detection of somatic mosaicism is difficult when using conventional methods. Potential candidates should benefit from the use of modern genetic tools.

Do neutrophil gelatinase-associated lipocalin and interleukin-18 predict renal dysfunction in patients with familial Mediterranean fever and amyloidosis?

Deveci K(1), Korkmaz S, Senel S, Deveci H, Sancakdar E, Uslu AU, Deniz A, Alkan F, Seker MM, Sencan M.

Author information:

(1)Department of Clinical Biochemistry, School of Medicine, Cumhuriyet University , Sivas , Turkey .

**BACKGROUND:** The aim of this study was to evaluate whether neutrophil gelatinase-associated lipocalin (NGAL) and interleukin-18 (IL-18) predict renal dysfunction in patients with familial Mediterranean fever (FMF).

**METHODS:** This prospective study consisted of 102 patients with FMF in attack-free period, and 40 matched healthy controls. Of the patients, nine were diagnosed as amyloidosis. The patients were divided into two groups according to eGFR as below 120 mL per minute and above 120 mL per minute. Also, patients were divided into three groups according to the degree of urinary albumin excretion as normoalbuminuric, microalbuminuric, and macroalbuminuric. The serum levels of IL-18 (sIL-18) and NGAL (sNGAL), and urinary levels of IL-18 (uIL-18) and NGAL (uNGAL) were measured by using ELISA kits.

**RESULTS:** The levels of sIL-18, sNGAL, uIL-18, and uNGAL were detected significantly higher in FMF patients, particularly in patients with amyloidosis, when compared to controls. sNGAL, uIL-18, and uNGAL were significantly higher in patients with eGFR < 120 mL per minute than in patients with eGFR ≥ 120 mL per minute. sNGAL, uIL-18, and uNGAL were correlated significantly with urinary albumin excretion, additionally, were inverse correlated with eGFR. The most remarkable findings of this study are of the higher values of sIL-18, sNGAL, uIL-18, and uNGAL in both normoalbuminuric FMF patients and patients with eGFR ≥ 120 mL per minute.

**CONCLUSIONS:** The results of this study suggest that sIL-18, uIL-18, sNGAL, and uNGAL are reliable markers of early renal dysfunction in FMF patients, and may let us take measures from the early stage of renal involvement.

Hemophagocytic lymphohistiocytosis: pathogenesis and treatment.

Janka GE(1), Lehmberg K.

Author information:

(1)1University Medical Center Eppendorf, Hamburg, Germany.

Hemophagocytic lymphohistiocytosis (HLH) is not an independent disease but rather a life-threatening clinical syndrome that occurs in many underlying conditions and in all age groups. HLH is the consequence of a severe, uncontrolled hyperinflammatory reaction that in most cases is triggered by an infectious

agent. Persistent stimulation of lymphocytes and histiocytes results in hypercytokinemia, leading to the characteristic symptoms of HLH. Genetic defects in familial HLH and in immunodeficiency syndromes associated with albinism affect the transport, processing, and function of cytotoxic granules in natural killer cells and cytotoxic T lymphocytes. This leads to defective killing of target cells and a failure to contract the immune response. The defects are increasingly found also in adolescents and adults. Acquired HLH occurs in autoinflammatory and autoimmune diseases (macrophage activation syndrome) and in patients with iatrogenic immunosuppression or with malignancies, but also in otherwise healthy persons with infections. Treatment of HLH aims at suppressing hypercytokinemia and eliminating the activated and infected cells. In genetic HLH, hematopoietic stem cell transplantation (HSCT) is needed for the correction of the immune defect. Treatment modalities include immunosuppressive, immunomodulatory, and cytostatic drugs; T-cell antibodies; and anticytokine agents. Using immunochemotherapy, familial HLH, which had been invariably fatal, has become a curable disease with more than 50% survivors. Reduced intensity conditioning for HSCT, which is associated with less transplantation-related mortality, will further improve cure rates.

Defect of suppression of inflammasome-independent interleukin-8 secretion from SW982 synovial sarcoma cells by familial Mediterranean fever-derived pyrin mutations.

Sugiyama R(1), Agematsu K, Migita K, Nakayama J, Mokuda S, Ogura F, Haraikawa K, Okumura C, Suehiro S, Morikawa S, Ito Y, Masumoto J.

Author information:

(1)Department of Molecular Pathology, Shinshu University Graduate School of Medicine, Matsumoto, Nagano, 390-8621, Japan.

Familial Mediterranean fever (FMF) is a recessive inherited autoinflammatory syndrome. Patients with FMF have symptoms such as recurrent fever and abdominal

pain, sometimes accompanied by arthralgia. Biopsy specimens have revealed substantial neutrophil infiltration into synovia. FMF patients have a mutation in the Mediterranean fever gene, encoding pyrin, which is known to regulate the inflammasome, a platform for processing interleukin (IL)-1 $\beta$ . FMF patients heterozygous for E148Q mutation, heterozygous for M694I mutation, or combined heterozygous for E148Q and M694I mutations, which were found to be major mutations in an FMF study group in Japan, suffer from arthritis, the severity of which is likely to be lower than in FMF patients with M694V mutations. Expression plasmids of wild-type (WT) pyrin and mutated pyrin, such as E148Q, M694I, M694V, and E148Q+M694I, were constructed, and SW982 synovial sarcoma cells were transfected with these expression plasmids. IL-8 and IL-6 were spontaneously secreted from the culture supernatant of SW982 cells without any stimulation, whereas IL-1 $\beta$  and TNF- $\alpha$  could not be detected even when stimulated with lipopolysaccharide. Notably, two inflammasome components, ASC and caspase-1, could not be detected in SW982 cells by Western blotting. IL-8 but not IL-6 secretion from SW982 cells was largely suppressed by WT pyrin, but less suppressed by mutated pyrin, which appeared to become weaker in the order of E148Q, M694I, E148Q+M694I, and M694V mutations. As for IL-8 and IL-6, similar results were obtained using stable THP-1 cells expressing the WT pyrin or mutated pyrans, such as M694V or E148Q, when stimulated by LPS. In addition, IL-8 secretion from mononuclear cells of FMF patients was significantly higher than that of healthy volunteers when incubated on a culture plate. Thus, our results suggest that IL-8 secretion from SW982 synovial sarcoma cells suppressed by pyrin independently of inflammasome is affected by pyrin mutations, which may reflect the activity in FMF arthritis.

Long-term outcome of renal transplantation in patients with familial Mediterranean fever amyloidosis: a single-center experience.

Abadi AS(1), Nakhjavani JM, Etemadi J.

Author information:

(1)Transplantation Ward, Imam Reza Hospital, Chronic Renal Disease Research

Center of Tabriz University of Medical Science, Tabriz, Iran. Electronic address:  
sima\_abedi@yahoo.com.

**INTRODUCTION:** Familial Mediterranean fever (FMF) is an autosomal-recessive disorder, affecting multiple organs. The AA type of amyloidosis is most common and serious complication cause nephropathy and end-stage renal disease (ESRD). Renal transplantation (RTX) remains treatment of choice for ESRD. We aimed to investigate long-term results of RTX in patients with FMF amyloidosis.

**PATIENTS AND METHODS:** We compared the outcomes of 18 patients (12 men and 6 women) with FMF amyloidosis among 601 (2.9%) transplants with 200 control patients. Demographic data and gene analysis were evaluated.

**RESULTS:** In our study the 1-year graft and patient survivals were 94.44% and 100%, respectively. At 5 years after RTX, they were 94.73% and 88.88%, respectively, in the FMF group without difference from controls. Mean creatinine level at 1 and 5 years were  $1.43 \pm 0.54$  and  $1.73 \pm 0.89$ , respectively. The results of MEFV mutation analyses were: M694V/M694V homozygote in 1 patient, M694V/EQ148 in 3, M694V/V726A in 2, 680M-I/E148Q in 3, M694V/M680I in 5, R202Q/M680I in 2, and M694V/R202Q in 2. Recurrence was noticed in 1 patient with M694V/M680I. One patient died because of graft loss and cardiac complications with M694V/M680I gene analysis. Colchicine was reduced in 4 patients owing to side effects.

**CONCLUSION:** Long-term outcomes of transplantation in patients with amyloidosis secondary to FMF is similar to that in the general transplant population and maintenance colchicine, even after decreasing its dose, effectively prevents recurrence of amyloidosis in the allograft.

Recurrent migratory angioedema as cutaneous manifestation in a familiar case of TRAPS: dramatic response to Anakinra.

Cattalini M(1), Meini A, Monari P, Gualdi G, Arisi M, Pelucchi F, Bolognini S, Gattorno M, Calzavara-Pinton PG, Plebani A.

Author information:

(1)University of Brescia.

**BACKGROUND:** Tumor Necrosis Factor Receptor Associated Periodic Syndrome (TRAPS) is a hereditary autoinflammatory syndrome characterized by recurrent episodes of fever and localized inflammation. Clinical presentation can be very variable in terms of duration of fever attacks, periodicity, and accompanying manifestations. One of the most characteristic symptoms is the occurrence of migrating skin rash with myalgia that is sustained by monocytic inflammation.

**OBSERVATIONS:** We herein present the case of a family suffering from TRAPS who had been misdiagnosed for a long period of time and whose main symptom was migrating angioedema. Skin biopsy from one of the patients documented a monocytic panniculitis. All the living patients responded dramatically to anakinra treatment.

**CONCLUSIONS:** The classic symptom of migratory angioedema with myalgia in TRAPS can be produced by monocytic panniculitis. This manifestation is so characteristic of TRAPS that its occurrence, even in the absence of other manifestations, should prompt genetic analysis. Our patient's condition responded promptly to anakinra treatment.

Anakinra for cryopyrin-associated periodic syndrome.

Koné-Paut I(1), Galeotti C.

Author information:

(1)Division of Paediatric Rheumatology, Reference Centre for Autoinflammatory Disorders CEREMAI, Bicêtre Hospital, University of Paris SUD, Le Kremlin Bicêtre Cedex, France.

Cryopyrin-associated periodic syndrome (CAPS) is a very rare auto-inflammatory syndrome, which has recently served as a pure model of IL-1 $\beta$ -driven diseases. CAPS is caused by mutations into the NLRP3 gene that encodes cryopyrin, which serves as a receptor of the innate immunity that senses danger signals and pathogens. Constitutive activation of cryopyrin in CAPS leads to an excessive secretion of IL-1 $\beta$ . CAPS patients experience symptoms of systemic inflammation, intense fatigue and have poor quality of life. In the most severe forms, they may develop serious organ damage such as visual and hearing impairment, neurological deterioration and renal insufficiency. Anti-IL-1 drugs are effective in treating symptoms of almost all CAPS patients and have radically transformed their lives. We describe the history of the 'revival' of CAPS patients through anti-IL-1 treatments with a special focus on anakinra, the first drug used in cohorts with variable disease severity and number of patients.

The study objective was to report treatment with an interleukin (IL)-1 receptor antagonist, anakinra, in patients with multiorgan Behcet's disease (BD). Comparison of clinical manifestations, previous treatments, markers of inflammation, concomitant medications, treatment regimen modifications, relapses, and adverse events before and during anakinra administration among patients with BD were evaluated. Nine BD patients (mean age  $34.55 \pm 16.30$  years) refractory to tumor necrosis factor blockers and standardized therapies are reported in our survey. Their mean age at disease onset was  $25 \pm 13.88$  years and their overall disease duration was  $9.55 \pm 5.33$  years. All patients were positive for the HLA-B51 allele. Within 1 or 2 weeks following the initiation of anakinra, eight out of nine patients promptly responded, and most of them were maintained on 100 mg of daily anakinra with low doses of prednisone. However, most patients experienced a relapse in one or more clinical manifestations over time (mean time to relapse  $29 \pm 21.65$  weeks), and only one patient remained completely under control on anakinra monotherapy. Despite a relapse in one or more disease manifestations, treatment was continued in most patients for a mean period of  $13.75 \pm 6.49$  months. No serious adverse events occurred. Eight out of nine refractory BD patients showed a prompt improvement after starting anakinra, supporting the concept that IL-1 plays a pathological role in this disease. Nevertheless, after several months, most patients experienced a relapse. It remains unclear whether increasing the dose of anakinra would have prevented the reoccurrence of disease activity.

Thyroid autoimmunity in patients with Familial Mediterranean Fever: preliminary results.

Dikbas O(1), Soy M, Bes C, Ankaralı H, Bugdayci G, Zeyrek A.

Author information:

(1)Department of Endocrinology and Metabolism, Abant İzzet Baysal University School of Medicine, Bolu, Turkey. oguzdikbas@yahoo.com.

AIM: We investigated whether there was a significant increase in thyroid autoimmunity in patients with Familial Mediterranean fever (FMF).

PATIENTS AND METHODS: In total, 220 patients, consisting of 42 with FMF, 75 with rheumatoid arthritis (RA), and 103 healthy controls, were enrolled. Serum thyroid-stimulating hormone (TSH), free triiodothyronine (fT3), free thyroxine (fT4), and thyroid autoantibodies (anti-thyroid peroxidase and anti-thyroglobulin) were measured in all participants.

RESULTS: After adjustment for age, gender, and smoking status, statistically significant differences between serum levels of anti-thyroglobulin antibody, anti-thyroid peroxidase antibody, and fT3 were found between the groups (all  $p < 0.001$ ). Serum TSH level did not differ between the groups ( $p > 0.05$ ). The frequency of autoimmune thyroiditis in FMF group is higher than control group. However, this difference did not reached the level of statistical significance ( $p > 0.05$ ).

CONCLUSIONS: Although statistically not significant, thyroid autoimmunity was observed more frequently in patients with FMF than in healthy controls. Thyroid autoantibodies were significantly higher in patients with FMF. Studies with greater number of patients are required for evaluating the frequency of the autoimmune thyroiditis in patients with FMF.

Spectrum of mutations in the familial Mediterranean fever gene (MEFV) in Turkish patients of the Central Anatolia region: a comparison of two mutation detection system.

Zamani AG(1), Acar A, Yildirim MS.

Author information:

(1)Department of Medical Genetics, Meram Medical Faculty, Necmettin Erbakan University, Meram, Konya, Turkey agzamani@yahoo.com.

The purpose of this study was to determine the spectrum of the most common mutations in the familial Mediterranean fever gene (MEFV) in Turkish patients from the Central Anatolia region, by using two different methods for detecting FMF-associated mutations with different screening panels, and compare our results with other diagnostic molecular genetics centers. A total of 1579 patients were analyzed. Genomic DNA from 304 patients was tested for 6 common mutations located in exon 2 (E148Q), and exon 10 (M680I, M694V, M694I, V726A, R761H) by real-time PCR while 1275 patients were tested for 17 mutations located in exon 2 (E148Q), and exon10 [M680I (G/C), M680I (G/A), I692del, M694V, M694I, K695R, V726A, S675N, G678E, M680L, T681I, M694L, K695M, R717S, I720M, V722M] by pyrosequencing. The most frequent mutation was M694V, followed by M680I, E148Q, and V726A. Ten mutations in the panel were not detected in any patients. Finally, we compared our results with those of other centers in Turkey to contribute to the identified spectrum of Turkish MEFV mutations and we discuss which MEFV mutations are informative for evaluating an FMF patient.

Citrullination of autoantigens implicates NETosis in the induction of autoimmunity.

Dwivedi N(1), Radic M.

Author information:

(1)Program in Cellular and Molecular Medicine, Boston Children's Hospital and Harvard Medical School, , Boston, Massachusetts, USA.

Tolerance blocks the expression of autoantibodies, whereas autoimmunity promotes it. How tolerance breaks and autoantibody production begins thus are crucial questions for understanding and treatment of autoimmune diseases. Evidence implicates cell death and autoantigen modifications in the initiation of autoimmune reactions. One form of neutrophil cell death called NETosis deserves attention because it requires the post-translational modification of histones and results in the extracellular release of chromatin. NETosis received its name from NET, the acronym given to Neutrophil Extracellular Trap. The extracellular chromatin incorporates histones in which arginines have been converted to citrullines by peptidylarginine deiminase IV (PAD4). The deiminated chromatin may function to capture or 'trap' bacterial pathogens, thus generating an extracellular complex of deiminated histones and bacterial cell adjuvants. The complex of bacterial antigens and deiminated chromatin may be internalised by host phagocytes during acute inflammatory conditions, as arise during bacterial infections or chronic autoinflammatory disorders. The uptake and processing of deiminated chromatin together with bacterial adjuvants by phagocytes may induce the presentation of modified histone epitopes and co-stimulation, thus yielding a powerful stimulus to break tolerance. Autoantibodies to deiminated histones are prevalent in Felty's syndrome patients and are present in systemic lupus erythematosus (SLE) and patients with rheumatoid arthritis (RA). These observations clearly implicate histone deimination as an epigenetic mark that can act as an autoantibody stimulant.

A 26-year-old woman presented with fever and pharyngitis. She previously experienced four periodic febrile episodes at 30- to 40-day intervals. We suspected periodic fever, aphthous stomatitis, pharyngitis, and adenitis (PFAPA) syndrome, and prescribed prednisolone, thereby her fever rapidly subsided. Her febrile episodes improved after daily cimetidine treatment. Genetic testing results of genomic DNA for periodic fever syndromes were negative, although she was heterozygous for p.Glu148Gln variation in MEFV, supporting the diagnosis of PFAPA syndrome.

Secondary amyloidosis (AA) is characterized by the extracellular tissue deposition of fibrils composed of fragments of an acute-phase reactant protein, serum amyloid A (SAA), due to chronic inflammatory diseases, infections and several neoplasms. AA amyloidosis may also complicate several hereditary diseases, where genetic factors play a pivotal role in the expression of amyloidosis. Familial Mediterranean fever (FMF) and tumour necrosis factor receptor-1 syndrome (TRAPS) are the most frequently involved. We describe a case of a 21-year-old Romanian woman who presented at the 35th week of gestation with acute abdominal pain, nausea and vomiting. The laboratory workup performed after delivery showed proteinuria in the nephrotic range and increased SAA protein.

Kidney amyloid deposits were detected and genetic testing for secondary amyloidosis was performed identifying two mutations, one involving the gene of FMF (MEFV), and the other involving the tumour necrosis factor receptor-1 gene (TNFRSF1A). To our knowledge, this is the first case in the literature where secondary amyloidosis develops in a patient carrying mutations involving the genes of both FMF and TRAPS.

Monogenic autoinflammatory syndromes (MAISs) are caused by innate immune system dysregulation leading to aberrant inflammasome activation and episodes of fever and involvement of skin, serous membranes, eyes, joints, gastrointestinal tract, and nervous system, predominantly with a childhood onset. To date, there are twelve known MAISs: familial Mediterranean fever, tumor necrosis factor receptor-associated periodic syndrome, familial cold urticaria syndrome, Muckle-Wells syndrome, CINCA syndrome, mevalonate kinase deficiency, NLRP12-associated autoinflammatory disorder, Blau syndrome, early-onset sarcoidosis, PAPA syndrome, Majeed syndrome, and deficiency of the interleukin-1 receptor antagonist. Each of these conditions may manifest itself with more or less severe inflammatory symptoms of variable duration and frequency, associated with findings of increased inflammatory parameters in laboratory investigation. The purpose of this paper is to describe the main genetic, clinical, and therapeutic aspects of MAISs and their most recent classification with the ultimate goal of increasing awareness of autoinflammation among various internal

medicine specialists.

Colonic lymphoid nodular hyperplasia in childhood: causes of familial Mediterranean fever need extra attention.

Gurkan OE(1), Yilmaz G, Aksu AU, Demirtas Z, Akyol G, Dalgic B.

Author information:

(1)\*Department of Pediatric Gastroenterology †Department of Pathology, Gazi University School of Medicine, Ankara, Turkey.

**OBJECTIVES:** The clinical importance and etiology of colonic lymphoid nodular hyperplasia (LNH) are not clear. It has been considered a response to some antigenic stimuli. Although food allergies, infections, inflammatory bowel diseases, and immunodeficiencies may be listed in the etiology of colonic LNH, the etiology has remained unclear in many cases. This study investigated the etiology of colonic LNH and its relation to familial Mediterranean fever (FMF) in children. FMF as an etiologic factor for colonic LNH has not been reported before in the literature.

**METHODS:** Medical files of patients who underwent colonoscopy between 2007 and 2011 were examined retrospectively. Demographic features, presenting symptoms, colonoscopy indications, colonoscopic findings, and final diagnoses of patients were evaluated. According to etiologies, patients with colonic LNH were divided into 2 groups: group A consisted of patients with FMF and group B consisted of diseases other than FMF.

**RESULTS:** A total of 311 patients were included in the study. Forty (12.6%) patients had isolated colonic LNH. In 23 (57.5%) patients, isolated LNH was observed in some colonic segments and total colonic LNH was noted in 17 (42.5%) patients. FMF was the etiologic factor in 6 (15%) patients. Thirty-four patients (85%) had etiologic factors other than FMF. We did not find any etiologic factor for LNH in 3.53% (11/311) of patients.

CONCLUSIONS: FMF may be an etiologic factor for colonic LNH in children besides food allergies, infections, inflammatory bowel diseases, and immunodeficiencies.

IL-1 is a master cytokine of local and systemic inflammation. With the availability of specific IL-1 targeting therapies, a broadening list of diseases has revealed the pathologic role of IL-1-mediated inflammation. Although IL-1, either IL-1 $\alpha$  or IL-1 $\beta$ , was administered to patients in order to improve bone marrow function or increase host immune responses to cancer, these patients experienced unacceptable toxicity with fever, anorexia, myalgias, arthralgias, fatigue, gastrointestinal upset and sleep disturbances; frank hypotension occurred. Thus it was not unexpected that specific pharmacological blockade of IL-1 activity in inflammatory diseases would be beneficial. Monotherapy blocking IL-1 activity in a broad spectrum of inflammatory syndromes results in a rapid and sustained reduction in disease severity. In common conditions such as heart failure and gout arthritis, IL-1 blockade can be effective therapy. Three IL-1 blockers have been approved: the IL-1 receptor antagonist, anakinra, blocks the IL-1 receptor and therefore reduces the activity of IL-1 $\alpha$  and IL-1 $\beta$ . A soluble decoy receptor, rilonacept, and a neutralizing monoclonal anti-interleukin-1 $\beta$  antibody, canakinumab, are also approved. A monoclonal antibody directed against the IL-1 receptor and a neutralizing anti-IL-1 $\alpha$  are in clinical trials. By specifically blocking IL-1, we have learned a great deal

about the role of this cytokine in inflammation but equally important, reducing IL-1 activity has lifted the burden of disease for many patients.

The latest clinical guideline includes three major hereditary disorders presenting with urticaria: urticaria pigmentosa (mastocytosis), hereditary

angioedema, and cryopyrin-associated periodic syndromes. Understanding the genetic cause and the consequent pathogenesis of such disorders helps in providing disease-specific essential therapeutic regimens. In recent years, distinct hereditary autoinflammatory syndromes with cold urticaria have been reported: NLRP12-associated periodic syndrome, and PLCG2-associated antibody deficiency and immune dysregulation. Moreover, some familial cases with urticaria still remain to be genetically defined. Rapid progress in genetic analysis and further insights into undefined hereditary urticaria promise the development of novel therapeutics in the near future.

Familial Mediterranean fever (FMF) is an autoinflammatory disorder characterized by recurrent febrile polyserositis and arthritis. Although accompanying seronegative spondyloarthropathy has been reported in FMF, coexistence with rheumatoid arthritis (RA) is very rare. This case report describes a Japanese female RA patient who presented with periodic fever. Genetic analysis revealed compound heterozygous mutations in exon 2 and 3 of the MEFV gene (E148Q/G304R/P369S/R408Q). The patient was successfully treated with colchicine with 3-year follow-up.

MEFV gene variations in patients with systemic lupus erythematosus.

Erer B(1), Cosan F, Oku B, Ustek D, Inanc M, Aral O, Gul A.

Author information:

(1)Division of Rheumatology, Department of Internal Medicine, Istanbul Faculty of Medicine , Istanbul 34390 , Turkey.

**OBJECTIVE:** The aim of this study was to investigate the frequency of familial Mediterranean fever (FMF)-associated MEFV gene variations in patients with systemic lupus erythematosus (SLE).

**METHODS:** The study group comprised 190 SLE patients and 101 healthy controls of Turkish origin with no clinical features of FMF. All individuals were genotyped for the four most common MEFV gene variations (M694V, M680I, V726A and E148Q) by PCR-restriction fragment length polymorphism analysis.

**RESULTS:** The frequency of carrying any of the four MEFV gene variations under study was 15 % in patients with SLE and 10 % in the healthy controls ( $p = 0.23$ ).

After the exclusion of the less penetrant E148Q variation, re-analysis for the three penetrant mutations revealed a significant association between exon 10 variations and pericarditis [ $p = 0.038$ , odds ratio (OR) 3.5, 95 % confidence interval (CI) 1.0-12.1], and pleural effusion ( $p = 0.043$ , OR 5.2, 95 % CI 0.8-30.9). No significant association was detected between the MEFV gene variations and a higher acute phase response.

**CONCLUSIONS:** The MEFV gene variations analyzed in our study do not seem to increase the overall susceptibility to SLE and do not have any strong association with its clinical manifestations. The possibility of a modest effect of penetrant exon 10 MEFV variants on the development of serosal effusions needs to be explored in a larger series of patients.

Acute abdominal pain is a common presenting complaint to both primary and secondary care, and is a frequent cause of hospital admission among deployed personnel. Identification of generalised peritonism on abdominal examination is a classical indicator of intra-abdominal pathology that may warrant exploratory laparotomy. Negative findings at laparotomy should serve as a diagnostic prompt to consider other non-surgical mimics of an acute abdomen.

Pulmonary Necrotizing Granulomas in a patient with familial mediterranean fever.

Kushima H(1), Ishii H, Ishii K, Kadota J.

Author information:

(1)a Department of Respiratory Medicine , Oita University Hospital , Oita , Japan.

We herein report a case of familial Mediterranean fever (FMF) presenting with granulomatous lung lesions with neuronal apoptosis inhibitory protein (NAIP), MHC

class II transcription activator (CIITA), incompatibility locus protein from *Podospora anserina* (HET-E), and telomerase-associated protein (TP1) (NACHT) leucine-rich-repeat 1-positive inflammatory cell infiltrates. FMF is an autoinflammatory disorder characterized by recurrent and self-limited attacks of pyrexia, arthritis and erysipelas-like skin lesions. Lung disorders associated with FMF are extremely rare. This is the first report of an immunologically-confirmed case of pulmonary manifestations of this disease.

Hereditary autoinflammatory disorders encompass manifold dysfunctions of innate immunity caused by mutations in genes coding for the main characters of the inflammatory scene: most of these conditions have an early onset, ranging from the first days of life to the first decades, and include hereditary periodic fevers, NLRP-related diseases, granulomatous and pyogenic syndromes, which are basically characterized by upturned inflammasome activity and overproduction of bioactive interleukin (IL)-1 $\beta$  and other proinflammatory cytokines. The discovery of a causative link between autoinflammation and IL-1 $\beta$  release has improved our understanding of the intimate mechanisms of innate immunity, and has likewise led to the identification of extraordinary treatments for many of these disorders.

Familial Mediterranean fever (FMF) is a well-described monogenic autosomal recessive disorder with highest occurrence in the Mediterranean region. In this article, we describe the experience of a center in the Czech Republic that follows four families with members bearing mutations in MEFV gene without provable ancestry from the Mediterranean region. We also discuss the clinical picture of the heterozygous variants that were present in our cohort. The typical clinical presentation in heterozygotes corresponds to data described in the international literature. The possibility of combination of mutations and/or polymorphisms in different genes and epigenetic or environmental influences on the clinical symptoms are taken into account.

A clinical guide to autoinflammatory diseases: familial Mediterranean fever and next-of-kin.

Ozen S(1), Bilginer Y(1).

Author information:

(1)Department of Paediatric Rheumatology, Hacettepe University Faculty of Medicine, Ankara 06100, Turkey.

Autoinflammatory diseases are associated with abnormal activation of the innate immune system, leading to clinical inflammation and high levels of acute-phase reactants. The first group to be identified was the periodic fever diseases, of which familial Mediterranean fever (FMF) is the most common. In FMF, genetic results are not always straightforward; thus, flowcharts to guide the physician in requesting mutation analyses and interpreting the findings are presented in this Review. The other periodic fever diseases, which include cryopyrin-associated periodic syndromes (CAPS), TNF receptor-associated periodic syndrome (TRAPS) and mevalonate kinase deficiency/hyperimmunoglobulin D syndrome (MKD/HIDS), have distinguishing features that should be sought for carefully during diagnosis. Among this group of diseases, increasing evidence exists for the efficacy of anti-IL-1 treatment, suggesting a major role of IL-1 in their pathogenesis. In the past decade, we have started to learn about the other rare autoinflammatory diseases in which fever is less pronounced. Among them are diseases manifesting with pyogenic lesions of the skin and bone; diseases associated with granulomatous lesions; diseases associated with psoriasis; and diseases associated with defects in the immunoproteasome. A better understanding of the pathogenesis of these autoinflammatory diseases has enabled us to provide targeted biologic treatment at least for some of these conditions.

Epigallocatechin-3-gallate (EGCG) is the most biologically active catechin in green tea. EGCG has been shown to have therapeutic effects in autoinflammatory diseases and obesity. Obesity is currently regarded-partly-as an inflammatory condition because of the inflammatory cytokines and higher Th1 cell differentiation detected in obese animal models and human cohort studies. In this work, the effects of EGCG on diet-induced obesity (DIO) mice and obese collagen-induced arthritis (CIA) mice were investigated. EGCG reduced the body weight and fat infiltration in liver tissue while improving serum lipid profiles in DIO mice. EGCG also induced a higher Treg/Th17 cell ratio in CD4(+) T-cell differentiation by decreasing the ratio of STAT3/STAT5 expression in DIO mice. EGCG was also effective in obese CIA mice. Reducing Th17 cells and increasing regulatory T (Treg) cells by affecting the STAT protein ratio were important effects of EGCG that might result in improved arthritic scores and levels of several inflammatory indicators. Thus, EGCG has an anti-inflammatory effect by suppressing STAT3 proteins and Th17-cell differentiation. EGCG thus shows promise for treating autoimmune conditions related to STAT3 or Th17 cells, such as metabolic syndrome, inflammatory arthritis, and some neoplastic diseases.

**BACKGROUND AND PURPOSE:** Degenerating cartilage releases potential danger signals that react with Toll-like receptor (TLR) type danger receptors. We investigated the presence and regulation of TLR1, TLR2, and TLR9 in human chondrocytes.

**METHODS:** We studied TLR1, TLR2, TLR4, and TLR9 mRNA (qRT-PCR) and receptor proteins (by immunostaining) in primary mature healthy chondrocytes, developing chondrocytes, and degenerated chondrocytes in osteoarthritis (OA) tissue sections of different OARSI grades. Effects of a danger signal and of a pro-inflammatory cytokine on TLRs were also studied.

**RESULTS:** In primary 2D-chondrocytes, TLR1 and TLR2 were strongly expressed. Stimulation of 2D and 3D chondrocytes with a TLR1/2-specific danger signal increased expression of TLR1 mRNA 1.3- to 1.8-fold, TLR2 mRNA 2.6- to 2.8-fold, and TNF- $\alpha$  mRNA 4.5- to 9-fold. On the other hand, TNF- $\alpha$  increased TLR1 mRNA expression 16-fold, TLR2 mRNA expression 143- to 201-fold, and TNF- $\alpha$  mRNA expression 131- to 265-fold. TLR4 and TLR9 mRNA expression was not upregulated. There was a correlation between worsening of OA and increased TLR immunostaining in the superficial and middle cartilage zones, while chondrocytes assumed a CD166(+) progenitor phenotype. Correspondingly, TLR expression was high soon after differentiation of mesenchymal stem cells to chondrocytes. With maturation, it declined (TLR2, TLR9).

**INTERPRETATION:** Mature chondrocytes express TLR1 and TLR2 and may react to cartilage matrix/chondrocyte-derived danger signals or degradation products. This leads to synthesis of pro-inflammatory cytokines, which stimulate further TLR and cytokine expression, establishing a vicious circle. This suggests that OA can act as an autoinflammatory disease and links the old mechanical wear-and-tear concept with modern biochemical views of OA. These findings suggest that the chondrocyte itself is the earliest and most important inflammatory cell in OA.

Clinical and genetic profile of children with periodic fever syndromes from a single medical center in South East Michigan.

Chandrakasan S, Chiwane S, Adams M, Fathalla BM.

**OBJECTIVE:** To report a cohort of children with periodic fever syndromes (PFS) from Southeast Michigan.

**METHODS:** A retrospective review of medical records for patients referred for periodic fever over 5 years.

**RESULTS:** Sixty-six patients including 21 FMF, 15 PFAPA, four TRAPS and one patient with combined HIDS and FMF were included. In addition, 25 patients were categorized as clinical PFS (cPFS) based on their clinical features however their genetic workup was either negative or inconclusive. Majority of the patients with

FMF were from Middle Eastern background (88 %), but positive family history was noted in only 55 % of cases. Mean age at diagnosis was 40.8 months with a mean delay in diagnosis of 24 months. Most common MEFV mutations were p.M694V and p.M694I. Four patients with TRAPS were from mixed European descent and age at onset of symptoms was 6, 12, 12, and 84 months respectively. TNFRSF1A sequence variants in the TRAPS patients included p.R121Q (R92Q) and p.C99G (C70G); one patient had a rare occurrence of a concurrent p.V726A/-MEFV mutation. One patient with HIDS and FMF presented with atypical overlapping PFS clinical manifestations and genetic evaluation showed a unique combination of p.I268T/p.V377I MVK mutations and p.E230K/-MEFV variant. All patients with PFAPA group were from mixed European descent, symptoms started at a mean age of 34.6 months with a mean delay in diagnosis of 23.3 months. Symptoms started during infancy in six patients. All patients fulfilled the diagnostic criteria for PFAPA. The mean age of onset of symptoms in cPFS group was 17.2 months. Empiric colchicine and glucocorticosteroids controlled flares in majority of patients with cPFS. No evidence of amyloidosis was found in this entire cohort of 66 patients after a mean of 29.2 months of follow-up.

CONCLUSION: PFS can present with atypical manifestations and should not be excluded based on a negative family history. Concomitant mutations in different autoinflammatory disorders genes can be present and possibly explain atypical manifestations. Various therapies may be considered even if genetic testing is inconclusive or negative.

Profile of paediatric rheumatology specialists and services in the state of São Paulo.

[Article in English, Portuguese]

Terreri MT, Campos LM, Okuda EM, Silva CA, Sacchetti SB, Marini R, Ferriani VP, Ventura MH, Fernandes T, Sato JO, Fernandes EC, Len C, Barbosa C, Lotito AP, Santos MC, Aikawa NE, Facó M, Piotto D, Bugni V, Kozu KT, Romanelli PR, Sallum AM, Febronio M, Fraga M, Magalhães CS.

**INTRODUCTION:** Paediatric rheumatology (PR) is an emerging specialty, practised by a limited number of specialists. Currently, there is neither a record of the profile of rheumatology patients being treated in Brazil nor data on the training of qualified rheumatology professionals in the country.

**OBJECTIVE:** To investigate the profile of PR specialists and services, as well as the characteristics of paediatric patients with rheumatic diseases, for estimating the current state of rheumatology in the state of São Paulo.

**PATIENTS AND METHODS:** In 2010, the scientific department of PR of the Paediatric Society of São Paulo administered a questionnaire that was answered by 24/31 accredited specialists in PR practising in state of São Paulo and by 8/21 institutions that provide PR care.

**RESULTS:** Most (91%) of the surveyed professionals practise in public institutions. Private clinics (28.6%) and public institutions (37.5%) reported not having access to nailfold capillaroscopy, and 50% of the private clinics reported not having access to acupuncture. The average duration of professional practise in PR was 9.4 years, and 67% of the physicians had attended postgraduate programmes. Seven (87.5%) public institutions perform teaching activities, in which new paediatric rheumatologists are trained, and five (62.5%) offer postgraduate programmes. Two-thirds of the surveyed specialists use immunosuppressants and biological agents classified as "restricted use" by the Health Secretariat. The disease most frequently reported was juvenile idiopathic arthritis (29.1-34.5%), followed by juvenile systemic lupus erythematosus (JSLE) (11.6-12.3%) and rheumatic fever (9.1-15.9%). The incidence of vasculitis (including Henoch-Schönlein purpura, Wegener's granulomatosis, and Takayasu's arteritis) and autoinflammatory syndromes was higher in public institutions compared to other institutions ( $P = 0.03$ ,  $P = 0.04$ ,  $P = 0.002$ , and  $P < 0.0001$ , respectively). Patients with JSLE had the highest mortality rate (68% of deaths), mainly due to infection.

**CONCLUSION:** The field of PR in the state of São Paulo has a significant number of specialists with postgraduate degrees who mostly practise at teaching institutions with infrastructures appropriate for the care of high-complexity patients.

Diagnostic dilemma in autoinflammatory disease in two patients: does the name matter?

Gülhan B(1), Büyükcım A, Touitou I, Özen S.

Author information:

(1)Division of Pediatric Nephrology and Rheumatology, Department of Pediatrics, Hacettepe University Faculty of Medicine, Ankara, Turkey.  
sezaozen@hacettepe.edu.tr.

The systemic autoinflammatory diseases are inflammatory disorders characterized by uncontrolled inflammation of the innate immune system. A common monogenic autoinflammatory disease is familial Mediterranean fever (FMF), associated with mutations in the MEFV gene. Another autoinflammatory disease group is cryopyrin-associated periodic syndromes (CAPS), which are characterized by urticarial rash and mutations of the gene NLRP. Systemic-onset juvenile idiopathic arthritis (sJIA) is classified as a multifactorial autoinflammatory disease. We report two cases of systemic autoinflammatory disease with homozygous E148Q mutation in the FMF gene. They had unusual features, such as urticarial rash, non-erysipeloid erythema, lymphadenopathy, and hepatosplenomegaly, and neurological findings in one. These patients met the "definition" criteria for FMF with two mutations in the MEFV gene. They fit the "description" criteria for CAPS with their fever, urticaria, and other clinical features. They also met the "classification" criteria for sJIA, with the fever, rash, arthritis, and accompanying systemic features.

(1)Mustafa Kemal University School of Medicine, Department of Otolaryngology, Turkey. Electronic address: drccevik@yahoo.com.

**OBJECTIVE:** Familial Mediterranean Fever is the most common congenital, periodic fever condition that affects over 100,000 people worldwide. In the literature, there is limited number of studies about hearing levels in children with Familial Mediterranean Fever. In the present study, we aimed to investigate hearing levels and cochlear functions by using Distortion product Otoacoustic Emission and High Frequency Audiometry (250-20,000 Hz) in pediatric patients with Familial Mediterranean Fever.

**METHODS:** The study included 62 children with Familial Mediterranean Fever and 27 healthy children with similar age and gender. After otoscopic examination, both groups underwent audiological evaluation including High Frequency Audiometry (250-20,000 Hz) and Distortion product Otoacoustic Emissions. The results obtained were assessed among groups. In addition, these results were compared regarding colchicine use, age at the onset of disease and duration of the diseases in the Familial Mediterranean Fever group.

**RESULTS:** Of the Familial Mediterranean Fever patients, 93.5% were on colchicine therapy and mean duration of colchicine use was  $19.9 \pm 13.9$  months. The mean age at diagnosis was  $6.57 \pm 2.86$  years (min-max: 2-14) and mean duration of disease was  $23 \pm 17$  months (min-max: 6-84). Pure tone audiometry values, and hearing levels between 9000 and 20,000 Hz were similar and within normal range in both groups. The Distortion product Otoacoustic Emissions responses at the frequencies of 1020, 2040, 3000, 4080 and 5040 Hz were similar for both groups.

**CONCLUSION:** To the best of our knowledge, this is the first study evaluating hearing levels at the frequencies of 18k Hz and 20k Hz in children with Familial Mediterranean Fever in the literature. In children with Familial Mediterranean Fever, Pure tone audiometry values, hearing values obtained at all frequencies from 250 to 20,000 Hz, and Distortion product Otoacoustic Emissions levels were within normal range. Furthermore, hearing levels were found to be similar to those in healthy children.

Monogenic diseases associated with intestinal inflammation: implications for the understanding of inflammatory bowel disease.

Uhlig HH.

Comment in

Gut. 2014 Aug;63(8):1367-8.

Gut. 2014 Nov;63(11):1831-2.

Gut. 2014 Jun;63(6):1031-2.

Inflammatory bowel disease (IBD), encompassing Crohn's disease and ulcerative colitis, has multifactorial aetiology with complex interactions between genetic and environmental factors. Over 150 genetic loci are associated with IBD. The genetic contribution of the majority of those loci towards explained heritability is low. Recent studies have reported an increasing spectrum of human monogenic diseases that can present with IBD-like intestinal inflammation. A substantial proportion of patients with those genetic defects present with very early onset of intestinal inflammation. The 40 monogenic defects with IBD-like pathology selected in this review can be grouped into defects in intestinal epithelial barrier and stress response, immunodeficiencies affecting granulocyte and phagocyte activity, hyper- and autoinflammatory disorders as well as defects with disturbed T and B lymphocyte selection and activation. In addition, there are defects in immune regulation affecting regulatory T cell activity and interleukin (IL)-10 signalling. Related to the variable penetrance of the IBD-like phenotype, there is a likely role for modifier genes and gene-environment interactions. Treatment options in this heterogeneous group of disorders range from anti-inflammatory and immunosuppressive therapy to blockade of tumour necrosis factor  $\alpha$  and IL-1 $\beta$ , surgery, haematopoietic stem cell transplantation or gene therapy. Understanding of prototypic monogenic 'orphan' diseases cannot only provide treatment options for the affected patients but also inform on immunological mechanisms and complement the functional understanding of the pathogenesis of IBD.

# The Central Role of Anti-IL-1 Blockade in the Treatment of Monogenic and Multi-Factorial Autoinflammatory Diseases.

Federici S(1), Martini A, Gattorno M.

Author information:

(1)2nd Division of Pediatrics, G. Gaslini Institute , Genoa , Italy.

Inherited autoinflammatory diseases are secondary to mutations of proteins playing a pivotal role in the regulation of the innate immunity leading to seemingly unprovoked episodes of inflammation. The understanding of the molecular pathways involved in these disorders has shed new lights on the pattern of activation and maintenance of the inflammatory response and disclosed new molecular therapeutic targets. Cryopyrin-associated periodic syndrome (CAPS) represents the prototype of an autoinflammatory disease. The study of the pathophysiological consequence of mutations in the cryopyrin gene (NLRP3) allowed the identification of intracellular pathways responsible for the activation and secretion of the potent inflammatory cytokine interleukin-1 $\beta$  (IL-1 $\beta$ ). It became clear that several multi-factorial inflammatory conditions display a number of pathogenic and clinical similarities with inherited autoinflammatory diseases. The dramatic effect of interleukin-1 (IL-1) blockade in CAPS opened new perspectives for the treatment of other inherited and multi-factorial autoinflammatory disorders. Several IL-1 blockers are now available on the market. In this review we outline the more recent novelties in the treatment with different IL-1 blockers in inherited and multi-factorial autoinflammatory diseases.

Detailed mechanistic analysis of gevokizumab, an allosteric anti-IL-1 $\beta$  antibody with differential receptor-modulating properties.

Issafras H(1), Corbin JA, Goldfine ID, Roell MK.

Author information:

(1)XOMA Corporation, Preclinical Department, Berkeley, California.

Interleukin-1 $\beta$  (IL-1 $\beta$ ) is a proinflammatory cytokine that is implicated in many autoinflammatory disorders, but is also important in defense against pathogens. Thus, there is a need to safely and effectively modulate IL-1 $\beta$  activity to reduce pathology while maintaining function. Gevokizumab is a potent anti-IL-1 $\beta$  antibody being developed as a treatment for diseases in which IL-1 $\beta$  has been associated with pathogenesis. Previous data indicated that gevokizumab negatively modulates IL-1 $\beta$  signaling through an allosteric mechanism. Because IL-1 $\beta$  signaling is a complex, dynamic process involving multiple components, it is important to understand the kinetics of IL-1 $\beta$  signaling and the impact of gevokizumab on this process. In the present study, we measured the impact of gevokizumab on the IL-1 $\beta$  system using Schild analysis and surface plasmon resonance studies, both of which demonstrated that gevokizumab decreases the binding affinity of IL-1 $\beta$  for the IL-1 receptor type I (IL-1RI) signaling receptor, but not the IL-1 counter-regulatory decoy receptor (IL-1 receptor type II). Gevokizumab inhibits both the binding of IL-1 $\beta$  to IL-1RI and the subsequent recruitment of IL-1 accessory protein primarily by reducing the association rates of these interactions. Based on this information and recently published structural data, we propose that gevokizumab decreases the association rate for binding of IL-1 $\beta$  to its receptor by altering the electrostatic surface potential of IL-1 $\beta$ , thus reducing the contribution of electrostatic steering to the rapid association rate. These data indicate, therefore, that gevokizumab is a unique inhibitor of IL-1 $\beta$  signaling that may offer an alternative to current therapies for IL-1 $\beta$ -associated autoinflammatory diseases.

Targeting the B-cell pathway in lupus nephritis: current evidence and future perspectives.

Pateinakis P(1), Pyrpasopoulou A.

Author information:

(1)Department of Nephrology, Papageorgiou Hospital, 56403 Thessaloniki, Greece.

Nephritis represents a frequent, severe complication of systemic lupus erythematosus. Autoantibodies appear to be fundamental in the pathogenesis of lupus nephritis. Several hypotheses are currently experimentally tested to further elucidate the direct induction of inflammation through interaction of the pathological autoantibodies with intrinsic glomerular components and the triggering of a complement-driven autoinflammatory cascade. B-cells have, in the last decade, emerged as a promising new therapeutic target, as biological treatments successfully attempting B-cell depletion, inhibition of B-cell proliferation and differentiation, or modulation of B-cell function have become bioengineered. Clinical trials have so far proved controversial regarding the efficacy of these new agents. Thus, despite the short and long-term side effects associated with immunosuppressive treatment alternative emerging treatments are still regarded "rescue" regimens in refractory patients. In an effort to accurately evaluate the potential of these therapies in lupus nephritis, several issues have been raised mainly in terms of patient selection criteria and trial duration. This review aims to expand on the proposed pathophysiologic mechanisms implicating the B-cell pathway in the pathogenesis of lupus nephritis and summarize current knowledge obtained from clinical trials introducing these biologics in its treatment. Finally, it will elaborate on potential applications of currently available biologic agents and forthcoming treatment options.

Autoinflammatory bone diseases.

Stern SM(1), Ferguson PJ.

Author information:

(1)Division of Immunology, Rheumatology, and Allergy, Department of Pediatrics, University of Utah, PO Box 581289, Salt Lake City, UT 84158, USA. Electronic address: Sara.Stern@hsc.utah.edu.

Autoinflammatory bone disease is a new branch of autoinflammatory diseases caused by seemingly unprovoked activation of the innate immune system leading to an osseous inflammatory process. The inflammatory bone lesions in these disorders are characterized by chronic inflammation that is typically culture negative with no demonstrable organism on histopathology. The most common autoinflammatory bone diseases in childhood include chronic nonbacterial osteomyelitis (CNO), synovitis, acne, pustulosis, hyperostosis, osteitis syndrome, Majeed syndrome, deficiency of interleukin-1 receptor antagonist, and cherubism. In this article, the authors focus on CNO and summarize the distinct genetic autoinflammatory bone syndromes.

Monogenic autoinflammatory diseases: disorders of amplified danger sensing and cytokine dysregulation.

Sanchez GA(1), de Jesus AA, Goldbach-Mansky R.

Author information:

(1)Translational Autoinflammatory Disease Section, National Institute of Arthritis and Musculoskeletal and Skin Diseases (NIAMS), National Institutes of Health (NIH), Building 10, Room 6D47-B, 10 Center Drive, Bethesda, MD 20892, USA.

The pathogenesis of monogenic autoinflammatory diseases converges on the presence of exaggerated immune responses that are triggered through activation of altered pattern recognition receptor (PRR) pathways and result in cytokine/chemokine

amplification loops and the inflammatory clinical phenotype seen in autoinflammatory patients. The PRR response can be triggered by accumulation of metabolites, by mutations in sensors leading to their constitutive overactivation, or by mutations in mediator cytokine pathways that lead to amplification and/or inability to downregulate an inflammatory response in hematopoietic and/or nonhematopoietic cells. The study of the pathogenesis of sterile inflammation in patients with autoinflammatory syndromes continues to uncover novel inflammatory pathways.

Relationship between response to colchicine treatment and MDR1 polymorphism in familial Mediterranean fever patients.

Uludag A(1), Silan C, Atik S, Akurut C, Uludag A, Silan F, Ozdemir O.

Author information:

(1)1 Department of Medical Genetics, Canakkale Onsekiz Mart University School of Medicine , Canakkale, Turkey .

AIM: Investigate the relationship between MDR1 C3435T polymorphism and colchicine response in Familial Mediterranean fever (FMF) patients.

MATERIALS AND METHODS: Patients (n=50) who received colchicine regularly, were willing to participate in the study, and attended control visits were included in the study. MDR1 C3435T genotype was defined by the real-time polymerase chain reaction method. Patients were divided into three groups. Patients, who recovered from episodes with standard colchicine treatment, and had no attack in the last 1 year were accepted as complete; patients whose episode number and intensity were decreased with the ongoing standard treatment as partial; and patients whose episodes were not decreased despite the standard treatment as nonresponders.

RESULTS: MDR1 C and T allele frequencies of FMF patients with colchicine

responses of complete, partial, and nonresponders were C=0.75 and T=0.25; C=0.56 and T=0.44; and C=0.50 and T=0.50, respectively. When complete responding patients were compared with the partial responding patients, subjects with CT genotype had 6.18 times more increased risk than with CC genotype (OR=6.18; p=0.015). Poor response risk of subjects with the T allele was increased 2.45 times more when compared with the C allele (p=0.03).

CONCLUSION: MDR1 gene C3435T polymorphism enacts an important role on colchicine response in FMF; good response to colchicine treatment was related to the C allele, whereas poor response was related to the T allele in FMF.

Is recurrent aseptic meningitis a manifestation of familial Mediterranean fever?  
A systematic review.

Capron J(1), Grateau G, Steichen O.

Author information:

(1)Neurology Department, AP-HP, Hôpital Saint Antoine, Paris, France.  
jean.capron@sat.aphp.fr.

**OBJECTIVES:** Familial Mediterranean fever (FMF) causes recurrent episodes of fever and painful serositis. It has been suggested that FMF can cause recurrent aseptic meningitis (RAM). Due to the rarity of both diseases, this claim cannot be assessed with epidemiological methods. We therefore decided to perform a systematic review of the literature to assess the number and validity of published case reports.

**METHODS:** Medline, Embase, Pascal, Web of Science and the proceedings of relevant conferences were searched. Two independent investigators selected reports asserting RAM in FMF patients, abstracted data and rated the strength of evidence with a custom tool designed to assess: (a) the diagnosis of FMF; (b) the diagnosis of RAM; and (c) the link between FMF and RAM. A causal link was supported by (i) evidence of inflammation and/or clinical FMF features during episodes of RAM; (ii) effectiveness of colchicine to prevent further bouts of meningitis; and (iii) the exclusion of other causes of RAM.

**RESULTS:** Among 944 retrieved references, 917 were rejected by title and abstract screening and 15 after full text review. The strength of evidence of 12 alleged cases of RAM due to FMF was assessed. FMF was unsupported in 4 cases and RAM in 3 further cases. Four of the 5 remaining cases did not provide adequate evidence to support a causal relationship between FMF and RAM.

CONCLUSIONS: The possibility of RAM due to FMF is poorly supported by a single fairly documented case report that does not, however, meet current diagnostic standards.

alessia.omenetti@gmail.com.

In this paper we provide a critical digest of the recent literature on inherited autoinflammatory diseases. We reviewed all the articles published during the last 24 months on monogenic autoinflammatory diseases and selected the most relevant studies regarding the pathogenesis, clinical aspects and management of these conditions. In particular, we focused the attention on the more frequent conditions, familial Mediterranean fever (FMF), cryopyrin-associated periodic syndrome (CAPS) and TNF-receptor associated periodic syndrome (TRAPS).

The year 2012-2013 has been a fertile one in the area of FMF inquiry. Recent studies have led to further insight into the possible mechanisms whereby pyrin mutations might cause the auto-inflammatory phenotype that is characteristic of FMF. Evidence-based guidelines for diagnosis of FMF, including the role of genetic testing, have become available. Risks for colchicine resistance have been partially defined, and a randomised, controlled trial showing efficacy of an interleukin-1 antagonist for treatment of colchicine-resistant or intolerant FMF patients was reported. In this review, we summarise these and other salient findings from the recent FMF literature, and discuss their significance for the clinician.

Polarization of the innate immune response by prostaglandin E2: a puzzle of receptors and signals.

Rodríguez M(1), Domingo E, Municio C, Alvarez Y, Hugo E, Fernández N, Sánchez Crespo M.

Author information:

(1)Department of Biochemistry and Molecular Biology, University of Valladolid, Valladolid, Spain (M.R., N.F.); and Institute of Biology and Molecular Genetics, Spanish National Research Council, Valladolid, Spain (E.D., C.M., Y.A., E.H., M.S.C.).

Eicosanoids tailor the innate immune response by supporting local inflammation and exhibiting immunomodulatory properties. Prostaglandin (PG) E<sub>2</sub> is the most abundant eicosanoid in the inflammatory milieu due to the robust production elicited by pathogen-associated molecular patterns on cells of the innate immune system. The different functions and cell distribution of E prostanoid receptors explain the difficulty encountered thus far to delineate the actual role of PGE<sub>2</sub> in the immune response. The biosynthesis of eicosanoids includes as the first step the Ca<sup>2+</sup>- and kinase-dependent activation of the cytosolic phospholipase A<sub>2</sub>, which releases arachidonic acid from membrane phospholipids, and later events depending on the transcriptional regulation of the enzymes of the cyclooxygenase routes, where PGE<sub>2</sub> is the most relevant product. Acting in an autocrine/paracrine manner in macrophages, PGE<sub>2</sub> induces a regulatory phenotype including the expression of interleukin (IL)-10, sphingosine kinase 1, and the tumor necrosis factor family molecule LIGHT. PGE<sub>2</sub> also stabilizes the suppressive function of myeloid-derived suppressor cells, inhibits the release of IL-12 p70 by macrophages and dendritic cells, and may enhance the production of IL-23. PGE<sub>2</sub> is a central component of the inflammasome-dependent induction of the eicosanoid storm that leads to massive loss of intravascular fluid, increases the mortality rate associated with coinfection by *Candida* spp. and bacteria, and inhibits fungal phagocytosis. These effects have important consequences for the outcome of infections and the polarization of the immune response into the T helper cell types 2 and 17 and can be a clue to develop pharmacological tools to address infectious, autoimmune, and autoinflammatory diseases.

Pregnancy outcome of five patients with renal amyloidosis regarding familial Mediterranean fever.

Turgal M(1), Selcuk I, Ozyuncu O.

Author information:

(1)Department of Obstetrics and Gynecology, Maternal Fetal Medicine Unit, School of Medicine, Hacettepe University , Ankara , Turkey.

Familial Mediterranean fever (FMF) is an autosomal recessive disease affecting mainly patients of the Mediterranean basin and its major complication is the development of renal AA amyloidosis. On the other hand pregnancy with amyloidosis is not common; nevertheless, amyloidosis will complicate pregnancies also with the underlying disease and may cause terrible perinatal morbidities and mortalities. We report here the cases of five pregnant women and their pregnancy outcomes, who have been diagnosed with FMF complicated by renal amyloidosis. In the five cases, we observed that increased pregnancy complication such as small for gestational age, intrauterine growth restriction, preeclampsia and preterm birth.

An update on autoinflammatory diseases.

Ciccarelli F, De Martinis M, Ginaldi L(1).

Author information:

(1)Director of Post-graduated School of Allergy and Clinical Immunology, University of L'Aquila Coppito, 67100 L'Aquila, Italy. lia.ginaldi@univaq.it.

Autoinflammatory diseases are a group of clinical conditions other than autoimmune diseases, characterized by recurrent inflammatory episodes. From a pathogenetic point of view they are determined by a dysregulation of innate immunity, without involvement of specific immunity (auto reactive T cells and auto antibodies). Recently, the increased knowledge in the field of auto inflammation highlighted shared immune mechanisms in the pathogenesis of both classical monogenetic and multifactorial auto inflammatory diseases and a broad spectrum of chronic

age-related inflammatory pathologies. The current increase in the prevalence of chronic inflammatory diseases makes this subject of topical interest. In the light of these considerations, we propose an update of auto inflammatory diseases and a new interpretation of auto inflammation with both theoretical and clinical implications.

Behçet's syndrome in Iranian Azari people.

Shahneh FZ(1), Babaloo Z, Baradaran B, Hamzavi F, Bayazi B, Bandehagh A.

Author information:

(1)Department of Immunology, Tabriz University of Medical Sciences, Iran.

Behçet's Syndrome (BS) is a chronic recurrent multisystemic inflammatory disorder characterized by oral and genital ulcers, ocular inflammation. Behçet's syndrome has a complex genetic etiology. However, epidemiological studies recommend that genetic factors have a significant influence to its pathogenesis, alike to other autoinflammatory disorders. Epidemiological statistics, clinical records and HLA typing were studied in Iranian Azari patients with Behçet's syndrome. This investigation considered HLA associations with BS and HLA with certain clinical characteristics, age and sex in the (Tabriz) Iran which has an ethnically homogeneous population. HLA-A and HLA-B typing was performed in 290 BS patients, conforming to International Study Group criteria and in 300 blood donors, as controls. Patient records were retrospectively reviewed and patients reassessed clinically. HLA-B5, HLA-B35, HLA-51, HLA-B52 and HLA-CW4 presented significantly high frequencies in all patients. No other HLA type was associated. There was a significant HLA link with male sex in BS patients and Mean age (34 +/- 1.1) was determined. We present the frequency and correlation between Iranian Azari patients with Behçet's syndrome and particular HLA antigens. Ninety nine percent had mouth ulceration, 64% genital ulceration, 72% skin lesions and 52% ocular involvement. This study supports HLA-B5, HLA-B35, HLA-51, HLA-B52 and HLA-CW4 immunogenetic predisposition in an ethnically homogeneous (Iranian Azari)

population.

Genotype-phenotype and genotype-origin correlations in children with mediterranean fever in Germany - an AID-net study.

Jeske M(1), Lohse P, Kallinich T, Berger T, Rietschel C, Holzinger D, Kamlah C, Lankisch P, Berendes R, Dueckers G, Horneff G, Lilienthal E, Haas JP, Giese A, Dressler F, Berrang J, Braunewell L, Neudorf U, Niehues T, Föll D, Lainka E.

Author information:

(1)Pediatric Rheumatology, University Children's Hospital, Essen, Germany.

Familial Mediterranean fever (FMF) is the most inherited common autoinflammatory disease (AID) with mutations in the MEFV (MEditerraneanFeVer) gene. The Mor- and Pras-Score modified for children and C-reactive protein (CRP) were used to assess FMF disease severity in Germany. We evaluate the applicability of the 2 severity scores and the correlations between ethnic origin, phenotype, and genotype. Among 242 children (median 5 age at diagnosis), we detected 431 pyrin mutations and 22 different sequence variants, including one new mutation (p.Gly488Asp). The 5 most -frequent alterations were p.Met694Val (55.2%), p.Met680Ile (11.8%), p.Val726Ala (10%), p.Glu148Gln (7.9%) and p.Met694Ile (2.3%). The prevailing ancestries of 223 cases were Turkish (82.5%) and Lebanese (8.1%). Homozygous p.Met694Val substitution (30.2%) was associated with a more severe disease activity by Mor-Score, as well as with a higher mean CRP (74 mg/l) compared to patients with other mutations. Indeed, Mor- and Pras-Score were inconsistent with each other. A typical distribution of mutations in different ethnic populations was obvious, but not statistically verifiable due to the low number of cases. The homozygous p.Met694Val substitution was associated with a more severe disease activity in our German cohort. The common severity scores were inconsistent in -children.

Behçet's Disease, Associated Large Vessel Thrombosis, and Coexistent Thrombophilia: A Distinct Nosological Entity?

Stoimenis D(1), Petridis N, Papaioannou N.

Author information:

(1)1st Department of Internal Medicine, "Georgios Papanikolaou" General Hospital, Exochi, 570 10 Thessaloniki, Greece.

Behçet's disease (BD) represents a multisystemic disorder that combines features of immune-mediated diseases and autoinflammatory disorders. Even though it is recognized that every type or size of vessel can be affected in this disease, there is an inability to describe a coherent model that sufficiently explains the predilection of certain patients with BD for manifesting severe large vessel thrombosis. The inconsistent epidemiologic data and the complex genetic background of BD, along with the controversy of multiple international studies regarding the coexistence of thrombophilia in patients with BD and large vessel thrombosis, make us think that a percentage of these patients may actually suffer from a distinct clinical entity. The stimulus for this concept arose from the clinical observation of three male patients who were admitted to our clinic due to extended vena cava thrombosis. On the occasion of those clinically and laboratory resembling cases, we performed a literature review concerning the epidemiology of BD, associated thrombosis, and coexistent thrombophilic factors, in order to present some evidence, which sustains our hypothesis that certain patients with large vessel thrombosis, who share features of BD and coexistent thrombophilia, should actually be further investigated for the possibility of suffering from a distinct nosological entity.

A novel mutation in the CIAS1/NLRP3 gene associated with an unexpected phenotype of cryopyrin-associated periodic syndromes.

Insalaco A(1), Prencipe G, Buonuomo PS, Ceccherini I, Bracaglia C, Pardeo M, Nicolai R, De Benedetti F.

Author information:

(1)Division of Rheumatology, Department of Pediatric Medicine, Bambino Gesù Children's Hospital, IRCCS, Rome, Italy. insalaco@opbg.net.

**OBJECTIVES:** Cryopyrin-associated periodic syndromes (CAPS) comprise a spectrum of distinct, rare, autosomal dominant autoinflammatory disorders of increasing severity caused by NLRP3 gene mutations.

**METHODS:** We describe a 13-year-old female who presented, in the initial phase of the disease, recurrent episodes of high fever, pericarditis, arthralgia, arthritis of the knees, abdominal pain and marked increase in inflammatory markers. In the subsequent months she developed recurrent episodes of chest pain, skin rash and swelling of the subcutaneous tissue, without fever, and with spontaneous resolution.

**RESULTS:** Molecular analysis of the CIAS1 gene revealed the presence of the Q703K variant and also a c.1105C>A mutation in the heterozygous state, that predicts a L369M amino acid substitution. The latter variant has never been reported. The L369M mutation was predicted to significantly affect protein structure (scoring as 'dangerous' and 'deleterious') by the Variant Effect Predictor tool. Therapy with anakinra was started with rapid disappearance of clinical symptoms and normalization of CRP levels in 24 hours.

**CONCLUSIONS:** The rapid response to IL-1 inhibition suggests that the disease of this patient is driven by IL-1 and supports the conclusion that this novel mutation is pathogenic and may be associated with a new CAPS phenotype. The role played by the concomitant presence of the mutation Q703K remains to be clarified.

Macrophage activation syndrome as the initial manifestation of tumour necrosis factor receptor 1-associated periodic syndrome (TRAPS).

Horneff G(1), Rhouma A, Weber C, Lohse P.

Author information:

(1)Center for Paediatric Rheumatology, Asklepios Clinic Sankt Augustin, Arnold-Janssen-Str. 29, 53757 Sankt Augustin, Germany. g.horneff@asklepios.com.

An 11-year-old Turkish girl from a non-consanguineous family was suffering from joint pain, fever, hepatosplenomegaly, and respiratory insufficiency. Laboratory abnormalities were thrombocytopenia, elevated levels of serum transaminases, lactate dehydrogenase, and C-reactive protein (up to 193 mg / l), a hyperferritinaemia of 8030 ng/ml, and an increased sCD25. The tentative diagnosis of macrophage activation syndrome (MAS) was confirmed by the detection of a histiocytosis with haemophagocytosis in the bone marrow. Treatment with dexamethasone, cyclosporine A, and VP16 was successful. However, the diagnosis of MAS on the background of a systemic juvenile idiopathic arthritis was questionable because of recurrent, spontaneously remitting fever phases of 5 to 7 days duration without an obvious infectious aetiology. A positive family history of febrile episodes in three consecutive generations raised the suspicion of a dominantly inherited disease. Genetic studies revealed a likely pathogenetically relevant E56D/p.Glu85Asp mutation in exon 3 of the TNFRSF1A gene. Alterations of the MEFV gene, in contrast, were not found. To our knowledge, this is the first case of a macrophage activation syndrome as the initial manifestation of TRAPS. Similar case reports in patients with the far more common familial Mediterranean fever (FMF) have been published already.

PMID: 24064022 [Indexed for MEDLINE]

The prevalence of atopy in patients with familial Mediterranean fever and Behçet's disease.

Yazici A(1), Orge Gonullu E, Kardes B, Cefle A.

Author information:

(1)Division of Rheumatology, Department of Internal Medicine, Medical Faculty, Kocaeli University, Kocaeli, Turkey. burakdefy@hotmail.com.

**OBJECTIVES:** The purpose of this study is to investigate the prevalence of atopy in patients with Behçet's disease (BD) and familial Mediterranean fever (FMF).

**METHODS:** In this study, 42 BD patients, 40 FMF patients and 49 healthy subjects were included. The skin test was applied to the whole group. If one or more allergen response was equal or greater than histamine response, it was accepted as atopy. At the same time, total serum IgE and peripheral blood eosinophil levels were also determined.

**RESULTS:** The frequency of atopy was found to be 2.4% (1/42 patients) in BD patients and 5% (2/40 patients) in FMF patients and 16.3% (8/49 individuals) in healthy controls. In the BD patients, positivity to skin prick test was significantly lower than the control group ( $p=0.035$ ). The mean serum total IgE level and eosinophil counts did not differ between the three groups. In 33.3% of BD patients, 39.8% of FMF patients and 20.8% of controls levels of IgE lower than 20 kU/L were found (both groups  $p<0.05$ ).

**CONCLUSIONS:** The related conditions with Th-2 cell response such as atopy seem to be low frequency in BD and FMF patients.

Fever in Behçet's syndrome.

Seyahi E(1), Karaaslan H, Ugurlu S, Yazici H.

Author information:

(1)University of Istanbul, Cerrahpasa Medical Faculty, Department of Rheumatology, University of Istanbul, Turkey. eseyahi@yahoo.com.

**OBJECTIVES:** Fever is taken to be rare in Behçet's syndrome (BS) and when present it is usually considered to be associated with vascular disease. The aim of this study was to formally investigate the presence of fever as a clinical feature in BS patients and suitable controls.

**METHODS:** The study consisted of 2 parts. In the first part, 500 patients with BS, 94 with familial Mediterranean fever (FMF), 100 with ankylosing spondylitis (AS), and 72 with systemic lupus erythematosus (SLE) along with 100 healthy controls (HC) were surveyed with the help of a questionnaire for the history of periodic fever episodes. In the second part, body temperature was measured in 98 newly diagnosed BS patients having at least one active BS lesion and 61 HC. Temperature was measured 3 times and the highest reading was used in the analyses.

**RESULTS:** First part: history of fever episodes was present in 22% patients with BS, 87% with FMF, 33% with SLE and 8% with AS. None of the HC recalled a fever episode. Patients with BS who reported fever episodes were more likely to have major organ involvement such as vascular, neurological or joint involvement. Second part: The mean body temperature reading was similar (albeit statistically different) among patients with BS ( $36.72 \pm 0.42^{\circ}\text{C}$ ) compared to that of the HC ( $36.56 \pm 0.27^{\circ}\text{C}$ ) ( $p=0.004$ ).

**CONCLUSIONS:** In this study, 22% of patients with BS reported a history of fever episodes. As previously reported, fever attacks seemed to be associated strongly with vascular, neurological or joint involvement. The increase in temperature accompanying active BS lesions was modest even when the highest values were considered.

MEFV gene mutations and their clinical significance in Korean patients with adult-onset Still's disease.

Kim JJ(1), Kim JK, Shim SC, Choe JY, Kim TH, Jun JB, Yoo DH.

Author information:

(1)Division of Rheumatology, Department of Internal Medicine, The Hospital for Rheumatic disease, Hanyang University School of Medicine, Seoul, Korea.  
predocj10@naver.com.

**OBJECTIVES:** Adult-onset Still's disease (AOSD) and periodic fever syndrome share clinical features in some aspects. Familial Mediterranean fever (MEFV) is a typical periodic fever syndrome and MEFV gene mutations may contribute to the

clinical features of certain rheumatic diseases. The purpose of this study is to research the incidence and clinical utility of MEFV gene mutations in Korean AOSD patients.

**METHODS:** The study included 96 AOSD patients and 165 healthy controls. In both groups, genomic DNA was isolated and genotyped using restriction fragment length polymorphism for 5 MEFV gene mutations (E148Q, P369S, M680I, V726A and M694V). In the AOSD patients, the clinical significance of MEFV mutation was assessed by the laboratory and clinical features.

**RESULTS:** M680I, V726A and M694V were not found in both groups. P369S was detected in 7 (7.3%) AOSD patients and 10 (6.1%) healthy controls. E148Q mutation was found in 77 (46.7%) among healthy controls with 6 QQ and 44 (45.8%) of AOSD patients with 5 QQ, respectively. The allele frequency of E148Q was 0.25 in AOSD patients, and that of P369S was 0.04. However, there was no significant difference in most clinical manifestations and laboratory findings by the presence and absence of E148Q mutation.

**CONCLUSIONS:** MEFV mutations including E148Q mutation were not associated with the development of AOSD patients in Korea. Although high incidence of E148Q mutation was found, E148Q mutation did not show major effect on the clinical features of AOSD. But we need to look for association with clinical response to certain treatments and long-term prognosis.

Vitamin B12 levels in familial Mediterranean fever patients treated with colchicine.

Gemici AI(1), Sevindik ÖG, Akar S, Tunca M.

Author information:

(1)Department of Hematology, Celal Bayar University School of Medicine, Manisa, Turkey. agemici21@yahoo.com.

**OBJECTIVES:** Familial Mediterranean fever (FMF) is an autosomal recessive autoinflammatory disease characterised by paroxysmal attacks of serosal inflammation. Colchicine is highly effective in preventing these attacks but it

may also disrupt the intestinal absorption of vitamin B12. We hypothesised that patients treated with colchicine for a prolonged period could develop deficiency of the vitamin.

**METHODS:** Ninety-five adult FMF patients on regular colchicine treatment for at least 2 years and age and sex-matched 90 healthy controls were enrolled and complete blood count with platelets, vitamin B12 and folic acid were measured in each person. We also investigated 15 adult FMF patients who were not yet on colchicine.

**RESULTS:** The mean vitamin B12 values were not significantly different between the groups (352.12 (SD=171.62) pg/mL vs. 360.96 (SD=146.53) pg/mL,  $p=0.71$ ), but there were significantly more vitamin B12 deficient cases among FMF patients (12 vs. 3;  $p=0.021$ ) and 3 out of these 12 had megaloblastic anaemia. None of the vitamin B12 deficient controls had anaemia. We could not identify any disorder which might have causative effect for the deficiency among this subgroup. The mean vitamin B12 value of 15 colchicine-naïve cases was not significantly different from patients on colchicine ( $p=0.356$ ).

**CONCLUSIONS:** We did not observe significant vitamin B12 deficiency among colchicine-treated FMF patients but some cases may be more prone to developing this potentially serious disorder.

Current trends in colchicine treatment in familial Mediterranean fever.

La Regina M(1), Ben-Chetrit E, Gasparyan AY, Livneh A, Ozdogan H, Manna R.

Author information:

(1)Department of Internal Medicine, S. Andrea Hospital, ASL 5 Liguria, La Spezia, Italy. micaela.laregina@asl5.liguria.it.

**OBJECTIVES:** Since the publication of the first reports on the efficiency of colchicine in familial Mediterranean fever (FMF), very few randomised studies have investigated issues related to its long-term use. Thus, different approaches taken by physicians involved in FMF care, are exclusively empiric, emulative, and based on case-reports or case-series. Problems such as colchicine intolerance and

colchicine resistance have not been solved yet. This paper aims to evaluate trends in colchicine therapy among physicians taking care of FMF patients around the world.

**METHODS:** We conducted a survey by sending questionnaires to FMF research and treatment centres in Europe and Asia. Many issues (such as dosages, schedules, side effects, interactions, efficacy and toxicity monitoring, definition of colchicine intolerance, colchicine resistance and responsiveness, etc) have been investigated. When more than 70% of physicians responded giving similar answers to an item, the response was considered as a 'trend'. A comparison between answers of physicians from FMF-prevalent and non-prevalent countries was also made.

**RESULTS:** Thirty-five physicians from 11 countries filled the questionnaires, taking care of a total of more than 15000 FMF patients (pts). Different approaches were evident among the various physicians. Statistically significant different approaches between physicians from FMF-prevalent countries with respect to those from non-prevalent countries were found in items like colchicine during pregnancy, severity score and blood tests for disease monitoring. No consensus was found regarding the definition of colchicine resistance.

**CONCLUSIONS:** The current study demonstrated significant variations in the strategy of colchicine therapy for FMF around the world and re-emphasised the need for standardised definitions of colchicine resistance and colchicine intolerance.

SAMHD1, a dNTP triphosphohydrolase (dNTPase), has a key role in human innate immunity. It inhibits infection of blood cells by retroviruses, including HIV, and prevents the development of the autoinflammatory Aicardi-Goutières syndrome (AGS). The inactive apo-SAMHD1 interconverts between monomers and dimers, and in the presence of dGTP the protein assembles into catalytically active tetramers. Here, we present the crystal structure of the human tetrameric SAMHD1-dGTP complex. The structure reveals an elegant allosteric mechanism of activation through dGTP-induced tetramerization of two inactive dimers. Binding of dGTP to four allosteric sites promotes tetramerization and induces a conformational change in the substrate-binding pocket to yield the catalytically active enzyme. Structure-based biochemical and cell-based biological assays confirmed the proposed mechanism. The SAMHD1 tetramer structure provides the basis for a mechanistic understanding of its function in HIV restriction and the pathogenesis of AGS.

Relationship between genetic mutation variations and acute-phase reactants in the attack-free period of children diagnosed with familial Mediterranean fever.

Kosan C(1), Cayir A, Turan MI.

Author information:

(1)Department of Pediatric Nephrology, Faculty of Medicine, Ataturk University, Erzurum, Turkey.

Familial Mediterranean fever (FMF) is a periodic autoinflammatory disease characterized by chronic inflammation. This study investigated the relationship between acute-phase reactants and gene mutations in attack-free periods of childhood FMF. Patients diagnosed with FMF were divided into four groups based on genetic features: no mutation, homozygous, heterozygous, and compound heterozygous. These groups were monitored for 2 years, and blood samples were collected every 6 months during attack-free periods. Erythrocyte sedimentation

rate, C-reactive protein, fibrinogen, and white blood cell count were measured. A disease severity score was determined for each patient. Mean values for erythrocyte sedimentation rate and fibrinogen were significantly different in the homozygous group. White blood cell count and C-reactive protein were similar between the groups. Disease severity score was higher in patients with the M694V mutation than in individuals without the mutation, as well as in those with other mutation groups. Periodic follow-up of patients with FMF MEFV mutations in subjects with acute-phase reactants may be useful in the prevention of morbidity.

Incidence of hereditary amyloidosis and autoinflammatory diseases in Sweden: endemic and imported diseases.

Hemminki K, Li X, Försti A, Sundquist J, Sundquist K.

**BACKGROUND:** Amyloidoses are a heterogeneous group of progressive diseases caused by tissue deposition of misfolded proteins. According to the International Classification of Diseases, hereditary amyloidosis is divided into neuropathic and non-neuropathic forms. In Sweden, neuropathic hereditary amyloidosis has been identified as familial amyloidotic polyneuropathy (FAP), a fatal disease that is treated by liver transplantation. The non-neuropathic form includes familial autoinflammatory diseases. As no incidence data on these hereditary diseases are available and as even diagnostic data on non-neuropathic forms are lacking we determined the incidence of these diseases and characterized non-neuropathic conditions.

**METHODS:** Patients were identified using data from the Swedish Hospital Discharge Register and from the Outpatient Register for 2001 through 2008. All patients discharged with hereditary amyloidosis diagnoses were included and standardized incidence rates were calculated.

**RESULTS:** Non-neuropathic disease was diagnosed in 210 patients, with an incidence of 2.83 per million. FAP was diagnosed in 221 patients, with an incidence of 2.02 per million. Two northern provinces that are home to 5% of the Swedish population accounted for 77% of FAP cases; the incidence in one of them, West Bothnia, was

100 times that in the rest of Sweden. Approximately 98% of non-neuropathic disease patients were immigrants, most of whom were from the Eastern Mediterranean area. Young Syrian descendants had the highest incidence rate, which was over 500-fold higher than that in individuals with Swedish parents. Even the early onset of these conditions identified them as familial autoinflammatory diseases.

CONCLUSIONS: FAP cases were highly concentrated in the two northernmost provinces. Non-neuropathic familial autoinflammatory diseases were of early-onset and immigrant origin most likely related to periodic fever syndromes.

Paradoxically, FAP has remained endemic, in spite of population movements within the country, while familial autoinflammatory diseases, with an incidence exceeding that of FAP, were brought into the country as a result of immigration mainly from the Eastern Mediterranean area.

Elevated levels of CXCL10 in the Periodic Fever, Aphthous stomatitis, Pharyngitis and cervical Adenitis syndrome (PFAPA) during and between febrile episodes; an indication of a persistent activation of the innate immune system.

Førsvoll J(1), Kristoffersen EK, Oymar K.

Author information:

(1)Department of Pediatrics, Stavanger University Hospital, Postboks 8100, 4068, Stavanger, Norway. fojo@sus.no.

BACKGROUND: The Periodic Fever, Aphthous stomatitis, Pharyngitis and cervical Adenitis syndrome (PFAPA) is the most common periodic fever syndrome in childhood. Clinically, PFAPA may resemble autoinflammatory diseases, but the etiology is not fully understood.

METHODS: We measured inflammatory proteins in plasma and hematologic parameters in children with PFAPA during and between febrile episodes, and in a control group with suspected bacterial pneumonia. In children with PFAPA, a first blood sample was taken within 24 hours of a febrile episode and a second sample between

episodes. In children with pneumonia, the first sample was taken shortly after admission and a second sample after full recovery.

**RESULTS:** A total of 22 children with PFAPA and 14 children with pneumonia were included. In children with PFAPA, levels of interleukin (IL) 6, CXCL10 and CCL4 were significantly increased during febrile episodes. The levels of IL-6 and CXCL10 were higher in children with PFAPA during febrile episodes than in children with pneumonia. The levels of CXCL10 remained higher in children with PFAPA between febrile episodes compared to children with pneumonia after recovery. Children with PFAPA had a relative eosinopenia and lymphocytopenia with reduced numbers of both CD4+ and CD8+ T cells during febrile episodes. This pattern was not observed in the children with pneumonia.

**CONCLUSIONS:** The results indicate an innate immune response as the initial step in PFAPA, and a subsequent adaptive response with activation and redistribution of T cells. Moreover, an activation of the innate immune system involving CXCL10 may persist between febrile episodes. CXCL10 may be a possibly clinical marker in children with PFAPA.

The expanding spectrum of rare monogenic autoinflammatory diseases.

Touitou I(1), Galeotti C, Rossi-Semerano L, Hentgen V, Piram M, Koné-Paut I; CeRéMAI, French reference center for autoinflammatory diseases.

Author information:

(1)Laboratoire de génétique des maladies rares et auto-inflammatoires, CHRU de Montpellier, Montpellier, France. isabelle.touitou@inserm.fr.

Monogenic autoinflammatory diseases are a group of hereditary disorders characterized by a clinical and biological inflammatory syndrome in which there is little or no evidence of autoimmunity. The discovery of the first causative gene in 1997 was rapidly followed by the identification of many others from the same group. The mutated proteins can be directly or indirectly involved in the regulation of inflammation. The available literature includes numerous reviews,

which address the principle diseases, but we wanted to focus on the most recent rare syndromes. A comprehensive review is thus provided, including taxonomic, genetic, and epidemiological data, along with characteristics defining positive and differential diagnoses and treatment. We believe that this update will assist physicians in correctly naming their patient's illness. This is an essential step for the effective and targeted management of an orphan disease.

Thorough investigation of a canine autoinflammatory disease (AID) confirms one main risk locus and suggests a modifier locus for amyloidosis.

Olsson M(1), Tintle L, Kierczak M, Perloski M, Tonomura N, Lundquist A, Murén E, Fels M, Tengvall K, Pielberg G, Dufaure de Citres C, Dorso L, Abadie J, Hanson J, Thomas A, Leegwater P, Hedhammar Å, Lindblad-Toh K, Meadows JR.

Author information:

(1)Science for Life Laboratory, Department of Medical Biochemistry and Microbiology, Uppsala University, Uppsala, Sweden.

Autoinflammatory disease (AID) manifests from the dysregulation of the innate immune system and is characterised by systemic and persistent inflammation. Clinical heterogeneity leads to patients presenting with one or a spectrum of phenotypic signs, leading to difficult diagnoses in the absence of a clear genetic cause. We used separate genome-wide SNP analyses to investigate five signs of AID (recurrent fever, arthritis, breed specific secondary dermatitis, otitis and systemic reactive amyloidosis) in a canine comparative model, the pure bred Chinese Shar-Pei. Analysis of 255 DNA samples revealed a shared locus on chromosome 13 spanning two peaks of association. A three-marker haplotype based on the most significant SNP ( $p < 2.6 \times 10^{-8}$ ) from each analysis showed that one haplotypic pair (H13-11) was present in the majority of AID individuals, implicating this as a shared risk factor for all phenotypes. We also noted that a genetic signature (F ST) distinguishing the phenotypic extremes of the breed

specific Chinese Shar-Pei thick and wrinkled skin, flanked the chromosome 13 AID locus; suggesting that breed development and differentiation has played a parallel role in the genetics of breed fitness. Intriguingly, a potential modifier locus for amyloidosis was revealed on chromosome 14, and an investigation of candidate genes from both this and the chromosome 13 regions revealed significant ( $p<0.05$ ) renal differential expression in four genes previously implicated in kidney or immune health (AOAH, ELMO1, HAS2 and IL6). These results illustrate that phenotypic heterogeneity need not be a reflection of genetic heterogeneity, and that genetic modifiers of disease could be masked if syndromes were not first considered as individual clinical signs and then as a sum of their component parts.

Comment in

J Rheumatol. 2013 Dec;40(12):1948-50.

OBJECTIVE: Reactive (AA) amyloidosis may complicate familial Mediterranean fever

(FMF), the prototype of autoinflammatory diseases. Thus, proteinuria in FMF is commonly viewed as resulting from amyloidosis, and kidney biopsy is deemed superfluous. However, nephropathy other than amyloidosis has been described in FMF, but its rate and distinctive characteristics are unknown. Our aim was to determine the rate and underlying pathology of FMF-related nonamyloidotic proteinuria and compare its clinical course, demographic, and genetic features to those of FMF-amyloid nephropathy.

**METHODS:** This study is a retrospective analysis of data from patients with FMF undergoing kidney biopsy for proteinuria above 0.5 g/24 h, over 10 years (2001-2011). Clinical, laboratory, genetic, and pathology data were abstracted from patient files. Biopsies were viewed by an experienced pathologist, as necessary.

**RESULTS:** Of the 25 patients referred for kidney biopsy, only 15 (60%) were diagnosed with amyloid kidney disease (AKD), and 10 were diagnosed with another nephropathy. The AKD and nonamyloid kidney disease (NAKD) groups were comparable on most variables, but showed distinct characteristics with regard to the degree of proteinuria ( $6.45 \pm 4.3$  g vs  $2.14 \pm 1.6$  g,  $p = 0.006$ ), rate of severe FMF (14 vs 5 patients,  $p = 0.022$ ), and rate of development of end stage renal disease (73.3% vs 20%,  $p = 0.015$ ), respectively.

**CONCLUSION:** NAKD is common in FMF and, compared to amyloidosis, it is featured with milder course and better prognosis. Contrary to common practice, it is highly recommended to obtain a kidney biopsy from patients with FMF and proteinuria more than 0.5 g/24 h.

Challenges in diagnosing Muckle-Wells syndrome: identifying two distinct phenotypes.

Kuemmerle-Deschner JB(1), Dembi Samba S, Tyrrell PN, Koné-Paut I, Marie I, Deschner N, Benseler SM.

Author information:

(1)University Hospital Tübingen, Tübingen, Germany.

**OBJECTIVE:** The diagnosis of Muckle-Wells syndrome (MWS) remains challenging due to the clinical heterogeneity and lack of diagnostic criteria. The aims of this study were to describe key elements of the diagnostic evaluation process in MWS and compare identified variables between patients diagnosed in childhood and adulthood.

**METHODS:** A cohort study of consecutive patients with a clinical and genetic diagnosis of MWS was conducted at 2 reference centers for autoinflammatory diseases. Demographic information, clinical presentation, access to care, and preclinical evaluation variables were captured. Presenting symptoms were compared between groups of patients diagnosed in childhood and adulthood. Prediction analysis explored variables associated with late diagnosis. Correspondence analysis identified clinical phenotypes.

**RESULTS:** A total of 34 MWS patients were included (16 males, 18 females) and median age at diagnosis was 31.5 years (range 0.5-75 years). Patients diagnosed during childhood reported musculoskeletal symptoms (62%), rash (62%), fever (54%), and abdominal pain (31%). Those diagnosed as adults described musculoskeletal symptoms (86%), rash (67%), hearing loss (52%), and fatigue (29%). Hearing loss was associated with late diagnosis, while access-to-care variables were not predictive. Correspondence analysis identified distinct clinical phenotypes as follows: an "inflammatory phenotype" (most commonly seen in patients diagnosed in childhood and characterized by relapsing fever and abdominal pain), an intermediate phenotype, and an "organ-disease" phenotype in patients diagnosed during adulthood and characterized by fatigue and hearing loss.

**CONCLUSION:** Distinct clinical phenotypes were identified in patients with MWS. These are closely related to age at diagnosis. The presence of these phenotypes has to be considered when developing diagnostic criteria for MWS.

Exome sequencing reveals RAG1 mutations in a child with autoimmunity and sterile chronic multifocal osteomyelitis evolving into disseminated granulomatous disease.

Reiff A, Bassuk AG, Church JA, Campbell E, Bing X, Ferguson PJ.

We describe a boy who developed autoinflammatory (chronic sterile multifocal osteomyelitis) and autoimmune (autoimmune cytopenias; vitiligo) phenotypes who subsequently developed disseminated granulomatous disease. Whole exome sequencing revealed homozygous RAG1 mutations thus expanding the spectrum of combined immunodeficiency with autoimmunity and granuloma that can occur with RAG deficiency.

Prolonged and recurrent fevers in children.

Marshall GS(1).

Author information:

(1)University of Louisville School of Medicine, 571 S. Floyd St., Suite 321, Louisville, KY 40202, USA. Electronic address: gary.marshall@louisville.edu.

Some children referred for prolonged fever are actually not having elevated temperatures; the approach here requires dissection of the history and correction of health misperceptions. Others have well-documented fevers associated with clinical, laboratory, or epidemiologic findings that should point to a specific diagnosis. "Fever-of-Unknown-Origin" (FUO) is the clinical scenario of daily fever for  $\geq 14$  days that defies explanation after a careful history, physical examination, and basic laboratory tests. The diagnostic approach requires a meticulous fever diary, serial clinical and laboratory evaluations, vigilance for the appearance of new signs and symptoms, and targeted investigations; the pace of the work-up is determined by the severity of the illness. Approximately half of children with FUO will have a self-limited illness and will never have a specific diagnosis made; the other half will ultimately be found to have, in order, infectious, inflammatory, or neoplastic conditions. Irregular,

intermittent, recurrent fevers in the well-appearing child are likely to be sequential viral illnesses. Monogenic autoinflammatory diseases should be considered in those who do not fit the picture of recurrent infections and who do not have hallmarks of immune deficiency. Stereotypical febrile illnesses that recur with clockwork periodicity should raise the possibilities of cyclic neutropenia, if the cycle is approximately 21 days, or periodic fever, aphthous stomatitis, pharyngitis, and adenitis (PFAPA) syndrome, the most common periodic fever in childhood.

Bimodal immune activation in psoriasis.

Christophers E(1), Metzler G, Röcken M.

Author information:

(1)Department of Dermatology, University Clinics, Kiel, Germany.

Comment in

Br J Dermatol. 2014 Jan;170(1):7-8.

Psoriasis is an immune-regulated skin disease with various clinical subtypes and disease activities. The majority of patients present with predominantly stable plaques. At the onset of new lesions, plaque-type psoriasis frequently demonstrates pin-sized and highly inflammatory papules sometimes with an inflammatory border. The histopathology of initial psoriasis differs from stable plaque-type psoriasis. Early lesions demonstrate innate immune cells with neutrophils, degranulating mast cells and macrophages. These are followed by interleukin (IL)-1-dependent T helper (Th)17 cells, finally resulting in the Th1-dominated immunopathology of stable plaque-type psoriasis, where mononuclear cells predominate with interspersed neutrophilic (Munro) microabscesses. These features suggest a bimodal immune pathway where alternate activation of either

innate (autoinflammatory) or adaptive (autoimmune) immunity predominates. Neutrophilic infiltrations appear during early psoriasis with Munro abscesses. They are time limited and occur periodically, clinically best seen in linear nail pitting. These features strongly suggest a critical role for an IL-1-Th17-dominated autoinflammation in the initiation of psoriasis, followed by a Th1-dominated late-phase reaction. The concept of bimodal immune activation helps to explain results from therapeutic interventions that are variable and previously only partly understood.

Familial mediterranean fever: a fascinating model of inherited autoinflammatory disorder.

Portincasa P(1), Scaccianoce G, Palasciano G.

Author information:

(1)Clinica Medica "A. Murri", Department of Biomedical Sciences and Human Oncology, University of Bari Medical School, Bari, Italy.

**BACKGROUND:** Familial Mediterranean fever (FMF) is a rare inherited autosomal recessive autoinflammatory disorder characterized by recurrent and self-limited episodes of fever and painful serositis, lasting 1-3 days. FMF occurs almost exclusively among ethnic groups of the Mediterranean basin, although cases have also been found in Japan and Korean populations. Diagnosis is based on clinical features, response to colchicine and genetic analysis. Novel drugs are emerging, allowing better management of colchicine-resistant/colchicine-intolerant patients. This review aims to attract the attention of the readers on differential diagnosis and management of patients with FMF.

**METHODS:** The current state-of-the-art on FMF is outlined, with respect to epidemiological, genetic, pathophysiological and therapeutic characteristics, based on critical analysis of solid scientific literature.

RESULTS: FMF is more frequent than it was thought before. The phenotypic expression of M694V is more severe than that of V726A. Patients with M694V/M694V homozygosity are exposed to a higher risk of developing renal amyloidosis, arthritis, dermatologic and oral lesions, higher fever and more frequent painful attacks. Life-long therapy with colchicine (1·0-2·4 mg/day) is effective and safe to prevent recurrent attacks and renal amyloidosis and to reverse proteinuria. In nonresponder patients, alternative novel approaches include interleukin-1 receptor antagonist anakinra and the interleukin-1 decoy receptor rilonacept.

CONCLUSIONS: The prognosis of FMF is normal if AA amyloidosis is prevented. Colchicine remains the first-line therapy to treat pain and prevent amyloidosis. A follow-up should include clinical evaluation, therapeutic adjustments, measurement of serum amyloid A and proteinuria.

Primary immunodeficiency in Japan; epidemiology, diagnosis, and pathogenesis.

Takada H(1).

Author information:

(1)Department of Pediatrics, Graduate School of Medical Sciences, Kyushu University, Fukuoka, Japan.

Primary immunodeficiency (PID) constitutes a large group of diseases, including almost 180 hereditary disorders. The patients show susceptibility to various infections due to congenital defects of the immune system. It is also known that PID patients suffer from non-infectious complications, including autoimmune diseases and malignant disorders. During the last 20 years the number of known PID has increased considerably. New PID conferring a specific predisposition to infections with one or a few pathogens have been described. Disorders of innate immunity and various autoinflammatory disorders were included in new categories. In contrast, the incidence, clinical manifestations, and genetic factors of PID

seem to be different among countries or races. The clinical manifestations can differ depending on the hygiene conditions, health-care environment, and vaccination policy, and so on. A nationwide survey on PID patients in Japan provided a lot of information regarding these issues, and it uncovered a previously unknown complication of PID, endocrine disorders. In this review, the data concerning epidemiology and clinical characteristics of PID in Japan obtained in the nationwide questionnaire survey, and the results of studies on the clinical and genetic characteristics of Japanese patients with Mendelian susceptibility to mycobacterial disease and interleukin-1 receptor-associated kinase 4 deficiency are presented in the light of their pathogenesis and pathophysiology.

Anti-CCP Antibodies Are Not Associated with Familial Mediterranean Fever in Childhood.

Onur H(1), Aral H, Arica V, Bercem G, Usta M, Kasapcopur O.

Author information:

(1)Department of Pediatric, Istanbul Training and Research Hospital, Istanbul, Turkey.

**Objective.** Anticyclic citrullinated peptide antibodies (anti-CCP) testing is useful in the diagnosis of rheumatoid arthritis (RA) with high specificity. Arthritis is a very common clinical manifestation in children with familial Mediterranean fever (FMF). The aim of the study was to show the presence of anti-CCP antibodies in child individuals diagnosed with FMF. **Material and Methods.** The study groups comprised one hundred and twenty-six patients (126) diagnosed with FMF (female/male (n): 66/60) and 50 healthy controls (female/male (n): 25/25). Clinical and laboratory assessments of the FMF patients were performed during attack-free periods. Erythrocyte sedimentation rate (ESR), serum C-reactive protein (CRP), fibrinogen, and anti-CCP antibody levels were measured.

Results. Anti-CCP was negative in healthy controls and also in all FMF patients. There was not a significant difference in anti-CCP between the patient and the control groups. Our study has shown that anti-CCP was correlated moderately with age ( $r_s = 0.271$ ;  $P = 0.0020$ ), duration of illness ( $r_s = 0.331$ ;  $P < 0.0001$ ), and colchicine therapy ( $r_s = 0.259$ ;  $P = 0.004$ ). Conclusion. Our data show that anti-CCP antibodies are not associated with FMF. Anti-CCP does not have a priority for identifying FMF arthritis from the other inflammatory arthritis.

The skin is one of the most common extraintestinal organ system affected in patients with inflammatory bowel disease (IBD), including both Crohn's disease and ulcerative colitis. The skin manifestations associated with IBD are polymorphic and can be classified into 4 categories according to their pathophysiology: (1) specific, (2) reactive, (3) associated, and (4) induced by IBD treatment. Cutaneous manifestations are regarded as specific if they share with IBD the same granulomatous histopathological pattern: perianal or metastatic

Crohn's disease (commonly presenting with abscesses, fistulas or hidradenitis suppurativa-like features) is the prototype of this setting. Reactive cutaneous manifestations are different from IBD in the histopathology but have close physiopathological links: pyoderma gangrenosum, a neutrophil-mediated autoinflammatory skin disease typically manifesting as painful ulcers, is the paradigm of this group. Among the cutaneous diseases associated with IBD, the most commonly seen are erythema nodosum, a form of panniculitis most commonly involving bilateral pretibial areas, and psoriasis, a T helper 1/T helper 17-mediated erythematous squamous inflammatory disease. Finally, the number of cutaneous adverse reactions because of IBD therapies is progressively increasing. The most frequent drug-induced cutaneous manifestations are psoriasis-like, eczema-like, and lichenoid eruptions, as well as cutaneous lupus erythematosus for biologics, and nonmelanoma skin cancer, mainly basal cell and squamous cell carcinomas for thiopurines.

The present study investigated the effects of vaccinating sows and piglets or piglets alone against *Haemophilus parasuis* on the prevalence of *H. parasuis* in nasal swabs, on the humoral and cellular immune responses, and on the production parameters of piglets at 3 Korean farms with a clinical history of polyserositis caused by *H. parasuis*. Piglets born to vaccinated or non-vaccinated sows were subdivided into 3 groups: vaccinated sows and vaccinated pigs (VS-VP), non-vaccinated sows and vaccinated pigs (NVS-VP), and non-vaccinated sows and non-vaccinated pigs (NVS-NVP). The proportion of piglets with positive nasal swabs was significantly lower ( $P < 0.05$ ) in the vaccinated animals (VS-VP and

NVS-VP groups) than in the non-vaccinated animals (NVS-NVP group) at 35 and 60 d of age at the 3 farms. The overall growth performance (from 7 to 60 d of age) of the vaccinated piglets was significantly better ( $P < 0.05$ ) than that of the non-vaccinated piglets at the 3 farms. Piglets in the VS-VP group had significantly higher levels ( $P < 0.05$ ) of *H. parasuis*-specific IgG antibodies, lymphocyte proliferation, and interferon- $\gamma$ -secreting cells than piglets in the NVS-VP and NVS-NVP groups on days 1, 7, 21, 35, and 60 after birth at the 3 farms.

Publisher: Ce projet visait à étudier les effets de la vaccination contre *Haemophilus parasuis* des truies et des porcelets ou des porcelets uniquement sur la prévalence d'*H. parasuis* dans des écouvillons nasaux, sur les réponses immunitaires humorale et cellulaire, et sur les paramètres de production des porcelets dans trois fermes coréennes avec une histoire de cas cliniques de polysérosites causés par *H. parasuis*. Les porcelets nés de truies vaccinées et non-vaccinées ont été répartis en trois groupes : truies vaccinées et porcelets vaccinés (VS-VP), truies non-vaccinées et porcelets vaccinés (NVS-VP), et truies non-vaccinées et porcelets non-vaccinés (NVS-NVP). La proportion de porcelets positifs pour *H. parasuis* à partir de l'écouvillon nasal était significativement plus faible ( $P < 0,05$ ) chez les animaux vaccinés (groupes VS-VP et NVS-VP) que chez les animaux non-vaccinés (groupe NVS-NVP) à 35 et 60 jours d'âge sur les trois fermes. Sur les 3 fermes, les performances de croissance globales (de 7 à 60 jours d'âge) des porcelets vaccinés étaient significativement meilleures ( $P < 0,05$ ) que celles des porcelets non-vaccinés. Sur les trois fermes, les porcelets du groupe VS-VP avaient des niveaux significativement plus élevés ( $P < 0,05$ ) d'anticorps IgG spécifiques contre *H. parasuis*, de prolifération lymphocytaire, et de cellules sécrétant de l'interféron- $\gamma$  que les porcelets dans les groupes NVS-VP et NVS-NVP aux jours 1, 7, 21, 35, et 60 après la naissance. SOCS3 deletion in T lymphocytes suppresses development of chronic ocular inflammation via upregulation of CTLA-4 and expansion of regulatory T cells.

Yu CR(1), Kim SH, Mahdi RM, Egwuagu CE.

Author information:

(1)Molecular Immunology Section, National Eye Institute, National Institutes of Health, Bethesda, MD 20892.

Suppressors of cytokine signaling (SOCS) proteins are negative-feedback regulators of the JAK/STAT pathway, and SOCS3 contributes to host immunity by regulating the intensity and duration of cytokine signals and inflammatory responses. Mice with *Socs3* deletion in myeloid cells exhibit enhanced STAT3 signaling, expansion of Th1 and Th17 cells, and develop severe experimental autoimmune encephalomyelitis. Interestingly, development of the unique IL-17/IFN- $\gamma$  double-producing (Th17/IFN- $\gamma$  and Tc17/IFN- $\gamma$ ) subsets that exhibit strong cytotoxic activities and are associated with pathogenesis of several autoimmune diseases has recently been shown to depend on epigenetic suppression of SOCS3 expression, further suggesting involvement of SOCS3 in autoimmunity and tumor immunity. In this study, we generated mice with *Socs3* deletion in the CD4 T cell compartment (CD4-SOCS3 knockout [KO]) to determine in vivo effects of the loss of *Socs3* in the T cell-mediated autoimmune disease, experimental autoimmune uveitis (EAU). In contrast to the exacerbation of experimental autoimmune encephalomyelitis in myeloid-specific SOCS3-deleted mice, CD4-SOCS3KO mice were protected from acute and chronic uveitis. Protection from EAU correlated with enhanced expression of CTLA-4 and expansion of IL-10-producing regulatory T cells with augmented suppressive activities. We further show that SOCS3 interacts with CTLA-4 and negatively regulates CTLA-4 levels in T cells, providing a mechanistic explanation for the expansion of regulatory T cells in CD4-SOCS3 during EAU. Contrary to in vitro epigenetic studies, Th17/IFN- $\gamma$  and Tc17/IFN- $\gamma$  populations were markedly reduced in CD4-SOCS3KO, suggesting that SOCS3 promotes expansion of the Th17/IFN- $\gamma$  subset associated with development of severe uveitis. Thus, SOCS3 is a potential therapeutic target in uveitis and other autoinflammatory diseases.

Colchicine is an ancient drug that is used for symptomatic relief in a wide range of inflammatory diseases including gout, Behçet syndrome, and familial Mediterranean fever. Recognition of its antiinflammatory properties and of its unpleasant gastrointestinal side effects date back thousands of years. Despite this, uncertainty remains concerning its mechanism of action and very few randomized controlled trials have been carried out to examine its safety and efficacy to date. Although it is an effective drug, its use is hindered by a very narrow therapeutic index. This review attempts to summarize recent developments concerning the use of colchicine in the treatment of gout with particular focus on its mechanism of action and toxicity.

The aim of this study is to evaluate the types and clinical characteristics of peripheral facial palsy in children. The hospital charts of children diagnosed with peripheral facial palsy were reviewed retrospectively. A total of 81

children (42 female and 39 male) with a mean age of  $9.2 \pm 4.3$  years were included in the study. Causes of facial palsy were 65 (80.2%) idiopathic (Bell palsy) facial palsy, 9 (11.1%) otitis media/mastoiditis, and tumor, trauma, congenital facial palsy, chickenpox, Melkersson-Rosenthal syndrome, enlarged lymph nodes, and familial Mediterranean fever (each 1; 1.2%). Five (6.1%) patients had recurrent attacks. In patients with Bell palsy, female/male and right/left ratios were 36/29 and 35/30, respectively. Of them, 31 (47.7%) had a history of preceding infection. The overall rate of complete recovery was 98.4%. A wide variety of disorders can present with peripheral facial palsy in children. Therefore, careful investigation and differential diagnosis is essential.

Colchicine treatment in children with familial Mediterranean fever: is it a risk factor for neuromyopathy?

Işıkay S(1), Yılmaz K, Yiğiter R, Balat A, Büyükçelik M.

Author information:

(1)Department of Pediatric Neurology, Gaziantep Children's Hospital, Gaziantep, Turkey. Electronic address: dr.sedatisikay@mynet.com.

**BACKGROUND:** We cared for a 17-year-old adolescent with familial Mediterranean fever under colchicine treatment. Because of the increased creatinine kinase level (3937 U/L) observed in this individual, we planned to assess all pediatric patients with familial Mediterranean fever under colchicine treatment to detect any resultant neuromyopathy.

**METHODS:** The study included 88 children with familial Mediterranean fever who were receiving colchicine. The patient with myopathy was not included in the study. Serum creatinine kinase levels were measured and nerve conduction studies were carried out in all patients.

**RESULTS:** The study included 88 patients (47 female, 53.4%) with an average age of  $10.1 \pm 3.35$  years. The average period of colchicine use was  $28.25 \pm 17.66$  months. Side effects of colchicine were detected in 10 patients (11%)--as diarrhea in eight patients, leukopenia in one patient, and hair loss in one patient. Nerve conduction studies determined incidental carpal tunnel syndrome in only one patient.

**CONCLUSIONS:** Our study did not suggest an elevated risk of neuromyopathy associated with the use of colchicine for familial Mediterranean fever.

The aim of this study was to determine the Mediterranean fever (MEFV) gene mutations and their clinical correlations in children with familial Mediterranean fever (FMF) in southeast Turkey. Clinical and laboratory characteristics of 147 (65 males, 82 females) consecutive children with FMF having a positive MEFV gene mutation were prospectively investigated. Patients with negative MEFV gene mutations or atypical FMF presentations and those from other regions of the country were excluded. Clinical manifestations and disease severity scores were recorded. The six most frequent MEFV mutations including M694V, V726A, R726H, P369S, E148Q and P369S were investigated by a reverse hybridization test method. The median age of study group was 9.0 years, median age at diagnosis was 7.8 years, median age at disease onset was 5.0 years, and median follow-up duration was 4.0 years. A positive family history of FMF and parent-to-offspring transmission was found in 58.5 and 42.2 % of families, respectively. The frequencies of independent alleles, with decreasing order, were E148Q (30.7 %), M694V (26.0 %), R761H (13.5 %), V726A (13.0 %), P369S (10.5 %) and M680I (6.3 %) in FMF patients. The M694V subgroup had higher mean disease severity score and longer attack duration compared with E148Q and other mutations subgroups ( $p < 0.05$ ). Two patients with amyloidosis had the M694V homozygote genotype. In conclusion contrast to other regions and many other ethnicities of the world, the most frequent MEFV gene mutation was E148Q in southeast Turkey. The M694V mutation frequency was lower, and disease severity was relatively mild in FMF children of this region.

ariane.standing@ucl.ac.uk.

Steady progress in our understanding of the genetic basis of autoinflammatory

diseases has been made over the past 16 years. Since the discovery of the familial Mediterranean fever gene MEFV (also known as marenostin) in 1997, 18 other genes responsible for monogenic autoinflammatory diseases have been identified to date. The discovery of these genes was made through the utilisation of many genetic mapping techniques, including next generation sequencing platforms. This review article clearly describes the gene hunting approaches, methods of data analysis and the technological platforms used, which has relevance to all those working within the field of gene discovery for Mendelian disorders.

A role for NADPH oxidase in antigen presentation.

Gardiner GJ(1), Deffit SN, McLetchie S, Pérez L, Walline CC, Blum JS.

Author information:

(1)Department of Microbiology and Immunology, Indiana University School of Medicine , Indianapolis, IN , USA.

The nicotinamide adenine dinucleotide phosphate (NADPH) oxidase expressed in phagocytes is a multi-subunit enzyme complex that generates superoxide ( $O_2^{\cdot-}$ ). This radical is an important precursor of hydrogen peroxide ( $H_2O_2$ ) and other reactive oxygen species needed for microbicidal activity during innate immune responses. Inherited defects in NADPH oxidase give rise to chronic granulomatous disease (CGD), a primary immunodeficiency characterized by recurrent infections and granulomatous inflammation. Interestingly, CGD, CGD carrier status, and oxidase gene polymorphisms have all been associated with autoinflammatory and autoimmune disorders, suggesting a potential role for NADPH oxidase in regulating adaptive immune responses. Here, NADPH oxidase function in antigen processing and presentation is reviewed. NADPH oxidase influences dendritic cell (DC) crosspresentation by major histocompatibility complex class I molecules through regulation of the phagosomal microenvironment, while in B lymphocytes, NADPH oxidase alters epitope selection by major histocompatibility complex class II

molecules.

(1)Research Center of Systemic Autoimmune and Autoinflammatory Diseases, Rheumatology Unit, Policlinico Le Scotte, University of Siena, Siena, Italy.

Tumor necrosis factor-receptor associated periodic syndrome (TRAPS) is a rare autosomal dominant autoinflammatory disorder characterized by recurrent episodes of long-lasting fever and inflammation in different regions of the body, such as the musculo-skeletal system, skin, gastrointestinal tract, serosal membranes and eye. Our aims were to evaluate circulating microRNAs (miRNAs) levels in patients with TRAPS, in comparison to controls without inflammatory diseases, and to correlate their levels with parameters of disease activity and/or disease severity. Expression levels of circulating miRNAs were measured by Agilent microarrays in 29 serum samples from 15 TRAPS patients carrying mutations known to be associated with high disease penetrance and from 8 controls without inflammatory diseases. Differentially expressed and clinically relevant miRNAs were detected using GeneSpring GX software. We identified a 6 miRNAs signature able to discriminate TRAPS from controls. Moreover, 4 miRNAs were differentially expressed between patients treated with the interleukin (IL)-1 receptor antagonist, anakinra, and untreated patients. Of these, miR-92a-3p and miR-150-3p expression was found to be significantly reduced in untreated patients, while their expression levels were similar to controls in samples obtained during anakinra treatment. MiR-92b levels were inversely correlated with the number of

fever attacks/year during the 1(st) year from the index attack of TRAPS, while miR-377-5p levels were positively correlated with serum amyloid A (SAA) circulating levels. Our data suggest that serum miRNA levels show a baseline pattern in TRAPS, and may serve as potential markers of response to therapeutic intervention.

Sufficient production of geranylgeraniol is required to maintain endotoxin tolerance in macrophages.

Kim J(1), Lee JN, Ye J, Hao R, Debose-Boyd R, Ye J.

Author information:

(1)Department of Molecular Genetics, University of Texas Southwestern Medical Center, Dallas, TX 75390.

Endotoxin tolerance allows macrophages to produce large quantities of proinflammatory cytokines immediately after their contact with lipopolysaccharides (LPSs), but prevents their further production after repeated exposure to LPSs. While this response is known to prevent overproduction of proinflammatory cytokines, the mechanism through which endotoxin tolerance is established has not been identified. In the current study, we demonstrate that sufficient production of geranylgeraniol (GGOH) in macrophages is required to maintain endotoxin tolerance. We show that increased synthesis of 3-hydroxy-3-methyl-glutaryl-CoA reductase (HMGCR) protein following LPS treatment is required to produce enough GGOH to inhibit expression of Malt1, a protein known to stimulate expression of proinflammatory cytokines, in macrophages repeatedly exposed to LPSs. Depletion of GGOH caused by inhibition of HMGCR led to increased Malt1 expression in macrophages subjected to repeated exposure to LPSs. Consequently, endotoxin tolerance was impaired, and production of interleukin 1- $\beta$  and other proinflammatory cytokines was markedly elevated in these cells. These results suggest that insufficient production of GGOH in macrophages may cause autoinflammatory diseases.

Systems approaches to human autoimmune diseases.

Banchereau R(1), Cepika AM, Pascual V.

Author information:

(1)Baylor Institute for Immunology Research, 3434 Live Oak, Dallas, TX 75204, USA.

Systemic autoimmune diseases result from interactions between genes and environmental triggers that lead to dysregulation of both innate and adaptive immunity. Systems biology approaches enable the global characterization of complex systems at the DNA, RNA and protein levels. Recent technological breakthroughs such as deep sequencing or high-throughput proteomics are revealing novel inflammatory pathways involved in autoimmunity. Herein, we review recent developments, challenges and promising avenues in the use of systems approaches to understand human systemic autoimmune and autoinflammatory diseases.

IL-33 markedly activates murine eosinophils by an NF- $\kappa$ B-dependent mechanism differentially dependent upon an IL-4-driven autoinflammatory loop.

Bouffi C(1), Rochman M, Zust CB, Stucke EM, Kartashov A, Fulkerson PC, Barski A, Rothenberg ME.

Author information:

(1)Division of Allergy and Immunology, Cincinnati Children's Hospital Medical Center, Cincinnati, OH 45229.

Eosinophils are major effector cells in type 2 inflammatory responses and become activated in response to IL-4 and IL-33, yet the molecular mechanisms and cooperative interaction between these cytokines remain unclear. Our objective was to investigate the molecular mechanism and cooperation of IL-4 and IL-33 in eosinophil activation. Eosinophils derived from bone marrow or isolated from IL5-transgenic mice were activated in the presence of IL-4 or IL-33 for 1 or 4 h, and the transcriptome was analyzed by RNA sequencing. The candidate genes were validated by quantitative PCR and ELISA. We demonstrated that murine-cultured eosinophils respond to IL-4 and IL-33 by phosphorylation of STAT-6 and NF- $\kappa$ B, respectively. RNA sequence analysis of murine-cultured eosinophils indicated that

IL-33 induced 519 genes, whereas IL-4 induced only 28 genes, including 19 IL-33-regulated genes. Interestingly, IL-33 induced eosinophil activation via two distinct mechanisms, IL-4 independent and IL-4 secretion/autostimulation dependent. Anti-IL-4 or anti-IL-4R $\alpha$  Ab-treated cultured and mature eosinophils, as well as IL4- or Stat6-deficient cultured eosinophils, had attenuated protein secretion of a subset of IL-33-induced genes, including Retnla and Ccl17. Additionally, IL-33 induced the rapid release of preformed IL-4 protein from eosinophils by a NF- $\kappa$ B-dependent mechanism. However, the induction of most IL-33-regulated transcripts (e.g., Il6 and Il13) was IL-4 independent and blocked by NF- $\kappa$ B inhibition. In conclusion, we have identified a novel activation pathway in murine eosinophils that is induced by IL-33 and differentially dependent upon an IL-4 auto-amplification loop.

Colchicine and the heart: pushing the envelope.

Deftereos S(1), Giannopoulos G, Papoutsidakis N, Panagopoulou V, Kossyvakis C, Raisakis K, Cleman MW, Stefanadis C.

Author information:

(1)Department of Cardiology, Athens General Hospital "G. Gennimatas", Athens, Greece; Section of Cardiovascular Medicine, Yale University School of Medicine, Yale University, New Haven, Connecticut.

Colchicine, a natural and ancient drug still used today, is traditionally considered the staple therapy for gout and a second-line treatment for pericarditis, as well as a basic part of familial Mediterranean fever and Behcet's disease management. It is commonly classified as an anti-inflammatory agent, although its mechanism of action does not involve the arachidonic acid pathway affected by non-steroid anti-inflammatory drugs and glucocorticoids. Colchicine inhibits microtubule polymerization by binding to tubulin, thus affecting any process that requires cytoskeletal changes, including cell mitosis

and neutrophil motility. Recent studies suggest that colchicine may prove to be useful in a much wider spectrum of cardiovascular diseases than previously suspected, rekindling the interest in this old drug. In this review we briefly present the biochemical characteristics, mechanism of action and side-effects of colchicine, as well as examine what is currently known about the promising role of colchicine in cardiovascular medicine beyond pericardial disease.

Incidence and clinical outcome of renal amyloidosis: a retrospective study.

Abdallah E(1), Waked E.

Author information:

(1)Department of Nephrology, Theodor Bilharz Research Institute, Cairo, Egypt.  
abdallahemad66@yahoo.com

The kidneys are affected in almost all patients with amyloid A in secondary amyloidosis (AA) amyloidosis but less frequently in immunoglobulin light chains in primary systemic amyloidosis (AL) amyloidosis. In this study, we present the incidence, etiology, clinical manifestations, biochemical features and clinical course of renal amyloidosis. We conducted a retrospective study on a group of 40 cases with renal biopsy-proven amyloidosis. They constituted 2.5% of the total cases of renal biopsies performed in the Theodor Bilharz Research Institute, Cairo, Egypt, during the period from February 2003 to May 2009. The mean age (30 males, ten females) was  $36.51 \pm 10.32$  years. Thirty-two of the cases had secondary AA amyloidosis and eight cases had primary AL amyloidosis. The causes of secondary amyloidosis were as follows: 12 (30%) familial Mediterranean fever (FMF), eight (20%) pulmonary tuberculosis, four (10%) chronic osteomyelitis, four (10%) bronchiectasis, three (7%) rheumatoid arthritis and one (2%) rheumatic heart disease. The eight cases of primary AL amyloidosis comprised of five cases that were associated with myeloma (13%) and three (8%) cases that were idiopathic.

Among the 23 patients with AA amyloidosis, after six months of treatment with colchicine, the proteinuria improved, serum albumin level increased and edema disappeared in 13 patients. In four cases of AA amyloidosis who were clinically and biochemically normal after colchicine therapy, a second renal biopsy disclosed decreased amyloid deposition compared with the first biopsy. In the three renal transplanted patients who had amyloidosis secondary to FMF and were treated with colchicines, AA amyloidosis did not recur in the transplanted kidney. It might be possible that in AL amyloidosis, treatment with methotrexate, melphalan and prednisolone may improve survival. The incidence of renal amyloidosis is increasing and colchicine can be used in secondary amyloidosis as it may have an effect on reducing the production of the amyloid precursor proteins and in reducing proteinuria.

**OBJECTIVES:** To validate the Auto-Inflammatory Diseases Activity Index (AIDAI) in the four major hereditary recurrent fever syndromes (HRFs): familial Mediterranean fever (FMF), mevalonate kinase deficiency (MKD), tumour necrosis factor receptor-associated periodic syndrome (TRAPS) and cryopyrin-associated periodic syndromes (CAPS).

**METHODS:** In 2010, an international collaboration established the content of a disease activity tool for HRFs. Patients completed a 1-month prospective diary with 12 yes/no items before a clinical appointment during which their physician assessed their disease activity by a questionnaire. Eight international experts in auto-inflammatory diseases evaluated the patient's disease activity by a blinded web evaluation and a nominal group technique consensus conference, with their consensus judgement considered the gold standard.

Sensitivity/specificity/accuracy measures and the ability of the score to discriminate active from inactive patients via the best cut-off score were calculated by a receiver operating characteristic analysis.

**RESULTS:** Consensus was achieved for 98/106 (92%) cases (39 FMF, 35 CAPS, 14 TRAPS and 10 MKD), with 26 patients declared as having inactive disease and 72 as having active disease. The median total AIDAI score was 14 (range=0-175). An AIDAI cut-off score  $\geq 9$  discriminated active from inactive patients, with sensitivity/specificity/accuracy of 89%/92%/90%, respectively, and an area under the curve of 98% (95% CI 96% to 100%).

**CONCLUSIONS:** The AIDAI score is a valid and simple tool for assessing disease activity in FMF/MKD/TRAPS/CAPS. This tool is easy to use in clinical practice and has the potential to be used as the standard efficacy measure in future clinical trials.

Br J Dermatol. 2014 May;170(5):1198-9.

YM is the first son of Tunisian consanguineous parents who developed, at 2 weeks of life, an erythematous and scaly eruption, with subsequent rapid evolution toward generalized pustular psoriasis. Afterward, cutaneous flares of diffuse erythematous rash and pustules involving the whole body appeared, with a once weekly periodicity. Intense irritability was present during flares without fever. Moreover, since 1 month of age the infant presented with diarrhea, dysphagia, and reduced feeding rate, with failure to thrive. Laboratory tests during acute flares showed marked leukocytosis, thrombocytosis, and anemia without C-reactive protein elevation. Skin biopsy and clinical presentation were consistent with pustular psoriasis; nevertheless, the patient did not respond to high-potency topical corticosteroids and retinoid acid. As the patient presented with repeated skin flares early after birth, as well as serious constitutional distress with failure to thrive, an autoinflammatory syndrome like interleukine-1-receptor

antagonist deficiency or interleukin-36-receptor antagonist deficiency (DITRA) was considered. The hypothesis was reinforced by parental consanguinity, and absence of skin lesion improvement under standard topical treatment. Genetic analyses showed a homozygous mutation in the IL36RN gene (L27P), which represents the same mutation recently described in DITRA patients. At age 6 months we started treatment with the recombinant interleukin-1 receptor antagonist anakinra with efficacy both on constitutional symptoms and skin involvement. DITRA is a recently described autoinflammatory disease characterized by repeated flares of generalized pustular psoriasis, high fever, asthenia, and systemic inflammation. We report herein the first exhaustive clinical description of an infant with DITRA who was successfully treated with anakinra.

**BACKGROUND:** The Cryopyrin-Associated Periodic Syndromes (CAPS) are a group of rare hereditary autoinflammatory diseases and encompass Familial Cold Autoinflammatory Syndrome (FCAS), Muckle-Wells Syndrome (MWS), and Neonatal Onset Multisystem Inflammatory Disease (NOMID). Canakinumab is a monoclonal antibody directed against IL-1 beta and approved for CAPS patients but requires post-approval monitoring due to low and short exposures during the licensing process. Creative approaches to observational methodology are needed, harnessing novel registry strategies to ensure Health Care Provider reporting and patient monitoring.

**METHODS:** A web-based registry was set up to collect information on long-term safety and effectiveness of canakinumab for CAPS.

**RESULTS:** Starting in November 2009, this registry enrolled 241 patients in 43

centers and 13 countries by December 31, 2012. One-third of the enrolled population was aged < 18; the overall population is evenly divided by gender. Enrolment is ongoing for children.

CONCLUSIONS: Innovative therapies in orphan diseases require post-approval structures to enable in depth understanding of safety and natural history of disease. The rarity and distribution of such diseases and unpredictability of treatment require innovative methods for enrolment and follow-up. Broad international practice-based recruitment and web-based data collection are practical.

Lipodystrophies represent a group of heterogeneous disorders characterized by loss of fat tissue. However, the underlying mechanisms remain poorly understood. Using mice carrying an ERCC1-XPF DNA repair defect systematically or in adipocytes, we show that DNA damage signaling triggers a chronic autoinflammatory response leading to fat depletion. Ercc1<sup>-/-</sup> and aP2-Ercc1F<sup>-/-</sup> fat depots show extensive gene expression similarities to lipodystrophic Pparγ(Δi/+ ) animals, focal areas of ruptured basement membrane, the reappearance of primary cilia, necrosis, fibrosis, and a marked decrease in adiposity. We find that persistent DNA damage in aP2-Ercc1F<sup>-/-</sup> fat depots and in adipocytes ex vivo triggers the induction of proinflammatory factors by promoting transcriptionally active

histone marks and the dissociation of nuclear receptor corepressor complexes from promoters; the response is cell autonomous and requires ataxia telangiectasia mutated (ATM). Thus, persistent DNA damage-driven autoinflammation plays a causative role in adipose tissue degeneration, with important ramifications for progressive lipodystrophies and natural aging.

Blau syndrome-associated uveitis and the NOD2 gene.

Pillai P(1), Sobrin L.

Author information:

(1)Uveitis Service, Massachusetts Eye and Ear Infirmary, Harvard Medical School , Boston, Massachusetts , USA.

Blau syndrome (BS), a rare autosomal dominant autoinflammatory syndrome, is an example of a monogenic disease. It was first described as a classic triad of uveitis, arthritis, and exanthema, typically seen in patients less than four years of age. Since that time, the phenotype has been expanded to include fever, cranial neuropathies, cardiovascular abnormalities, and granulomas of the liver and kidney. The ocular inflammation is often a panuveitis that occurs later in the disease course and typically carries the greatest morbidity in BS. BS has been mapped to the chromosomal region 16q12-21, also known as the NOD2 gene (formerly CARD15/NOD2). The disease is secondary to a single amino acid mutation NOD2 that leads to peptidoglycan-independent activity of nuclear factor (NF)- $\kappa$ B. Clinical and genetic aspects of BS will be discussed, as well as recent advances in treatment protocols.

**BACKGROUND/AIMS:** Chronic arthritis of familial Mediterranean fever (FMF) involves weight-bearing joints and can occur in patients without a history of acute attack. Our aim was to investigate a possible causal relationship between FMF and osteoarthritis in a population in which FMF is quite common.

**METHODS:** Patients with late stage primary osteoarthritis were enrolled, and five MEFV gene mutations were investigated. The frequency of MEFV gene mutations was compared among patients with osteoarthritis and a previous healthy group from our center.

**RESULTS:** One hundred patients with primary osteoarthritis and 100 healthy controls were studied. The frequency of MEFV gene mutations was significantly lower in the osteoarthritis group (9% vs. 19%). M694V was the most frequent mutation (5%) in the osteoarthritis group, whereas in the control group, E148Q was the most common (16%). In subgroup analyses, the mutation frequency of patients with hip osteoarthritis was not different from that of patients with knee osteoarthritis and controls (7.1%, 9.7%, and 19%, respectively). There were no differences among the three groups with respect to MEFV gene mutations other than E148Q (8.1% vs. 3.6%). E148Q was significantly lower in the osteoarthritis group than in the controls (16% vs. 1%), although the mutations did not differ between patients with knee osteoarthritis and controls.

**CONCLUSIONS:** In a population with a high prevalence of MEFV gene mutations, we did not find an increased mutation rate in patients with primary osteoarthritis. Furthermore, we found that some mutations were significantly less frequent in patients with osteoarthritis. Although the number of patients studied was insufficient to claim that E148Q gene mutation protects against osteoarthritis, the potential of this gene merits further investigation.

Gout is an ancient autoinflammatory disease that affects millions of people worldwide. It is characterized by unbearable recurrent pain due to the massive local inflammation caused by the metabolic product, monosodium urate crystals. Although conventional therapies for gout can reduce the pain in patients, the severe undesirable side effects require the urgent need for novel therapies that can more specifically target gout-associated inflammatory pathways. Recent scientific advance on the mechanistic study of gout-associated inflammation is discussed and the potential of targeting the transient receptor potential melastatin 2 is highlighted as a novel therapeutic approach for the treatment of gout.

Digoxigenin-labeled in situ hybridization for the detection of *Streptococcus suis* DNA in polyserositis and a comparison with biotinylated in situ hybridization.

Kang I(1), Seo HW, Park C, Oh Y, Lee J, You OH, Kim SH, Gottschalk M, Chae C.

Author information:

(1)Department of Veterinary Pathology, College of Veterinary Medicine, Seoul National University, 1 Gwanak-ro, Gwanak-gu, Seoul 151-742, Republic of Korea.

The objective of this study was to develop digoxigenin-labeled in situ hybridization (ISH) for the detection of *Streptococcus suis* in naturally infected pigs with polyserositis and to compare it with biotinylated ISH. Digoxigenin-labeled hybridization signals for *S. suis* were observed in cells that had infiltrated the fibrous polyserositis and microcolonies in the blood vessels. Mock hybridization showed no hybridization signals for endogenous digoxigenin. Biotinylated hybridization signals for *S. suis* were observed in cells that had infiltrated the fibrous polyserositis. However, similar hybridization signals were also observed in the fibrous inflammatory area using mock hybridization for endogenous biotin. The present study demonstrated that digoxigenin-labeled ISH is a valuable diagnostic tool for specific detection of *S. suis* in polyserositic tissues without nonspecific reactions compared with biotinylated ISH.

Increased intracellular oxygen radical production in neutrophils during febrile episodes of periodic fever, aphthous stomatitis, pharyngitis, and cervical adenitis syndrome.

Sundqvist M(1), Wekell P, Osla V, Bylund J, Christenson K, Sävman K, Foell D, Cabral DA, Fasth A, Berg S, Brown KL, Karlsson A.

Author information:

(1)University of Gothenburg, Gothenburg, Sweden.

**OBJECTIVE:** Periodic fever, aphthous stomatitis, pharyngitis, and cervical adenitis (PFAPA) syndrome is an autoinflammatory disease of unknown etiology that primarily affects preschool-aged children. PFAPA syndrome is characterized by

recurrent attacks of fever and symptoms of inflammation consistent with the disease acronym. Since autoinflammatory diseases are, by definition, mediated by cells of the innate immune system, the aim of this study was to evaluate the functional features of neutrophils, the most abundant innate immune cell in the circulation, in children with PFAPA syndrome.

**METHODS:** Blood polymorphonuclear leukocytes (PMNs), obtained from patients with PFAPA syndrome during both febrile and asymptomatic, afebrile phases of the disease, as well as from healthy children (afebrile controls) and children with fever and abdominal pain (febrile controls), were analyzed for 3 key neutrophil characteristics: 1) apoptosis (measured by annexin V/7-aminoactinomycin D staining), 2) production of reactive oxygen species (ROS) (measured by luminol/isoluminol-amplified chemiluminescence), and 3) priming status (measured as responsiveness to galectin-3 and up-regulation of CD11b).

**RESULTS:** Compared to PMNs obtained from patients with PFAPA syndrome during an afebrile interval and those from febrile controls, PMNs obtained from patients during a PFAPA syndrome flare produced elevated levels of intracellular NADPH oxidase-derived ROS, had significantly diminished rates of spontaneous apoptosis, and displayed signatures of priming. In contrast, PMNs from afebrile patients with PFAPA syndrome had a significantly elevated rate of spontaneous apoptosis compared to PMNs from afebrile controls.

**CONCLUSION:** These findings demonstrate that 3 key aspects of neutrophil innate immune function, namely, apoptosis, priming, and generation of an intracellular oxidative burst, are altered, most prominently during febrile attacks, in children with PFAPA syndrome.

MEFV gene mutations in Henoch-Schönlein purpura.

Altug U(1), Ensari C, Sayin DB, Ensari A.

Author information:

(1)Department of Paediatrics, Kirikkale University Medical School, Ankara, Turkey.

**AIM:** Coexistence of familial Mediterranean fever (FMF) with various systemic vasculitides, including Henoch-Schönlein purpura (HSP) and other inflammatory disorders has been reported and the MEFV gene has been suggested to play an important role in the pathogenesis of this association. In the present study, the mutation rate of the MEFV gene in HSP and its association with the clinical course of the disease were evaluated.

**METHOD:** The study group comprised 68 children (36 boys and 32 girls) diagnosed as having HSP. The spectrum and degree of organ involvement and the levels of serum C-reactive protein (CRP) and erythrocyte sedimentation rate (ESR) were documented for each patient. Allele-specific PCR using oligonucleotide probes which include 12 MEFV mutations (E148Q, P369S, F479L, M680I [G/C], M680I [G/A], I692del, M694V, M694I, K695R, V726A, A744S, R761H) were used for mutation analysis.

**RESULTS:** Of the 68 patients studied, 50 (74%) showed no mutation, while 18 (26%) had MEFV mutation. Mutation analysis of the whole group revealed that 15 (22%) patients were heterozygous for one of the screened MEFV mutations, while three (4.5%) patients were compound heterozygous for two of the studied mutations, and one (1.5%) patient was homozygous for E148Q/E148Q mutations. Gastrointestinal and joint involvement, and edema were more frequently observed in patients with MEFV mutations, while ESR and CRP levels were significantly higher ( $P < 0.05$ ) in patients with MEFV mutations.

**CONCLUSION:** MEFV mutations, especially, E148Q and M694V, mutations might be associated with HSP and may affect clinical presentation and laboratory findings in HSP patients.

New insights in the pathogenesis and therapy of idiopathic recurrent pericarditis in children.

Gaspari S(1), Marsili M, Imazio M, Brucato A, Di Blasi Lo Cuccio C, Chiarelli F, Breda L.

Author information:

(1)Department of Pediatrics, University of Chieti, Chieti, Italy.  
gasparistefania@libero.it.

Pericarditis has several different causes, however, in about 70% of paediatric patients, a specific aetiology cannot be detected and the pericarditis is considered idiopathic. Recurrences may occur in up to 15-30% of cases. The pathogenesis of recurrent disease is controversial. Infectious, autoimmune and autoinflammatory pathways have been proposed as mechanisms involved in recurrences. Therapeutic strategies are not standardised, non-steroidal anti-inflammatory drugs at high dosages being the mainstay of therapy with the possible addition of low dose colchicine to prevent recurrences. Biological agents are considered a possible new therapeutic frontiers in the care of idiopathic recurrent pericarditis.

Retrospective evaluation of pregnancy outcomes in women with familial Mediterranean fever.

Yasar O(1), Iskender C, Kaymak O, Taflan Yaman S, Uygur D, Danisman N.

Author information:

(1)Department of Perinatology, Dr Zekai Tahir Burak Research and Training Hospital , Ankara , Turkey.

**AIM:** Familial Mediterranean fever (FMF) is an autosomal recessive condition characterized by periodic attacks of fever, aseptic serositis and synovitis. In this study, we investigated maternal and neonatal outcomes in pregnant patients with FMF.

**METHODS:** This retrospective study consisted of 46 pregnant patients with FMF who attended the perinatology clinic of Dr Zekai Tahir Burak Research and Training Hospital between January 2008 and December 2012. The following clinical and demographic data were obtained by reviewing the patients' medical records: maternal age, colchicine use during pregnancy, obstetric history, pregnancy outcome and maternal and neonatal complications during the current pregnancy.

**RESULTS:** The patients with FMF had higher rates of premature rupture of membranes (PROM) and Cesarean delivery as well as low birth weight infants; however, rates of stillbirth, gestational diabetes, preeclampsia did not differ between the groups. Preterm delivery rates were higher in the study group, but this difference did not reach statistical significance. Patients with pregnancy complications had significantly more basal proteinuria than did patients without complications. Nine patients did not receive colchicine therapy in the previous or current pregnancies. Within this subgroup, four (44.4%) of the patients had a history of two or more previous miscarriages. However, there were only three cases (8.1%) of two or more miscarriages among 37 patients who received colchicine; this difference was statistically significant

**CONCLUSIONS:** FMF leads to higher rates of PROM, recurrent miscarriage and preterm deliveries. Colchicine treatment is safe in pregnancy and may lead to a decreased miscarriage rate.

Skin rash and arthritis a simplified appraisal of less common associations.

Cozzi A(1), Doria A, Gisondi P, Girolomoni G.

Author information:

(1)Department of Medicine, Section of Dermatology and Venereology, University of Verona, Verona, Italy.

Skin and joint manifestations are part of the clinical spectrum of many disorders. Well-known associations include psoriatic arthritis and arthritis associated with autoimmune connective tissue diseases. This review focuses on less common associations where skin lesions can provide easily accessible and valuable diagnostic clues, and directly lead to the specific diagnosis or limit the list of possibilities. This may also affect health care resources as diagnostic tests are often low-specific, highly expensive and poorly available. This group of diseases can be divided into two subsets, based on the presence/absence of fever, and then further classified according to elementary skin lesions (macular, urticarial, maculo-papular, vesico-bullous, pustular, petechial and nodular). In most instances joint involvement occurs as peripheral migrating polyarthritis. Erythematous macular or urticarial rashes occur in most febrile disorders such as monogenic autoinflammatory syndromes, Schnitzler's syndrome, Still's disease and rheumatic fever and afebrile diseases as urticarial vasculitis. Pustular rash may be observed in chronic recurrent multifocal osteomyelitis (CRMO) and pyogenic arthritis with pyoderma gangrenosum and acne (PAPA) syndrome (both febrile) as well as in Behcet's disease and Synovitis, acne, pustulosis, hyperostosis and osteitis syndrome (both non-febrile). Papular lesions are typical of secondary syphilis, sarcoidosis, interstitial granulomatous dermatitis, papular petechial of cutaneous small-vessel vasculitis and nodular lesions of polyarteritis nodosa and multicentric reticulohistiocytosis all of which are afebrile. Differential diagnosis includes infections and drug reactions which may mimic several of these conditions. To biopsy the right skin lesion at the right time it is essential to obtain relevant histological information.

S100A8 and S100A9 induce cytokine expression and regulate the NLRP3 inflammasome via ROS-dependent activation of NF- $\kappa$ B(1.).

Simard JC(1), Cesaro A, Chapeton-Montes J, Tardif M, Antoine F, Girard D, Tessier PA.

Author information:

(1)Laboratoire de Recherche en Inflammation des Granulocytes, Université du Québec Institut National de la Recherche Scientifique, Institut Armand-Frappier, Laval, Québec, Canada.

S100A8 and S100A9 are cytoplasmic proteins expressed by phagocytes. High concentrations of these proteins have been correlated with various inflammatory conditions, including autoimmune diseases such as rheumatoid arthritis and Crohn's disease, as well as autoinflammatory diseases. In the present study, we examined the effects of S100A8 and S100A9 on the secretion of cytokines and chemokines from PBMCs. S100A8 and S100A9 induced the secretion of cytokines such as IL-6, IL-8, and IL-1 $\beta$ . This secretion was associated with the activation and translocation of the transcription factor NF- $\kappa$ B. Inhibition studies using antisense RNA and the pharmacological agent BAY-117082 confirmed the involvement of NF- $\kappa$ B in IL-6, IL-8, and IL-1 $\beta$  secretion. S100A8- and S100A9-mediated activation of NF- $\kappa$ B, the NLR family, pyrin domain-containing 3 (NLRP3) protein, and pro-IL-1 $\beta$  expression was dependent on the generation of reactive oxygen species. This effect was synergistically enhanced by ATP, a known inflammasome activator. These results suggest that S100A8 and S100A9 enhance the inflammatory response by inducing cytokine secretion of PBMCs.

Common MEFV gene mutations in Turkish patients with Behcet's disease.

Tasliyurt T(1), Yigit S, Rustemoglu A, Gul U, Ates O.

Author information:

(1)Tokat Gaziosmanpasa University, Medical Faculty, Dept. of Internal Medicine, Turkey.

Behcet's disease (BD) is a chronic systemic inflammatory disorder whose etiology has not been fully established yet. The Mediterranean Fever (MEFV) gene has been identified as the cause of Familial Mediterranean Fever (FMF). BD shows similarities with FMF, in terms of clinical findings and treatments, as well as their geographical and ethnic co-occurrence. In this study we investigated common MEFV gene mutation frequencies in Turkish patients with BD in an area of Turkey where both diseases are frequently encountered. We screened 207 BD patients who had no symptoms and family history for FMF and 200 healthy subjects for five common MEFV gene mutations (E148Q, M680I, M694V, V726A, P369S) and clinical features. Seventy-five patients were found to carry a single MEFV mutation, and six patients were compound heterozygous. The difference in the frequency of the MEFV mutation between the BD and control groups was statistically significant ( $p < 0.001$ , odds ratio [OR] 2.74, 95% confidence interval [CI] 1.75-4.29). The frequencies of E148Q and M680I mutations were significantly higher in the BD group ( $p = 0.001$ ,  $p = 0.046$ , respectively). The frequency of uveitis was significantly lower in patients with the mutation than in patients without the mutation ( $p = 0.029$ , OR 0.54, 95% CI 0.30-0.98). There was no statistical significance between carriers and non-carriers with respect to gender and other manifestations of BD. The frequency of the MEFV mutation was significantly higher in patients with BD compared to the healthy control group. Based on our results, MEFV mutations appear to have a role in the pathogenesis of BD.

From the Mediterranean to the sea of Japan: the transcontinental odyssey of autoinflammatory diseases.

Rigante D(1), Frediani B, Galeazzi M, Cantarini L.

Author information:

(1)Institute of Pediatrics, Università Cattolica Sacro Cuore, Rome, Italy.

Autoinflammatory diseases are comprehensively caused by aberrant production of proinflammatory cytokines and are revealed by cyclically and spontaneously occurring inflammatory events. Over the last decade, there has been a revolution in the understanding of periodic fever syndromes, cryopyrinopathies, and skin disorders with pyogenic, granulomatous, or dystrophic features, which have been recognized across different countries spanning from the Mediterranean basin to the Japanese archipelago. Many children and adults with autoinflammatory diseases continue to elude diagnosis, and the diagnostic delay of many years puts these patients at risk of long-term severe complications, such as amyloidosis. Any hint of suspicion of autoinflammatory disease thus needs to be highlighted in various medical specialties, and this review examines their frequencies around the world, trying to match them with geographic location, ethnic and genetic data, in an attempt to realize a geoepidemiologic map for most of these conditions.

Treatment of monogenic autoinflammatory disorders, an expanding group of

hereditary diseases characterized by apparently unprovoked recurrent episodes of inflammation, without high-titre autoantibodies or antigen-specific T cells, has been revolutionized by the discovery that several of these conditions are caused by mutations in proteins involved in the mechanisms of innate immune response, including components of the inflammasome, cytokine receptors, receptor antagonists, and oversecretion of a network of proinflammatory molecules. Aim of this review is to synthesize the current experience and the most recent evidences about the therapeutic approach with biologic drugs in pediatric and adult patients with monogenic autoinflammatory disorders.

Obvious optic disc swelling in a patient with cryopyrin-associated periodic syndrome.

Kawai M(1), Yoshikawa T, Nishikomori R, Heike T, Takahashi K.

Author information:

(1)Department of Ophthalmology, Kansai Medical University, Osaka, Japan.

Cryopyrin-associated periodic syndrome (CAPS) is a group of rare hereditary autoinflammatory diseases caused by mutations of the NLRP3 gene, and leads to excessive production of the proinflammatory cytokine, interleukin-1 $\beta$ . A 35-year-old male presented with recurrent symptoms of urticarial-like rash, periodic fever, arthralgia, headache, and eye redness. His best-corrected visual acuity was 1.0 OD and 0.9 OS. Slit-lamp examination showed conjunctival and episcleral injection in both eyes. Ophthalmoscopy revealed obvious bilateral optic disc swelling and retinal vascular sheathing around the optic discs. Spectral domain optical coherence tomography also showed obvious optic disc swelling. Steroid and nonsteroidal anti-inflammatory drugs did not improve these symptoms. Genetic testing detected a heterozygous mutation of c.907G>A. Thus, the patient was genetically confirmed with CAPS. Visual acuity did not decrease for 3 years, although the optic discs became white in color. CAPS should therefore be distinguished from other disorders when examining optic disc swelling and/or uveitis patients with urticarial-like rash and periodic fever.

**OBJECTIVE:** To evaluate the genetic findings, demographic features and clinical presentation of tumour necrosis factor receptor-associated autoinflammatory syndrome (TRAPS) in patients from the Eurofever/EUROTRAPS international registry.

**METHODS:** A web-based registry collected retrospective data on patients with TNFRSF1A sequence variants and inflammatory symptoms. Participating hospitals included paediatric rheumatology centres and adult centres with a specific interest in autoinflammatory diseases. Cases were independently validated by experts in the disease.

**RESULTS:** Complete information on 158 validated patients was available. The most common TNFRSF1A variant was R92Q (34% of cases), followed by T50M (10%). Cysteine residues were disrupted in 27% of cases, accounting for 39% of sequence variants. A family history was present in 19% of patients with R92Q and 64% of those with other variants. The median age at which symptoms began was 4.3 years but 9.1% of patients presented after 30 years of age. Attacks were recurrent in 88% and the commonest features associated with the pathogenic variants were fever (88%), limb pain (85%), abdominal pain (74%), rash (63%) and eye manifestations (45%). Disease associated with R92Q presented slightly later at a median of 5.7 years with significantly less rash or eye signs and more headaches. Children were more likely than adults to present with lymphadenopathy, periorbital oedema and abdominal pains. AA amyloidosis has developed in 16 (10%) patients at a median age of 43 years.

**CONCLUSIONS:** In this, the largest reported case series to date, the genetic heterogeneity of TRAPS is accompanied by a variable phenotype at presentation. Patients had a median 70 symptomatic days a year, with fever, limb and abdominal pain and rash the commonest symptoms. Overall, there is little evidence of a significant effect of age or genotype on disease features at presentation.

Microbial activation of gut dendritic cells and the control of mucosal immunity.

Owen JL(1), Mohamadzadeh M.

Author information:

(1)1 Department of Infectious Diseases and Pathology, University of Florida ,  
Gainesville, Florida.

Current data support a role for gut colonization in maintaining balanced mucosal and systemic immune responses and have suggested aberrant innate immune recognition of enteric bacteria as an initiator of the adaptive immune damage associated with inflammatory bowel disease (Crohn's disease and ulcerative colitis). In fact, data from human studies and experimental mouse models have implicated transformation of the gut microbiota from a beneficial symbiotic state to one of imbalance or "dysbiosis" in the pathogenesis of several autoinflammatory diseases, including allergic skin and respiratory disorders, rheumatoid arthritis, type I diabetes, and colorectal cancer. The host has evolved to co-exist and maintain a mutualistic relationship with the commensal microbes of the gut, and it is the function of the host innate immune system to initiate and maintain this homeostasis, while retaining the ability to respond appropriately to pathogenic organisms. In this review, we discuss the molecular and cellular interactions of the mucosal immune system that decide this delicate balance of mutualism. Furthermore, we will highlight the role of dendritic cells in preserving this precarious balance and how gene products of commensal microbes may play an integral role in re-establishing this balance once it has gone awry.

Comment in

J Korean Med Sci. 2014 Jan;29(1):153.

J Korean Med Sci. 2014 Jan;29(1):153-4.

Interleukin (IL)-33 is an important mediator of innate immunity. Behcet's disease (BD) is an autoinflammatory disorder characterized by hyperactivity of the innate immune response. We measured serum levels of IL-33 and its receptor soluble ST2 (sST2) in patients with BD to investigate their association with disease activity. Serum levels of both IL-33 and sST2 were higher in patients with BD compared with those in normal controls (IL-33:  $594.48 \pm 175.04$  pg/mL in BD and  $224.23 \pm 56.64$  pg/mL in normal controls [ $P=0.048$ ], sST2:  $99.01 \pm 15.92$  pg/mL in BD and  $23.56 \pm 3.25$  pg/mL in normal controls [ $P<0.001$ ]). IL-33 and sST2 expression in skin tissue, as shown by immunohistochemistry, was higher in patients with BD compared with that in the normal controls. Serum sST2 level correlated significantly with the BD currently active form (BDCAF), Iranian BD dynamic activity measure (IBDDAM), erythrocyte sedimentation rate and C-reactive protein. Multiple linear regression showed that serum sST2 was an independent factor associated with IBDDAM (regression coefficient, 0.374;  $P=0.004$ ), and BDCAF (regression coefficient, 0.236;  $P=0.047$ ). These results demonstrate that IL-33 and sST2 are highly expressed in patients with BD and that serum sST2 is an independent factor associated with IBDDAM and BDCAF, suggesting a potential role for sST2 as a surrogate marker of disease activity in patients with BD.

The expanding role of NLRs in antiviral immunity.

Lupfer C(1), Kanneganti TD.

Author information:

(1)Department of Immunology, St. Jude Children's Research Hospital, Memphis, TN 38105-3678, USA.

Nucleotide oligomerization and binding domain (NOD)-like receptors (NLRs) are a major constituent of the cytosolic innate immune-sensing machinery and participate in a wide array of pathways including nuclear factor  $\kappa$ B (NF- $\kappa$ B), mitogen-activated protein kinase (MAPK), inflammasome, and type I interferon (IFN) signaling. NLRs have known roles in autoimmune, autoinflammatory, and infectious diseases. With respect to virus infection, NLRP3 is the most extensively studied NLR, including mechanisms of activation and inhibition. Furthermore, the importance of NLRP3 in both innate and adaptive immunity has been demonstrated. In comparison to NLRP3, the roles of other NLRs during virus infection are only just emerging. NLRC2 is an important activator of innate antiviral signaling and was recently found to mitigate inflammation during virus infection through autophagy. Finally, functions for NLRX1 in immune modulation and reactive oxygen species production require further examination and the importance of NLRC5 as a transactivator of major histocompatibility complex (MHC) class I and antigen presentation is currently developing. In this review, we discuss current knowledge pertaining to viruses and NLRs as well as areas of potential research, which will help advance the study of NLR biology during virus infection.

Immunosuppressive treatment plays a crucial role in the management of autoimmune and autoinflammatory diseases. Knowledge about the ensuing immune deficits resulting from these therapies as well as common infections in immunocompromised patients should be familiar to all doctors involved in the prescription and administration of immunosuppressive drugs. Comprehensive pretreatment screening, regular monitoring both during and following treatment as well common sense preventive measures, such as vaccination can help further minimise the risk of infection.

A new infant case of Nakajo-Nishimura syndrome with a genetic mutation in the immunoproteasome subunit: an overlapping entity with JMP and CANDLE syndrome related to PSMB8 mutations.

Kunimoto K(1), Kimura A, Uede K, Okuda M, Aoyagi N, Furukawa F, Kanazawa N.

Author information:

(1)Department of Dermatology, Wakayama Medical University, Wakayama, Japan.

Nakajo-Nishimura syndrome (NNS) is a very rare hereditary autoinflammatory disorder that generally has its onset in infancy with pernio-like rashes and gradually develops into partial lipodystrophy. A distinct homozygous PSMB8 mutation encoding an immunoproteasome subunit has recently been identified as its genetic cause. Here, we report a new case of a patient with NNS who developed exudative erythemas on his face and extremities at 2 months of age, along with high fever, elevated serum hepatic aminotransferase levels and hepatosplenomegaly. Massive infiltration of inflammatory cells was observed histologically in the dermis and subcutis without apparent leukocytoclastic vasculitis. These symptoms improved with oral corticosteroids but recurred periodically, and a thin angular face with long clubbed fingers gradually

developed. Identification of the PSMB8 mutation finalized the diagnosis of NNS at 5 years of age. Understanding a variety of clinicopathological features at the developmental stages is necessary to make an early diagnosis of NNS.

Evaluation of non-surgical causes of cardiac tamponade in children at a cardiac surgery center.

Ozturk E(1), Tanidir IC, Saygi M, Ergul Y, Guzeltas A, Odemis E.

Author information:

(1)Department of Pediatric Cardiology, Istanbul Mehmet Akif Ersoy, Thoracic and Cardiovascular Surgery Center and Research Hospital, Istanbul, Turkey.

**BACKGROUND:** The aim of this study was to examine the causes of cardiac tamponade in children undergoing percutaneous pericardiocentesis.

**METHOD:** Patients who presented with other complaints but were diagnosed with cardiac tamponade based on clinical and echocardiographic findings between January 2010 and January 2013 were retrospectively investigated.

Electrocardiography, telecardiography and transthoracic echocardiography were performed. Pericardiocentesis was performed percutaneously under continuous blood pressure and rhythm monitoring with echocardiography and fluoroscopy. Pericardial fluid was analyzed on hemography and biochemistry.

**RESULTS:** Fourteen patients (six boys, eight girls; median age, 7 years) underwent pericardiocentesis for cardiac tamponade. At presentation, 78% had dyspnea, 56% chest pain, and 49% fever. All had cardiomegaly, and their cardiothoracic index was 0.56-0.72. Also, all patients had sinus tachycardia; 78%, low QRS voltage; 70%, ST-T changes; and 50% QRS alternans. On echocardiography the widest diameter of pericardial effusion was between 12 mm and 36 mm depth around the heart. The pericardial fluid was purulent in one, serohemorrhagic in seven, serofibrinous in two, and serous in four cases. Pericardiocentesis was unsuccessful in two patients, who underwent open surgical drainage, with no complications. Based on pericardial fluid characteristics and additional tests, cardiac tamponade was caused by an infection in five patients, hypothyroidism in two, familial

Mediterranean fever in two, malignancy in one, acute rheumatic fever in one, collagen tissue disease (systemic lupus erythematosus) in one, catheter placement-associated damage in one, and idiopathic pulmonary arterial hypertension in one patient.

CONCLUSION: Pericardial effusion and cardiac tamponade in children have varied causes, and early treatment is life saving.

Myositis in a patient with familial Mediterranean fever and spondyloarthritis successfully treated with anakinra.

Estublier C(1), Stankovic Stojanovic K, Bergerot JF, Broussolle C, Sève P.

Author information:

(1)Department of Internal Medicine, Hôpital de la Croix-Rousse, 93, Grande-Rue de la Croix-Rousse, 69317 Lyon Cedex 04, France. Electronic address: charline.estublier@yahoo.fr.

Familial Mediterranean fever is an autosomal-recessive autoinflammatory disorder more commonly observed in Mediterranean populations and characterized by recurrent episodes of fever, serositis, myalgia and arthritis. There is rarely any association with spondyloarthritis. The most important long-term complication is progressive systemic type AA amyloidosis. Treatment with colchicine is effective in reducing the frequency of attacks and prevents the development of amyloidosis. However, 5% of cases are considered resistant to colchicine. We here describe the case of a 39-year-old man, with a history of arthritis, arthralgias, and sacroiliitis in the course of a familial Mediterranean fever. He is homozygous for the M694I mutation in the MEFV gene. He subsequently developed myositis of the right quadriceps muscle confirmed by magnetic resonance imaging, electromyography and histology. He had frequent and severe arthralgias, despite colchicine, then etanercept and adalimumab, impairing his quality of life. The

patient was successfully treated with the IL-1 receptor antagonist anakinra with a dramatic improvement of muscular and articular symptoms. To our knowledge, our patient is the first patient with coexisting FMF, spondyloarthritis and myositis responding to anakinra treatment. Moreover this is the second case in the literature of myositis associated with familial Mediterranean fever.

Can serum fetuin-A be regarded as an inflammatory marker among patients with familial Mediterranean fever?

Oncu K(1), Yazgan Y, Tanoglu A, Kaplan M, Ermis F, Ipcioglu OM, Kara M, Kucuk I, Ozari HO.

Author information:

(1)Gastroenterology Department, GATA Haydarpasa Training Hospital, Uskudar, 34668, Istanbul, Turkey, koncu971@hotmail.com.

**BACKGROUND/AIM:** Familial Mediterranean fever (FMF), the most frequent periodic fever syndrome, is an autosomal recessive inherited disease that predominantly affects eastern Mediterranean populations. Fetuin-A is a well known negative acute-phase protein. Studies of this glycoprotein as a marker of inflammation in FMF are limited. We have investigated the relationship between serum levels of fetuin-A and inflammatory markers in patients with FMF before, during, and after FMF attacks.

**METHODS:** Sixty-seven patients with FMF were enrolled in this study. Serum fetuin-A, seruloplasmin, fibrinogen, C reactive protein (CRP), white blood cell count (WBC), calcium, and erythrocyte sedimentation rate (ESR) were measured three times: during the attack-free period, 12 h after FMF attacks, and 7 days after FMF attacks. Plasma fetuin-A concentration was measured by use of an enzyme-linked immunoassay (ELISA) kit. Correlations and differentiation between

the serum fetuin-A and other inflammatory markers in patients with FMF were investigated by use of the paired-samples T test and the Pearson correlation test ( $p < 0.01$ ).

**RESULTS:** Serum fetuin-A levels of all FMF patients in the attack period were significantly lower than in the attack-free period ( $p < 0.001$ ). In contrast, serum seruloplasmin ( $p < 0.05$ ), fibrinogen ( $p < 0.001$ ), CRP ( $p < 0.05$ ), WBC ( $p < 0.05$ ), and ESR ( $p < 0.05$ ) were all significantly higher than in the attack-free period. Plasma fetuin-A is significantly and inversely highly correlated with the other inflammatory markers.

**CONCLUSION:** Fetuin-A might be a novel indicator of disease activity in patients with FMF and could be used as an adjunctive marker for differentiation of FMF attacks. The negative correlation between serum fetuin-A and other inflammatory markers may also be indicative of inflammation-dependent downregulation of fetuin-A expression in FMF patients.

Autoinflammatory bone disorders: update on immunologic abnormalities and clues about possible triggers.

Sharma M(1), Ferguson PJ.

Author information:

(1)Divisions of Rheumatology in Internal Medicine and Pediatrics, University of Iowa, Iowa City, Iowa 52240, USA.

**PURPOSE OF REVIEW:** To provide an update on the genetics and immunologic basis of autoinflammatory bone disorders including chronic recurrent multifocal osteomyelitis including the monogenic forms of the disease.

**RECENT FINDINGS:** Ongoing research in murine, canine and human models of sterile bone inflammation has solidified the hypothesis that sterile bone inflammation can be genetically driven. Mutations in *Pstpip2*, *LPIN2* and *IL1RN* have been identified in monogenic autoinflammatory bone disorders that have allowed more detailed dissection of the immunologic defects that can produce sterile osteomyelitis. Recent studies in murine chronic multifocal osteomyelitis, deficiency of the interleukin-1 receptor antagonist (DIRA), Majeed syndrome and SAPHO syndrome reveal abnormalities in innate immune system function. IL-1 pathway dysregulation is present in several of these disorders and blocking IL-1 therapeutically has resulted in control of disease in DIRA, Majeed syndrome and in some cases of SAPHO and CRMO. Basic research demonstrates the importance of the innate immune system in disease pathogenesis and offers clues about potential disease triggers.

**SUMMARY:** Research and clinical data produced over the last several years support the important role of innate immunity in sterile osteomyelitis. Based on what has been learned in the monogenic autoinflammatory bone disorders, IL-1 is emerging as an important pathway in the development of sterile bone inflammation.

Assessment of ovarian reserve based on hormonal parameters, ovarian volume, and antral follicle count in women with familial Mediterranean fever.

Oner G(1), Muderris II.

Author information:

(1)Department of Obstetric and Gynecology, Bogazlıyan State Hospital, Yozgat, Turkey. Electronic address: onerg@yahoo.com.

**OBJECTIVE:** To evaluate ovarian reserve in women with familial Mediterranean fever (FMF).

**STUDY DESIGN:** Thirty women with FMF (20-29 years) and thirty healthy controls (20-29 years) were admitted to this study. Basal serum levels of follicle-stimulating hormone (FSH), oestradiol (E2), luteinizing hormone (LH) and inhibin B were measured on cycle day 3. All participants underwent transvaginal ultrasonographic examination on the third day of their menstrual cycle for the determination of ovarian volume (OV) and total antral follicle count (AFC).

**RESULTS:** Women with FMF had significantly higher concentrations of FSH, LH and E2 than healthy controls. Total AFC was significantly lower in women with FMF than in healthy controls. OV was also lower in the FMF group but there was no statistically significant difference in OV between the groups. Age was negatively associated with FSH and LH. Inhibin B was found to be negatively correlated with LH and OV.

**CONCLUSIONS:** In this preliminary study, the first in FMF patients, we found that ovarian reserve was reduced in women with FMF compared with healthy controls. FMF may affect the ovarian reserve but the mechanism of this effect is unclear.

Anakinra pharmacokinetics in children and adolescents with systemic-onset juvenile idiopathic arthritis and autoinflammatory syndromes.

Urien S, Bardin C, Bader-Meunier B, Mouy R, Compeyrot-Lacassagne S, Foissac F, Florkin B, Wouters C, Neven B, Treluyer JM, Quartier P.

**BACKGROUND:** Anakinra pharmacokinetics and pharmacodynamics were investigated in

children and adolescents treated for systemic-onset juvenile idiopathic arthritis (SJIA) and autoinflammatory syndromes.

**METHODS:** Anakinra was given subcutaneously at doses between 2 and 10 mg/kg (maximum 100 mg) per day. Anakinra concentrations were recorded in patients, as well as C-reactive protein (CRP) levels, on different occasions. The data were fitted to a pharmacokinetic-pharmacodynamic model via a population approach using Monolix.

**RESULTS:** A total of 87 children and adolescents, 8 months to 21 years old, were available for pharmacokinetic evaluation. A one compartment model with linear absorption and elimination described the pharmacokinetics. Taking into account bodyweight to explain variations in apparent clearance (CL/F) and distribution volume (V/F) significantly reduced the associated between-subject and between-occasion variabilities. The final estimates were 6.24 L/h/70 kg and 65.2 L/70 kg for CL/F and V/F respectively. A mixture pharmacodynamic model described the CRP level change during anakinra treatment for the SJIA patients with 2 subpopulations, patients with high baseline and large CRP decrease and patients with low baseline and small CRP decrease followed by a re-increase in CRP levels. There was no significant effect of the combined anti-inflammatory treatment. The proportion of patients for which the development of a resistance to treatment was significant was 62% and the corresponding time was approximately 60 days.

**CONCLUSIONS:** Based on effects in SJIA, a prospective dosage adjustment was proposed based on a 0.4 mg/L C<sub>ss</sub> target in order to obtain a CRP decrease to 10 mg/L or below.

Department of Molecular Genetics, Center of Medical Genetics and Primary Health Care, Yerevan, Armenia.

(2)Department of Molecular Genetics, Center of Medical Genetics and Primary Health Care, Yerevan, Armenia.

(3)Department of Medical Genetics, Morava, Glendale, California, USA.

**PURPOSE:** In this study, we present clinical data from 16,000 familial Mediterranean fever patients. We also discuss the clinical manifestation of a subset of these patients and their potential symptom associations with other disorders.

**METHODS:** Familial Mediterranean fever patients were confirmed using Tel-Hashomer criteria and were tested for the 12 most common mutations using the familial Mediterranean fever StripAssay. A total of 100 samples were selected, and their MEFV gene exons and intron junctions were completely sequenced.

**RESULTS:** We observed that in children severe phenotypes with polyserositis, erysipelas-like erythema, splenomegaly, and vasculitis are associated with high penetrance of exon 10 mutations, particularly M694V. Several forms of arthritis were associated with familial Mediterranean fever, including acute mono/oligoarthritis in the lower extremities, destructive arthritis, ankylosing spondylitis, sacroiliitis, arthritis of the hip joint, and juvenile chronic arthritis. Severe life-threatening complications, such as adhesive intestinal obstruction, renal amyloidosis, and uncommon/rare symptoms were sometimes the only form of familial Mediterranean fever manifestation.

**CONCLUSION:** We suggest performing familial Mediterranean fever genetic testing for patients presenting with rare/uncommon symptoms also common in other disorders, to prevent misdiagnosis or delayed diagnosis. In our experience, the most effective patient management for familial Mediterranean fever was its rapid diagnosis through genetic testing, initiation of colchicine therapy, and promotion of attack prevention through counseling.

Technical advance: Inhibition of neutrophil chemotaxis by colchicine is modulated through viscoelastic properties of subcellular compartments.

Paschke S(1), Weidner AF, Paust T, Marti O, Beil M, Ben-Chetrit E.

Author information:

(1)1.University of Ulm, 89081 Ulm, Germany. michael.beil@uni-ulm.de.

Colchicine is an efficient drug for the management of inflammatory diseases, such as gouty arthritis and familial Mediterranean fever. It affects neutrophil activity by interfering with the formation of microtubules. To test the hypothesis that therapeutic concentrations of colchicine modulate the mechanical properties of these cells, we applied a combination of biophysical techniques (optical stretching and microrheology) to analyze cellular deformability. The contribution of the subcellular compartments to the regulation of cell mechanics was determined by fitting a multicomponent model of cellular viscoelasticity to time-dependent deformation curves. Neutrophils were found to be less deformable in response to 10 ng/ml colchicine. The model-based analysis of cellular deformation revealed a decrease in cytoplasmatic elasticity and a substantial increase in both elasticity and viscosity of the cell membrane compartment in response to colchicine. These results correlate with a reduced number of cytoplasmatic microtubules and an increase in subcortical actin filaments. The latter finding was confirmed by microrheology and fluorescence microscopy. Neutrophil migration through small pores requiring substantial cellular deformations, but not through large pores, was significantly impaired by colchicine. These data demonstrate that colchicine determines mechanics of neutrophils and, thereby, motility in confined spaces, which is crucial during extravasation of neutrophils in response to inflammatory stimuli.

The most recent advances in pathophysiology and management of tumour necrosis factor receptor-associated periodic syndrome (TRAPS): personal experience and literature review.

Tumour necrosis factor-receptor associated periodic syndrome (TRAPS) is a rare autosomal dominant autoinflammatory disorder characterised by recurrent episodes of long-lasting fever and inflammation in different regions of the body, as musculo-skeletal system, skin, gastrointestinal tube, serosal membranes and eye. Inflammatory attacks usually start in the pediatric age with initial corticosteroid-responsiveness. Most reported cases of TRAPS involve patients of European ancestry and diagnosis can be formulated by the combination of genetic analysis and a compatible phenotype. Its prognosis is strictly dependent on the appearance of amyloidosis, secondary to uncontrolled relapsing inflammation. Thanks to a better understanding of its pathogenesis, the disease is now managed with anti-interleukin (IL)-1 antagonists, rather than corticosteroids or tumour necrosis factor (TNF) inhibitors. The aim of this review is to describe the current understanding and advances of TRAPS genetic basis, pathogenesis and management options by integrating the most recent data in the medical literature.

Bloody Diarrhea as a Presentation Manifestation of Familial Mediterranean Fever in a Patient with Compound Heterozygote Mutations of the MEFV Gene.

Fallahi GH(1), Rezaei N, Sadjadei N.

Author information:

(1)Department of Gastroenterology, Pediatrics Center of Excellence, Children's Medical Center, Tehran University of Medical Sciences School of Medicine, Tehran, Iran.

Familial Mediterranean fever (FMF) is a hereditary autoinflammatory disease characterized by episodic fever and inflammatory polyserositis, which could lead to a variety of manifestations, including recurrent abdominal pain. Herein, a 12-year-old boy who has suffered from fever and bloody diarrhea since early childhood is described. All structural and underlying disorders leading to bleeding were excluded. Genetic studies indicated compound heterozygote mutations of M680I/R761H in the MEFV gene, which confirmed the diagnosis of FMF. Therefore, treatment with colchicine was started, which led to symptom relief. As gastrointestinal manifestations appear to be the main features of FMF, bloody diarrhea could also be considered an initial symptom of FMF.

(1)Swiss Cardiovascular Centre Bern, Switzerland.

**BACKGROUND:** Coronary atherosclerosis begins early in life, but acute coronary syndromes in adults aged <30 years are exceptional. We aimed to investigate the rate of occurrence, clinical and angiographic characteristics, and long-term clinical outcome of acute coronary syndrome (ACS) in young patients who were referred to two Swiss hospitals.

**METHODS:** From 1994 to 2010, data on all patients with ACS aged <30 years were retrospectively retrieved from our database and the patients were contacted by phone or physician's visit. Baseline, lesion and procedural characteristics, and clinical outcome were compared between patients in whom an underlying atypical aetiology was found (non-ATS group; ATS: atherosclerosis) and patients in whom no such aetiology was detected (ATS group). The clinical endpoint was freedom from any major adverse cardiac event (MACE) during follow-up.

**RESULTS:** A total of 27 young patients with ACS aged <30 years were admitted during the study period. They accounted for 0.05% of all coronary angiograms performed. Mean patient age was  $26.8 \pm 3.5$  years and 22 patients (81%) were men. Current smoking (81%) and dyslipidaemia (59%) were the most frequent risk factors. Typical chest pain ( $n = 23$ ; 85%) and ST-segment elevation myocardial infarction (STEMI;  $n = 18$  [67%]) were most often found. The ATS group consisted of 17 patients (63%) and the non-ATS group of 10 patients (37%). Hereditary thrombophilia was the most frequently encountered atypical aetiology ( $n = 4$ ; 15%). At 5 years, mortality and MACE rate were 7% and 19%, respectively.

**CONCLUSION:** ACS in young patients is an uncommon condition with a variety of possible aetiologies and distinct risk factors. In-hospital and 5-year clinical outcome is satisfactory.

Involvement of the same TNFR1 residue in mendelian and multifactorial inflammatory disorders.

Jéru I(1), Charmion S, Cochet E, Copin B, Duquesnoy P, Garcia MT, Le Borgne G, Cathebras P, Gaillat J, Karabina S, Dodé C, Lohse P, Hentgen V, Amselem S.

**OBJECTIVES:** TNFRSF1A is involved in an autosomal dominant autoinflammatory disorder called TNFR-associated periodic syndrome (TRAPS). Most TNFRSF1A mutations are missense changes and, apart from those affecting conserved cysteines, their deleterious effect remains often questionable. This is especially true for the frequent R92Q mutation, which might not be responsible for TRAPS per se but represents a susceptibility factor to multifactorial inflammatory disorders. This study investigates TRAPS pathophysiology in a family exceptional by its size (13 members) and compares the consequences of several mutations affecting arginine 92.

**METHODS:** TNFRSF1A screening was performed by PCR-sequencing. Comparison of the 3-dimensional structure and electrostatic properties of wild-type and mutated TNFR1 proteins was performed by in silico homology modeling. TNFR1 expression was assessed by FACS analysis, western blotting and ELISA in lysates and supernatants of HEK293T cells transiently expressing wild-type and mutated TNFR1.

**RESULTS:** A TNFRSF1A heterozygous missense mutation, R92W (c.361C>T), was shown to perfectly segregate with typical TRAPS manifestations within the family investigated ( $p < 5.10(-4)$ ). It was associated with very high disease penetrance (0.9). Prediction of its impact on the protein structure revealed local conformational changes and alterations of the receptor electrostatic properties. R92W also impairs the TNFR1 expression at the cell surface and the levels of soluble receptor. Similar results were obtained with R92P, another mutation previously identified in a very small familial form with incomplete penetrance and variable expressivity. In contrast, TNFR1-R92Q behaves like the wild-type receptor.

**CONCLUSIONS:** These data demonstrate the pathogenicity of a mutation affecting arginine 92, a residue whose involvement in inflammatory disorders is deeply debated. Combined with previous reports on arginine 92 mutations, this study discloses an unusual situation in which different amino acid substitutions at the same position in the protein are associated with a clinical spectrum bridging Mendelian to multifactorial conditions.

Advances in the diagnosis and treatment of tumor necrosis factor receptor-associated periodic syndrome.

Aguado-Gil L(1), Irarrazaval-Armendáriz I, Pretel-Irazabal M.

Author information:

(1)Departamento de Dermatología, Clínica Universidad de Navarra, Pamplona, Spain. [laguado@unav.es](mailto:laguado@unav.es)

Tumor necrosis factor receptor-associated periodic syndrome (TRAPS) is a rare autosomal dominant disease included in the group of autoinflammatory syndromes. It is characterized by recurrent episodes of fever and inflammation in different regions of the body. The main clinical manifestations are myalgia, migratory erythematous rash, periorbital edema, and abdominal pain. The diagnosis is reached using gene analysis and prognosis depends on the appearance of amyloidosis secondary to the recurrent episodes of inflammation. Tumor necrosis factor inhibitors and corticosteroids are the most widely used treatments. In recent years, significant advances have been made in the diagnosis and treatment of TRAPS, thanks to a better understanding of its pathogenesis. Dermatologists must be aware that the skin manifestations of TRAPS are particularly important, as they are often diagnostic.

Autoinflammatory disorders are characterized by spontaneous episodes of systemic inflammation deriving from inherited defects of the innate immune system. Childhood is usually the lifetime involved in most inherited autoinflammatory disorders, but a moderate number of patients may experience disease onset during adulthood. Herein we report our experience in the clinical and genetic approach to the diagnosis of autoinflammatory disorders in regard of the first 500 pediatric and adult patients evaluated during the period 2007-2012 in our Center, due to histories of periodically-recurring inflammatory attacks, giving emphasis to the differences observed according to patients' age and to the most relevant data differentiating child and adult-onset autoinflammatory disorders in the medical literature.

Disease severity in adult patients of Turkish ancestry with familial mediterranean fever living in Germany or Turkey. Does the country of residence affect the course of the disease?

Giese A(1), Örnek A, Kilic L, Kurucay M, Şendur SN, Lainka E, Henning BF.

Author information:

(1)Central Patient Admission Unit/Emergency Department, Marienhospital Herne, Ruhr-University Bochum, Herne, Germany. arnd.giese@rub.de

BACKGROUND: The environment may affect the course of familial Mediterranean fever

(FMF).

**OBJECTIVE:** The objective of this study was to compare disease severity between adult FMF patients in Turkey (TR) and Germany (G).

**METHODS:** Adult FMF patients of Turkish ancestry on colchicine living in Turkey (n = 40) or G (n = 35) were compared. Disease severity, C-reactive protein (CRP), and erythrocyte sedimentation rate were assessed.

**RESULTS:** Groups differed significantly in the following aspects: age at onset of disease (TR: 15.6, G: 10.8 years;  $P = 0.02$ ), delay between onset and initiation of colchicine treatment (TR: 6.8 years, G: 14.9 years;  $P < 0.001$ ), female gender (TR: 80%, G: 57.1%;  $P = 0.04$ ), and duration of disease (TR: 14.4 years, G: 23.4 years;  $P < 0.001$ ). There was no significant difference in colchicine treatment concerning average dosing and duration of therapy. No significant difference could be found between the 2 groups in CRP and disease severity as assessed by the score of Pras et al. (Am J Med Genet. 1998;75:216-219) even after adjusting for potential confounding variables. Mean erythrocyte sedimentation rate was significantly higher among patients living in G (TR: 13.2 mm/first hour, G: 26.3 mm/first hour;  $P < 0.001$ ). Among patients living in Germany, there was a significant difference in age at FMF onset depending on their country of birth (born in TR: 14.9 years, born in G: 6.9 years;  $P = 0.0001$ ).

**CONCLUSIONS:** In adult FMF patients living in Turkey or Germany, no difference in disease activity or CRP could be found. German patients were younger at onset of disease and had a longer delay between onset and initiation of colchicine treatment.

Erratum in

Clin Pharmacol Ther. 2014 Jan;95(1):110.

Familial Mediterranean fever (FMF), an inherited autosomal recessive disorder, is characterized by sporadic, paroxysmal attacks of fever and serosal inflammation, lasting 1-3 days. Patients may develop renal amyloidosis, arthritis, serositis, and skin and oral lesions. Diagnosis is based on clinical features, response to treatment with colchicine, and genetic analysis. Colchicine prevents attacks and renal amyloidosis, in addition to reversing proteinuria. Nonresponders may receive novel therapy, including interleukin (IL)-1 receptor antagonists and IL-1 decoy receptor. Recently, new options have been considered.

Is neutrophil/lymphocyte ratio associated with subclinical inflammation and amyloidosis in patients with familial Mediterranean fever?

Uslu AU(1), Deveci K, Korkmaz S, Aydin B, Senel S, Sancakdar E, Sencan M.

Author information:

(1)Department of Internal Medicine, Faculty of Medicine, Cumhuriyet University, 58140 Sivas, Turkey.

**BACKGROUND:** The purpose of the present study is to determine the association between neutrophil/lymphocyte ratio and both subclinical inflammation and amyloidosis in familial Mediterranean fever.

**METHODS:** Ninety-four patients with familial Mediterranean fever and 60 healthy volunteers were included in the study. Of the patients, 12 had familial Mediterranean fever related amyloidosis. The neutrophil/lymphocyte ratio of the patients was obtained from the hematology laboratory archive.

**RESULTS:** The neutrophil/lymphocyte ratio was significantly higher among persons with familial Mediterranean fever compared to healthy individuals ( $P < 0.0001$ ).

Also, neutrophil/lymphocyte ratio was significantly higher in patients with amyloidosis than in amyloidosis-free patients ( $P < 0.0001$ ). Since NLR was evaluated in nonamyloid and amyloid stages of the same patient population (type 1 phenotype), we obtained significant statistical differences ( $1.95 \pm 0.30$  versus  $2.64 \pm 0.48$ ,  $P < 0.05$ , resp.). With the cutoff value of neutrophil/lymphocyte ratio  $>2.21$  and AUC = 0.734 ( $P = 0.009$ ), it was a reliable marker in predicting the development of amyloidosis.

**CONCLUSION:** The neutrophil/lymphocyte ratio, an emerging marker of inflammation, is higher in patients with familial Mediterranean fever in attack-free periods. The neutrophil/lymphocyte ratio may be a useful marker in predicting the development of amyloidosis.

Mediterranean Fever gene analysis in the azeri turk population with familial mediterranean Fever: evidence for new mutations associated with disease.

Mohammadnejad L(1), Farajnia S.

Author information:

(1)1. Biotechnology Research Center, Tabriz University of Medical Sciences, Tabriz, Iran.

**OBJECTIVE:** Familial Mediterranean fever (FMF) is an autosomal recessive disorder characterized by recurrent febrile attacks accompanied by serosal and synovial membrane inflammation. FMF is caused by mutations in the MEFV gene and are found usually among Mediterranean populations, Armenians, Turks, Arabs and Jews. The aim of this study was to determine the frequency of MEFV gene mutations among FMF

patients in the Azeri Turk population in North-West of Iran.

**MATERIALS AND METHODS:** In this descriptive study, 130 FMF patients with Azeri Turk origin were screened for mutations in four exons (2, 3, 5 and 10) of MEFV gene. Genomic DNA was extracted from whole blood and entered in ARMS-PCR and PCR-RFLP reactions. When cases were negative in ARMS-PCR and PCR-RFLP, the exons were amplified and subjected to direct sequencing.

**RESULTS:** Our results showed that the most common mutations in this study population was M694V (40.19%) followed by E148Q (17.64%), V726A (13.72%), M680I (12.74%) and M694I (2.94%) mutations. Four new mutations including K618N, K716M, S614F and G136E were identified in our study.

**CONCLUSION:** The prevalence of five common mutations in our study was highly similar to previous studies analysing the Mediterranean basin populations. Investigation by sequencing also revealed four new variants in the study population. The main genotype-phenotype correlation finding was the presence of M694V mutation in homozygote or compound heterozygote state in the patients with renal manifestations.

Posterior reversible encephalopathy syndrome in a renal transplanted patient.

Alparslan M(1), Bora U, Hüseyin K, Ayhan D, Gültekin S.

Author information:

(1)Department of Internal Medicine, Akdeniz University Hospital, Antalya, Turkey.

**PATIENT:** Male, 28 **FINAL DIAGNOSIS:** Posterior reversible encephalopathy syndrome

**Symptoms:** Headache • pain around umbilical region • seizures • visual disturbances

**MEDICATION:** Mycophenolate mofetil **Clinical Procedure:** Treatment of parasitosis •

antiepileptic treatment • control of hypertension • changing mycophenolate

mofetil to everolimus **Specialty:** Transplantology.

**OBJECTIVE:** Unusual or unexpected effect of treatment.

**BACKGROUND:** Posterior reversible encephalopathy syndrome (PRES) is characterized by reversible neurological findings with clinical hallmarks such as headache,

confusion, seizures, cortical visual disturbances, and other focal neurological signs.

CASE REPORT: A 28-year-old male patient was hospitalized secondary to diarrhea and abdominal pain. He had renal transplantation due to renal amyloidosis secondary to familial Mediterranean fever (FMF). In his clinical follow-up, he had seizures, hemiparesis, blurred vision, and vomited an *Ascaris lumbricoides*. MRI results led to diagnosis of PRES. Mycophenolate mofetil was changed to everolimus, his systolic blood pressure kept below 140 mm hg, and his intestinal parasitosis was treated. During follow-up, he had no pain and no diarrhea. His neurological symptoms turned to normal within 48 hours and neuroradiological findings returned to normal within 2 weeks.

CONCLUSIONS: PRES is a rare disorder of unknown incidence in renal transplantation patients. Early diagnosis is very important to prevent irreversible neurological sequelae. PRES is totally reversible with cessation of the offending agent, rapid control of hypertension, and treatment of the underlying disease. For early diagnosis and to reduce morbidity and mortality, stool sample examination should be made in patients taking immunosuppressive drugs.

This case report describes a Japanese girl with systemic lupus erythematosus who had recurrent fevers and erythema nodosum. She was later found to carry the complex allele E148Q/R202Q/P369S/R408Q of MEFV, the gene responsible for familial

Mediterranean fever.

**OBJECTIVES:** Our aim was to investigate whether the maternal serum concentrations of first and second trimester serum analytes are altered in familial Mediterranean fever (FMF) pregnancies.

**MATERIALS AND METHODS:** The screening tests were compared in a series of 16 serum samples from FMF pregnancies and in a cohort of 48 pregnant women with normal pregnancy. Serum samples were obtained between 11 and 13 weeks; 16 and 18 weeks gestation.

**RESULTS:** Serum pregnancy-associated plasma protein-A (PAPP-A) levels, expressed as multiples of the median ( $0.9 \pm 0.45$  MoM) in the control group, were significantly higher than FMF patients ( $0.6 \pm 0.3$  MoM) ( $p = 0.027$ ). Analyses of alpha-fetoprotein, human chorionic gonadotropin and oestriol levels showed no significant differences between FMF and normal pregnancies.

**CONCLUSIONS:** Our study revealed that low levels of PAPP-A are associated with FMF.

Inflammasome activation and inhibition in primary murine bone marrow-derived

cells, and assays for IL-1 $\alpha$ , IL-1 $\beta$ , and caspase-1.

Schneider KS(1), Thomas CJ, Groß O.

Author information:

(1)Institut für Klinische Chemie und Pathobiochemie, Klinikum rechts der Isar, Technische Universität München, Munich, Germany.

Through its ability to control the proteolytic maturation and secretion of interleukin-1 family cytokines, the inflammasome occupies a central role in the activation of inflammation and also influences the shaping of adaptive immunity. Since it affects a multitude of different immune responses from autoinflammatory diseases to host defense, vaccine efficacy, and even cancer, it has become of interest to many researchers. Here, we describe a straightforward method for inflammasome assays in primary murine bone marrow--derived myeloid cells. The protocol encompasses cell handling, inflammasome activation and inhibition, as well as the detection of IL-1 $\beta$ , caspase-1, and IL-1 $\alpha$  by ELISA and Western blot.

MEFV Variants in Patients with PFAPA Syndrome in Japan.

Taniuchi S(1), Nishikomori R, Iharada A, Tuji S, Heike T, Kaneko K.

Author information:

(1)Department of Pediatrics, Kansai Medical University, Japan.

**BACKGROUND:** The pathogenesis of PFAPA (periodic fever, aphthous stomatitis, pharyngitis, adenitis) syndrome is unknown as yet. In order to understand whether genes implicated in other auto-inflammatory diseases might be involved in the pathogenesis of PFAPA, all variants in the genes causing familial Mediterranean fever (FMF), tumor necrosis factor (TNF) receptor-associated periodic syndrome (TRAPS), and Hyper IgD syndrome were analyzed in children with PFAPA.

**PATIENTS AND METHODS:** All variants in MEFV, TNFRSF1A, and MVK were analyzed in 20

patients with PFAPA. PFAPA were diagnosed by previous published criteria. The findings of all analyses in PFAPA patients were compared with those of unaffected normal subjects (n=62).

**RESULTS:** In the 13 children of 20 with PFAPA, the heterozygous variants of MEFV (5 patients: E148Q-L110P, 2 patients: E148Q, 1 patient: E148Q-L110P/E148Q, 1 patient: E148Q-P369S-R408Q-E84K, 1 patient: E148Q-L110P-P369S-A408G, 1 patient: R202Q, 1 patient: P115R) were found. No variants belonging to TNFRSF1A or MVK were detected in children with PFAPA. The frequency of the E148Q-L110P variants in children with PFAPA was significantly higher than that observed in unaffected normal subjects (7/20 versus 8/62). The duration of the episodes of illness in PFAPA children with MEFV variants was shorter than that of patients without variants.

**CONCLUSION:** Genes involved in the development and progression of MEFV may affect the incidence and the phenotype of PFAPA in children.

The risk of familial Mediterranean fever in MEFV heterozygotes: a statistical approach.

Jéru I(1), Hentgen V, Cochet E, Duquesnoy P, Le Borgne G, Grimpel E, Stojanovic KS, Karabina S, Grateau G, Amselem S.

Author information:

(1)UMR\_S933, Institut National de la Santé et de la Recherche Médicale, Paris, France. isabelle.jeru@trs.aphp.fr

**BACKGROUND:** Familial Mediterranean fever (FMF) is an autosomal recessive autoinflammatory disorder due to MEFV mutations and one of the most frequent Mediterranean genetic diseases. The observation of many heterozygous patients in whom a second mutated allele was excluded led to the proposal that heterozygosity could be causal. However, heterozygosity might be coincidental in many patients due to the very high rate of mutations in Mediterranean populations.

**OBJECTIVE:** To better delineate the pathogenicity of heterozygosity in order to

improve genetic counselling and disease management.

**METHODS:** Complementary statistical approaches were used: estimation of FMF prevalence at population levels, genotype comparison in siblings from 63 familial forms, and genotype study in 557 patients from four Mediterranean populations.

**RESULTS:** At the population level, we did not observe any contribution of heterozygosity to disease prevalence. In affected siblings of patients carrying two MEFV mutations, 92% carry two mutated alleles, whereas 4% are heterozygous with typical FMF diagnosis. We demonstrated statistically that patients are more likely to be heterozygous than healthy individuals, as shown by the higher ratio heterozygous carriers/non carriers in patients ( $p < 10^{-7}$ ) ( $p < 0.003$ ). The risk for heterozygotes to develop FMF was estimated between  $2.1 \times 10^{-3}$  and  $5.8 \times 10^{-3}$  and the relative risk, as compared to non carriers, between 6.3 and 8.1.

**CONCLUSIONS:** This is the first statistical demonstration that heterozygosity is not responsible for classical Mendelian FMF per se, but constitutes a susceptibility factor for clinically-similar multifactorial forms of the disease. We also provide a first estimate of the risk for heterozygotes to develop FMF.

Is colchicine therapy effective in all patients with secondary amyloidosis?

Unverdi S(1), Inal S, Ceri M, Unverdi H, Batgi H, Tuna R, Ozturk MA, Guz G, Duranay M.

Author information:

(1)Department of Nephrology, Ankara Educational and Training Hospital, Ankara, Turkey. selmanunverdi@yahoo.com

**OBJECTIVE:** Although colchicine is effective on prevention and regression of amyloidosis in many cases, rate of unresponsiveness to colchicine therapy is not too low. However, there is no sufficient data about which factors effect to response of colchicine therapy on regression of amyloidosis.

**MATERIALS AND METHODS:** 24 patients with renal amyloidosis were enrolled into the

study. The patients were divided in two groups according to urinary protein excretions: non-nephrotic stage (14/24) and nephrotic stage (10/24). The patients were also categorized according to the etiology of amyloidosis; familial Mediterranean fever (FMF)-associated amyloidosis (15/24) versus rheumatoid disorders (RD)-associated amyloidosis (9/24). The changes of amount of proteinuria and estimated glomerular filtration rates were investigated after colchicine treatment started in these groups.

RESULTS: The mean follow-up period was  $27.7 \pm 19.2$  months. After initiating colchicine therapy, the degree of proteinuria was decreased higher than 50% in 11/14 (78%) of non-nephrotic patients and elevated only in three (22%) patients.

In nephrotic group, proteinuria was increased in 5/10 (50%) of patients.

Glomerular filtration rates were stable in nephrotic and non-nephrotic groups.

Presenting with nephrotic syndrome was higher in RD-associated amyloidosis (RD\_A) group (5/9) than FMF-associated amyloidosis (FMF\_A) group (5/15) without statistical significance ( $p > 0.05$ ). After colchicine treatment, proteinuria was decreased in 12/15 patients in FMF\_A group, however, the significant decreasing of proteinuria was not observed in RD\_A group ( $p = 0.05$  vs.  $p > 0.05$ ).

CONCLUSION: Colchicine therapy was found more effective in low proteinuric stage of amyloidosis. The beneficial effect of colchicine therapy was not observed in patients with RD- associated amyloidosis.

How should we approach classification of autoinflammatory diseases?

Grateau G(1), Hentgen V, Stojanovic KS, J  ru I, Amselem S, Steichen O.

Author information:

(1)French Reference Centre for Amyloidosis of Inflammatory Origin and Familial Mediterranean Fever, H  pital Tenon, Assistance Publique-H  pitaux de Paris (AP-HP), 4 rue de la Chine, Paris, F-75020 France.

The notion of 'autoinflammatory' disease was introduced at the end of the 1990s, and, since then, this concept has rapidly evolved. As a result, multiple

definitions of autoinflammatory disease, and classifications of conditions encompassed by these definitions, have been proposed; this succession highlights advances that have been made in understanding of the innate immune system, and especially the roles of IL-1 $\beta$  and the inflammasome in autoinflammatory conditions. However, the definitions and classifications that have been suggested to date face a number of structure and content issues. We therefore propose another, more clinically-oriented, definition: autoinflammatory diseases are diseases with clinical signs of inflammation, associated with elevated levels of acute-phase reactants, which are attributable to dysfunction of the innate immune system, genetically-determined or triggered by an endogenous factor. From this foundation, we propose a clinically-based classification of autoinflammatory diseases, and go on to discuss how immunological diseases as a whole, including autoimmune diseases, can be appropriately located within a continuum only if the classification process is multidimensional. For this purpose, we appeal to the philosophical concepts of family resemblance and signature.

Recurrent peripheral facial palsy in a child with familial Mediterranean fever.

Yılmaz U(1), Gülez N, Cubukçu D, Güzel O, Akinci G, Oztürk A.

Author information:

(1)Department of Pediatric Neurology, Dr. Behçet Uz Children's Hospital, Izmir, Turkey. Electronic address: drunsalyilmaz@yahoo.com.

**BACKGROUND:** Recurrent peripheral facial palsy is uncommon in children. It mostly occurs as an idiopathic disorder and to a lesser extent in the setting of some infectious, genetic, or systemic disorders. However, its association with familial Mediterranean fever has not been reported before.

**PATIENT:** We present a 14-year-old girl who experienced three episodes of right-sided peripheral facial palsy during a 9-month interval. She had a diagnosis of familial Mediterranean fever (homozygous with M694V mutation) and she had been receiving colchicine for 8 years. Recurrent peripheral facial palsy

could be a neurological manifestation of vasculitis in familial Mediterranean fever.

CONCLUSION: Recurrent peripheral facial palsy may be a manifestation of familial Mediterranean fever in children.

Novel IL36RN mutation in a Japanese case of early onset generalized pustular psoriasis.

Kanazawa N(1), Nakamura T, Mikita N, Furukawa F.

Author information:

(1)Department of Dermatology, Wakayama Medical University, Wakayama, Japan.

Generalized pustular psoriasis is a distinct type of psoriasis characterized by recurrent febrile attacks with disseminated subcorneal pustules on generalized skin rashes. Recently, homozygous and compound heterozygous mutations of the IL36RN gene, which encodes the anti-inflammatory cytokine interleukin (IL)-36 receptor antagonist, were identified in familial and sporadic cases of various ethnicities with generalized pustular psoriasis. Here we report a 39-year-old Japanese male patient who had suffered from repeated attacks of generalized pustular psoriasis since infancy with intervals of several years. At presentation, erythematous lesions with a few pustules were found only on some parts of the body and controlled with topical corticosteroids. An analysis of the IL36RN gene revealed compound heterozygous mutations of c.28C>T and c.368C>T. While the former mutation causing the premature termination p.Arg10X is recurrent in Japanese cases, the latter missense mutation causing p.Thr123Met substitution is novel, but another mutation in the same position has been reported in one Japanese case. Our report further supports the presence of the Japanese-specific hot spots in the IL36RN gene, 28C and 368C, and suggests the functional significance of Thr123. This special type of generalized pustular psoriasis caused by IL36RN mutations has been designated as deficiency for IL-36 receptor

antagonist, a new hereditary autoinflammatory disease, and its phenotypes have emerged to include other related pustular disorders, palmoplantar pustulosis, acrodermatitis continua of Hallopeau, and acute generalized exanthematous pustulosis. The genetic analysis of the cases with these diseases would be important for establishment and application of the specific treatments targeting the IL-36 signaling.

Familial Mediterranean fever without fever as a cause of monoarthritis.

Mattiassich G(1), Semlitsch G, Nadler K, Rainer F.

Author information:

(1)Trauma Center Linz, Linz, Austria. georg.mattiassich@gmx.at

Familial Mediterranean fever (FMF) is an autosomal recessive hereditary disease. FMF-related arthritis affects large joints, especially in the lower extremities. It starts with acute pain and swelling and affects one joint at a time. Fever is the most common symptom in FMF. Monoarthritis as the sole symptom is relatively rare and thus delayed diagnosis of the disease in a patient who had been suffering from monoarthritis for several years. Genetic analysis showing typical mutations in the patient eventually resulted in correct diagnosis, although classical clinical diagnostic criteria were not met. The patient received appropriate therapy with colchicine, which led to remission of the symptoms.

Colchicine (Col) is a microtubule depolymerizing drug, widely used for treatment of familial Mediterranean fever (FMF). Mechanisms by which Col exerts its beneficial effects are not yet completely understood, especially with respect to gene expression in polymorphonuclear neutrophils (PMNs), the main effector cells in acute inflammatory attacks of FMF. This study was, therefore, designed to elucidate possible modulatory effect of Col on expression of inflammation-related genes in circulating PMNs from 16 FMF patients in the remission period and 11 healthy subjects. In vitro effect of Col exposure (1 microg/ml) on expression of 8 selected genes was examined using quantitative real-time RT-PCR. Col up-regulated expression of IL-8 and IL-1beta genes in FMF (13-fold and 2.7-fold, p less than 0.05, respectively) and healthy (3-fold and 6.5-fold, p less than 0.05, respectively) PMNs, and down-regulated caspase-1 in FMF neutrophils (3-fold, p less than 0.05). In FMF PMNs treated with Col mRNAs of IL-8 (51-fold, p less than 0.01) and c-FOS (7-fold, p less than 0.05) transcripts were elevated compared to those from healthy subjects. By contrast, caspase-1 mRNA was decreased in FMF neutrophils compared to healthy cells (1.6-fold, p less than 0.05). Hereby, we provide evidence that, at least in vitro, Col displays pro-inflammatory potential in respect to IL-1beta and IL-8 genes. At the same time, our findings implicate suppression of caspase-1 expression by Col as a potential mechanism for its effects in FMF treatment.

Circulating galectin-3 in infections and non-infectious inflammatory diseases.

ten Oever J(1), Giamarellos-Bourboulis EJ, van de Veerdonk FL, Stelma FF, Simon A, Janssen M, Johnson M, Pachot A, Kullberg BJ, Joosten LA, Netea MG.

Author information:

(1)Department of Medicine, Radboud University Nijmegen Medical Center, Nijmegen, The Netherlands, j.tenoever@aig.umcn.nl.

Recent studies point to a dual role for galectin-3 as both a circulating damage-associated molecular pattern and a cell membrane-associated pattern recognition receptor. The aim of this study was to assess the potential of circulating galectin-3 for discriminating between infections and non-infectious inflammatory disorders on the one hand, and between fungal and bacterial infections on the other. Galectin-3 and C-reactive protein (CRP) were measured in the plasma of 127 patients with either non-infectious inflammatory disorders (gout, autoinflammatory syndrome or pancreatitis) or an infection (viral lower respiratory tract infection, bacterial sepsis or candidaemia). Circulating galectin-3 concentrations were increased in patients with infections when compared with healthy volunteers or patients with non-infectious inflammatory diseases. At cut-off values with a specificity of 95%, the sensitivity of galectin-3 ( $>20.6$  ng/ml) to discriminate between an infection and non-infectious inflammation was higher than that of CRP ( $>156$  mg/l): 43% [95% confidence interval (CI) 33-53%] versus 27% (95% CI 19-37%),  $p = 0.03$ . After exclusion of patients with CRP  $<156$  mg/l, galectin-3 concentration  $>20.6$  ng/ml could identify 41 % (95% CI 29-53%) of the patients with an infection at the cost of one false-positive with non-infectious inflammation. Using this sequential approach, 57% of the patients with an infection could be selected. Galectin-3 concentrations were similar in patients with bacterial and Candida sepsis, while being lower in viral respiratory infections. Although galectin-3 does not discriminate between bacterial and Candida sepsis, the sequential use of CRP and galectin-3 in distinguishing infectious diseases from non-infectious inflammation may be superior to CRP alone.

The continuous advance in the search for the cause and pathogenesis of the autoinflammatory syndromes, as well as reports of the efficacy of specific inflammation-mediator suppressors, has changed the way these syndromes are approached and treated; both the acute and long-term treatment of these diseases has improved significantly. Etiologic and pathophysiologic manipulation is and will be the future for controlling, even curing, this new and rare set of diseases.

The recent molecular, biologic, and genetic understanding of the inflammasome has revolutionized the diagnosis of and therapy for the phenotypically heterogeneous group of rare oligogenic disorders, now recognized to have autoinflammatory origin. This article reviews the importance of inflammasome activation in the central and peripheral mechanisms underlying a common, multifactorial, lifestyle-related, and polygenetic disease (type 2 diabetes mellitus), and conceptualizes the notion that this health challenge should now be recognized to have an autoinflammatory cause. It is hoped that targeting these mechanisms will enable the introduction of novel therapies that attack the basic pathogenetic mechanisms of type 2 diabetes mellitus rather than the epiphenomena that are its consequences.

Autoinflammatory diseases (AIDs) are characterized by recurrent episodes of systemic and organ-specific inflammation. Many of these diseases share fever as a common presenting feature. Physicians need to consider AIDs in children with recurrent, unexplained fevers, when infectious and malignant causes have been discarded. This article discusses the differential diagnosis of recurrent fever in children, with a focus on AIDs. It discusses pharyngitis, and cervical adenitis and the monogenic autoinflammatory diseases that cause recurrent fevers including familial Mediterranean fever, hyper-immunoglobulin (Ig) D and periodic fever syndrome, tumor necrosis factor receptor-associated periodic syndrome, cryopyrin associated periodic syndromes, deficiency of interleukin-36 receptor antagonist, Majeed syndrome, chronic atypical neutrophilic dermatosis with lipodystrophy and increased temperature syndrome, and deficiency of the interleukin-1 receptor antagonist. In addition, the granulomatous disorders, pyogenic sterile arthritis, pyoderma gangrenosum, and acne and Blau syndrome, will be discussed.

Autoinflammatory syndromes comprise a diagnostically challenging group of systemic inflammatory disorders uniquely related by (1) dysregulation of innate immunity, (2) inflammasome activation, (3) dramatic clinical features (high fevers, neutrophilic rashes, and bone or synovial involvement), (4) impressive

acute phase responses, and (5) effective treatment with cytokine inhibitors. This review details some of the more common autoinflammatory disorders, their distinguishing features and dermatologic manifestations, and how an accurate diagnosis can be established in patients presenting with periodic or intermittent febrile disorders.

Autoinflammatory disorders, pain, and neural regulation of inflammation.

Chen MC(1), Meckfessel MH.

Author information:

(1)Galderma Laboratories, LP, 14501 North Freeway, Fort Worth, TX 76177, USA.  
michael.chen@galderma.com

Autoinflammatory disorders are disorders of the innate immune system that are distinct from autoimmune disorders. Dysregulation of the innate immune system, specifically an increase in interleukin-1 beta (IL-1 $\beta$ ), gives rise to a spectrum of symptoms marked by inflammation and pain. Identification of causative gene mutations led to the discovery of the inflammasome. Many autoinflammatory disorders also have a strong pain component. The contribution of IL-1 $\beta$  to pain and neural involvement is underappreciated. This article provides an overview of the current autoinflammatory disorders and highlights the contribution IL-1 $\beta$  makes to pain in these disorders.

Psoriasis as autoinflammatory disease.

Rivas Bejarano JJ(1), Valdecantos WC.

Author information:

(1)Immunology, Global Medical Affairs, AbbVie, 1 North Waukegan Road, North Chicago, IL 60064, USA. bejarano.0214@yahoo.com

This article presents a summary of the evidence for a link between autoinflammatory diseases and psoriasis. The main concepts regarding the disease state of psoriasis are discussed and these lead to a change in the perspective on the clinical and pathophysiologic nature of psoriasis as a chronic, recurrent disease with important genetically defined features, and an associated or concomitant systemic inflammatory state that involves a multifactorial cellular and molecular network, transforming the old perception of psoriasis as a localized autoimmune skin disease, to one of psoriasis as a systemic inflammatory disease with autoinflammatory features and severe associated comorbid conditions.

What do autoinflammatory syndromes teach about common cutaneous diseases such as pyoderma gangrenosum? A commentary.

Butler D(1), Shinkai K.

Author information:

(1)University of Arizona School of Medicine, 1510 N Campbell Avenue, PO Box 245017, Tucson, AZ 85724, USA.

Pyoderma gangrenosum (PG) is a neutrophilic dermatosis characterized by ulcerating skin lesions with rapid onset and recalcitrant treatment course. PG treatment targets an array of inflammatory pathways with variable success. One of the hallmark features of PG is its association with a broad spectrum of systemic disorders. The authors hypothesize that there are common inflammatory pathways linking these systemic disorders to neutrophilic dermatoses. Rare autoinflammatory diseases offer insights into the understanding of inflammatory skin conditions. This article explores observations of the natural history of PG that illuminate aspects of PG pathogenesis, highlighting the role of autoinflammatory mediators.

This article provides a new categorization of inflammatory pustular dermatoses in the context of recent genetic and biological insights. Monogenic diseases with pustular phenotypes are discussed, including deficiency of interleukin 1 receptor antagonist, deficiency of the interleukin 36 receptor antagonist, CARD14-associated pustular psoriasis, and pyogenic arthritis, pyoderma gangrenosum, and acne. How these new genetic advancements may inform how previously described pustular diseases are viewed, including pustular psoriasis and its clinical variants, with a focus on historical classification by clinical phenotype, is also discussed.

Autoinflammatory diseases in dermatology: CAPS, TRAPS, HIDS, FMF, Blau, CANDLE.

Tripathi SV(1), Leslie KS.

Author information:

(1)Department of Dermatology, University of California San Francisco, 1701 Divisadero Street, Third Floor, San Francisco, CA 94143, USA.

Autoinflammatory diseases, including CAPS, TRAPS, HIDS, FMF, Blau, and CANDLE, have unique dermatologic presentations that can be a clue to diagnosis. Although these conditions are rare, the morbidity and mortality can be severe, and well-informed physicians can place these conditions in their differential diagnosis when familiar with the dermatologic manifestations. This review article presents a brief overview of each condition, clues to diagnosis that focus of dermatologic manifestations and clinical images, basic laboratory tests and follow-up, a brief review of treatments, and concludes with an overview for these autoinflammatory conditions and their differential diagnoses.

Autoinflammatory syndromes and diseases are a group of disorders of innate immunity. This group has grown rapidly in recent years as a result of research advancements in molecular biology and genetics. These diseases often present with skin manifestations and the dermatologist may not recognize the constellation of symptoms and medical history as a systemic inflammatory disease. Dermatologists would benefit from a deeper understanding of these diseases and the new treatments available for them.

Familial Mediterranean fever (FMF) is an autosomal recessive auto inflammatory disease, characterized by acute attacks of serositis, arthritis or skin rash.

Systemic lupus erythematosus (SLE) is a chronic, autoimmune disease characterized by multisystem inflammatory lesions affecting any organ systems in the body.

Coexistence of FMF and SLE is rare in literature. In this report, we present three patients with FMF associated with SLE.

Effect of chronic periodontitis on serum and gingival crevicular fluid oxidant and antioxidant status in patients with familial Mediterranean fever before and after periodontal treatment.

Bostanci V(1), Toker H, Senel S, Ozdemir H, Aydin H.

Author information:

(1)Department of Periodontology, Faculty of Dentistry, Cumhuriyet University, Sivas, Turkey.

**BACKGROUND:** The aim of this study is to investigate the impact of periodontal status on oxidant/antioxidant status in patients with chronic periodontitis (CP) who experienced familial Mediterranean fever (FMF) and their response to non-surgical periodontal therapy.

**METHODS:** Data were obtained from 13 patients with FMF with generalized CP (FMF-CP), 15 systemically healthy patients with generalized CP, 15 systemically and periodontal healthy controls (HCs), and 14 periodontally healthy patients with FMF (FMF-HC). Each participant's total oxidant status (TOS), total antioxidant status (TAS), and oxidative stress index (OSI) in their gingival crevicular fluid (GCF) and serum were recorded. Probing depth, clinical attachment level, and gingival and plaque indices in each participant were also measured. The GCF and clinical parameters at baseline and 6 weeks after periodontal treatment were recorded.

**RESULTS:** The study showed statistically significant improvement of clinical parameters in both FMF-CP and CP groups after periodontal treatment. The baseline GCF-TOS and OSI levels were significantly higher in the CP group compared with the FMF-CP group ( $P < 0.05$ ). After periodontal treatment, the GCF-TOS levels were significantly reduced in members of the FMF-CP group ( $P < 0.05$ ). The GCF-TAS levels in members of the FMF-CP group were significantly higher than those of members of the HC group at baseline ( $P < 0.05$ ). Serum-TAS levels in the FMF-CP group were significantly higher than those in the CP and HC groups at baseline ( $P < 0.05$ ). The GCF-TOS level in the FMF-CP group was significantly higher than that

in the FMF-HC group at baseline and 6 weeks. However, there were no significant differences in the serum-TOS and serum-OSI levels of those in the FMF-CP and CP groups at baseline and 6 weeks ( $P > 0.05$ ).

**CONCLUSION:** The results of the present study show that patients with FMF-CP displayed reduced oxidative stress and increased antioxidant status compared with those in the CP and HC groups.

Periodic fevers are acquired or inherited disorders of innate immunity, which were first described in the 1940s. The patients are typically young at onset and have regularly recurring fevers for a few days to a few weeks with systemic inflammatory symptoms that are interrupted by symptom-free periods. There is a variety of clinical manifestations including gastrointestinal complaints, myalgias, arthralgias, and rash. A differential diagnosis in these patients may include recurrent infections, other inflammatory disorders, and neoplastic disease. This clinical review focuses on a sample of autoinflammatory disorders including familial Mediterranean fever, tumor necrosis factor receptor 1-associated periodic syndrome, hyperimmunoglobulinemia D syndrome, the cryopyrin-associated periodic syndrome, and periodic fever, aphthous stomatitis, pharyngitis, and cervical adenitis syndrome. We review the basics, pertinent clinical and laboratory features, and management of each entity.

Vaccinations in juvenile chronic inflammatory diseases: an update.

Silva CA(1), Aikawa NE, Bonfa E.

Author information:

(1)Pediatric Rheumatology Unit, Instituto da Criança, Faculty of Medicine, University of São Paulo, Avenida Dr. Eneas de Carvalho Aguiar 647, Cerqueira Cesar, São Paulo, SP, Brazil. clovis.silva@hc.fm.usp.br

Vaccination is a powerful tool to reduce the burden of infectious diseases in paediatric patients with chronic rheumatic diseases. Live attenuated vaccines are not recommended for profoundly immunosuppressed patients, but nonlive vaccines have adequate safety and efficacy profiles in the few (admittedly underpowered) studies published to date. No severe vaccine-specific or disease-specific adverse events have been observed in patients with juvenile idiopathic arthritis (JIA) or childhood-onset systemic lupus erythematosus (SLE) who have been vaccinated with live or nonlive agents. The immune response to live vaccines is variable in these patients but generally adequate, despite concomitant use of immunosuppressive and biologic agents. The proposal that onset of autoimmune rheumatic diseases could be induced by vaccination is controversial and primarily based on case reports; however, patients with mevalonate kinase deficiency can experience febrile attacks after immunizations. Adequately powered studies of live and nonlive vaccination in patients with paediatric rheumatic diseases are necessary to clarify safety and efficacy issues. This narrative Review discusses vaccination in patients with JIA, childhood-onset SLE, juvenile dermatomyositis, juvenile systemic sclerosis, primary vasculitis and autoinflammatory syndromes. Vaccine safety, short-term and long-term changes in disease parameters, and the immunogenicity and influence of immunosuppressive agents are outlined for each combination of disease and vaccine.

(1)Department of Surgery and Anatomy, Ribeirão Preto Faculty of Medicine, University of São Paulo, Avenida Bandeirantes 3900, 14048-900 Ribeirão Preto, SP, Brazil.

A modern concept considers acute coronary syndrome as an autoinflammatory disorder. From the onset to the healing stage, an endless inflammation has been presented with complex, multiple cross-talk mechanisms at the molecular, cellular, and organ levels. Inflammatory response following acute myocardial infarction has been well documented since the 1940s and 1950s, including increased erythrocyte sedimentation rate, the C-reactive protein analysis, and the determination of serum complement. It is surprising to note, based on a wide literature overview including the following 30 years (decades of 1960, 1970, and 1980), that the inflammatory acute myocardium infarction lost its focus, virtually disappearing from the literature reports. The reversal of this historical process occurs in the 1990s with the explosion of studies involving cytokines. Considering the importance of inflammation in the pathophysiology of ischemic heart disease, the aim of this paper is to present a conceptual overview in order to explore the possibility of curbing this inflammatory process.

Familial Mediterranean fever (FMF) is a systemic hereditary autoinflammatory disorder. The present study aimed to investigate the relationship of enthesitis to FMF and to search the potential association between enthesitis and MEFV gene missense variations in patients with FMF. The study consisted of 72 FMF patients (mean age  $29.12 \pm 11.47$  years, 32 females), 29 patients with ankylosing spondylitis (AS) (mean age  $34.14 \pm 11.73$  years, 16 females), and 34 healthy volunteers (mean age  $23.06 \pm 6.41$  years, 8 females). FMF patients were classified according to the kind of MEFV gene mutation. Doppler ultrasound was used to determine enthesitis based on the Outcome Measures in Rheumatoid Arthritis Clinical Trials (OMERACT) scoring system. OMERACT score was significantly different between FMF patients and control group ( $p < 0.001$  in all patients,  $p = 0.009$  in men, and  $p = 0.002$  in women). However, it was not significantly different between FMF and AS patients in both sexes. OMERACT score did not differ between FMF patients with and without M694V gene mutation. The best cutoff point of OMERACT score to predict enthesitis was found as  $\geq 0.5$  with sensitivity of 29 %, specificity of 100 %, positive predictive value of 100 %, and negative predictive value of 40 %.

Comment in

Immunity. 2013 Jun 27;38(6):1088-90.

Omega-3 fatty acids ( $\omega$ -3 FAs) have potential anti-inflammatory activity in a variety of inflammatory human diseases, but the mechanisms remain poorly understood. Here we show that stimulation of macrophages with  $\omega$ -3 FAs, including eicosapentaenoic acid (EPA), docosahexaenoic acid (DHA), and other family members, abolished NLRP3 inflammasome activation and inhibited subsequent caspase-1 activation and IL-1 $\beta$  secretion. In addition, G protein-coupled receptor 120 (GPR120) and GPR40 and their downstream scaffold protein  $\beta$ -arrestin-2 were shown to be involved in inflammasome inhibition induced by  $\omega$ -3 FAs. Importantly,  $\omega$ -3 FAs also prevented NLRP3 inflammasome-dependent inflammation and metabolic disorder in a high-fat-diet-induced type 2 diabetes model. Our results reveal a mechanism through which  $\omega$ -3 FAs repress inflammation and prevent inflammation-driven diseases and suggest the potential clinical use of  $\omega$ -3 FAs in gout, autoinflammatory syndromes, or other NLRP3 inflammasome-driven inflammatory diseases.

# Frequency of MEFV mutation and genotype-phenotype correlation in cases with dysmenorrhea.

Ocak Z(1), Ocak T, Duran A, Ozlü T, Kocaman EM.

## Author information:

(1)Department of Medical Genetics, Suleymaniye Maternity Hospital for Research and Training, Istanbul, Turkey. zeynep\_ipek@yahoo.com

**AIM:** We aimed to investigate the relation between mutations and polymorphisms playing roles in the onset of clinical findings of Familial Mediterranean Fever (FMF) and clinical phenotypic reflections manifesting with painful episodes, such as dysmenorrhea.

**MATERIAL AND METHODS:** A total of 1000 female patients who had not responded well to non-steroidal anti-inflammatory drugs in the menstrual period, and who had presented to the emergency room with the complaint of recurrent pain episodes were included in the study. All the patients were Turkish women living in Istanbul. In this study, the mutations most frequently seen in the Mediterranean Fever Gene (MEFV), namely M694V, E148Q, M680I(G/C), V726A, P369S, R761H, A744S, M694I, K695R, F479L, M680I(G/A), and I692del were examined using the DNA sequence analysis following DNA isolation.

**RESULTS:** The number of individuals who had a mutation in at least one allele for FMF was 511 out of 1000 patients. Of these 511 patients, homozygous mutations were found in 21% (n = 109), compound heterozygous mutations were found in 27% (n = 136), and heterozygous mutations were found in 52% (n = 266). The most frequent homozygous genotype seen in our study population was M694V/M694V. The most common compound heterozygote genotypes were M694V/M680I, M694V/V726A, M694V/E148Q, and M680I/V726A; and 11.7% (n = 60) of the families in whom mutations were found had consanguinity.

**CONCLUSION:** Women who present to the emergency room with the complaint of dysmenorrhea that is irresponsive to non-steroidal anti-inflammatory drugs may have several types of MEFV mutations that are responsible for FMF.

Increased levels of macrophage migration inhibitory factor in patients with familial mediterranean Fever.

Savran Y(1), Sari I, Kozaci DL, Gunay N, Onen F, Akar S.

Author information:

(1)Dokuz Eylul University School of Medicine, Department of Internal Medicine, Izmir, Turkey.

**OBJECTIVE:** To determine the level of macrophage migration inhibitory factor (MIF), its relationship with Mediterranean fever (MEFV) gene mutations and oxidative stress in familial Mediterranean fever (FMF).

**METHODS:** Fifty one unrelated attack free FMF patients (24 M and 27 F,  $32.8 \pm 8.7$  years) and 30 healthy controls (16 M and 14 F,  $32.7 \pm 7$  years) were included in the study. Serum MIF, total oxidant status (TOS) and total anti-oxidant status (TAS) were studied.

**RESULTS:** Age, sex distribution, anthropometrical indices, smoking status, serum lipids and TAS concentrations were similar between the patients and controls. However; erythrocyte sedimentation rate (ESR), C-reactive protein (CRP), MIF, and TOS were significantly higher in the patients' group compared with healthy subjects. MIF, TOS and TAS levels were not different between patients with or without M694V mutations.

**CONCLUSION:** We found increased concentrations of MIF in patients with FMF. Increased MIF levels were significantly correlated with oxidative stress and in regression analysis MIF concentrations were independent from the inflammatory activity as assessed by ESR and CRP. M694V mutations seem no effect on MIF and oxidative stress.

Comment in

Inflammation. 2014 Jun;37(3):833-4.

Familial Mediterranean fever (FMF), which is an autosomal recessive disease, is characterised by recurrent febrile episodes in association with peritonitis, pleuritis and arthritis and has ongoing subclinical inflammation during attack-free period. In this study, we aimed to investigate the relationship between FMF with neutrophil-to-lymphocyte ratio (NLR), which is determined in many chronic inflammations as a new potential inflammatory mediator. We included 62 patients and 41 healthy subjects who were similar in terms of age and sex. We found that the NLR values of the patients were significantly higher than those of the control group, and C-reactive protein values were correlated with NLR. Another finding was the NLR values were significantly higher in the FMF patient with M694V mutation than with other mutations. As a result, NLR might be used in the FMF patient as an indicator of the subclinical inflammation, and the FMF patients with M694V mutation should be followed up closely because of increased subclinical inflammation risk.

Author information:

(1)Health Genetics Unit, Institute for Maternal and Child Health-IRCCS Burlo Garofolo, Trieste, Italy. annalisa.marcuzzi@burlo.trieste.it

**BACKGROUND:** Mevalonate kinase deficiency (MKD) is a rare genetic autoinflammatory disease caused by blocking of the enzyme mevalonate kinase in the pathway of cholesterol and isoprenoids. The pathogenic mechanism originating an immune response in MKD patients has not been clearly understood.

**METHODS:** We investigated the dysregulation of expression of selected cytokines and chemokines in the serum of MKD patients. The results have been compared with those observed in an MKD mouse model obtained by treating the mice with aminobisphosphonate, a molecule that is able to inhibit the cholesterol pathway, mimicking the genetic block characteristic of the disease.

**RESULTS:** Interleukin (IL)-1 $\beta$ , IL-5, IL-6, IL-9, IL-17, granulocyte colony-stimulating factor, monocyte chemotactic protein-1, tumor necrosis factor- $\alpha$ , and IL-4 expression were dysregulated in sera from MKD patients and mice. Moreover, geraniol, an exogenous isoprenoid, when administered to MKD mice, restored cytokines and chemokines levels with values similar to those of untreated mice.

**CONCLUSION:** Our findings, which were obtained in patients and a mouse model mimicking the human disease, suggest that these cytokines and chemokines could be MKD specific and that isoprenoids could be considered as potential therapeutic molecules. The mouse model, even if with some limitations, was robust and suitable for routine testing of potential MKD drugs.

A roadmap for fever of unknown origin in children.

Rigante D(1), Esposito S.

Author information:

(1)Institute of Pediatrics, Universita' Cattolica Sacro Cuore, Rome, Italy.

Fever of unknown origin (FUO) in adults is conventionally defined by the occurrence of body temperatures above 38.3 degrees C (101 degrees F) for a period of 3 weeks without any identified etiology after a period of 1-week hospitalization. The issue of FUO in pediatrics is rather hazy and still represents a challenging diagnostic dilemma. Most of the available data are limited to nationwide cohorts of patients of any age. The major difficulty in establishing a diagnosis is that the characteristic features rendering specific disorders clinically recognizable are absent or subtle, hence only a painstaking questioning on family background may elicit the correct investigative path. No diagnostic algorithms are actually available and clinicians must rely on a very careful step-by-step evaluation of the single patient. The need for invasive diagnostic techniques should be closely taken into consideration when laboratory tests or simple imaging procedures fail to discern the origin of FUO. Fevers with no reasonable explanation and no localizing signs often conceal different common diseases in children, which tend to display an unusual or atypical pattern. The principal causes behind FUO in pediatric age remain infections, followed by collagen vascular diseases and neoplastic disorders, although most children with malignancies present other systemic signs or suggestive laboratory abnormalities. The possibility of autoinflammatory syndromes, drug fever, and factitious fever should also be taken into account.

Psoriasis is an autoinflammatory skin disease of unknown etiology. Topical application of Aldara cream containing the Toll-like receptor (TLR)7 agonist Imiquimod (IMQ) onto patients induces flares of psoriasis. Likewise, in mice IMQ triggers pathological changes closely resembling psoriatic plaque formation. Key cytokines like IL-23 and type-I IFN (IFN-I), both being produced mainly by dendritic cells (DCs), have been implicated in psoriasis. Although plasmacytoid DCs (pDCs) are the main source of IFN $\alpha$  and thought to initiate disease, conventional DCs (cDCs) appear to maintain the psoriatic lesions. Any role of cDCs during lesion formation remains elusive. Here, we report that selective activation of TLR7 signaling specifically in CD11c(+) DCs was sufficient to induce psoriasiform skin disease in mice. Intriguingly, both pDCs and the IFN-I pathway were dispensable for the development of local skin inflammation. Selective TLR7 triggering of Langerin(+) DCs resulted in attenuated disease, whereas their depletion did not alter the severity of skin lesions. Moreover, after IMQ-painting, IL-23 was exclusively produced by Langerin(neg) DCs in vivo. In conclusion, TLR7-activated Langerin(neg) cDCs trigger psoriatic plaque formation via IL-23-mediated activation of innate IL-17/IL-22-producing lymphocytes, independently of pDCs or IFN-I. These results suggest therapeutic targeting of IL-23 production by cDCs to refine current treatment strategies for psoriasis.

Although idiopathic recurrent acute pericarditis (IRAP) is generally presumed to derive from an autoimmune process, increasing interest is currently being devoted to autoinflammatory diseases, a group of disorders of the innate immune system caused by mutations of genes involved in the regulation or activation of the inflammatory response, without any apparent involvement of autoimmunity. The tumour necrosis factor receptor-1-associated periodic syndrome is the most common autosomal dominant autoinflammatory disorder and is caused by mutations in the TNFRSF1A gene encoding the 55-kD receptor for tumour necrosis factor- $\alpha$ . IRAP patients carrying TNFRSF1A gene mutations have been recently described. We report

herein the first IRAP patients carrying the rare R104Q and D12E TNFRSF1A gene mutations, thus expanding the spectrum of tumour necrosis factor receptor-1-associated periodic syndrome mutations in IRAP patients.

**AIM:** Familial Mediterranean Fever (FMF) is the most common recurrent autoinflammatory fever syndrome. Still, many issues-e.g.: colchicine dosage adjustment, maximum dosage of colchicine in children and adults, definition of colchicine resistance, alternative treatment solutions in colchicine-resistant patients, and genetic screening for asymptomatic siblings-have not yet been standardized. The current paper aims at summarizing consensus recommendations to approach these issues.

**METHODS:** A literature review concerning these practical management questions was performed through PubMed. On the basis of this analysis, expert recommendations were developed during a consensus meeting of caregivers from France and Israel.

**RESULTS:** A patient experiencing more than four FMF attacks a year needs colchicine dose adjustment. In case of persistent attacks ( $\geq 6$  per year) in patients with maximum doses of colchicine (2 mg in children; 3 mg in adults), alternative treatment to colchicine with IL1 inhibitors should be considered.

Routine genetic testing for MEFV mutations in asymptomatic siblings of an index case is not recommended.

CONCLUSION: This is a first attempt to resolve practical questions in the daily management of FMF patients.

**BACKGROUND & AIMS:** Caspase recruitment domain 9 (CARD9) is an adaptor protein that integrates signals downstream of pattern recognition receptors. CARD9 has been associated with autoinflammatory disorders, and loss-of-function mutations have been associated with chronic mucocutaneous candidiasis, but the role of CARD9 in intestinal inflammation is unknown. We characterized the role of Card9 in mucosal immune responses to intestinal epithelial injury and infection.

**METHODS:** We induced intestinal inflammation in Card9-null mice by administration of dextran sulfate sodium (DSS) or *Citrobacter rodentium*. We analyzed body weight, assessed inflammation by histology, and measured levels of cytokines and chemokines using quantitative reverse-transcription polymerase chain reaction and enzyme-linked immunosorbent assay. Cell populations were compared between wild-type and Card9-null mice by flow cytometry analysis.

**RESULTS:** Colon tissues and mesenteric lymph nodes of Card9-null mice had reduced levels of interleukin (IL)-6, interferon- $\gamma$ , and T-helper (Th)17 cytokines after administration of DSS, compared with wild-type mice. IL-17A and IL-22 expression were reduced in the recovery phase after DSS administration, coincident with decreased expression of antimicrobial peptides and the chemokine (C-C motif) ligand 20 (Ccl20). Although Card9-null mice had more intestinal fungi based on 18S analysis, their Th17 responses remained defective even when an antifungal agent was administered throughout DSS exposure. Moreover, Card9-null mice had impaired immune responses to *C. rodentium*, characterized by decreased levels of colonic IL-6, IL-17A, IL-22, and regenerating islet-derived 3 gamma (RegIII $\gamma$ ), as well as fewer IL-22-producing innate lymphoid cells (ILCs) in colon lamina propria.

**CONCLUSIONS:** The adaptor protein CARD9 coordinates Th17- and innate lymphoid cell-mediated intestinal immune responses after epithelial injury in mice.

Monogenic autoinflammatory syndromes are caused by mutations in protein-coding genes that have a pivotal role in the regulation of the inflammatory response. Due to their genetic nature, most of these syndromes usually begin during childhood. They are clinically characterized by recurrent episodes of systemic inflammation (fever with different clinical manifestations, such as skin rash, serositis or arthritis) associated with elevation of acute phase reactants. During symptom-free intervals, patients achieve clinical well-being and normalize inflammatory parameters. Amyloidosis is a serious long-term complication. In this update we will discuss the clinical presentation and therapeutic strategies for these diseases in pediatrics.

Pigmentary hypertrichosis and non-autoimmune insulin-dependent diabetes mellitus (PHID) syndrome is associated with severe chronic inflammation and cardiomyopathy, and represents a new monogenic autoinflammatory syndrome.

Senniappan S, Hughes M, Shah P, Shah V, Kaski JP, Brogan P, Hussain K.

Mutations in SLC29A3 lead to pigmentary hypertrichosis and non-autoimmune insulin-dependent diabetes mellitus (PHID) and H syndromes, familial Rosai-Dorfman disease, and histiocytosis-lymphadenopathy plus syndrome. We report a new association of PHID syndrome with severe systemic inflammation, scleroderma-like changes, and cardiomyopathy. A 12-year-old girl with PHID syndrome presented with shortness of breath, hepatosplenomegaly, and raised

erythrocyte sedimentation rate and C-reactive protein. An echocardiogram showed biventricular myocardial hypertrophy, and cardiac magnetic resonance imaging showed circumferential late gadolinium enhancement of the myocardium. No systemic amyloid deposits were observed on a whole-body serum amyloid P scintigraphy scan. Abdominal ultrasound revealed intra-abdominal fat surrounding the solid organs, suggesting a possibility of evolving lipodystrophy with visceral adiposity. PHID syndrome is a novel monogenic autoinflammatory syndrome (AIS) associated with severe elevation of serum amyloid. Lipodystrophy, cutaneous sclerodermatous changes, and cardiomyopathy were also present in this case. In contrast to other AIS, blockade of interleukin-1 and tumor necrosis- $\alpha$  was ineffective.

Treatment of Muckle-Wells syndrome: analysis of two IL-1-blocking regimens.

Kuemmerle-Deschner JB, Wittkowski H, Tyrrell PN, Koetter I, Lohse P, Ummenhofer K, Reess F, Hansmann S, Koitschev A, Deuter C, Bialkowski A, Foell D, Benseler SM.

**OBJECTIVES:** Muckle-Wells syndrome (MWS) is an autoinflammatory disease characterized by excessive interleukin-1 (IL-1) release, resulting in recurrent fevers, sensorineural hearing loss, and amyloidosis. IL-1 inhibition with anakinra, an IL-1 receptor antagonist, improves clinical symptoms and inflammatory markers. Subclinical disease activity is commonly observed. Canakinumab, a fully human IgG1 anti-IL-1 $\beta$  monoclonal antibody, can abolish excess IL-1 $\beta$ . The study aim was to analyze the efficacy and safety of these two anti-IL-1 therapies.

**METHODS:** Two cohorts of patients with severe MWS and confirmed NLRP3 mutation were treated with anakinra and/or canakinumab. Clinical and laboratory features including ESR, CRP, SAA, and the neutrophil marker S100A12 were determined serially. Disease activity was captured by MWS disease activity scores (MWS-DAS). Remission was defined as MWS-DAS  $\leq 5$  plus normal CRP and SAA. Treatment efficacy and safety were analyzed.

**RESULTS:** The study included 12 anakinra- and 14 canakinumab-treated patients; the median age was 33.5 years (3.0 years to 72.0 years); 57% were female patients.

Both treatment regimens led to a significant reduction of clinical disease activity and inflammatory markers. At last follow-up, 75% of anakinra-treated and 93% of canakinumab-treated patients achieved remission. During follow-up, S100A12 levels mirrored recurrence of disease activity. Both treatment regimens had favorable safety profiles.

CONCLUSIONS: IL-1 blockade is an effective and safe treatment in MWS patients. MWS-DAS in combination with MWS inflammatory markers provides an excellent monitoring tool set. Canakinumab led to a sustained control of disease activity even after secondary failure of anakinra therapy. S100A12 may be a sensitive marker to detect subclinical disease activity.

Familial Mediterranean fever (FMF, MIM 249100) is an autosomal recessive disease affecting mainly patients of the Mediterranean basin. It is an autoinflammatory periodic disorder characterized by recurrent episodes of fever and abdominal pain, synovitis, and pleuritis. The major complication of FMF is the development of renal AA amyloidosis. Treatment with colchicine prevents the occurrence of recurrent seizures and renal amyloidosis. The disease is caused by mutations in the MEFV gene. We report here the cases of two unrelated patients, who have been late diagnosed with FMF complicated by renal amyloidosis. We focus on the importance of early diagnosis of FMF, both to start rapidly treatment with colchicine and avoid renal amyloidosis, and to provide genetic counseling to families.

[fraarcuri@libero.it](mailto:fraarcuri@libero.it)

Oral lichen planus is a chronic autoinflammatory mucositis. Oral lesions are predominantly white; they tend to be bilateral while involving the buccal mucosa especially cheek, tongue, gums, lips, and palate. Many topical and systemic agents are currently used with unpredictable results. Fat grafting is characterized by the placement of multiple parcels of purified fat with blunt cannulas; at the beginning, it was introduced to improve facial aesthetics. Recently, it has been translated to other surgical cases such as posttraumatic deformities and craniofacial anomalies and as ancillary reconstructive procedure after tumor resections. The successful results of this procedure encouraged us to use this approach to a clinical case of oral lichen planus refractory to conventional therapy.

Monogenic autoinflammatory diseases: concept and clinical manifestations.

Almeida de Jesus A(1), Goldbach-Mansky R.

Author information:

(1)Translational Autoinflammatory Diseases Section, National Institute of Arthritis, Musculoskeletal and Skin diseases (NIAMS), National Institutes of Health (NIH), Bethesda, MD 20814, USA.

The objective of this review is to describe the clinical manifestations of the growing spectrum of monogenic autoinflammatory diseases including recently described syndromes. The autoinflammatory diseases can be grouped based on clinical findings: 1. the three classic hereditary "periodic fever syndromes", familial Mediterranean Fever (FMF); TNF receptor associated periodic syndrome (TRAPS); and mevalonate kinase deficiency/hyperimmunoglobulinemia D and periodic fever syndrome (HIDS); 2. the cryopyrin associated periodic syndromes (CAPS), comprising familial cold autoinflammatory syndrome (FCAS), Muckle-Wells syndrome (MWS) and neonatal-onset multisystem inflammatory disease (NOMID) or CINCA, and; 3. pediatric granulomatous arthritis (PGA); 4. disorders presenting with skin pustules, including deficiency of interleukin 1 receptor antagonist (DIRA); Majeed syndrome; pyogenic arthritis, pyoderma gangrenosum and acne (PAPA) syndrome; deficiency of interleukin 36 receptor antagonist (DITRA); CARD14 mediated psoriasis (CAMP5), and early-onset inflammatory bowel diseases (EO-IBD); 5. inflammatory disorders caused by mutations in proteasome components, the proteasome associated autoinflammatory syndromes (PRAAS) and 6. very rare conditions presenting with autoinflammation and immunodeficiency.

Brain stem infarction associated with familial Mediterranean fever and central nervous system vasculitis.

Luger S(1), Harter PN, Mittelbronn M, Wagner M, Foerch C.

Author information:

(1)Department of Neurology, Goethe-University, Frankfurt am Main, Germany.  
sebastian.luger@kgu.de.

Familial Mediterranean fever (FMF) is an autoinflammatory autosomal recessive disease caused by mutations of the Mediterranean fever (MEFV) gene on chromosome 16p. Clinically, it is characterized by recurrent episodes of fever and painful polyserositis. An association of FMF with systemic vasculitis, namely Henoch-Schönlein purpura, polyarteritis nodosa and Behçet's disease has been described. Neurological manifestations of FMF occur rarely and include demyelinating (MS-like) lesions, posterior reversible encephalopathy syndrome, and pseudotumour cerebri. Hitherto hardly known, we herein present a young patient with a genetically proven FMF who suffered a brain stem infarction during a typical FMF attack. After a careful diagnostic workup including cerebrospinal fluid analysis, intra-arterial angiography and leptomeningeal biopsy, a FMF-associated central nervous system vasculitis was identified as the cause of stroke. The pathophysiological background and potential therapeutic strategies are discussed.

Inflammasome and cytokine blocking strategies in autoinflammatory disorders.

Moll M(1), Kuemmerle-Deschner JB.

Author information:

(1)Division of Pediatric Rheumatology, Department of Pediatrics, University Children's Hospital Tuebingen, Germany.

Autoinflammatory disorders are characterized by usually unprovoked recurrent episodes of features of inflammation caused by activation of the innate immune system. Many autoinflammatory disorders - the monogenetic defects in particular - are associated with alterations of inflammasomes. Inflammasomes are complex multimolecular structures, which respond to "danger" signals by activation of cytokines. Among these, IL-1 is the key player of the innate immune response and inflammation. Consequently, IL-1 blocking strategies are specific pathway targeting therapies in autoinflammatory diseases and applied in CAPS,

colchicine-resistant FMF, TRAPS, HIDS and DIRA. A number of rare genetic disorders involve inflammasome malfunction resulting in enhanced inflammatory response. IL-1 inhibition to date is the most successful specific therapy in autoinflammatory disorders. Here, current treatment strategies in autoinflammatory disorders are reviewed with a focus on inflammasome and cytokine inhibition.

Different presentations in patients with tumor necrosis factor receptor-associated periodic syndrome mutations: report of two cases.

Celebi-Tayfur A(1), Bilginer Y, Finetti M, Gattorno M, Ozen S.

Author information:

(1)Department of Pediatric Nephrology&Rheumatology, Hacettepe University Faculty of Medicine, Ankara, Turkey.

Tumor necrosis factor receptor-associated periodic syndrome (TRAPS) is an autosomal dominant autoinflammatory disorder caused by mutations in the TNFRSF1A gene encoding the 55-kDa receptor for tumor necrosis factor (TNF)- $\alpha$ . It is characterized by recurrent prolonged episodes of fever accompanied by abdominal pain, pleuritis, migratory skin rashes, fasciitis, headache, conjunctivitis, and periorbital edema. We report two children, one with a severe mutation in the TNFRSF1A gene causing the typical phenotype. The second patient had a homozygous R92Q-type mutation and displayed a periodic fever with aphthous stomatitis, pharyngitis and adenitis (PFAPA) syndrome-like phenotype. In the eastern Mediterranean region, TRAPS is probably underdiagnosed because of the overwhelming frequency of familial Mediterranean fever (FMF). However, TRAPS should be sought for in patients with atypical symptoms for FMF.

A case of hyperimmunoglobulinemia d syndrome successfully treated with canakinumab.

Tsitsami E(1), Papadopoulou C, Speletas M.

Author information:

(1)Pediatric Rheumatology Unit, 1st Department of Pediatrics, Children's Hospital "Aghia Sophia", University of Athens, 115 27 Athens, Greece.

Hyperimmunoglobulinemia D syndrome is a rare autosomal recessive autoinflammatory disorder caused by mutations in the mevalonate kinase gene (MVK). In a proportion of patients, however, no MVK mutations are detected. Although various standard anti-inflammatory drugs have been tried, until now there is no consensus about how HIDS should be treated. We present a case of HIDS in an 8-year-old girl whose clinical picture had started before the end of the first year of life. The patient had consistently elevated IgD levels but no mutations were found after a full-length analysis of the MVK gene. The method of MVK mutational analysis is presented in details. Treatment with canakinumab in a final single dose of 4 mg/kg every 4 weeks resulted in the disappearance of febrile attacks and a considerable improvement of patients' quality of life during a 12-month follow-up period. The drug has been well tolerated, and no side effects were observed.

The Inhibition of Inflammasome by Brazilian Propolis (EPP-AF).

Hori JI(1), Zamboni DS, Carrão DB, Goldman GH, Berretta AA.

Author information:

(1)Departamento de Biologia Celular, Molecular e Bioagentes Patogênicos, Faculdade de Medicina de Ribeirão Preto, Universidade de São Paulo, FMRP/USP, 14049-900 Ribeirão Preto, SP, Brazil.

Propolis extracts have gained the attention of consumers and researchers due to their unique chemical compositions and functional properties such as its anti-inflammatory activity. Recently, it was described a complex that is also important in inflammatory processes, named inflammasome. The inflammasomes are a large molecular platform formed in the cell cytosol in response to stress signals, toxins, and microbial infections. Once activated, the inflammasome induces caspase-1, which in turn induces the processing of inflammatory cytokines such as IL-1  $\beta$  and IL-18. So, to understand inflammasomes regulation becomes crucial to treat several disorders including autoinflammatory diseases. Since green propolis extracts are able to regulate inflammatory pathways, this work purpose was to investigate if this extract could also act on inflammasomes regulation. First, the extract was characterized and it demonstrated the presence of important compounds, especially Artepillin C. This extract was effective in reducing the IL-1  $\beta$  secretion in mouse macrophages and this reduction was correlated with a decrease in activation of the protease caspase-1. Furthermore, we found that the extract at a concentration of 30  $\mu$ g/mL was not toxic to the cells even after a 18-hour treatment. Altogether, these data indicate that Brazilian green propolis (EPP-AF) extract has a role in regulating the inflammasomes.

Linkage of bacterial colonization of skin and the urticaria-like rash of NLRP3-mediated autoinflammatory syndromes through mast cell-derived TNF- $\alpha$ .

Nakamura Y(1), Kambe N.

Author information:

(1)Department of Dermatology, Chiba University Graduate School of Medicine, 1-8-1

Inohana, Chuo-ku, Chiba 260-8670, Japan.

As anti-cytokine therapies were developed for clinical use during the last decade, anti-IL-1 therapies have emerged as a highly effective treatment for cryopyrin-associated periodic syndromes (CAPSs), including the "urticaria-like rash." Based on clinical observations, we hypothesized that NLRP3 activation and IL-1 $\beta$  production, in particular in mast cells (MCs), are important for the development of this eruption, due to the observation that CAPS patients have gain-of-function mutations in NLRP3 that result in unregulated excess levels of IL-1 $\beta$ . To further address our hypothesis, we employed gene-targeted mice carrying Nlrp3 mutations and found that signaling in MCs following bacterial colonization of skin is essential for IL-1 $\beta$ -dependent inflammation. Intradermal administration of a molecule that induces the release of granule-associated molecules from MCs showed that MCs and TNF- $\alpha$  were necessary for the inflammation in CAPS-mimicking mice. However, adult CAPS mice exhibited a persistent skin phenotype and did not respond to anti-TNF- $\alpha$  antibody, indicating that TNF- $\alpha$  is important only for the onset of the disease and is dispensable during the chronic phase of CAPS. Thus, in this review, we highlight our recent findings on how MCs play an important role, not only in ordinary urticaria, but also in the "urticaria-like rash" associated with NLRP3 mutations.

Serum soluble fas ligand levels in familial Mediterranean fever.

Ceri M(1), Unverdi S, Senes M, Altay M, Yilmaz R, Yucel D, Duranay M.

Author information:

(1)Department of Nephrology, Ankara Education and Research Hospital, Ankara, Turkey. tscer@yahoo.com

**INTRODUCTION:** Fas/FasL system plays an important role in the regulation of cell life and death, and circulating levels of sFasL have been shown to increase in some inflammatory conditions. However, there is no sufficient information about the levels of sFasL in patients with FMF. This study was designed to evaluate the serum sFasL levels in patients with FMF during attack and attack-free periods.

**METHODS:** Twenty-five FMF patients in attack and forty-four in free-attack period, and 20 age-, sex-, and BMI-matched healthy controls were included in this study. Participants with any chronic diseases were excluded. Blood samples were obtained within the first 24 h of the attack period and between febrile attacks, and levels of WBC, ESR, Fibrinogen, hsCRP and sFasL were determined.

**RESULTS:** The levels of traditional acute phase reactants during the attack were significantly higher than the attack-free and controls ( $p < 0.05$ ). The serum sFasL levels in the FMF study groups did not differ from the control group ( $0.70 \pm 0.08$  vs.  $0.73 \pm 0.12$ ;  $0.70 \pm 0.08$  vs.  $0.83 \pm 0.14$ ;  $0.73 \pm 0.12$  vs.  $0.83 \pm 0.14$ , respectively,  $p > 0.05$ ). Moreover, the sFasL levels during the attack were not significantly different from those in attack-free patients ( $0.70 \pm 0.08$  vs.  $0.83 \pm 0.14$ ,  $p > 0.05$ ).

**CONCLUSION:** In this study, we demonstrated that serum sFasL levels were not markedly affected in FMF and cannot be used as a supportive marker to differentiate attacks from attack-free periods. However, further studies are needed to determine its usefulness as a marker in clinical practice.

Pseudogout-associated inflammatory calcium pyrophosphate dihydrate microcrystals induce formation of neutrophil extracellular traps.

Pang L(1), Hayes CP, Buac K, Yoo DG, Rada B.

Author information:

(1)Department of Infectious Diseases, College of Veterinary Medicine, University of Georgia, Athens, GA 30602, USA.

Pseudogout is an autoinflammatory condition triggered by calcium pyrophosphate

dehydrate (CPPD) crystal deposition in the joints. The innate immune system is irritated by and responds to the presence of the crystals with an inflammatory response. The synovial fluid contains activated inflammatory macrophages and neutrophil granulocytes. Several details of crystal-induced macrophage activation were recently uncovered, but very little is known about interactions of CPPD crystals with neutrophils. In this study, we show that human neutrophils engulf CPPD crystals and form large amounts of neutrophil extracellular traps (NETs) in vitro. Released extracellular DNA binds myeloperoxidase and citrullinated histone H4. CPPD crystal-stimulated neutrophils and their nuclear DNA undergo morphological changes characteristic for NET formation. The ERK/MEK signaling pathway, heat shock protein 90, PI3K, and an intact cytoskeleton are required for CPPD-induced NET formation. Blocking crystal-activated respiratory burst has, however, no effect on NETs. Human neutrophils release IL-1 $\beta$  and IL-8 in response to CPPD crystals, and blocking CXCR2, the main IL-8R, diminishes NET formation. Proinflammatory cytokines, TNF- $\alpha$ , GM-CSF, and IL-1 $\beta$ , increase NET release by the crystals. Enhanced bacterial killing by CPPD-induced NETs demonstrates their ability to cause cellular damage. Our work documents and provides details about extracellular trap release in human neutrophils activated by CPPD microcrystals. We suggest that crystal-triggered NET formation can be a novel contributor to inflammatory conditions observed in CPPD crystal-driven synovitis.

Comment in

Familial Mediterranean fever (FMF) is an inflammatory disorder that is leading cause of secondary amyloidosis (AA). This study was designed to investigate the level of mean platelet volume (MPV) in AA. Seventy-four FMF, 29 AA patients and 180 healthy controls, were included. There was no significant difference between the cases in terms of sex and age. MPV levels were measured in all groups. In the FMF group, MPV level was significantly higher when compared to the control group. MPV level was significantly lower in AA group in comparison with the FMF and healthy control groups. In summary, our present study showed low MPV values in AA due to FMF.

goknurkalkan@yahoo.com

Recurrent aphthous stomatitis (RAS) has a multifactorial etiopathogenesis, an interaction between predisposing factors and/or systemic conditions and immunological components in genetically predisposed subjects. The Mediterranean fever (MEFV) gene has already been identified as being responsible for familial Mediterranean fever. Because the association between MEFV gene mutations and Behçet's disease has been reported before in several studies, we considered that the role of MEFV gene mutations should be studied in patients with RAS, because of the clinical similarities of both diseases. The aim of this study was to explore the frequency and clinical significance of MEFV gene mutations in a cohort of Turkish patients with RAS. The study population comprised 100 unrelated patients with a clinical diagnosis of RAS and 156 healthy controls. Genomic DNA

was isolated and genotyped using polymerase chain reaction and restriction fragment length polymorphism for the four MEFV gene mutations (M694V, M680I, V726A and E148Q). There were statistically significant differences of the MEFV gene mutation carrier rates and allele frequencies between RAS patients and healthy controls ( $P = 0.042$ , odds ratio [OR] = 1.9, 95% confidence interval [CI] = 1.01-3.41; and  $P = 0.039$ , OR = 1.8, 95% CI = 1.02-3.14, respectively). Even if it is not statistically significant, the E148Q allele frequency was higher in patients with RAS than the control group. A statistically significant increased prevalence of MEFV variants in RAS patients was found. This is the first study to report that missense mutations of MEFV is associated with RAS in the Turkish population.

[Diffuse lipid infiltration and squamous metaplasia accompanying amyloid goiter: case report].

[Article in Turkish]

Eren R(1), Sayar H, Çiralik H, Ezberci F.

Author information:

(1)Department of Pathology, Kahramanmaraş Sütçü İmam University, Faculty of Medicine, Kahramanmaraş, Turkey.

Systemic amyloidosis is one of the serious complications of Familial Mediterranean Fever (FMF). Amyloid accumulation secondary to FMF can cause pressure symptoms in thyroid gland rarely. A 17-year-old male patient with the diagnosis of FMF performed the complaints of dyspnea during his follow-up period. He has demonstrated a rapidly increasing mass localized in front of his neck within the last three months that was diagnosed as a diffuse, hyperplastic and pressuring thyroid gland. Total thyroidectomy was performed. Histopathological investigation of the material obtained after thyroidectomy revealed diffuse

lipid infiltration in parenchyma, intense amyloid accumulation around and between the follicles that caused pressure on the follicles, and cystic areas in the tissue. Squamous metaplasia foci in cyst epithelium were detected. Upon these findings the case was diagnosed as amyloid goiter accompanied by metaplastic variations. In conclusion, it can be appropriate to take into account the possibility that metaplastic variations could accompany amyloid goiter in patients with long-term FMF.

Chronic recurrent multifocal osteomyelitis.

Roderick MR(1), Ramanan AV.

Author information:

(1)Bristol Royal Hospital for Children, Bristol, UK. rodericks1000@hotmail.com

Chronic recurrent multifocal osteomyelitis (CRMO) is an autoinflammatory bone disease occurring primarily in children and adolescents. Episodes of systemic inflammation occur due to immune dysregulation without autoantibodies, pathogens or antigen-specific T cells. CRMO is characterised by the insidious onset of pain with swelling and tenderness over the affected bones. Clavicular involvement was the classical description; however, the metaphyses and epiphyses of long bones are frequently affected. Lesions may occur in any bone, including vertebrae. Characteristic imaging includes bone oedema, lytic areas, periosteal reaction and soft tissue reaction. Biopsies from affected areas display polymorphonuclear leucocytes with osteoclasts and necrosis in the early stages. Subsequently, lymphocytes and plasma cells predominate followed by fibrosis and signs of reactive new bone forming around the inflammation. Diagnosis is facilitated by the use of STIR MRI scanning, potentially obviating the need for biopsy and unnecessary long-term antibiotics due to incorrect diagnosis. Treatment options include non-steroidal anti-inflammatory drugs and bisphosphonates. Biologics have been tried in resistant cases with promising initial results. Gene identification has not proved easy although research in this area continues. Early descriptions of the disease suggested a benign course; however, longer-term follow up shows

that it can cause significant morbidity and longer-term disability. Although it has always been thought of as very rare, the prevalence is likely to be vastly underestimated due to poor recognition of the disease.

Common presentations of pediatric rheumatologic diseases: a generalist's guide.

Reyhan I(1), Goldberg BR, Gottlieb BS.

Author information:

(1)The Steven and Alexandra Cohen Children's Medical Center of New York, The Hofstra North Shore-LIJ School of Medicine, Hempstead, New York, USA.

**PURPOSE OF REVIEW:** To present a case-based approach of three common scenarios which often present to the primary care physician. The approach to these cases and the differential diagnosis are discussed for these common rheumatologic diseases.

**RECENT FINDINGS:** Numerous healthy children and adolescents are referred to pediatric rheumatologists for the evaluation of suspected rheumatologic diseases. Often, general rheumatologic laboratory tests are sent which are not necessarily specific to the clinical situation. There is a high false-positive rate associated with many of these tests and undue anxiety and referrals result from these. Directed laboratory studies based on history and exam findings are more prudent and useful in the evaluation of these children. Routine antinuclear antibody testing, for example, is not recommended without supportive symptoms or signs.

**SUMMARY:** A practical approach for primary care physicians is described for the evaluation of patients suspected of having some of the more common pediatric rheumatologic symptoms and diseases.

Practical algorithm for diagnosing patients with recurrent wheals or angioedema.

Maurer M(1), Magerl M, Metz M, Siebenhaar F, Weller K, Krause K.

Author information:

(1)Department of Dermatology and Allergy, Allergie-Centrum-Charité, Charité - Universitätsmedizin Berlin, Berlin, Germany. marcus.maurer@charite.de

**BACKGROUND:** Chronic urticaria is a common disorder characterized by recurrent wheals, angioedema, or both. Several differential diagnoses need to be considered in patients presenting with wheals and/or angioedema. These include rare diseases such as autoinflammatory syndromes and urticarial vasculitis in patients with recurrent wheals and bradykinin-mediated angioedema in patients with recurrent swellings. **AIM AND RESULT:** In order to not miss these conditions, we have developed a symptom-based diagnostic algorithm for the management of patients with wheals and/or angioedema.

**DISCUSSION AND CONCLUSION:** By asking the right questions and performing a limited diagnostic workup as suggested here, this algorithm may help to establish the right diagnosis and treat patients early and more effectively.

Association between fibromyalgia syndrome and polymorphism of the IL-4 gene in a Turkish population.

Yigit S(1), Inanir A, Tekcan A, Inanir S, Tural S, Ates O.

Author information:

(1)Gaziosmanpasa University, Faculty of Medicine, Department of Medical Biology, Tokat, Turkey. yigit.serbulent@gmail.com

**PURPOSE:** Fibromyalgia (FM) syndrome is a form of non-articular rheumatism characterized by long term and widespread musculoskeletal pain, morning stiffness, sleep disturbance, paresthesia, and pressure hyperalgesia at characteristic sites, called soft tissue tender points. The etiology of FM is still obscure. Genetic factors may predispose individuals to FM. Cytokines may play a role in the pathophysiology of FM. The aim of this study was to investigate the interleukin-4 (IL-4) 70 bp VNTR variations in Turkish patients with FM and evaluate if there was an association with clinical features, especially between these polymorphisms.

**METHODS:** The study included 300 patients with FM and 270 healthy controls. Genomic DNA was isolated and genotyped using polymerase chain reaction (PCR) for the IL-4 gene 70 bp VNTR polymorphisms.

**RESULTS:** There was statistically significant difference between the groups with respect to IL-4 genotype distribution and allele frequencies ( $p < 0.0001$ ). The homozygous P1P1 genotype and P1 allele were significantly higher in FM patients than in healthy controls ( $p = 0.04$ ; OR: 3.25, 95% CI: 1-10,  $p < 0.0001$ ; OR: 4.84, 95% CI: 3-7.7). There was not any difference between the groups respect to IL-4 genotype distribution and allele frequencies ( $p > 0.05$ ) and clinical characteristics.

**CONCLUSION:** Our findings suggest that there is an association of IL-4 gene 70 bp VNTR polymorphism with susceptibility of a person for development of FM. As a result, further studies are necessary to determine whether IL-4 may be a genetic marker for FM in the Turkish population.

Autologous fat grafting for treatment of facial atrophy in Behcet's disease: a case report.

Lee ZH(1), Khoobehi K, Chiu ES.

Author information:

(1)NYU Langone Medical Center, Institute of Reconstructive Plastic Surgery, USA.

Behcet's disease (BD) is an autoimmune & autoinflammatory disease of unclear etiology characterized by recurrent oral & genital ulcers as well as other systemic manifestations. A key pathogenesis is excessive inflammatory wound healing response. While descriptions of the cutaneous manifestations of disease are limited to short-term consequences such as extensive pustule and papule formation in response to minor tissue injury, the long-term consequences are significant fibrosis and scarring of epithelial tissue. We describe the case of a patient with Behcet's disease who presented with unilateral facial atrophy secondary to minor trauma to the oral mucosa. She was treated with autologous fat grafting. Though a rare disease, plastic surgeons should be aware of the entity of Behcet's disease and its complications of tissue atrophy that may require reconstructive surgery.

Assesment life quality of familial Mediterranean fever patients by short form-36 and its relationship with disease parameters.

Sahin S(1), Yalcin I, Senel S, Ataseven H, Uslu A, Yildirim O, Semiz M.

Author information:

(1)Department of Internal Medicine, Faculty of Medicine, Gazi Osmanpasa University, Tokat, Turkey. drsafaksahin@gmail.com

**BACKGROUND:** Familial Mediterranean fever is an auto-inflammatory disorder. Long term complications of the disease include decreased quality of life. The measurement of quality of life in the patients with chronic disease has become an important research topic during the last years.

**AIM:** We aimed to evaluate life quality of the FMF patients by SF-36, and examine its relationship with the disease parameters.

**PATIENTS AND METHODS:** One hundred voluntary patients (69 female, 31 male) admitted to the rheumatology clinic were included in the study. The control group consisted of 100 healthy individuals. All subjects in the study were asked to complete SF-36 questionnaire. Age of onset of FMF, age at diagnosis, age at the beginning of colchicine therapy, number of attacks per month, family history of FMF and dialysis were inquired of patients with FMF. Disease severity was determined using the FMF severity score.

**RESULTS:** The mean age of the patient group was  $31 \pm 12$  and that of the control group was  $29 \pm 9$ . Sixty-nine patients (69%) were female, and 31 patients were male (31%) in both groups. The mean scores of the physical function, physical role function, emotional role function, mental health, and general health parameters of the patients were statistically significantly lower than those of healthy volunteers ( $p < 0.05$ ). The difference in social function and vitality between two groups was found to be insignificant ( $p > 0.05$ ).

**CONCLUSIONS:** We have shown that FMF had a negative impact on SF-36. FMF reduces quality of life both in physical and mental dimensions.

2391. Gene. 2013 Jul 25;524(2):412-4. doi: 10.1016/j.gene.2013.04.039. Epub 2013 Apr 29.

Innate immunity functional gene polymorphisms and gout susceptibility.

Qing YF, Zhang QB, Zhou JG.

Gout is a common autoinflammatory disease characterized with elevated serum urate and recurrent attacks of intra-articular crystal deposition of monosodium urate.

Accumulating evidence has demonstrated that MSU crystal-induced inflammation is a paradigm of innate immunity and the TLRs, NALP3 inflammasome and IL1R pathways are involved in gout development. Innate immunity components containing TLR2, TLR4, CD14, NALP3, ASC, Caspase-1 and CARD-8 are essential in the development of gouty inflammation. Recent studies suggest that innate immunity component gene functional mutations contribute to the development of autoinflammatory diseases including hereditary periodic fever syndrome, arthritis as well as inflammatory bowel disease. Taking into account these genetic findings, we would like to propose a novel hypothesis that the gene functional mutations might make innate

immunity components as attractive susceptibility candidates and genetic markers for gout. Further clinical genetic studies need to be performed to confirm the role of innate immunity in the etiology of gout.

From genetics of inflammatory bowel disease towards mechanistic insights.

Graham DB(1), Xavier RJ.

Author information:

(1)Broad Institute of MIT and Harvard, Cambridge, MA, USA.

dgraham@broadinstitute.org

Advancements in human genetics now poise the field to illuminate the pathophysiology of complex genetic disease. In particular, genome-wide association studies (GWAS) have generated insights into the mechanisms driving inflammatory bowel disease (IBD) and implicated genes shared by multiple autoimmune and autoinflammatory diseases. Thus, emerging evidence suggests a central role for the mucosal immune system in mediating immune homeostasis and highlights the complexity of genetic and environmental interactions that collectively modulate the risk of disease. Nevertheless, the challenge remains to determine how genetic variation can precipitate and sustain the inappropriate inflammatory response to commensals that is observed in IBD. Here, we highlight recent advancements in immunogenetics and provide a forward-looking view of the innovations that will deliver mechanistic insights from human genetics.

[Familial Mediterranean fever: not to be missed].

[Article in Dutch]

Frenkel J(1), Bemelman FJ, Potter van Loon BJ, Simon A.

Author information:

(1)Universitair Medisch Centrum Utrecht, afd. Algemene Pediatrie, Utrecht, the Netherlands. j.frenkel@umcutrecht.nl

Familial Mediterranean fever (FMF) is common among Turkish and Moroccan migrants. We describe three patients with FMF. A 3-year-old girl with recurrent fever and abdominal pain who was diagnosed early with FMF and treated effectively with colchicine. An adolescent girl who required interleukin (IL)-1 blockade to achieve disease remission. And a 37-year-old woman in whom the attacks of FMF had not been recognised, but who developed end-stage kidney failure due to AA amyloidosis. Mutations in the MEFV gene underlie the disease in most but not all patients. Therefore, FMF remains a clinical diagnosis. FMF patients suffer recurrent bouts of inflammation, often with fever, serositis or arthritis. The major complication is AA amyloidosis. The inflammatory process is mediated by IL-1 $\beta$ . When started early, colchicine prophylaxis can prevent amyloidosis. When colchicine fails, IL-1 blockade has shown promising results. Timely diagnosis and treatment can make the difference between near normal health and end-stage kidney failure.

Author information:

(1)Inflammatory Disease Section, Medical Genetics Branch, National Human Genome Research Institute, National Institutes of Health, Bethesda, MD 20892-1849, USA.

Genome-wide association studies (GWAS) are a powerful means of identifying genes with disease-associated common variants, but they are not well-suited to detecting genes with disease-associated rare and low-frequency variants. In the current study of Behçet disease (BD), nonsynonymous variants (NSVs) identified by deep exonic resequencing of 10 genes found by GWAS (IL10, IL23R, CCR1, STAT4, KLRK1, KLRC1, KLRC2, KLRC3, KLRC4, and ERAP1) and 11 genes selected for their role in innate immunity (IL1B, IL1R1, IL1RN, NLRP3, MEFV, TNFRSF1A, PSTPIP1, CASP1, PYCARD, NOD2, and TLR4) were evaluated for BD association. A differential distribution of the rare and low-frequency NSVs of a gene in 2,461 BD cases compared with 2,458 controls indicated their collective association with disease. By stringent criteria requiring at least a single burden test with study-wide significance and a corroborating test with at least nominal significance, rare and low-frequency NSVs in one GWAS-identified gene, IL23R ( $P = 6.9 \times 10^{-5}$ ), and one gene involved in innate immunity, TLR4 ( $P = 8.0 \times 10^{-4}$ ), were associated with BD. In addition, damaging or rare damaging NOD2 variants were nominally significant across all three burden tests applied ( $P = 0.0063$ - $0.045$ ). Furthermore, carriage of the familial Mediterranean fever gene (MEFV) mutation Met694Val, which is known to cause recessively inherited familial Mediterranean fever, conferred BD risk in the Turkish population (OR, 2.65;  $P = 1.8 \times 10^{-12}$ ). The disease-associated NSVs in MEFV and TLR4 implicate innate immune and bacterial sensing mechanisms in BD pathogenesis.

In cancer patients, active immunotherapy has gained significant importance in recent years by implementation of novel substances into standard clinical care.

These new drugs represent strategies which either use defined cancer associated antigens as vaccines or induce tumor-directed immune responses through generation of a general inflammatory state which has extensive autoinflammatory side effects by induction of autoreactive immune cells. Hence, the definition of suitable target antigens for immunotherapy remains a major challenge. These antigens should ideally be specific markers for individual tumors or should be at least structures overexpressed on the tumor as compared to normal cells. Recent approaches have defined algorithms and refined analytical methods for antigen identification and immunological validation that have already been evaluated in clinical studies. This article summarizes recent developments in tissue analysis on genome, transcriptome and HLA-ligandome levels and of antigen application in recent clinical vaccination trials.

Author information:

(1)The Triangle Regional Research and Development Center, P. O. Box-2167, Kfar Qari'-30075, Israel. rajachsharkia@hotmail.com

Familial Mediterranean Fever (FMF) is an autosomal recessive disease that is widely spread in the populations of the Mediterranean region. It is characterized by recurrent fever and inflammatory attacks. A total of 1700 suspected patients, belonging to various communities in Israel: Jews (Ashkenazi and non-Ashkenazi), Arabs (Muslims and Christians) and Druze, was subjected to examination for FMF mutation screening. The patients were screened for the most common six MEFV gene mutations namely, M680I, M694V, M694I, V726A, E148Q and K695R. Fifty-five percent of the cases were confirmed to have MEFV mutations. The most common mutations

among all the cases studied were M694V, E148Q and V726A. The common mutations in the respective communities were: among the Jews M694V with a frequency of 69.9% (76.8% for non-Ashkenazi Jews and 43.6% for Ashkenazi Jews), among the Arabs V726A with a frequency of 32.7% (32.7% for Muslims and 32.1% for Christians) and among Druze it was E148Q with a frequency of 52.1%. The characteristic mutation present in Jews was K695R and the one in Arabs was M680I, while no characteristic mutation was found in Druze. On the other hand, mutation E148Q was observed to have a considerable occurrence in patients of all ethnic groups studied.

Furthermore, our results revealed that homozygous mutations accounted for 168 cases (18%). The homozygote mutation M694V was the most prevalent among Jews and the E148Q mutation was the most common among Druze, while, among Arabs there were three homozygous mutations having maximum prevalence, namely, V726A, M694V and M694I. Our study comprehensively provided a spectrum of FMF mutations in various communities of Israeli society.

Mean platelet volume as a potential predictor of proteinuria and amyloidosis in familial Mediterranean fever.

Sakallı H(1), Kal O.

Author information:

(1)Department of Pediatric Nephrology, Baskent University Faculty of Medicine, Konya, Turkey. hales1972@yahoo.com

Comment in

Clin Rheumatol. 2013 Aug;32(8):1245-6.

This study aims to compare the mean platelet volume (MPV) levels in children and adults diagnosed with familial Mediterranean fever (FMF) during attack-free periods in order to find out whether it reflects the emergence of

microalbuminuria/proteinuria and the development of amyloidosis or not. The study consisted of 63 pediatric patients (group 1), 50 adult patients (group 2), 50 healthy children (group 3), and 43 healthy adults (group 4). Demographic data, age at diagnosis, duration of the disease and colchicine treatment, and FMF gene mutations were recorded, and erythrocyte sedimentation rate, C-reactive protein, fibrinogen, hemoglobin, white blood cell count, platelet count, MPV, blood urea nitrogen, creatine, albumin, and urine microalbumin and protein levels were evaluated. According to the presence of microalbuminuria/proteinuria, patient groups were subgrouped into two by themselves as pediatric and adult groups with and without proteinuria. The most frequent mutation was M694V. MPV was significantly higher in FMF patients than those in the healthy control groups. Microalbuminuria/proteinuria were detected in 18 (28.57 %) of 63 pediatric patients and 26 (52 %) of 50 adult patients. Amyloidosis has been identified in 3 (16.6 %) of 18 pediatric patients and 18 (69.23 %) of 26 adult patients with proteinuria. Subgroup comparisons revealed that MPV levels were significantly higher in patients with proteinuria than patients without proteinuria in both pediatric and adult groups. Moreover, MPV levels were also significantly higher in adult patients with or without proteinuria than in pediatric patients with or without proteinuria. There were significant differences in terms of serum albumin levels between the groups with and without proteinuria as expected. The increase in MPV over the years of the disease, especially in groups with proteinuria, may be an important predictor of continuing increase of subclinical inflammation, the emergence of the microalbuminuria/proteinuria, and the developing of amyloidosis, but further studies are needed in order to support this proposal.

E148Q MEFV mutation carriage and longevity in individuals of Ashkenazi origin.

Lidar M(1), Shinar Y, Goldberg M, Ben-Zvi I, Langevitz P, Livneh A.

Author information:

(1)Medicine F and Heller Institute of Medical Research, Sheba Medical Center, Tel-Hashomer, Israel. merav.lidar@gmail.com

The high carriage rate of MEFV mutations in at risk populations suggests that they confer a selective advantage, possibly by way of protection from infections. Here, we sought to assess whether this putative protection contributes to longevity, by studying MEFV mutation status in nonagenarians and the association of mutation carriage with life-threatening conditions. DNA samples and a medical history questionnaire were obtained from 200 nonagenarians (>90 years of age), who received medical treatment at a large tertiary hospital in Israel. The prevalence of MEFV mutations in the study group was compared to the known prevalence, by ethnic group, in the Israeli population. The presence of associated diseases in mutation carriers versus noncarriers was compared. The majority of study subjects were females (67.5 %) of Ashkenazi origin (78%). A fifth carried an MEFV mutation, most commonly E148Q (73% of total mutations), followed by V726A (5%). Only the frequency of E148Q in Ashkenazi subjects was found to be higher than expected in the general Ashkenazi population (19.8 vs. 2.6%,  $p < 0.0001$ ). Cardiac arrhythmias and hypothyroidism were more common in mutation carriers, while no difference was noted, between carriers and noncarriers, in the rates of ischemic heart disease, diabetes, stroke and a wide range of other serious conditions. Our findings suggest that E148Q carriage contributes to longevity in the Ashkenazi population, perhaps by enhancing resistance to infections.

Gastrointestinal mucosal involvement without amyloidosis in children with familial Mediterranean fever.

Gurkan OE(1), Dalgic B.

Author information:

(1)Department of Pediatric Gastroenterology, Gazi University School of Medicine, Ankara, Turkey. odulmd2003@yahoo.com

BACKGROUND AND OBJECTIVES: Familial Mediterranean fever (FMF) and inflammatory bowel disease togetherness is well described in the literature. Abdominal pain

and various gastrointestinal manifestations may arise directly from FMF or secondary to FMF-associated diseases such as inflammatory bowel disease, vasculitides, or amyloidosis. The aim of the study was to document gastrointestinal involvement in familial Mediterranean fever.

**METHODS:** The medical files of the patients who were diagnosed as having FMF at the Department of Pediatric Gastroenterology, Gazi University School of Medicine between 2007 and 2012 were examined retrospectively. FMF diagnosis was made through performing clinical, laboratory, colonoscopy, endoscopy, and genetic analysis.

**RESULTS:** Thirty-six patients were diagnosed as having FMF during this period. Among them, 11 patients were admitted with vomiting or diarrhea. Colonoscopy and upper gastrointestinal endoscopy were performed. Colonic inflammation and multiple gastric aphthous ulcerations were observed.

**CONCLUSIONS:** In this report, we described 11 patients who presented with gastrointestinal symptoms and eventually diagnosed as having FMF. Gastrointestinal mucosal involvement without amyloidosis is documented by endoscopic and histopathologic investigations in these patients. We concluded that mucosal involvement of the gastrointestinal tract may be attack-related manifestations in these patients.

Clinical profile of generalized vitiligo patients with associated autoimmune/autoinflammatory diseases.

van Geel N(1), Speeckaert M, Brochez L, Lambert J, Speeckaert R.

Author information:

(1)Department of Dermatology, Ghent University Hospital, Ghent, Belgium.

**BACKGROUND:** The significance of associated autoimmune/autoinflammatory diseases in generalized vitiligo patients with respect to their clinical profile has not yet been completely established.

**OBJECTIVE:** The objective of this study was to evaluate the clinical significance

of associated autoimmune/autoinflammatory diseases in generalized vitiligo patients with respect to some general clinical variables, distribution pattern, disease activity and treatment response.

**METHODS:** Seven hundred generalized vitiligo patients were included in this retrospective observational cohort study.

**RESULTS:** Associated autoimmune/autoinflammatory diseases were present in 15.4% of the patient population and were more common in women compared with men, especially concerning thyroid disease. Only vitiligo patients with thyroid disease had clear different clinical characteristics. The percentage of total body surface area involvement was significantly ( $P = 0.005$ ) higher in the presence of thyroid disease which was more pronounced in women compared with men. Patients with thyroid disease had a particular predisposition to acral and joint depigmentations. No clear differences in disease activity or response to therapy were observed in vitiligo patients with or without autoimmune/autoinflammatory disorders.

**CONCLUSION:** The presence of associated autoimmune/autoinflammatory diseases seems to influence the clinical profile of generalized vitiligo patients. Our results support the hypothesis that in the presence of a thyroid disorder, the disease activity of vitiligo is more extensive, in particular on areas prone to friction.

MEFV gene mutations in Turkish children with juvenile idiopathic arthritis.

Comak E(1), Dogan CS, Akman S, Koyun M, Gokceoglu AU, Keser I.

Author information:

(1)Pediatric Nephrology and Rheumatology, Akdeniz University, School of Medicine, 07070, Antalya, Turkey. elif\_comak@hotmail.com

Mutations of the Mediterranean fever (MEFV) gene, which encodes pyrin protein,

leads to familial Mediterranean fever (FMF) and a connection between MEFV mutations and rheumatic diseases has been suggested. The aim of this study was to explore the frequency and clinical significance of MEFV mutations in children with juvenile idiopathic arthritis (JIA). In this study, children with JIA, who had no typical symptoms of FMF, were screened for the mutations in exons 2 and 10 of the MEFV gene by direct sequencing. A total of 96 children, 56 girls (58.3%), with a median age of 11 years (2-18 years) were included. Patients were classified according to JIA subgroups as oligoarthritis in 43 (44.8%), rheumatoid factor-negative polyarthritis in 22 (22.9%), rheumatoid factor-positive polyarthritis in 2 (2.1%), systemic arthritis in 12 (12.5%) patients, enthesitis-related arthritis in 16 (16.7%), and psoriatic arthritis 1 (1.04%). A total of 31 children (32.3%) had MEFV mutations: 25 heterozygous, 2 homozygous, and 4 compound heterozygous. There were 22 (11.4%) exon 10 mutations (M694V, R761H, K695R, V726A, R653H) and 15 (7.8%) exon 2 mutations (E148Q, G304R, E148V, T267I). The allele frequencies of MEFV mutations were found to be 19.27%, which is higher than the general population [ $p = 0.03$ , (odds ratio (OR):1.93, 95% confidence interval (CI): 1.09-3.41)]. MEFV mutation carrier rates were significantly higher in antinuclear antibody (ANA) negative than in ANA positive patients [ $p = 0.01$ , (OR: 0.25, 95% CI: 0.085-0.74)] and in males than in females [ $p = 0.001$ , (OR: 0.197, 95% CI: 0.078-0.495)]. Also, there was a statistically significant difference between the MEFV mutation carrier rates and the subgroups of JIA ( $p = 0.005$ ). CONCLUSION: These findings suggest that mutations of the MEFV gene may be responsible for rheumatic diseases other than FMF, and patients with JIA especially males, ANA negatives, and ERA subgroups should be screened for MEFV gene mutations in countries where FMF is frequent.

Neutrophilic dermatoses and inflammatory bowel diseases.

Marzano AV(1), Menicanti C, Crosti C, Trevisan V.

Author information:

(1)Department of Pathophysiology and Transplantation, University of Milan, Fondazione IRCCS Ca' Granda, Ospedale Maggiore Policlinico, Italy.

Pyoderma gangrenosum (PG) and Sweet's Syndrome (SS) are inflammatory skin diseases caused by the accumulation of neutrophils in the skin and, rarely, in internal organs, which led to coining the term of neutrophilic dermatoses (ND) to define these conditions. Recently, ND have been included among the autoinflammatory diseases, which are forms due to mutations of genes regulating the innate immune responses. Both PG and SS are frequently associated with inflammatory bowel diseases (IBD), a group of chronic intestinal disorders which comprises ulcerative colitis and Crohn's disease and whose pathogenesis involves both the innate and adaptive immunity in genetically prone individuals. Patients with IBD develop PG in 1-3% of cases, while SS is rarer. PG presents with deep erythematous-to-violaceous painful ulcers with undermined borders, but bullous, pustular, and vegetative variants can also occur. SS, also known as acute febrile neutrophilic dermatosis, is characterized by the abrupt onset of fever, peripheral neutrophilia, tender erythematous skin lesions and a diffuse neutrophilic dermal infiltrate. In this review that will be focused on PG and SS, we will describe also the aseptic abscesses syndrome, a new entity within the spectrum of ND which frequently occurs in association with IBD and is characterized by deep abscesses mainly involving the spleen and skin and by polymorphic cutaneous manifestations including PG- and SS-like lesions.

We describe a form of the autoimmune/autoinflammatory syndrome induced by adjuvants (ASIA syndrome) in commercial sheep, linked to the repetitive inoculation of aluminum-containing adjuvants through vaccination. The syndrome shows an acute phase that affects less than 0.5% of animals in a given herd, it appears 2-6 days after an adjuvant-containing inoculation and it is characterized by an acute neurological episode with low response to external stimuli and acute meningoencephalitis, most animals apparently recovering afterward. The chronic phase is seen in a higher proportion of flocks, it can follow the acute phase, and it is triggered by external stimuli, mostly low temperatures. The chronic phase begins with an excitatory phase, followed by weakness, extreme cachexia, tetraplegia and death. Gross lesions are related to a cachectic process with muscular atrophy, and microscopic lesions are mostly linked to a

neurodegenerative process in both dorsal and ventral column of the gray matter of the spinal cord. Experimental reproduction of ovine ASIA in a small group of repeatedly vaccinated animals was successful. Detection of Al(III) in tissues indicated the presence of aluminum in the nervous tissue of experimental animals. The present report is the first description of a new sheep syndrome (ovine ASIA syndrome) linked to multiple, repetitive vaccination and that can have devastating consequences as it happened after the compulsory vaccination against bluetongue in 2008. The ovine ASIA syndrome can be used as a model of other similar diseases affecting both human and animals. A major research effort is needed in order to understand its complex pathogenesis.

Platelets in rheumatic diseases: friend or foe?

Gasparian AY, Ayvazyan L, Pretorius E, Kitas GD(1).

Author information:

Platelets are intimately involved in hemostasis, inflammation, innate and

adaptive immunity, tissue regeneration and other physiological and pathological processes. Their granular structure is programmed to release a wide range of bioactive substances in response to agonists. Upon activation, platelet membranes display thrombotic and inflammatory agents, which may take an active part in the pathophysiology of autoimmune and autoinflammatory disorders. The aim of this review is to analyze current evidence of platelet (dys)function in inflammatory rheumatic diseases and overview platelet-targeting mechanisms of antirheumatic drug therapies. A comprehensive search through Medline/PubMed, SciVerse/Scopus and Web of Science was performed for English-language original research papers, using the keywords related to platelets in autoimmune and autoinflammatory rheumatic disorders. Additionally, the Cochrane Collaboration database was searched for the literature on the effects of antirheumatic drugs on platelet function. A variety of platelet markers have been tested in systemic lupus erythematosus, rheumatoid arthritis, systemic sclerosis, spondyloarthropathies, vasculitides, and some autoinflammatory disorders. It has been shown that platelets circulate in an activated state in most of these disorders and tend to form complexes with other inflammatory and immune cells. Thrombotic and inflammatory agents, released from platelets, may trigger disease-specific complications (e.g., extraarticular features, fibrosis in systemic sclerosis) and propagate endothelial dysfunction. Whether platelet activation is a primary or secondary feature in rheumatic disorders remains to be elucidated. Some widely used antirheumatic drugs may suppress thrombopoiesis and platelet activity, however the clinical implications of this effect have yet to be examined in specifically designed prospective studies. Large retrospective cohort studies supported the use of low-dose aspirin for suppressing platelet function and preventing cerebrovascular events in giant-cell arteritis. However, emerging data suggest that the release rate of activated platelets applied topically to the inflamed cartilage in arthritis or skin ulcers in scleroderma may suppress the inflammation and facilitate tissue repair. Taken together, current evidence necessitates a balanced approach to platelet-activating and suppressing drug therapies in inflammatory rheumatic diseases.

Leukopenia in familial Mediterranean fever: case series and literature review with special emphasis on pathogenesis.

Aslan D(1).

Author information:

(1)Section of Hematology, Department of Pediatrics, Faculty of Medicine, Gazi University, Ankara, Turkey.

Comment in

Pediatr Hematol Oncol. 2014 Mar;31(2):129-30.

Leukopenia is a blood disease in which the number of circulating white blood cells diminishes. All underlying causes of leukopenia are not yet known. The subjects of this study are 15 leukopenic patients who were assessed by a systemic workup, including physical examination, blood tests, and molecular analysis. A common and unusual cause was revealed in all patients. This cause was a disorder with a laboratory characteristic of leukocytosis, namely familial Mediterranean fever (FMF). It was discussed that leukopenia arising in the context of FMF is mainly due to autophagy and apoptosis processes. These two pathophysiological characteristics of FMF were thought to explain the particular (episodic and self-limited) leukopenia in this disorder. Based on the results of this study in conjunction with the currently existing literature data, we suggest that FMF causes leukopenia. Leukopenic cases should be investigated for FMF, particularly if the leukopenia is episodic in nature. Early recognition of FMF would help to skip unnecessary invasive procedures and to prevent the development of amyloidosis, the devastating complication of FMF.

Author information:

(1)Ege University, School of Dentistry, Department of Oral Maxillofacial Radiology, Izmir, Turkey. esogur@yahoo.com.

**OBJECTIVES:** The aim of this study was to investigate oral and general health-related quality of life (QoL) in patients with familial Mediterranean fever (FMF) disease.

**METHODS:** In this cross-sectional study, 45 patients with FMF, 50 age- and sex-matched healthy controls (HC), and 50 patients with Behçet's disease (BD) as the disease control group were included. FMF disease activity was evaluated by using the FMF-severity score, as well as with erythrocyte sedimentation rate (ESR), and serum C-reactive protein and fibrinogen levels. Oral health-related QoL and general QoL were evaluated using oral health impact profile-14 (OHIP-14) and Medical Outcomes Short-Form Health Survey Questionnaire 36 (SF-36), respectively.

**RESULTS:** Only the numbers of extracted teeth ( $4.13 \pm 4.72$  vs.  $1.55 \pm 3.6$ ) and filled teeth ( $2.33 \pm 3.19$  vs.  $0.66 \pm 1.46$ ) were significantly higher in FMF group compared to HC group ( $p=0.005$  and  $p=0.013$ , respectively). OHIP-14 score was significantly higher in FMF and BD groups compared to HC group. In FMF patients, OHIP-14 score was positively correlated with the number of extracted teeth ( $r=0.38$ ,  $p=0.010$ ), while the number of carious teeth was positively correlated with ESR ( $r=0.43$ ,  $p=0.003$ ). When FMF patients were sub-classified according to disease severity, no significant difference was observed with respect to oral health status.

**CONCLUSIONS:** In patients with FMF, some of the parameters of oral health status were found to be worse compared to HC group. Tooth loss appears to be a critical factor contributing to impaired oral QoL. In general, oral health status in FMF patients is better than in BD patients.

Congenital sideroblastic anemias (CSAs) are a heterogeneous group of inherited disorders identified by pathological erythroid precursors with perinuclear mitochondrial iron deposition in bone marrow. An international collaborative group of physicians and laboratory scientists collated clinical information on cases of CSA lacking known causative mutations, identifying a clinical subgroup of CSA associated with B immunodeficiency, periodic fevers, and development delay. Twelve cases from 10 families were identified. Median age at presentation was 2 months. Anemia at diagnosis was sideroblastic, typically severe (median hemoglobin, 7.1 g/dL) and markedly microcytic (median mean corpuscular volume, 62.0 fL). Clinical course involved recurrent febrile illness and gastrointestinal disturbance, lacking an infective cause. Investigation revealed B-cell lymphopenia (CD19<sup>+</sup> range, 0.016-0.22 × 10<sup>9</sup>/L) and panhypogammaglobulinemia in most cases. Children displayed developmental delay alongside variable neurodegeneration, seizures, cerebellar abnormalities, sensorineural deafness, and other multisystem features. Most required regular blood transfusion, iron chelation, and intravenous immunoglobulin replacement. Median survival was 48 months, with 7 deaths caused by cardiac or multiorgan failure. One child underwent bone marrow transplantation aged 9 months, with apparent cure of the

hematologic and immunologic manifestations. We describe and define a novel CSA and B-cell immunodeficiency syndrome with additional features resembling a mitochondrial cytopathy. The molecular etiology is under investigation.

Role of interleukin-1 inhibitors in the management of gout.

Tran TH(1), Pham JT, Shafeeq H, Manigault KR, Arya V.

Author information:

(1)New York Presbyterian Hospital/Columbia Medical Center, College of Pharmacy and Health Sciences, St. John's University, Queens, New York 11439, USA.

Trant1@stjohns.edu

Erratum in

Pharmacotherapy. 2014 Feb;34(2):212.

Interleukin-1 (IL-1) inhibitors potentially have a role as antiinflammatory agents in refractory gout or for patients who are unable to tolerate conventional therapy, such as nonsteroidal antiinflammatory drugs (NSAIDs), colchicine, or glucocorticoids, for acute attacks. Additionally, IL-1 inhibitors may also help patients with polyarticular and tophaceous gout by making them less vulnerable to breakthrough attacks during initiation of chronic urate-lowering treatment, the mainstay of gout therapy. Because evidence highlights the role of proinflammatory cytokine IL-1 in the inflammation process during an acute gouty attack, IL-1 inhibitors are used to modulate the pathogenesis of a variety of autoinflammatory diseases, providing support for its potential role in the inflammatory process of gout. After NSAIDs, colchicine, and steroids, IL-1 inhibitors are beneficial as fourth-line therapy for acute gout attacks due to their high cost and limited clinical experience. The IL-1 inhibitors used in gout are anakinra, canakinumab, and rilonacept. Based on published evidence, anakinra has limited support in the form of anecdotal case reports to justify its use for treating gout.

Canakinumab's toxic profile in clinical trials precludes its use in treating

patients for gout, and rilonacept shows promise with a few well-designed studies to support its use in gout patients initiating urate-lowering treatment. When combined with current traditional therapies, these newer agents present clinicians and patients with more potential treatment options in the difficult-to-treat gout population.

Genetic fever syndromes or hereditary recurrent fever syndromes (HRF) are considered to be part of the autoinflammatory diseases (AID) which result from errors in the innate immune system. Patients typically have self-limiting episodes of fever and high levels of inflammation markers. The mode of inheritance is autosomal recessive or autosomal dominant. The diseases of the HRF include familial Mediterranean fever, tumor necrosis factor receptor 1-associated periodic syndrome, hyper-IgD syndrome and cryopyrin-associated periodic fever syndromes. The disease known as deficiency of interleukin 1 (IL1) receptor antagonist does not fully belong to this group because fever is not a typical symptom. The therapy depends on the type and severity of the disease. Effective prophylaxis is possible for FMF. Biologicals, especially IL1 blocking agents are highly effective in very severe fever syndromes. In order to collect more information on AID, to establish a biobank and coordinate research in this field the AID-Net project was founded. Currently 606 patients with AID are registered

of whom 381 have HRF.

Renal involvement in AA amyloidosis: clinical outcomes and survival.

Yilmaz M(1), Unsal A, Sokmen M, Kaptanogullari OH, Alkim C, Kabukcuoglu F, Ozagari A, Bor E.

Author information:

(1)Nephrology Department, Bakirkoy Dr. Sadi Konuk Training and Research Hospital, Istanbul, Turkey. murvetyilmaz@hotmail.com

**BACKGROUND:** The natural history of AA amyloidosis is typically progressive, leading to multiple organ failure and death. We analyzed the etiology as well as clinical and laboratory features of patients with biopsy-proven AA amyloidosis and evaluated the ultimate outcome.

**METHODS:** Seventy-three patients (24 female; mean age  $41.85 \pm 15.89$  years) were analyzed retrospectively. Demographic, clinical and laboratory features were studied and the outcome was assessed.

**RESULTS:** Familial Mediterranean Fever and tuberculosis were the most frequent causes of amyloidosis. Mean serum creatinine and proteinuria at diagnosis were  $4.65 \pm 4.89$  mg/dl and  $8.04 \pm 6.09$  g/day, respectively; and stage I, II, III, IV and V renal disease were present in 19.2%, 13.7%, 16.4%, 11%, and 39.7% of the patients, respectively. ESRD developed in 16 patients during the follow-up period. All of the ESRD patients started a dialysis programme. Thirty patients (41%) died during the follow-up period; median patient survival was  $35.9 \pm 6.12$  months. Old age, tuberculosis etiology, advanced renal disease and low serum albumin levels were associated with a worse prognosis. Serum albumin was a predictor of mortality in logistic regression analysis.

**CONCLUSION:** The ultimate outcome of the patients with AA amyloidosis is poor, possibly due to the late referral to the nephrology clinics. Early referral may be helpful to improve prognosis.

Autoinflammatory gene polymorphisms and susceptibility to UK juvenile idiopathic arthritis.

Hinks A(1), Martin P, Thompson SD, Sudman M, Stock CJ, Thomson W, Day TG, Packham J; Childhood arthritis prospective study (CAPS); BSPAR study group, Ramanan AV, Donn RP.

Author information:

(1)Arthritis Research UK Epidemiology Unit, Stopford Building, The University of Manchester, Manchester Academic Health Science Centre, School of Translational Medicine, Oxford Road, Manchester M13 9PT, UK. [Rachelle.donn@manchester.ac.uk](mailto:Rachelle.donn@manchester.ac.uk).

**BACKGROUND:** To investigate the autoinflammatory hereditary periodic fever syndrome genes MVK and TNFRSF1A, and the NLRP1 and IL1 genes, for association with juvenile idiopathic arthritis (JIA).

**METHODS:** For MVK, TNFRSF1A and NLRP1 pair-wise tagging SNPs across each gene were selected and for IL1A SNPs from a prior meta-analysis were included. 1054 UK Caucasian JIA patients were genotyped by Sequenom iPLEX MassARRAY and allele and genotype frequencies compared with 5380 unrelated healthy UK Caucasian controls.

**RESULTS:** Four SNPs were significantly associated with UK JIA: rs2071374 within intron 4 of IL1A (ptrend=0.006), rs2228576 3' of TNFRSF1A (ptrend=0.009) and 2 SNPs, rs11836136 and rs7957619, within MVK (ptrend=0.006, ptrend=0.005 respectively). In all cases the association appeared to be driven by the systemic-onset JIA (SoJIA) subtype. Genotype data for the two MVK SNPs was available in a validation cohort of 814 JIA (oligoarticular and RF negative polyarticular) cases and 3058 controls from the US. Replication was not confirmed, however, further suggesting that this association is specific to SoJIA.

**CONCLUSIONS:** These findings extend the observations of the relevance of studying monogenic loci as candidates for complex diseases. We provide novel evidence of association of MVK and TNFRSF1A with UK JIA, specifically driven by association

with SoJIA and further confirm that the IL1A SNP association with SoJIA is subtype specific. Replication is required in independent cohorts.

Autoimmune/autoinflammatory syndrome induced by adjuvants (ASIA) has been recently proposed by Shoenfeld and Agmon-Levin as a new entity that comprises several conditions: the macrophagic-myofasciitis syndrome, the Gulf War syndrome, silicosis and post-vaccination phenomena, autoimmunity related to infectious fragments, hormones, aluminum, silicone, squalene oil, and pristane. We report the case of a 23-year-old woman who developed serial episodes of high fever, extreme fatigue, transient thrombocytopenia, multiple cervical adenopathies, hepatosplenomegaly, anemia, neutropenia, severe proteinuria and urine sediment abnormalities, elevated serum ferritin levels, and transient low positive antinuclear antibodies 1 year after she had a nickel-titanium chin implant for cosmetic reasons. The clinical picture simulated a variety of probable diseases: systemic lupus erythematosus, Kikuchi-Fujimoto syndrome, adult onset Still's disease, antiphospholipid syndrome, and hemophagocytic syndrome, among others, so she underwent an extensive medical investigation including two lymph node biopsies. She received treatment accordingly with steroids, methotrexate, and mofetil mycophenolate, with initial improvement of her symptoms, which recurred every time the dose was reduced. Two and a half years later the patient decided to retire the chin implant and afterwards all her systemic symptoms have disappeared. She remains in good health, without recurrence of any symptom and off medications until today. Albeit this patient fulfills proposed major ASIA criteria, to our knowledge it would be the first description of systemic features of autoinflammation in connection with a metal implant.

Over 15 years have passed since the discovery of the first autoinflammatory gene, MEFV, responsible for familial Mediterranean fever. The identification of another gene, TNFRSF1A, in 1999 led to the concept of autoinflammation which characterises rheumatological conditions triggered by a defective innate immunity. Substantive progress has been made since then with the identification of 18 autoinflammatory genes accounting for up to 24 disease entities showing overlapping symptoms. The accumulation of studies reporting patients with missing or excess mutations as compared with expected numbers favours the hypothesis that these diseases are distributed along a continuum ranging from monogenic to multifactorial conditions, rather than featuring only classical modes of inheritance. Moreover, the probable interactions of environmental and epigenetic factors further obscure our understanding of the mechanisms underlying the phenotypic expression of patients. This review explores the history of autoinflammatory gene discovery, discusses the nosological disparities stemming from the clinical versus pathophysiological definition of autoinflammatory diseases and summarises various inheritance patterns. This review calls for a consistent disease nomenclature and presents a reconciling hypothesis which places different sequence variants within the autoinflammatory disease continuum. Integrating these new concepts should help to facilitate communication between health professionals and promote personalised patient care.

The question of the effect of anti-TNF-alpha in skin carcinogenesis is especially relevant in view of the increased use of these drugs for the treatment of

autoinflammatory immune diseases. Since ultraviolet radiation and human papillomavirus are involved in skin carcinogenesis, we wished to investigate the effect of TNF-alpha antagonists on the UVB-induced apoptosis of keratinocytes infected by HPV38. Our results indicate that anti-TNF agent, infliximab, does not contribute to the survival of HPV38-transduced keratinocytes with UVB-induced DNA damages.

**OBJECTIVE:** There are many studies demonstrating deteriorated ventricle and endothelium functions in familial Mediterranean fever (FMF) patients. As FMF is an autoinflammatory disease with an ongoing inflammatory activity and inflammation plays an important role in the development and progression of atherosclerosis in some of the rheumatic diseases, we aimed to investigate the early markers of atherosclerosis in patients with FMF by the measurements of serum paraoxonase-1 (PON-1) activity, mean platelet volume (MPV) and malondialdehyde (MDA) level.

**METHODS:** This study is a cross-sectional, observational study. Forty consecutive patients with FMF and twenty healthy volunteers were selected to form the study population. The diagnosis of FMF was based on Tel-Hashomer criteria. Serum PON-1 activity, MPV and MDA level were determined to examine their association with FMF. Student's t-test, Mann-Whitney U test, Pearson correlation analysis were used for statistical analysis.

**RESULTS:** The mean PON-1 activity in FMF patients was significantly lower than in the healthy population ( $141.46 \pm 38.29$  vs.  $179.62 \pm 10.73$  U/l,  $p < 0.01$ ). Serum MDA levels were the same between the groups ( $1.08 \pm 0.66$  vs.  $1.08 \pm 0.33$  nmol/mL,  $p = 0.99$ ). MPV was higher in FMF patients than in the control I group ( $8.87 \pm 0.99$  vs.  $8.22 \pm 0.45$  fl,  $p = 0.04$ ). PON, MPV and MDA levels were the same in FMF patients with acute attack and attack -free period.

**CONCLUSION:** Our results show that PON-1 activity is lower in patients with FMF. Reduced PON-1 activity and increased MPV, independent of the oxidative stress status of these patients, may lead to increased atherosclerotic propensity in FMF.

**Publisher: AMAÇ:** Ailevi Akdeniz Ateşi (AAA) hastalarında bozulmuş ventrikül ve endotel fonksiyonlarını gösteren pek çok çalışma bulunmaktadır. AAA devamlı enflamatuvar aktivite ile seyreden bir otoenflamatuvar hastalık olduğundan ve bazı romatizmal hastalıklarda enflamasyon ateroskleroz gelişimi ve ilerlemesinde önemli rol oynadığından, AAA hastalarında serum paraoksonaz-1 (PON-1) aktivitesi, ortalama trombosit hacmi (OTH) ve malondialdehit (MDA) seviyesi ölçerek aterosklerozun erken belirteçlerini araştırmayı amaçladık. **YÖNTEM:** Bu çalışma kesitsel ve gözlemsel bir çalışmadır. Kırk AAA'lı hasta ve yirmi sağlıklı gönüllü çalışma topluluğunu oluşturmak için seçildi. AAA tanısı Tel-Hashomer kriterlerine göre konuldu. AAA, MDA seviyesi, OTH ve PON-1 aktivitesi arasındaki ilişkiyi araştırmak için serum PON-1 aktivitesi ve MDA seviyesi ve OTH ölçüldü. İstatistiksel analiz için Student's t-testi, Mann-Whitney U testi, Pearson korelasyon analizi kullanıldı. **BULGULAR:** AAA hastalarında ortalama PON-1 aktivitesi normal bireylere göre önemli olarak daha düşüktü ( $141.46 \pm 38.29$  karşın  $179.62 \pm 10.73$  U/L,  $p < 0.01$ ). Gruplar arasında serum MDA seviyeleri aynıydı ( $1.08 \pm 0.66$  karşın  $1.08 \pm 0.33$  nmol/mL,  $p = 0.99$ ). OTH normal bireylere göre önemli olarak daha yüksekti ( $8.87 \pm 0.99$  vs.  $8.22 \pm 0.45$  fl,  $p = 0.04$ ). AAA hastalarında akut atak sırasında ve ataksız dönemlerde PON-1 aktivitesi, MDA seviyeleri ve OTH aynıydı. **SONUÇ:** Sonuçlar göstermektedir ki AAA hastalarında PON-1 aktivitesi düşüktür. Azalmış PON-1 aktivitesi ve artmış OTH bu hastalarda, oksidatif stres durumundan bağımsız olarak, AAA'de artmış ateroskleroz yatkınlığına işaret ediyor olabilir.

isabelle.melki@nck.aphp.fr

Germline mutations in the SLC29A3 gene result in a range of recessive, clinically related syndromes: H syndrome, pigmented hypertrichosis with insulin-dependent diabetes mellitus syndrome, Faisalabad histiocytosis, and sinus histiocytosis with massive lymphadenopathy. The main symptoms of these diseases are hyperpigmentation with hypertrichosis, sensorineural deafness, diabetes, short stature, uveitis, and Rosai-Dorfman like histiocytosis. Here, we report the case of an 11-month-old boy with early-onset, recurrent episodes of unprovoked fever lasting 7 to 10 days and associated with pericardial effusion, abdominal pain, diarrhea, and inflammation. Physical examination revealed hyperpigmentation with hypertrichosis, dysmorphic features, and spleen and liver enlargement. Failure to thrive, sensorineural deafness, retarded psychomotor development, and a Rosai-Dorfman like cheek lesion developed subsequently. The febrile episodes did not respond to tumor necrosis factor  $\alpha$  antagonists and interleukin-1. Sequencing of the SLC29A3 gene revealed a homozygous missense mutation c.1088G>A (p.Arg363Gln). These observations suggest that a newly identified mutation in the SLC29A3 gene may be associated with an autoinflammatory disorder. Genetic defects in SLC29A3 should be considered in patients with autoinflammatory manifestations, recurrent febrile attacks, and 1 or more of the symptoms found in the broad spectrum of SLC29A3-related disorders (especially hyperpigmentation with hypertrichosis).

[Article in German]

Hong JB(1), Prucha H, Melnik B, Ziai M, Ring J, Chen W.

Author information:

(1)Klinik für Dermatologie, National Taiwan University Hospital, Taipei.

Acne is an intriguing model for the study of interactions between hormones, innate immunity, inflammation and wound healing (scarring). The manifestations and involvement of acne in different systemic diseases and some rare syndromes demonstrate its multifaceted nature.

Synovitis-Acne-Pustulosis-Hyperostosis-Osteitis (SAPHO) and Pyogenic Arthritis-Pyoderma gangrenosum-Acne (PAPA) syndromes, both regarded as autoinflammatory diseases, highlight the attributes of inflammation in acne. While SAPHO syndrome can be used to explore the pathogenic role of *Propionibacterium acnes* in acne, PAPA syndrome and Apert syndrome can help understand the genetic influence on acne. The genetic defects in the gain-of-function of FGFR2 mutations in Apert syndrome and acne nevus of Munro lend further support to the hypothesis that the interaction of forkhead box class O (FoxOs)-mediated transcriptional regulation with androgen receptor transactivation and insulin/insulin like growth factor-1(IGF-1)-signaling is crucial in acne pathogenesis. Novel biologics, such as tumor necrosis factor (TNF) blockers and IL-1 inhibitors, appear promising in opposing the inflammation associated with SAPHO and PAPA syndromes, but it remains to be seen if they can also improve severe acne particularly in the long term.

Erysipelas-like erythema of familial Mediterranean fever syndrome: a case report with emphasis on histopathologic diagnostic clues.

Kolivas A(1), Provost P, Thompson CT.

Author information:

(1)Department of Dermatology and Dermatopathology, Saint-Pierre Hospital, Université Libre de Bruxelles, Brussels, Belgium. kolivas@gmail.com

We report histopathological findings in a case of familial Mediterranean fever (FMF) syndrome with an erysipelas-like erythema (ELE). ELE is the only pathognomic cutaneous manifestation of FMF. ELE is characterized by well-demarcated, tender, erythematous and infiltrated plaques recurring on the same site and resolving spontaneously within 48-72 h. FMF is a monogenic autoinflammatory syndrome highlighted by recurrent fever associated with polyserositis involving mainly the peritoneum, synovium and pleura. FMF results from a mutation of the MEFV gene, which encodes for pyrin, leading to IL-1 $\beta$  activation and promoting neutrophil migration into the dermis. Histopathological findings in our case showed a sparse superficial perivascular and interstitial lymphocytic infiltrate admixed with some neutrophils, no eosinophils and mild papillary dermal edema. Venules and lymphatics were dilated, though no vasculitis was identified. Neutrophils are the most common cutaneous marker of autoinflammation, and cutaneous manifestations of monogenic autoinflammatory syndromes are represented by the spectrum of aseptic neutrophilic dermatoses.

Neutrophils in the presence of recurrent fever and in the correct clinical context of recurrent erysipelas in the same site are a diagnostic clue for FMF.

Heart-type fatty acid binding protein level in familial Mediterranean fever.

Karakurt Arıtürk Ö(1), Üreten K, Sarı M, Yazıhan N, Yılmaz E, Ergüder I.

Author information:

(1)Department of Cardiology, Balıkesir State Hospital, Balıkesir, Turkey.  
ozlemkarakurt55@yahoo.com.

**OBJECTIVES:** Familial Mediterranean fever (FMF) is an autosomal recessive disorder and the most frequent periodic syndrome characterized by recurrent attacks of polyserositis. Heart-type fatty acid-binding protein (h-FABP) is an intracellular molecule engaged in the transport of fatty acids through the myocardial cytoplasm and a rapid marker of myocardial injury. FMF is an autoinflammatory disease characterized by ongoing inflammatory activity. Inflammation also plays an important role in the development and progression of atherosclerosis in some rheumatic diseases. We aimed to investigate markers of atherosclerosis in patients with FMF by the measurement of serum h-FABP and malondialdehyde levels (MDA).

**STUDY DESIGN:** Forty consecutive patients with FMF and twenty healthy volunteers were selected to participate in the study. The diagnosis of FMF was based on Tel-Hashomer criteria. Serum h-FABP and MDA levels were determined to examine the association.

**RESULTS:** The mean h-FABP level in FMF patients was significantly higher than the normal population ( $4.89 \pm 0.83$  vs.  $3.06 \pm 2.13$  ng/ml,  $p < 0.01$ ). The mean platelet volume was significantly higher in FMF patients than in the normal group ( $8.87 \pm 0.99$  vs.  $8.22 \pm 0.45$  fl,  $p = 0.04$ ). Serum MDA levels were the same between the groups ( $1.08 \pm 0.66$  vs.  $1.08 \pm 0.33$  nmol/ml,  $p = 0.99$ ). h-FABP and MDA levels were the same in FMF patients with an acute attack and during an attack free period.

CONCLUSION: Our results show that h-FABP increases in patients with FMF. Higher h-FABP levels may lead to increased atherosclerotic propensity in FMF, independent of the oxidative stress status of these patients.

TRPM2 links oxidative stress to NLRP3 inflammasome activation.

Zhong Z(1), Zhai Y, Liang S, Mori Y, Han R, Sutterwala FS, Qiao L.

Author information:

(1)Department of Microbiology and Immunology, Stritch School of Medicine, Loyola University Chicago, Maywood, Illinois 60153, USA.

Exposure to particulate crystals can induce oxidative stress in phagocytes, which triggers NLRP3 inflammasome-mediated interleukin-1 $\beta$  secretion to initiate undesirable inflammatory responses that are associated with both autoinflammatory and metabolic diseases. Although mitochondrial reactive oxygen species have a central role in NLRP3 inflammasome activation, how reactive oxygen species signal

assembly of the NLRP3 inflammasome remains elusive. Here, we identify liposomes as novel activators of the NLRP3 inflammasome and further demonstrate that liposome-induced inflammasome activation also requires mitochondrial reactive oxygen species. Moreover, we find that stimulation with liposomes/crystals induced reactive oxygen species-dependent calcium influx via the TRPM2 channel and that macrophages deficient in TRPM2 display drastically impaired NLRP3 inflammasome activation and interleukin-1 $\beta$  secretion. Consistently, Trpm2(-/-) mice are resistant to crystal-/liposome-induced interleukin-1 $\beta$ -mediated peritonitis in vivo. Together, these results identify TRPM2 as a key factor that links oxidative stress to the NLRP3 inflammasome activation. Therefore, targeting TRPM2 may be effective for the treatment of NLRP3 inflammasome-associated inflammatory disorders.

Familial Mediterranean fever in heterozygotes: are we able to accurately diagnose the disease in very young children?

Hentgen V(1), Grateau G, Stankovic-Stojanovic K, Amselem S, J  ru I.

Author information:

(1)Centre Hospitalier de Versailles, Le Chesnay, France.

vhentgen@ch-versailles.fr

**OBJECTIVE:** Familial Mediterranean fever (FMF) is an autosomal-recessive autoinflammatory disease due to mutations in MEFV. Descriptions of disease manifestations among patients carrying a single mutated MEFV allele are becoming more frequent, although no data are available on the long-term outcome. We undertook this study to assess the accuracy of clinical diagnosis in children carrying a single mutated MEFV allele with symptoms of recurrent autoinflammatory disorder.

**METHODS:** We performed a retrospective single-center study of 33 patients with autoinflammatory disorders age <6 years at disease onset with 1 mutated MEFV allele. The phenotype of the patients was investigated in detail, and the

clinical picture and outcome of 18 patients with an initial FMF diagnosis according to current clinical criteria were compared to those of 25 homozygous or compound heterozygous FMF patients.

**RESULTS:** No major differences in presenting signs or initial response to colchicine were observed between patient groups. During followup, heterozygotes had a milder disease course compared to homozygotes and were less prone than homozygotes to experience new clinical signs of FMF. At puberty, clinical signs of FMF completely disappeared in 5 of 18 heterozygotes, allowing them to discontinue colchicine without recurrence of symptoms or increases in inflammatory marker levels.

**CONCLUSION:** Our data suggest that the clinical diagnosis of FMF in very young heterozygous children should be made with caution. At this young age they can present with an FMF-like disease-similar to that seen in patients carrying 2 mutated alleles-that is not necessarily predictive of life-long illness.

Biliary atresia (BA) is characterized by progressive inflammation and fibrosis of bile ducts. A theory of pathogenesis entails autoimmune-mediated injury targeting bile duct epithelia. One of the strongest genetic associations with autoimmunity is with HLA genes. In addition, apparently dissimilar HLA alleles may have similar antigen-binding sites, called shared epitopes, that overlap in their

capacity to present antigens. In autoimmune disease, the incidence of the disease may be related to the presence of shared epitopes, not simply the HLA allelic association. AIM: To determine HLA allele frequency (high-resolution genotyping) and shared epitope associations in BA.

RESULTS: Analysis of every allele for HLA-A, -B, -C, -DRB1, -DPB1 and -DQB1 in 180 BA and 360 racially-matched controls did not identify any significant HLA association with BA. Furthermore, shared epitope analysis of greater than 10 million possible combinations of peptide sequences was not different between BA and controls.

CONCLUSIONS: This study encompasses the largest HLA allele frequency analysis for BA in the United States and is the first study to perform shared epitope analysis. When controlling for multiple comparisons, no HLA allele or shared epitope association was identified in BA. Future studies of genetic links to BA that involve alterations of the immune response should include investigations into defects in regulatory T cells and non-HLA linked autoinflammatory diseases.

BACKGROUND: Mutations in the TNFRSF1A gene encoding the tumour necrosis factor  $\alpha$  cell surface receptor, TNFR1, cause TNFR-associated periodic syndrome (TRAPS) and polymorphisms in TNFRSF1A, including rs4149570, rs767455 and rs1800692, are associated with inflammatory diseases.

OBJECTIVES: To describe a new exon 2-spliced transcript-TNFR1-d2-and the impact

of these three single nucleotide polymorphisms on exon 2 splicing, transcriptional activity of TNFRSF1A and TRAPS phenotype.

**METHODS:** Expression of TNFRSF1A transcripts was performed by reverse-transcription-PCR in a range of human cells and tissues. Exon 2 splicing and transcriptional activity were analysed in HEK293T and SW480 cells by in vitro alternative splicing and luciferase assays, respectively. We constructed haplotypes containing rs4149570, rs767455 and rs1800692 in controls (n=72), patients with TRAPS (n=111) and in TRAPS-like patients (n=450) to compare their distribution and association with clinical features of TRAPS.

**RESULTS:** TNFR1-d2 was expressed in a tissue-specific manner, whereas TNFR1 expression was ubiquitous. Alternative splicing assays showed that the T-A-T haplotype at rs4149570-rs767455-rs1800692 had a significantly higher expression of exon 2-skipping product ( $p=0.02$ ) compared with the G-G-C haplotype.

Transcriptional activity from the T-T haplotype at rs4149570-rs1800692 was increased compared with the G-C haplotype ( $p=0.03$ ). In patients with TRAPS, rs1800692 T/T homozygotes were excessively rare ( $p<10^{-4}$ ) and TRAPS-like patients with this genotype experienced less fever.

**CONCLUSIONS:** Our study provides a new mechanism of TNFRSF1A regulation whereby three polymorphisms in the promoter, exon 1 and intron 4 have a functional and combined effect on exon 2 splicing, via a coupling mechanism between transcription and splicing. These polymorphisms may affect the phenotype of TRAPS and TRAPS-like patients.

Increased NLRP3-dependent interleukin 1 $\beta$  secretion in patients with familial Mediterranean fever: correlation with MEFV genotype.

Omenetti A(1), Carta S, Delfino L, Martini A, Gattorno M, Rubartelli A.

Author information:

(1)Pediatrics II Unit, G Gaslini IRCCS and University of Genoa, , Genoa, Italy.

**OBJECTIVES:** To define in patients affected by familial Mediterranean fever (FMF)

whether or not interleukin (IL)-1 $\beta$  secretion (1) is enhanced, (2) correlates with the type of MEFV mutation and (3) is mediated by NLRP3.

**METHODS:** Freshly isolated monocytes from 21 patients with FMF (12 homozygous and 9 heterozygous), 14 MEFV healthy carriers and 30 healthy donors (HDs), unstimulated or after lipopolysaccharide (LPS)-induced activation, were analysed for redox state (production of reactive oxygen species (ROS) and antioxidant responses) and IL-1 $\beta$  and IL-1 receptor antagonist (IL-1Ra) secretion. NLRP3 down-modulation was induced by in vitro silencing of the NLRP3 gene.

**RESULTS:** LPS-stimulated monocytes from patients with FMF displayed enhanced IL-1 $\beta$  secretion, which correlated with number and penetrance of MEFV mutations.

Silencing of NLRP3 consistently inhibited IL-1 $\beta$  secretion. As in other autoinflammatory diseases, FMF monocytes produced more ROS than genetically negative cells from HDs. Unlike in cryopyrin-associated periodic fever syndromes (CAPS), however, they were characterised by a conserved and sustained antioxidant response. Consistent with this finding, activated MEFV-mutated monocytes did not exhibit the functional indicators of oxidative stress observed in CAPS, including accelerated IL-1 $\beta$  secretion and deficient production of IL-1Ra.

**CONCLUSIONS:** MEFV-mutated monocytes display enhanced IL-1 $\beta$  secretion, which correlates with number of high-penetrance mutations and level of endogenous ROS. Unlike NLRP3-mutated cells, monocytes carrying MEFV mutations withstand oxidative stress and preserve IL-1Ra production, thereby limiting inflammation. Finally, in contrast with that found in the animal model, the increased secretion of IL-1 $\beta$  by LPS-stimulated FMF monocytes is NLRP3-dependent.

**OBJECTIVES:** Autoinflammatory disorders are disorders of the innate immune system. Standard genetic testing provided no correct diagnosis in a female patient from a non-consanguineous family of British descent with a colchicine-responsive autosomal dominant periodic fever syndrome. We aimed to unravel the genetic cause of the symptoms.

**METHODS:** Whole exome sequencing was used to screen for novel sequence variants, which were validated by direct Sanger sequencing. Ex vivo stimulation with peripheral blood mononuclear cells was performed to study the functional consequences of the mutation. mRNA and cytokine levels were measured by quantitative PCR and ELISA, respectively.

**RESULTS:** Whole exome sequencing revealed a novel missense sequence variant, not seen in around 6800 controls, mapping to exon 8 of the MEFV gene (c.1730C>A; p.T577N), co-segregating perfectly with disease in this family. Other mutations at the same amino acid (c.1730C>G; p.T577S and c.1729A>T; p.T577S) were found in a family of Turkish descent, with autosomal dominant inheritance of familial Mediterranean fever (FMF)-like phenotype, and a Dutch patient, respectively. Moreover, a mutation (c.1729A>G; p.T577A) was detected in two Dutch siblings, who had episodes of inflammation of varying severity not resembling FMF. Peripheral blood mononuclear cells from one patient of the index family showed increased basal interleukin 1 $\beta$  mRNA levels and cytokine responses after lipopolysaccharide stimulation. Responses normalised with colchicine treatment.

**CONCLUSIONS:** Heterozygous mutations at amino acid position 577 of pyrin can induce an autosomal dominant autoinflammatory syndrome. This suggests that T577, located in front of the C-terminal B30.2/SPRY domain, is crucial for pyrin function.

**OBJECTIVE:** There are limited data on long-term comorbidities and mortality among patients with familial Mediterranean fever (FMF). Our objective was to evaluate comorbidities and death rates among individuals with FMF.

**METHODS:** We studied a nationwide, population-based, retrospective cohort of 1225 individuals with FMF (59% men) in a database of 1 244 350 adolescents (16-20 years of age) medically evaluated for military service between 1973 and 1997. This cohort was linked with the national mortality, cancer and end-stage renal disease (ESRD) registries in Israel. Study outcomes were all-cause mortality, occurrence of ESRD and malignancy by the age of 50 years.

**RESULTS:** During 30 years of follow-up, death rates were 8.73/10(4) versus 4.32/10(4) person-years in the FMF and control groups, respectively ( $p=0.002$ ). In a multivariable analysis adjusted for age, birth year, socio-economic status, education, ethnicity and body mass index, FMF was associated with increased mortality in men ( $HR=1.705$  (95% CI 1.059 to 2.745),  $p=0.028$ ) and women ( $HR=2.48$  (1.032 to 5.992),  $p=0.042$ ). Renal amyloidosis accounted for 35% and 60% of deaths in men and women, respectively. FMF was not associated with an increased incidence of cancer.

**CONCLUSIONS:** FMF is associated with increased all-cause mortality that is likely attributed to reduced colchicine compliance or responsiveness. Individuals with FMF do not have an increased incidence of cancer. These results support the awareness among medical community to decrease the higher than average mortality rate among participants with FMF.

Corticosteroid therapy in a patient with cerebral amyloid angiopathy-related inflammation.

Kimura A(1), Sakurai T, Yoshikura N, Hayashi Y, Takemura M, Takahashi H, Inuzuka T.

Author information:

(1)Department of Neurology, Gifu University Graduate School of Medicine, 1-1 Yanagido, Gifu, 501-1194, Japan. kimura1@gifu-u.ac.jp

We studied longitudinal changes of the levels of anti-amyloid  $\beta$  (anti-A $\beta$ ) antibody, amyloid  $\beta$  (A $\beta$ ) protein, and interleukin 8 (IL-8) in cerebrospinal fluid (CSF) of a patient with cerebral amyloid angiopathy-related inflammation (CAA-ri) in whom steroid treatment resulted in clinical improvement. The diagnosis of CAA-ri was established with brain biopsy. Levels of anti-A $\beta$  42 antibody, A $\beta$  40, A $\beta$  42 and IL-8 in CSF were measured in the CAA-ri patient at 23 time points in the 8-month clinical course. These CSF samples were divided into 2 groups: those obtained before (n = 12) and those after (n = 11) oral corticosteroid therapy was started. We compared these levels between CSF samples obtained before and after therapy. The mean levels of anti-A $\beta$  42 antibody and IL-8 were significantly higher in CSF samples of the CAA-ri patient before oral corticosteroid therapy than those after therapy. A positive correlation was noted between levels of anti-A $\beta$  42 antibodies and IL-8 in CSF of this patient. There were no significant differences of mean levels of A $\beta$  40 and A $\beta$  42 between CSF samples obtained before and after oral corticosteroid therapy. It was possible that the autoinflammatory process with anti-A $\beta$  42 antibodies and IL-8 may have been involved in the pathogenesis of CAA-ri, and that corticosteroid therapy directly affected levels of anti-A $\beta$  42 antibody and IL-8. In summary, CAA-ri encephalopathy is a relapsing or progressive disorder and may be treatable by adequate immunosuppressive therapy. The anti-A $\beta$  42 antibody in CSF is a useful biological marker for therapeutic monitoring of CAA-ri.

Proteomics and metabolomics in inflammatory bowel disease.

Yau Y(1), Leong RW, Zeng M, Wasinger VC.

Author information:

(1)Bioanalytical Mass Spectrometry Facility, Mark Wainwright Analytical Centre, The University of New South Wales, Sydney, Australia.

Genome-wide studies in inflammatory bowel disease (IBD) have allowed us to understand Crohn's disease and ulcerative colitis as forms of related autoinflammatory disorders that arise from a multitude of pathogenic origins. Proteomics and metabolomics are the offspring of genomics that possess unprecedented possibilities to characterize unknown pathogenic pathways. It has been about a decade since proteomics was first applied to IBD, and 5 years for metabolomics. These techniques have yielded novel and potentially important findings, but turning these results into beneficial patient outcomes remains challenging. This review recounts the history and context of clinical IBD developments before and after proteomics and metabolomics IBD in this field, discusses the challenges in consolidating high complexity data with physiological understanding, and provides an outlook on the emerging principles that will help interface the bioanalytical laboratory with IBD prognosis.

AIMS: Pro-inflammatory cytokines and chemokines, in particular IL-1 $\beta$ , IFN $\gamma$ , and CXCL10, contribute to  $\beta$ -cell failure and loss in DM via IL-1R, IFN $\gamma$ R, and TLR4 signaling. IL-1 signaling deficiency reduces diabetes incidence, islet IL-1 $\beta$  secretion, and hyperglycemia in animal models of diabetes. Further, IL-1R antagonism improves normoglycemia and  $\beta$ -cell function in type 2 diabetic patients. Inhibition of lysine deacetylases (KDACi) counteracts  $\beta$ -cell toxicity induced by the combination of IL-1 and IFN $\gamma$  and reduces diabetes incidence in non-obese diabetic (NOD) mice. We hypothesized that KDACi breaks an autoinflammatory circuit by differentially preventing  $\beta$ -cell expression of the

$\beta$ -cell toxic inflammatory molecules IL-1 $\beta$  and CXCL10 induced by single cytokines. RESULTS: CXCL10 did not induce transcription of IL-1 $\beta$  mRNA. IL-1 $\beta$  induced  $\beta$ -cell IL-1 $\beta$  mRNA and both IL-1 $\beta$  and IFN $\gamma$  individually induced Cxcl10 mRNA transcription. Givinostat inhibited IL-1 $\beta$ -induced IL-1 $\beta$  mRNA expression in INS-1 and rat islets and IL-1 $\beta$  processing in INS-1 cells. Givinostat also reduced IFN $\gamma$  induced Cxcl10 transcription in INS-1 cells but not in rat islets, while IL-1 $\beta$  induced Cxcl10 transcription was unaffected in both.

MATERIALS AND METHODS: INS-1 cells and rat islets of Langerhans were exposed to IL-1 $\beta$ , IFN $\gamma$  or CXCL10 in the presence or absence of KDACi (givinostat). Cytokine and chemokine mRNA expressions were quantified by real-time qPCR, and IL-1 $\beta$  processing by western blotting of cell lysates.

CONCLUSION/INTERPRETATION: Inhibition of  $\beta$ -cell IL-1 $\beta$  expression and processing and Cxcl10 transcription contributes to the  $\beta$ -cell protective actions of KDACi.

In vitro  $\beta$ -cell destructive effects of CXCL10 are not mediated via IL-1 $\beta$  transcription. The differential proinflammatory actions of KDACs may be attractive novel drug targets in DM.

Clinical genetic testing of periodic fever syndromes.

Marcuzzi A(1), Piscianz E, Kleiner G, Tommasini A, Severini GM, Monasta L, Crovella S.

Author information:

(1)Laboratory of Immunopathology, Institute for Maternal and Child Health (IRCCS) "Burlo Garofolo", 34137 Trieste, Italy. marcuzzi@burlo.trieste.it

Periodic fever syndromes (PFSs) are a wide group of autoinflammatory diseases. Due to some clinical overlap between different PFSs, differential diagnosis can be a difficult challenge. Nowadays, there are no universally agreed recommendations for most PFSs, and near half of patients may remain without a genetic diagnosis even after performing multiple-gene analyses. Molecular analysis of periodic fevers' causative genes can improve patient quality of life

by providing early and accurate diagnosis and allowing the administration of appropriate treatment. In this paper we focus our discussion on effective usefulness of genetic diagnosis of PFSs. The aim of this paper is to establish how much can the diagnostic system improve, in order to increase the success of PFS diagnosis. The mayor expectation in the near future will be addressed to the so-called next generation sequencing approach. Although the application of bioinformatics to high-throughput genetic analysis could allow the identification of complex genotypes, the complexity of this definition will hardly result in a clear contribution for the physician. In our opinion, however, to obtain the best from this new development a rule should always be kept well in mind: use genetics only to answer specific clinical questions.

jewoockyu@yuhs.ac

Human pyrin with gain-of-function mutations in its B30.2/SPRY domain causes the autoinflammatory disease familial Mediterranean fever by assembling an ASC-dependent inflammasome that activates caspase-1. Wild-type human pyrin can also form an inflammasome complex with ASC after engagement by autoinflammatory PSTPIP1 mutants. How the pyrin inflammasome is activated in the absence of disease-associated mutations is not yet known. We report here that ribotoxic stress triggers the assembly of the human pyrin inflammasome, leading to ASC oligomerization and caspase-1 activation in THP-1 macrophages and in a 293T cell line stably reconstituted with components of the pyrin inflammasome. Knockdown of

pyrin and selective inhibition of p38 MAPK greatly attenuated caspase-1 activation by ribotoxic stress, whereas expression of the conditional mutant  $\Delta$ MEKK3:ER\* allowed the activation of caspase-1 without ribotoxic stress. Disruption of microtubules by colchicine also inhibited pyrin inflammasome activation by ribotoxic stress. Together, our results indicate that ribotoxic stress activates the human pyrin inflammasome through a mechanism that requires p38 MAPK signaling and microtubule stability.

Endocrine side effects induced by immune checkpoint inhibitors.

Corsello SM(1), Barnabei A, Marchetti P, De Vecchis L, Salvatori R, Torino F.

Author information:

(1)Endocrinology Unit, Università Cattolica, Via Federico Cesi 72, I-00193 Rome, Italy. corsello.sm@mclink.it

CONTEXT: In recent years, progress has been made in cancer immunotherapy by the development of drugs acting as modulators of immune checkpoint proteins, such as the cytotoxic T-lymphocyte antigen-4 (CTLA4) and programmed death-1 (PD-1), two co-inhibitory receptors that are expressed on T cells upon activation. These molecules play crucial roles in maintaining immune homeostasis by down-regulating T-cell signaling, thereby preventing unbridled T-cell proliferation while maintaining tolerance to self-antigens, such as tumor-associated antigens. CTLA4 blockade through systemic administration of the CTLA4-blocking antibody ipilimumab was shown to confer significant survival benefit and prolonged stable disease in patients affected by advanced cutaneous melanoma. Other immune checkpoint inhibitors are under clinical evaluation. However, immune checkpoint blockade can lead to the breaking of immune self-tolerance, thereby inducing a novel syndrome of autoimmune/autoinflammatory side effects, designated as "immune-related adverse events," mainly including rash, colitis, hepatitis, and endocrinopathies.

DATA ACQUISITION: We searched the medical literature using the words "hypophysitis," "hypopituitarism," "thyroid," "adrenal insufficiency," and "endocrine adverse events" in association with "immune checkpoint inhibitors," "ipilimumab," "tremelimumab," "PD-1," and "PD-1-L."

EVIDENCE SYNTHESIS: The spectrum of endocrine disease experienced by patients treated with ipilimumab includes most commonly hypophysitis, more rarely thyroid disease or abnormalities in thyroid function tests, and occasionally primary adrenal insufficiency. Hypophysitis has emerged as a distinctive side effect of CTLA4-blocking antibodies, establishing a new form of autoimmune pituitary disease. This condition, if not promptly recognized, may be life-threatening (due to secondary hypoadrenalism). Hypopituitarism caused by these agents is rarely reversible, and prolonged or lifelong substitutive hormonal treatment is often required. The precise mechanism of injury to the endocrine system triggered by these drugs is yet to be fully elucidated.

CONCLUSIONS: Although reports of endocrine side effects caused by cancer immune therapy are abundant, their exact prevalence and mechanism are unclear. Well-designed correlative studies oriented to finding and validating predictive factors of autoimmune toxicity are urgently needed.

T helper 17 polarization in familial Mediterranean fever.

Ovadia A(1), Livneh A, Feld O, Ben-Zvi I, Kukuy E, Kivity S, Lidar M, Barda-Saad M, Shinar Y.

Author information:

(1)Heller Institute of Medical Research, Sheba Medical Center, Tel Hashomer, Israel.

Autoinflammatory attacks in familial Mediterranean fever (FMF) are accompanied by elevated levels of interleukin-6 (IL-6), and are controllable by IL-1-targeting drugs. In combination, IL-6 and IL-1 are known to be potent inducers of T helper (Th) 17 cells development. Therefore, we studied the Th17 population size, and activation potential, of FMF patients. Based on the relative mRNA expression of

the Th1, Th2, Treg and Th17 transcription factors T-bet, GATA3, FOXP3 and retinoic acid-related orphan receptor  $\gamma$ T (ROR $\gamma$ T), respectively, the Th17 population in peripheral blood mononuclear cells (PBMCs) of healthy subjects was estimated at 2.5% of the entire Th population and 4.4% in FMF patients in remission (n=6 for each group, P=0.03). IL-17 secretion after universal stimulation of the T-cell receptor in PBMCs culture was twice higher in cultures of patients with frequent attacks (n=18) than in those of patients with infrequent attacks (n=10, 1124 $\pm$ 266 vs 615 $\pm$ 196 pg ml<sup>-1</sup>, P=0.009). IL-17 secretion correlated well with IL17A mRNA level. Part of the increased secretion was related to the deleterious, MEFV p.M694V homozygous genotype (n=19, 1.5-fold, P=0.03). Almost all IL-17 producer cells were CD4-positive (CD4(+)/IL-17(+)). In conclusion, frequent attacks and the deleterious FMF genotype appear to drive FMF patients to a heightened Th17 response.

Comment in

Ann Rheum Dis. 2014 Aug;73(8):e53.

Ann Rheum Dis. 2014 Aug;73(8):e52.

BACKGROUND AND AIM: Familial Mediterranean fever (FMF) is an autoinflammatory

disease caused by mutations of the MEFV gene. We analyse the impact of ethnic, environmental and genetic factors on the severity of disease presentation in a large international registry.

**METHODS:** Demographic, genetic and clinical data from validated paediatric FMF patients enrolled in the Eurofever registry were analysed. Three subgroups were considered: (i) patients living in the eastern Mediterranean countries; (ii) patients with an eastern Mediterranean ancestry living in western Europe; (iii) Caucasian patients living in western European countries. A score for disease severity at presentation was elaborated.

**RESULTS:** Since November 2009, 346 FMF paediatric patients were enrolled in the Eurofever registry. The genetic and demographic features (ethnicity, age of onset, age at diagnosis) were similar among eastern Mediterranean patients whether they lived in their countries or western European countries. European patients had a lower frequency of the high penetrance M694V mutation and a significant delay of diagnosis ( $p < 0.002$ ). Patients living in eastern Mediterranean countries had a higher frequency of fever episodes/year and more frequent arthritis, pericarditis, chest pain, abdominal pain and vomiting compared to the other two groups. Multivariate analysis showed that the variables independently associated with severity of disease presentation were country of residence, presence of M694V mutation and positive family history.

**CONCLUSIONS:** Eastern Mediterranean FMF patients have a milder disease phenotype once they migrate to Europe, reflecting the effect of environment on the expression of a monogenic disease.

We report the case of a 22-year-old Caucasian woman presenting with a new-onset nephrotic syndrome with normal renal function during the 35th week of pregnancy. AA (secondary) amyloidosis was further diagnosed at the renal biopsy. Extensive genetic testing revealed that the patient was heterozygous for both TNFRSF1A p.R92Q and MEFV p.M694I mutations leading to an autoinflammatory syndrome characterized by amyloid deposition as the sole manifestation.

[Interleukin-1-mediated diseases].

[Article in German]

Holzinger D(1), Becker H, Jacobi AM.

Author information:

(1)Institut für Immunologie, Universitätsklinikum Münster, Münster.

Interleukin-1 (IL-1)-mediated diseases are caused by an inappropriately high production and release of IL-1 beta which results in a multitude of symptoms, e.g. arthritis, exanthema, conjunctivitis, serositis, fever and loss of hearing. If IL-1-mediated diseases remain unrecognized or are recognized and treated too late, long-term complications, such as amyloidosis may occur. In recent years the diagnostic and therapeutic options with respect to IL-1-mediated diseases have drastically improved. These diseases often manifesting in childhood can now be treated with monoclonal antibodies against IL-1 or with IL-1 receptor antagonists. Increased IL-1 secretion does not only play a role in relatively rare hereditary diseases, such as cryopyrin-associated periodic fever syndromes or familial Mediterranean fever but also in widespread diseases, such as gout or type 2 diabetes. This article will focus on pathogenic, diagnostic and therapeutic aspects of IL-1-mediated inflammatory diseases.

[Cutaneous polymorph manifestations of familial Mediterranean fever in a child].

[Article in French]

Gonzales F(1), Begon Lours J, Kalach N, Gosset P, Lasek Duriez A.

Author information:

(1)Service de pédiatrie, université catholique de Lille, hôpital Saint-Vincent-de-Paul, boulevard de Belfort, 59020 Lille, France.

We describe the case of a 4-year-old child with Mediterranean fever characterized by cutaneous features. Familial Mediterranean fever is an autosomal recessive disorder characterized by recurrent attacks of fever and polyserositis including peritonitis, pleuritis, and arthritis. Skin involvement is less common. In our case, the successively patient presented erysipelas-like erythema, edemas of the palmar and plantar regions, and purpuric lesions. From these clinical observations, several diagnoses were raised: infectious erysipelas, Kawasaki disease, Henoch-Schönlein purpura, and familial Mediterranean fever. Only the latter diagnosis was confirmed after exploration and then confirmed with genetic analysis, which found a M694V homozygous mutation. Erysipelas-like erythema is the most frequent cutaneous sign reported in the literature and the only one to be associated with the M694V homozygous mutation. The originality of this case is the dominancy and polymorphism of the skin lesions.

Autoinflammation: From monogenic syndromes to common skin diseases.

Nguyen TV(1), Cowen EW, Leslie KS.

Author information:

(1)Department of Dermatology, University of California, San Francisco, California 94143, USA.

Autoinflammation is characterized by aberrant regulation of the innate immune system and often manifests as periodic fevers and systemic inflammation involving multiple organs, including the skin. Mutations leading to abnormal behavior or activity of the interleukin 1 beta (IL-1 $\beta$ )-processing inflammasome complex have been found in several rare autoinflammatory syndromes, for which anticytokine therapy such as IL-1 or tumor necrosis factor- $\alpha$  inhibition may be effective. It is becoming clear that features of autoinflammation also affect common dermatoses, some of which were previously thought to be solely autoimmune in origin (eg, vitiligo, systemic lupus erythematosus). Recognizing the pathogenetic role of autoinflammation can open up new avenues for the targeted treatment of complex, inflammatory dermatoses.

Canakinumab in pediatric rheumatic diseases.

Wulffraat NM(1), Woo P.

Author information:

(1)University medical Center Utrecht, Department Pediatric Rheumatology, Utrecht, Netherlands. N.wulffraat@umcutrecht.nl

INTRODUCTION: Hitherto, some of the most severe forms of arthritis with onset in

the neonatal period and early childhood have been resistant to conventional and anti-tumour necrosis factor agents. Recent results from drug trials of novel monoclonal antibodies will significantly alter the treatment of two of these diseases. This review is for canakinumab, a new monoclonal antibody to interleukin 1 $\beta$  that has been shown to be specifically efficacious in two groups of arthritis with systemic features.

**AREAS COVERED:** The clinical features and treatment to-date in the autoinflammatory disease, cryopyrin associated periodic fever syndrome and systemic juvenile idiopathic arthritis are briefly reviewed. An overview of current IL-1 inhibitors is provided. Clinical trials of Canakinumab in the treatment of these two diseases are evaluated.

**EXPERT OPINION:** The last decade has seen a major advance in treatment leading to remission while on therapy for many children with CAPS and sJIA. The outcomes of the anti-IL-1 $\beta$  and the anti-IL-6 trials for sJIA are quite similar and do not enable preferential use of either biological in a given patient.

Colchicine toxicity precipitated by interaction with sunitinib.

Abodunde OA(1), LevakaVeera RR, Desai R, Nweke N, Berrou M.

Author information:

(1)Department of Internal Medicine, Abington Memorial Hospital, Abington, PA 19001, USA. oabodunde@amh.org

**WHAT IS KNOWN AND OBJECTIVE:** Colchicine is an anti-inflammatory agent used primarily in treatment of gout and familial Mediterranean fever. Toxicity is uncommon, and depends on dose, hepatic or renal impairment, co-administration with P-glycoprotein or CYP3A4 inhibitors and route of administration. In patients taking p-glycoprotein inhibitors, maximum recommended dose is 0.3 mg per day. In renal or hepatic impairment, recommendation is to avoid concomitant administration of p-glycoprotein inhibitors and colchicine.

**CASE SUMMARY:** We present an 82 year old patient, with a history of gout, chronic

kidney disease and recurrent renal cell carcinoma who was admitted with features of colchicine toxicity after taking a cumulative dose of 41.4 mg over ten days, and taking sunitinib 50 mg daily from day seven of his high dose colchicine regimen. Symptoms started after commencing his cycle of sunitinib, which he had taken in 14 day cycles for many years. He developed severe diarrhea, normal anion gap metabolic acidosis, fever, pneumonia, white cell abnormalities including 30% bands and toxic granulation with Dohle bodies. Red cell abnormalities included anemia, burr cells and acanthocytosis. He also developed acute cardiovascular collapse with hypotension and acute systolic heart failure. Cardiac catheterization showed previously known coronary artery disease, with no significant progression to explain degree of cardiovascular collapse.

WHAT IS NEW AND CONCLUSION: P-glycoprotein inhibition by sunitinib has been demonstrated. Interaction with colchicine metabolism precipitated colchicine toxicity in this case. Knowledge of p-glycoprotein and its role in drug interactions and potential drug toxicity may not be widespread among clinicians. We report the first case of colchicine toxicity precipitated by interaction with a tyrosine kinase inhibitor.

Hearing loss in Muckle-Wells syndrome.

Kuemmerle-Deschner JB(1), Koitschev A, Ummenhofer K, Hansmann S, Plontke SK, Koitschev C, Koetter I, Angermair E, Benseler SM.

Author information:

(1)University Hospital Tuebingen, Tuebingen, Germany.

OBJECTIVE: Muckle-Wells syndrome (MWS) is an inherited autoinflammatory disease characterized by fevers, rashes, arthralgia, conjunctivitis, and sensorineural hearing loss. In MWS, NLRP3 gene mutations are associated with excessive interleukin-1 release. The aims of this study were to determine the otologic characteristics of MWS, define trajectories of hearing loss, and explore the

association with distinct NLRP3 genotypes.

**METHODS:** A prospective observational cohort study of children and adults diagnosed as having MWS was conducted at a single center. NLRP3 gene mutations were determined. Patients underwent standardized clinical, laboratory, and otologic assessments, including pure tone audiometry, vestibular organ testing, and tinnitus evaluation. Trajectories of hearing loss were defined for each genotype. The genotype-specific risk of progression of hearing loss was determined.

**RESULTS:** A total of 33 patients ages 3-75 years who were members of 5 families with 4 different NLRP3 gene mutations were included. The majority of patients (67%) experienced bilateral sensorineural hearing loss. Even in cases of profound hearing loss vestibular reactivity remained normal. Fourteen adult patients reported nondebilitating tinnitus. Overall, hearing impairment progressed with age. Patients with the T348M mutation were at highest risk of rapid progression of sensorineural hearing loss.

**CONCLUSION:** Patients with MWS are at risk of developing progressive sensorineural hearing loss without vestibular involvement. Hearing impairment starts at high frequencies and can subsequently progress to profound hearing loss. Progression is age dependent. Patients with different NLRP3 mutations had distinctly different trajectories of hearing loss, suggesting a mutation-specific risk that should be considered when making treatment decisions.

The contribution of SAA1 polymorphisms to Familial Mediterranean fever susceptibility in the Japanese population.

Migita K(1), Agematsu K, Masumoto J, Ida H, Honda S, Jiuchi Y, Izumi Y, Maeda Y, Uehara R, Nakamura Y, Koga T, Kawakami A, Nakashima M, Fujieda Y, Nonaka F, Eguchi K, Furukawa H, Nakamura T, Nakamura M, Yasunami M.

**BACKGROUND/AIMS:** Familial Mediterranean Fever (FMF) has traditionally been considered to be an autosomal-recessive disease, however, it has been observed that substantial numbers of patients with FMF possess only 1 demonstrable MEFV mutation. The clinical profile of familial Mediterranean fever (FMF) may be influenced by MEFV allelic heterogeneity and other genetic and/or environmental factors.

**METHODOLOGY/PRINCIPAL FINDINGS:** In view of the inflammatory nature of FMF, we investigated whether serum amyloid A (SAA) and interleukin-1 beta (IL-1 $\beta$ ) gene polymorphisms may affect the susceptibility of Japanese patients with FMF. The genotypes of the -13C/T SNP in the 5'-flanking region of the SAA1 gene and the two SNPs within exon 3 of SAA1 (2995C/T and 3010C/T polymorphisms) were determined in 83 Japanese patients with FMF and 200 healthy controls. The same samples were genotyped for IL-1 $\beta$ -511 (C/T) and IL-1 receptor antagonist (IL-1Ra) variable number of tandem repeat (VNTR) polymorphisms. There were no significant differences between FMF patients and healthy subjects in the genotypic distribution of IL-1 $\beta$ -511 (C/T), IL-1Ra VNTR and SAA2 polymorphisms. The frequencies of SAA1.1 allele were significantly lower (21.7% versus 34.0%), and inversely the frequencies of SAA1.3 allele were higher (48.8% versus 37.5%) in FMF patients compared with healthy subjects. The frequency of -13T alleles, associated with the SAA1.3 allele in the Japanese population, was significantly higher (56.0% versus 41.0%,  $p=0.001$ ) in FMF patients compared with healthy subjects.

**CONCLUSIONS/SIGNIFICANCE:** Our data indicate that SAA1 gene polymorphisms, consisting of -13T/C SNP in the 5'-flanking region and SNPs within exon 3 (2995C/T and 3010C/T polymorphisms) of SAA1 gene, are associated with susceptibility to FMF in the Japanese population.

MEFV gene variations in patients with systemic lupus erythematosus.

Erer B(1), Cosan F, Oku B, Ustek D, Inanc M, Aral O, Gul A.

Author information:

(1)Division of Rheumatology, Department of Internal Medicine, Istanbul Faculty of Medicine, Istanbul, 34390, Turkey, burakerer@yahoo.com.

**OBJECTIVE:** The aim of this study was to investigate the frequency of familial Mediterranean fever (FMF)-associated MEFV gene variations in patients with systemic lupus erythematosus (SLE). **METHODS:** The study group comprised 190 SLE patients and 101 healthy controls of Turkish origin with no clinical features of FMF. All individuals were genotyped for the four most common MEFV gene variations (M694V, M680I, V726A and E148Q) by PCR-restriction fragment length polymorphism analysis. **RESULTS:** The frequency of carrying any of the four MEFV gene variations under study was 15 % in patients with SLE and 10 % in the healthy controls ( $p = 0.23$ ). After the exclusion of the less penetrant E148Q variation, re-analysis for the three penetrant mutations revealed a significant association between exon 10 variations and pericarditis [ $p = 0.038$ , odds ratio (OR) 3.5, 95 % confidence interval (CI) 1.0-12.1], and pleural effusion ( $p = 0.043$ , OR 5.2, 95 % CI 0.8-30.9). No significant association was detected between the MEFV gene variations and a higher acute phase response. **CONCLUSIONS:** The MEFV gene variations analyzed in our study do not seem to increase the overall susceptibility to SLE and do not have any strong association with its clinical manifestations. The possibility of a modest effect of penetrant exon 10 MEFV variants on the development of serosal effusions needs to be explored in a larger series of patients.

ettore.salsano@istituto-besta.it

Autoinflammatory diseases are rare illnesses characterized by apparently unprovoked inflammation without high-titer auto-antibodies or antigen-specific T cells. They may cause neurological manifestations, such as meningitis and hearing loss, but they are also characterized by non-neurological manifestations. In this work we studied a 30-year-old man who had a chronic disease characterized by meningitis, progressive hearing loss, persistently raised inflammatory markers and diffuse leukoencephalopathy on brain MRI. He also suffered from chronic recurrent osteomyelitis of the mandible. The hypothesis of an autoinflammatory disease prompted us to test for the presence of mutations in interleukin-1-pathway genes and to investigate the function of this pathway in the mononuclear cells obtained from the patient. Search for mutations in genes associated with interleukin-1-pathway demonstrated a novel NLRP3 (CIAS1) mutation (p.I288M) and a previously described MEFV mutation (p.R761H), but their combination was found to be non-pathogenic. On the other hand, we uncovered a selective interleukin-6 hypersecretion within the central nervous system as the likely pathogenic mechanism. This is also supported by the response to the anti-interleukin-6-receptor monoclonal antibody tocilizumab, but not to the recombinant interleukin-1-receptor antagonist anakinra. Exome sequencing failed to identify mutations in other genes known to be involved in autoinflammatory diseases. We propose that the disease described in this patient might be a prototype of a novel category of autoinflammatory diseases characterized by prominent neurological involvement.

tigdav@excite.com

In the innate immune system, cellular adaptation regulates neutrophil activation and chemotaxis, which have a pivotal role in Familial Mediterranean Fever (FMF) pathogenesis. We investigated neutrophil F-actin, phagocytosis and macropinocytosis dynamics during neutrophil chemoattractant-dependent activation in FMF patients carrying mutations in the MEFV locus. We found that while a non-stimulated neutrophil shows an increased overall F-actin content in patients with FMF, the activation-dependent F-actin dynamics in the presence of chemoattractant peptide is significantly reduced. Neither overall F-actin content nor F-actin dynamics was changed in FMF patient's neutrophils in the presence of double doses of chemoattractant, while in healthy donors it occurred with significant reduction of F-actin content and dynamics. The neutrophil shows increased phagocytosis and macropinocytosis dynamics for a relatively short period, which may contribute to the decreasing of plasticity of the cellular cytoskeleton during FMF. Colchicine causes reduction of overall F-actin content and shows a distinctively unequal effect on chemoattractant-activated neutrophil F-actin dynamics in FMF patients compared with healthy donors. These data suggested that mutations in MEFV cause the dissolution of cellular adaptation to chemoattractant stimuli due to alterations in neutrophil F-actin and phagocytosis dynamics, which could serve as a major target for FMF treatment.

Author information:

(1)Service de Néphrologie, Dermatologie et Rhumatologie Pédiatrique, HFME, Hôpital Louis Pradel, Bron, France.

We report a case of an immunocompetent child who developed parvovirus B19 infection complicated by autoinflammatory disease with myocarditis, tamponade and macrophage activation syndrome. He recovered with immunotherapy including prednisone, immunoglobulins, cyclosporin and anakinra (anti-interleukin-1). The report shows that parvovirus can provoke severe systemic inflammation with acute heart injury and that anti-interleukin-1 might be considered in such parvovirus-related inflammation.

Paraoxonase 1 and arylesterase levels in children with familial Mediterranean fever.

Kosan C(1), Cayir A, Turan MI, Ustebay S.

Author information:

(1)Ataturk University, Faculty of Medicine, Department of Pediatric Nephrology, Erzurum, Turkey.

**BACKGROUND:** The pathogenesis of Familial Mediterranean Fever (FMF) is not clearly elucidated. It emerges as a result of triggering of the several environmental factors at the people who are genetically vulnerable.

**OBJECTIVES:** To evaluate the anti-oxidant enzymes at the remission period of familial mediterranean fever (FMF).

**MATERIALS AND METHODS:** Study group is consisted of 80 patients between the age of 2 and 16 years old who are routinely followed up. The control group is consisted of 80 healthy children whose physical examination is normal, and whose demographic findings are similar to the study group. Paraoxonase 1 (PON1) and arylesterase (ARE) levels are measured at both study and control group.

**RESULTS:** The difference between the levels of ARE and PON1 are statistically significant between the FMF and control group ( $p = 0.007$ ,  $p = 0.001$ ). According to the weight scoring, ARE and PON1 levels of light cases are higher versus the levels of moderate cases ( $p < 0.01$ ).

**CONCLUSIONS:** Endogenous anti-oxidants Paraoxonase 1 and arylesterase levels are important in evaluating the inflammation at the remission period of FMF.

Identification of a homozygous PSTPIP1 mutation in a patient with a PAPA-like syndrome responding to canakinumab treatment.

Geusau A(1), Mothes-Luksch N, Nahavandi H, Pickl WF, Wise CA, Pourpak Z, Ponweiser E, Eckhart L, Sunder-Plassmann R.

Author information:

(1)Division of Immunology, Allergy, and Infectious Diseases, Department of Dermatology, Medical University of Vienna, Waehringer Guertel 18-20, 1090 Vienna, Austria. alexandra.geusau@meduniwien.ac.at

**BACKGROUND:** Pyogenic sterile arthritis, pyoderma gangrenosum, and acne (PAPA) syndrome (OMIM 604416) is a rare autosomal dominant inherited autoinflammatory syndrome characterized by pyogenic sterile arthritis and less frequently accompanied by pyoderma gangrenosum and acne. It is associated with dominant missense mutations in the proline-serine-threonine phosphatase-interacting protein 1 gene (PSTPIP1) located on chromosome 15. The patient was diagnosed as having features of a PAPA-like syndrome in which cutaneous manifestations, such as pyoderma gangrenosum and acne fulminans, predominated.

**OBSERVATIONS:** Sequencing of the PSTPIP1 gene was performed in the patient and his extended family. The patient's DNA analysis revealed a homozygous nucleotide exchange c.773G>C in the PSTPIP1 gene, leading to the substitution of glycine 258 by alanine (p.Gly258Ala), a previously reported heterozygous polymorphism. Heterozygous changes were identified in both of the patient's parents and in 7 other family members, all of whom were asymptomatic. The patient was treated with canakinumab, a human anti-interleukin 1 $\beta$  monoclonal antibody, which led to rapid remission of the symptoms.

**CONCLUSIONS:** To our knowledge, this is the first reported case of the resolution of dermatological symptoms associated with a PAPA-like syndrome using canakinumab treatment. Further study of the p.Gly258Ala variant is warranted to determine whether this mutation has a role in causing an apparently recessive cutaneous syndrome resembling PAPA syndrome.

Clinical characteristics in subjects with NLRP3 V198M diagnosed at a single UK center and a review of the literature.

Rowczenio DM, Trojer H, Russell T, Baginska A, Lane T, Stewart NM, Gillmore JD, Hawkins PN, Woo P, Mikoluc B, Lachmann HJ.

**INTRODUCTION:** Mutations in the NLRP3 gene are associated with the dominantly inherited cryopyrin-associated periodic syndrome (CAPS). The significance of the V198M variant is unclear; it has been reported in association with various CAPS phenotypes and as a variant of uncertain consequence. The aim of this study was to characterize the clinical phenotypes and treatments in individuals with V198M assessed in a single UK center.

**METHODS:** DNA samples from 830 subjects with fever syndromes or a family history of CAPS were screened for mutations in the NLRP3 gene with polymerase chain reaction (PCR) and sequencing. A detailed medical history was available in all cases. Inflammatory disease activity was monitored monthly with measurements of serum amyloid A protein (SAA) and C-reactive protein (CRP) in symptomatic individuals.

**RESULTS:** NLRP3 V198M was identified in 19 subjects. It was found in association with CAPS in five cases, in one patient with Schnitzler syndrome, in three patients who also had a nucleotide alteration in another fever gene, and in three other patients with evidence of an autoinflammatory phenotype. Seven asymptomatic individuals were detected during screening of family members.

**CONCLUSIONS:** The NLRP3 V198M variant shows variable expressivity and reduced penetrance. It may be associated with classical inherited or apparently sporadic CAPS and with atypical autoinflammatory disease of varying severity, intriguingly including Schnitzler syndrome. The factors that influence the pathogenic consequences of this variant remain unknown. However, the remarkable response to interleukin 1 (IL-1) blockade in all but one individual in our series confirms that their clinical features are indeed mediated by IL-1.

Impact of microbes on autoimmune diseases.

Danzer C(1), Mattner J.

Author information:

(1)Mikrobiologisches Institut, Klinische Mikrobiologie, Immunologie Und Hygiene, Universitätsklinikum Erlangen and Friedrich-Alexander Universität Erlangen-Nürnberg, Wasserturmstr. 3/5, 91054 Erlangen, Germany.

Autoimmune and autoinflammatory diseases arise as a consequence of complex interactions of environmental factors with genetic traits. Although specific allelic variations cluster in predisposed individuals and promote the generation and/or expansion of autoreactive T and B lymphocytes, autoimmunity appears in various disease phenotypes and localizes to diverging tissues. Furthermore, the discovery that allelic variations within genes encoding components of the innate immune system drive self-reactive immune responses as well, led to the distinction of immune responses against host tissues into autoimmune and autoinflammatory diseases. In both categories of disorders, different pathogenic mechanisms and/or subsequent orders of tissue assaults may underlie the target cell specificity of the respective autoimmune attack. Furthermore, the transition from the initial tissue assault to the development of full-blown disease is likely driven by several factors. Thus, the development of specific forms of autoimmunity and autoinflammation reflects a multi-factorial process. The delineation of the specific factors involved in the pathogenic process is hampered by the fact that certain symptoms are assembled under the umbrella of a specific disease, although they might originate from diverging pathogenic pathways. These multi-factorial triggers and pathogenic pathways may also explain the inter-individual divergent courses and outcomes of diseases among humans. Here, we will discuss the impact of different environmental factors in general and microbial pathogens in particular on the regulation/expression of genes encoded within susceptibility alleles, and its consequences on subsequent autoimmune and/or autoinflammatory tissue damage utilizing primarily the chronic

cholestatic liver disease primary biliary cirrhosis as model.

New paraneoplastic syndrome in chronic basophilic leukemia.

Cehreli C(1), Ates H, Cehreli R, Sercan Z, Demirkan F.

Author information:

(1)Division of Hematology, Dokuz Eylul University School of Medicine, Inciralti, Izmir, Turkey. cehrelcavit@gmail.com

Chronic basophilic leukemia (CBL) is an extremely rare disorder. A female patient presented with recurrent attacks of chills, fever and abdominal pain was found to have simultaneous cyclic oscillation in leukocyte counts and C-reactive protein values. She was initially diagnosed with familial Mediterranean fever and treated with colchicine. Diagnosis of CBL was established by morphologic studies of peripheral blood and bone marrow. Her febrile attacks recurred with marked elevation in serum interleukin-6 (IL-6) level when basophil counts climbed to peak levels during cyclic oscillation. Molecular studies by real-time PCR showed IL-6 gene expression in neoplastic basophils separated by magnetic-activated cell sorting infiltrating the bone marrow, suggesting that IL-6 is released by neoplastic basophils of an underlying CBL, resulting in a new paraneoplastic syndrome that mimics autoinflammatory disorders.

Fetscherstrasse 74, 01307 Dresden, Germany.  
michael.heyman@uniklinikum-dresden.de

Inflammasomes are multiprotein complexes that serve as activating platforms for the enzyme caspase-1 in response to various danger signals. Active caspase-1 can cleave the precursors of the pro-inflammatory cytokines IL-1 $\beta$  and IL-18 and thereby activate them. Deregulation of this cascade caused by mutations in genes coding for inflammasomal components and their interaction partners can lead to severe disease. This review summarizes the contribution of deregulated inflammasomes to the field of autoinflammatory syndromes. In addition, it gives insight into currently available mouse models that are used to study and characterize the role of the inflammasome components in the pathophysiology of these diseases.

Lack of an effect of CYP3A4 and MDR1 gene polymorphisms on colchicine pharmacogenetics in the treatment of Familial Mediterranean fever.

Dogruer D(1), Tug E, Bes C, Soy M.

Author information:

(1)Department of Medical Genetics, Faculty of Medicine, Abant Izzet Baysal University, Bolu, Turkey.

The P-gp/MDR1 multidrug transporter mediates detoxification of numerous drugs, including colchicine, and CYP3A4 is key to the biotransformation of colchicine.

We investigated the effects of CYP3A4 and P-gp/MDR1 polymorphisms on bioavailability of colchicine in patients with Familial Mediterranean fever (FMF). Forty-eight Turkish patients with FMF treated with colchicine were genotyped for 3435C>T, (-)1A>G, 61A>G, 1199G>A, 1236C>T, 2677G>A, 2677G>T polymorphisms in the P-gp/MDR1 gene and 3435C>T, 1B(-392A>G), 2(15713T>C), 3(23171T>C), 12(21896C>T), 17(15615T>C) polymorphisms in the CYP3A4 gene. Doses of colchicine administered to patients did not differ with respect to P-gp/MDR1 or CYP3A4 gene polymorphism. We also determined the genotype distributions of CYP3A4 and P-gp/MDR1 genes among FMF patients. There was no significant gender difference in the P-gp/MDR1 polymorphism, whereas there were significant gender differences in the frequencies of 15713T>C and 15615T>C polymorphisms in the CYP3A4 gene. No significant relationship was found between colchicine doses that would introduce optimal clinical response and affect the therapeutic dose and CYP3A4 and P-gp/MDR1 gene polymorphisms in these FMF patients.

A very rare cause of pleuritic chest pain: bilateral pleuritis as a first sign of familial mediterranean Fever.

Ozkaya S(1), Butun SE, Findik S, Atici A, Dirican A.

Author information:

(1)Department of Pulmonary Medicine, Samsun Medicalpark Hospital, Samsun, Turkey.

The familial Mediterranean fever (FMF), also called recurrent polyserositis, is characterized by recurrent episodes of serositis at pleura, peritoneum, and synovial membrane and fever. We present a patient with recurrent bilateral pleural effusion due to serositis attacks as a first sign of FMF. A 59-year-old Turkish man suffered from recurrent pleuritic chest pain due to pleural effusion and atelectasis. The etiology was not found, and his symptoms were spontaneously recovered during several weeks. The pleuritic chest pain was associated with abdominal pain in the last attack. The gene mutation analysis revealed the homozygosity of FMF (F479L) gene mutation in both our patient and his grandchild. After the colchicine treatment, the attack has not developed. In conclusion,

recurrent pleural effusion and pleuritic chest pain may be the first signs of the FMF.

Erratum in

J Korean Med Sci. 2013 Mar;28(3):493.

Familial Mediterranean fever (FMF) is an autosomal recessive disease characterized by recurrent episodes of fever accompanied by peritonitis, pleuritis, arthritis, or erysipelas-like erythema. It is known to occur mainly among Mediterranean and Middle Eastern populations such as non-Ashkenazi Jews,

Arabs, Turks, and Armenians. FMF is not familiar to clinicians beyond this area and diagnosing FMF can be challenging. We report a 22-yr old boy who presented with fever, arthralgia and abdominal pain. He had a history of recurrent episodes of fever associated with arthralgia which would subside spontaneously or by antipyretics. Autosomal recessive periodic fever syndromes were suspected. Immunoglobulin D (IgD) level in the serum was elevated and DNA analysis showed complex mutations (p.Glu148Gln, p.Pro369Ser, p.Arg408Gln) in the MEFV gene. 3D angio computed tomography showed total thrombosis of splenic vein with partial thrombosis of proximal superior mesenteric vein, main portal vein and intrahepatic both portal vein. This is a case of FMF associated with multiple venous thrombosis and elevated IgD level. When thrombosis is associated with elevated IgD, FMF should be suspected. This is the first adult case reported in Korea.

Comment in

Clin Rheumatol. 2014 Feb;33(2):291-2.

Biologic antirheumatic drugs (BIO) have been reported to be potent therapeutic agents in the prevention of inflammatory joint destruction in rheumatoid arthritis (RA). The aim of this study was to investigate the immune-inflammatory cells, including Toll-like receptor (TLR)-equipped cells, in synovial tissue

samples from RA patients on BIO compared to patients, who are only on conventional disease-modifying antirheumatic drug (DMARD). We analyzed immune-inflammatory cells in RA synovitis in patients of BIO group (n = 20) or DMARD group (n = 20). The grading scores of synovitis was 1.7 and 1.8 in each BIO and DMARD group and correlated best with the CD3(+) T ( $r = 0.71/0.70$ ,  $p < 0.05$ ) and CD20(+) B ( $r = 0.80/0.84$ ,  $p < 0.05$ ) cells in the both groups, but less well with the CD68(+) macrophages and S-100(+) dendritic cells (DCs). Interestingly, both T (116 vs. 242,  $p < 0.05$ ) and B (80 vs. 142,  $p < 0.05$ ) cell counts were lower in the BIO than in the DMARD group, whereas macrophage and DC counts did not differ. In contrast, the C-reactive protein (CRP) and disease activity score DAS28-CRP did not show clear-cut correlations with the inflammatory grade of the synovitis ( $r$  range, 0-0.35). Similar numbers of cells immunoreactive for TLR-1 to TLR-6 and TLR-9 were found in synovitis in both groups. Patients clinically responding to biologics might still have the potential of moderate/severe local joint inflammation, composed in particular of and possibly driven by the autoinflammatory TLR(+) cells.

New tricks from an old dog: mitochondrial redox signaling in cellular inflammation.

Pelletier M(1), Lepow TS, Billingham LK, Murphy MP, Siegel RM.

Author information:

(1)Immunoregulation Section, Autoimmunity Branch, National Institute of Arthritis and Musculoskeletal and Skin Diseases, National Institutes of Health, Bethesda, MD 20892, United States.

Reactive oxygen species (ROS) such as superoxide ( $O(2)(-)$ ) and hydrogen peroxide ( $H(2)O(2)$ ) have long been implicated as pro-inflammatory, yet the sources of ROS and the molecular mechanisms by which they enhance inflammation have been less clear. Recent advances in the understanding of the molecular basis of inflammation mediated by the innate immune system have allowed these issues to be

revisited. Although the Nox2 NADPH oxidases generate the bulk of ROS for antimicrobial host defense, recent studies have found that NADPH oxidase-dependent ROS production can actually dampen macrophage inflammatory responses to sterile pro-inflammatory stimuli. Instead, production of mitochondrial ROS has emerged as an important factor in both host defense and sterile inflammation. Excess mitochondrial ROS can be generated by either damage to the respiratory chain or by alterations of mitochondrial function such as those that increase membrane potential and reduce respiratory electron carriers. In autoinflammatory diseases, where key components of innate immune responses are activated by genetic mutations or environmental stimuli, inflammation has been found to be particularly sensitive to inhibition of mitochondrial ROS production. These findings have highlighted mitochondrial ROS as a novel generator of pro-inflammatory ROS and a potential therapeutic target in inflammatory diseases.

Tailoring gut immune responses with lipoteichoic acid-deficient *Lactobacillus acidophilus*.

Lightfoot YL(1), Mohamadzadeh M.

Author information:

(1)Department of Infectious Diseases and Pathology, College of Veterinary Medicine, University of Florida Gainesville, FL, USA ; Division of Gastroenterology Hepatology & Nutrition, Department of Medicine, College of Medicine, University of Florida Gainesville, FL, USA.

As highlighted by the development of intestinal autoinflammatory disorders when tolerance is lost, homeostatic interactions between gut microbiota, resident immune cells, and the gut epithelium are key in the maintenance of gastrointestinal health. Gut immune responses, whether stimulatory or regulatory, are dictated by the activated dendritic cells (DCs) that first interact with

microorganisms and their gene products to then elicit T and B cell responses. Previously, we have demonstrated that treatment with genetically modified *Lactobacillus acidophilus* is sufficient to tilt the immune balance from proinflammatory to regulatory in experimental models of colitis and colon cancer. Given the significant role of DCs in efficiently orchestrating intestinal immune responses, characterization of the signals induced within these cells by the surface layer molecules, such as lipoteichoic acid (LTA), and proteins of *L. acidophilus* is critical for future treatment and prevention of gastrointestinal diseases. Here, we discuss the potential regulatory pathways involved in the downregulation of pathogenic inflammation in the gut, and explore questions regarding the immune responses to LTA-deficient *L. acidophilus* that require future studies.

**BACKGROUND:** Familial Mediterranean Fever (FMF) is an autosomal recessive disease characterized by short lived, febrile serosae inflammatory attacks. FMF has various effects in multiple systems and organs.

**AIM:** In the present study, our aim was to evaluate adrenal steroidogenesis in female FMF patients.

**PATIENTS AND METHODS:** There were 71 women in the study including 41 women with FMF and 30 women as healthy control group (HC group). Of 41 FMF patients, twenty were evaluated in attack period (AP-FMF group) whereas 21 of them were evaluated in attack-free period (AFP-FMF group). In all subjects; serum free testosterone, 17-OHP levels as hormones, IL-1 beta, TNF-alpha, IL-6, IL-18 as proinflammatory

cytokines, CRP, fibrinogen, white blood cell (WBC) counts, and erythrocyte sedimentation rate (ESR) as acute phase reactants were measured in samples of venous blood taken in the morning before breakfast.

RESULTS: Serum 17-OHP levels in AP-FMF group and AFP-FMF group were higher than in HC group ( $p < 0.001$ ). A positive correlation was detected between serum levels of 17-OHP and IL-1 beta in FMF patients ( $p = 0.006$ ;  $r = 0.486$ ). There was no difference between FMF patients and HC group in terms of free testosterone levels ( $p > 0.05$ ).

CONCLUSIONS: Our results showed an increase in 17-OHP levels in FMF patients. These results may indicate that, regardless to the attack period adrenal steroidogenesis could be affected negatively in FMF patients.

Cystatin C in serum as an early marker of renal involvement in Familial Mediterranean Fever patients.

Deveci K(1), Gokakin AK, Senel S, Deveci H, Uslu AU, Sancakdar E.

Author information:

(1)Department of Clinical Biochemistry, School of Medicine, Cumhuriyet University, Sivas, Turkey. drkdeveci@gmail.com.tr

BACKGROUND: The major renal involvement in Familial Mediterranean Fever (FMF) is the occurrence of amyloidosis that primarily affects the kidneys manifested by proteinuria and ending in death from renal failure.

AIM: This study aims to investigate whether serum cystatin (cys-C) levels could be used as an early marker of renal involvement in FMF patients.

PATIENTS AND METHODS: Forty-six patients with FMF during the attack period (AP), and 41 patients with FMF during attack-free periods (AFP), and 11 patients with FMF associated amyloidosis, and 38 healthy controls were enrolled in the study. We determined cys-C levels in the serum of FMF patients and healthy controls.

RESULTS: Serum cys-C levels were significantly increased in patients with FMF and secondary amyloidosis, and serum cys-C is a more accurate and efficient marker for detecting renal involvement than estimated glomerular filtration rate (e-GFR)

in patients with FMF.

CONCLUSIONS: We propose a cutoff level of the serum cys-C of 876.5 pg/mL for screening renal involvement in patients with FMF, and amyloidosis should be strongly suspected when the serum cys-C reaches 1565.5 pg/mL.

The pathogenesis of neonatal autoimmune and autoinflammatory diseases: a comprehensive review.

Chang C(1).

Author information:

(1)Department of Pediatrics, Division of Allergy and Immunology, Thomas Jefferson University, Nemours/A.I. duPont Hospital for Children, Wilmington, DE 19803, USA. cchang@nemours.org

Autoimmune and autoinflammatory diseases are two distinct disease entities that can present in the neonate. Autoimmune diseases of the newborn primarily include neonatal lupus and neonatal anti-phospholipid syndrome, but other diseases have been reported as well. The pathogenic mechanisms behind autoimmune diseases of the newborns are unknown, but an association with antibodies to Ro and La is present in most cases. The extent to which these antibodies play a pathogenic role is unknown. Because the phenotype of clinical neonatal lupus is variable in many mothers who possess the antibodies, other mechanisms may be necessary to confer disease. The primary theories include apoptosis of cardiac cells, maternal microchimerism, cross-reactivity of the autoantibodies with cardiac tissue, T cell dysregulation and inhibitory receptors, and a genetic predisposition. The autoinflammatory diseases are unrelated to neonatal autoimmune diseases and include the cryopyrin-associated periodic syndromes (CAPS). These diseases include familial cold autoinflammatory syndrome (FCAS), Muckle-Wells syndrome and neonatal onset multisystem inflammatory disease (NOMID). All of these diseases share a defect in a common gene--the CIAS1 or NALP3 gene on chromosome 1. The diseases vary in severity and involvement of different physiologic systems, with

FCAS being the mildest form and NOMID being the most severe form with involvement of the neurologic and hematologic systems. Aberrant functioning of the inflammasome may play a role in the pathogenesis of autoinflammatory diseases.

Long chain fatty acid (Lcfa) abnormalities in hyper IgD syndrome (Hids) and Familial Mediterranean Fever (Fmf): new insight into heritable periodic fevers.

Simon A(1), Drenth JP, Matern D, Goetzman ES, Hager EJ, Gibson KM.

Author information:

(1)Department of General Internal Medicine, Radboud University of Nijmegen Medical Center, The Netherlands.

**OBJECTIVE:** To examine essential fatty acids (EFAs) in hyper-IgD syndrome (HIDS) and Familial Mediterranean Fever (FMF).

**METHODS:** EFAs were determined in sera derived from an archival, cross-sectional group of HIDS/FMF patients, stratified for presence and absence of fever. Control populations included healthy afebrile adults, and individuals with non-periodic fever (septic shock). EFAs were quantified using isotope dilution gas chromatography-mass spectrometry and data analyzed employing a Kruskal-Wallis non-parametric ANOVA with Dunn's post-hoc test.

**RESULTS:** Sera samples derived from HIDS patients showed significantly decreased C20, C26, phytanic and pristanic acids during febrile crises that normalized in the afebrile state, and a significantly increased afebrile C22\_4ω6 level that normalized with fever. Samples derived from FMF patients revealed increased ω-oxidized LCFAs as compared to controls, and the trend was for these same species to be increased in comparison to febrile, but not afebrile, HIDS patients. Individuals with non-periodic fever demonstrated global decreases in C10-C24 fatty acids, both saturated and unsaturated, accompanied by an elevated triene/tetraene ratio.

**CONCLUSIONS:** Our results suggest that different mechanisms are active in hereditary periodic fever syndromes that appear unrelated to fever, including depletion of very long chain fatty acids (VLCFAs) in febrile HIDS patients and increased  $\omega$ -oxidized LCFAs in patients with FMF. These findings underscore new roles for EFAs in the potential production of inflammatory species in patients with hereditary periodic fever.

Management of familial Mediterranean fever by colchicine does not normalize the altered profile of microbial long chain fatty acids in the human metabolome.

Ktsoyan ZA(1), Beloborodova NV, Sedrakyan AM, Osipov GA, Khachatryan ZA, Manukyan GP, Arakelova KA, Hovhannisyan AI, Arakelyan AA, Ghazaryan KA, Zakaryan MK, Aminov RI.

Author information:

(1)Institute of Molecular Biology, National Academy of Sciences, Yerevan, Republic of Armenia.

In our previous works we established that in an autoinflammatory condition, familial Mediterranean fever (FMF), the gut microbial diversity is specifically restructured, which also results in the altered profiles of microbial long chain fatty acids (LCFAs) present in the systemic metabolome. The mainstream management of the disease is based on oral administration of colchicine to suppress clinical signs and extend remission periods and our aim was to determine whether this therapy normalizes the microbial LCFA profiles in the metabolome as well.

Unexpectedly, the treatment does not normalize these profiles. Moreover, it results in the formation of new distinct microbial LCFA clusters, which are well separated from the corresponding values in healthy controls and FMF patients without the therapy. We hypothesize that the therapy alters the proinflammatory

network specific for the disease, with the concomitant changes in gut microbiota and the corresponding microbial LCFAs in the metabolome.

Familial Mediterranean fever occurring in an elderly Japanese woman with recent-onset rheumatoid arthritis.

Mori S(1), Yonemura K, Migita K.

Author information:

(1)Department of Rheumatology, Clinical Research Center for Rheumatic Disease, NHO Kumamoto Saishunsou National Hospital, Japan. moris@saisyunsou1.hosp.go.jp

A 60-year-old woman with a two-year history of rheumatoid arthritis (RA) developed recurrent two- to three-day attacks of fever ( $>38^{\circ}\text{C}$ ) accompanied by monoarthritis of the right hip joint. The first attack occurred two months after beginning anti-tumor necrosis factor- $\alpha$  therapy. Since a diagnosis of infectious arthritis was suspected, the therapy was discontinued. Thereafter, the patient repeated similar episodes; however, oral colchicine effectively controlled the attacks. The patient was diagnosed to have familial Mediterranean fever (FMF). The clinical manifestations of FMF mimic infectious complications during anti-RA therapy. Clinicians should therefore consider the possibility of FMF development in RA patients exhibiting recurrent febrile attacks.

Autoinflammatory bone disorders.

Morbach H(1), Hedrich CM, Beer M, Girschick HJ.

Author information:

(1)Department of Pediatrics, University of Würzburg, Würzburg, Germany.

Autoinflammatory bone disorders are characterized by chronic non-infectious osteomyelitis and inflammation-induced bone resorption and result from aberrant activation of the innate immune system. Sporadic chronic non-bacterial osteomyelitis (CNO) is the most common disease subtype. The clinical picture is highly variable and the exact underlying pathophysiology remains to be determined. Recently, novel insights in the pathophysiology of sterile bone inflammation have been gathered by analyzing patients with rare, monogenic inflammatory diseases. In this overview CNO and Majeed syndrome, cherubism, hypophosphatasia and primary hypertrophic osteoarthropathy will be discussed. For the latter four disorders, a genetic cause affecting bone metabolism and leading to chronic bone inflammation has been described. The exact pathophysiology of CNO remains to be determined. Insights from monogenic autoinflammatory bone diseases and the identification of distinct inflammatory pathways may help to understand the pathogenesis of bone inflammation and inflammation-induced bone resorption in more common diseases.

Amyloidosis is a common complication of poorly controlled familial Mediterranean

fever (FMF). A variety of organs including kidneys, heart, liver, thyroid and adrenal glands may be clinically affected. However, involvement of adrenal glands leading to significant inefficiency is rarely seen in FMF patients with amyloidosis. The impairment of neuroendocrine immune system in FMF together with proteinuria in renal amyloidosis is a challenge while interpreting adrenal function tests. Here we present a case report of a 42-year-old man with FMF and renal failure due to amyloidosis whose disease course was complicated by adrenal insufficiency.

Chronic exposure of astrocytes to interferon- $\alpha$  reveals molecular changes related to Aicardi-Goutieres syndrome.

Cuadrado E(1), Jansen MH, Anink J, De Filippis L, Vescovi AL, Watts C, Aronica E, Hol EM, Kuijpers TW.

Author information:

(1)Department of Astrocyte Biology and Neurodegeneration, Netherlands Institute for Neuroscience—an Institute of the Royal Netherlands Academy of Arts and Sciences, Amsterdam, The Netherlands. e.cuadrado@nin.knaw.nl

Aicardi-Goutières syndrome is a genetically determined infantile encephalopathy, manifesting as progressive microcephaly, psychomotor retardation, and in ~25% of patients, death in early childhood. Aicardi-Goutières syndrome is caused by mutations in any of the genes encoding TREX1, RNASEH2-A, -B, -C and SAMHD1, with protein dysfunction hypothesized to result in the accumulation of nucleic acids within the cell, thus triggering an autoinflammatory response with increased interferon- $\alpha$  production. Astrocytes have been identified as a major source of interferon- $\alpha$  production in the brains of patients with Aicardi-Goutières syndrome. Here, we study the effect of interferon- $\alpha$  treatment on astrocytes derived from immortalized human neural stem cells. Chronic interferon- $\alpha$  treatment promoted astrocyte activation and a reduction in cell proliferation. Moreover, chronic exposure resulted in an alteration of genes and proteins involved in the

stability of white matter (ATF4, eIF2B $\alpha$ , cathepsin D, cystatin F), an increase of antigen-presenting genes (human leukocyte antigen class I) and downregulation of pro-angiogenic factors and other cytokines (vascular endothelial growth factor and IL-1). Interestingly, withdrawal of interferon- $\alpha$  for 7 days barely reversed these cellular alterations, demonstrating that the interferon- $\alpha$  mediated effects persist over time. We confirmed our in vitro findings using brain samples from patients with Aicardi-Goutières syndrome. Our results support the idea of interferon- $\alpha$  as a key factor in the pathogenesis of Aicardi-Goutières syndrome relating to the observed leukodystrophy and microangiopathy. Because of the sustained interferon- $\alpha$  effect, even after withdrawal, therapeutic targets for Aicardi-Goutières syndrome, and other interferon- $\alpha$ -mediated encephalopathies, may include downstream interferon- $\alpha$  signalling cascade effectors rather than interferon- $\alpha$  alone.

Association of MEFV gene mutations with rheumatoid factor levels in patients with rheumatoid arthritis.

Inanir A(1), Yigit S, Karakus N, Tekin S, Rustemoglu A.

Author information:

(1)Department of Physical Therapy and Rehabilitation, Faculty of Medicine, Gaziosmanpasa University, Tokat, Turkey. inanira@gmail.com

**PURPOSE:** Rheumatoid arthritis (RA) is a systemic autoimmune disease primarily affecting the joints. Arthritis disorders are associated with mutations of the Mediterranean fever (MEFV) gene. This gene has already been identified as being responsible for familial Mediterranean fever. The aim of this study was to explore the frequency and clinical significance of MEFV gene mutations in a cohort of Turkish patients with RA.

**METHODS:** The study included 101 patients with RA and 110 healthy controls. Genomic DNA was isolated and genotyped using polymerase chain reaction and restriction fragment length polymorphism for the 5 MEFV gene mutations (M694V, M680I, V726A, E148Q, and P369S).

RESULTS: Carrier rates of MEFV gene mutations were 31 (30.7%) of 101 and 26 (23.6%) of 110 in the RA and healthy control groups, respectively ( $P > 0.05$ ; odds ratio, 1.4; 95% CI, 0.77-2.65). Whereas deformed joint count was relatively higher in the mutation carrier group than those of the noncarrier group, the rheumatoid factor levels were significantly higher in the carrier group of patients with RA ( $P = 0.001$ ).

CONCLUSIONS: The results of this study suggest that MEFV gene mutations are not positively associated with a predisposition to develop RA but might increase the severity of RA. Further research is needed to determine the actual pathogenic role of MEFV mutations in this disease.

Innate immune signals in autoimmune and autoinflammatory uveitis.

Rosenbaum JT(1), Kim HW.

Author information:

(1)Oregon Health & Science University, Casey Eye Institute, Portland, OR, USA.

rosenbaj@ohsu.edu

Although traditionally the adaptive immune system has been viewed as the essential contributor to autoimmune diseases, the evidence implicating the innate immune system has grown considerably in recent years. Several multisystem inflammatory diseases affect the uvea and occur as a result of a mutation in a gene coding for a component of the innate immune system. Diseases associated with uveitis such as ankylosing spondylitis, sarcoidosis, Behcet's disease and inflammatory bowel disease can best be conceptually understood by hypotheses that consider microbial infection and innate immunity as contributing factors.

Evaluation of circulating endothelial biomarkers in familial Mediterranean fever.

Pamuk BO(1), Sari I, Selcuk S, Gokce G, Kozaci DL.

Author information:

(1)Department of Internal Medicine, Bozyaka Training and Research Hospital, Izmir, Turkey.

The aim of this was to evaluate some of the vascular biomarkers and cytokines related with atherosclerosis in regularly treated and attack-free familial Mediterranean fever (FMF) patients. Forty (21 males [M] and 19 females [F], 31 [15-58] years) FMF patients and eighteen healthy controls (11 M and 7 F, 35.5 [19-46] years) with no known cardiovascular (CV) risk factors were included. All patients were receiving regular colchicine treatment, and examinations were performed during attack-free periods. Serum samples were used for the determination of high-sensitive C-reactive protein (hs-CRP), tissue factor (TF), tissue plasminogen activator (t-PA), osteoprotegerin (OPG), interleukin-6 (IL-6), IL-17, and IL-23. Plasma samples were used for the determination of asymmetric dimethylarginine (ADMA) and thrombomodulin (TM). Age, sex distribution, waist circumference, body mass index, smoking status, and serum lipids were similar between the patients and controls ( $P > 0.05$ ). The concentrations of (hs-CRP) and IL-17 were significantly higher in FMF patients compared with controls ( $P < 0.05$ ). On the other hand, IL-6 and IL-23 levels were not different between the groups ( $P > 0.05$ ). ADMA, OPG, and TM concentrations were significantly lower in the patients' group compared to those of controls ( $P < 0.05$ ). However, vWF, TF, and t-PA levels were similar between the groups ( $P > 0.05$ ). FMF patients receiving regular colchicine therapy during inactive disease state had significantly lower levels of vascular injury parameters.

High prevalence of spondyloarthritis and ankylosing spondylitis among familial Mediterranean fever patients and their first-degree relatives: further evidence

for the connection.

Akar S, Soysal O, Balci A, Solmaz D, Gerdan V, Onen F, Tunca M, Akkoc N.

**INTRODUCTION:** Familial Mediterranean fever (FMF) is an auto-inflammatory disease characterized by recurrent attacks of fever and serositis. Limited data suggest that the prevalence of sacroiliitis is increased in patients with FMF. In our present study, we assessed the prevalence of spondyloarthritis (SpA), including ankylosing spondylitis (AS), among a cohort of FMF patients and their unaffected first-degree relatives (FDRs).

**METHODS:** The current study cohort comprised a consecutive group of 201 unrelated patients with FMF and 319 FDRs ( $\geq 16$  years old). These subjects were examined according to a standard protocol.

**RESULTS:** A total of 157 FMF patients (78.1%) and 233 (73%) unaffected FDRs reported back pain. Fifteen FMF patients (7.5%) and nine unaffected FDRs fulfilled the modified New York (mNY) criteria for AS. One additional FDR with AS was identified after review of the medical records. None of the FMF patients with AS was HLA-B27 positive. The allele frequency of M694V among the FMF patients with radiographic sacroiliitis was significantly higher in comparison with those without sacroiliitis (OR 4.3). When compared with the general population, the risk ratios for SpA and AS among the FDRs of our FMF patients were 3.3 (95% CI; 2.0 to 5.5) and for AS 2.9 (95% CI; 1.3 to 6.4), respectively.

**CONCLUSIONS:** Our study suggests that a) factors other than HLA-B27 play a role in the association of FMF and SpA/AS; b) MEFV gene variations may be one of the geographic/region-specific potential pathogenetic links between these two disorders in the Turkish population.

Nucleotide-binding oligomerization domain containing 2: structure, function, and diseases.

Yao Q(1).

Author information:

(1)Department of Rheumatic and Immunologic Diseases/A50, Cleveland Clinic, 9500 Euclid Avenue, Cleveland, OH 44195, USA. yaoq@ccf.org

**OBJECTIVES:** To systematically review literature about the structure and function of nucleotide-binding oligomerization domain containing 2 (NOD2) and its disease association.

**METHODS:** The English literature was searched using keywords "NOD2" and "disease". Relevant original and review articles were reviewed.

**RESULTS:** NOD2 is an intracellular protein and shares similar molecular structure with NOD1, pyrin, and cryopyrin. There are more than 100 NOD2 gene mutations, some of which have been linked to diseases such as Crohn disease, Blau syndrome, and NOD2-associated autoinflammatory disease (NAID). The NOD2 variants located in the leucine-rich repeat (LRR) region are susceptible to Crohn disease, and the variants in the nucleotide-binding domain (NBD) and in between the NBD and LRR are associated with Blau syndrome and NAID, respectively. No disease association with the gene variants has been found in rheumatoid arthritis, systemic lupus erythematosus, ankylosing spondylitis, psoriasis/psoriatic arthritis, adult sarcoidosis, granulomatous polyangiitis, or multiple sclerosis. The potential association of the NOD2 variants with graft-versus-host-disease remains controversial. NOD2 functions mainly through RICK or RIP2 to activate p38 mitogen-activated protein kinases and NF- $\kappa$ B, resulting in inflammatory response, and enhanced autophagic activity. Biologic therapy may be beneficial for NOD2-associated diseases, and new drug development may be realized based upon the signaling pathways.

**CONCLUSIONS:** NOD2 gene mutations are associated with several diseases, and some of the mutations are of diagnostic value in Blau disease and NAID. To understand the NOD2 function, disease association, and its pathogenesis is important given the ever increasing clinical significance of NOD2.

Increased enthesopathy in patients with familial Mediterranean fever: evaluation with a new sonographic enthesitis index.

Ozkan F(1), Cetin GY, Inci MF, Bakan B, Yuksel M, Ekerbicer HC, Sayarlioglu M.

Author information:

(1)Department of Radiology, Medical Faculty, Kahramanmaras Sutcu Imam University, Kahramanmaras, Turkey. drfozkan@yahoo.com

**OBJECTIVES:** The aim of this study was to determine the frequency of enthesopathy in familial Mediterranean fever by using a newly developed sonographic method, the Madrid Sonographic Enthesitis Index (MASEI).

**METHODS:** The study included 50 consecutive patients with familial Mediterranean fever and 57 healthy sex- and age-matched control participants. Six enthesal sites (olecranon tuberosity, superior and inferior poles of the patella, tibial tuberosity, and superior and inferior poles of the calcaneus) on both lower limbs were evaluated. All sonographic findings were identified according to MASEI. Validity was analyzed by receiver operating characteristic curves.  $P < .05$  was considered significant.

**RESULTS:** Mean total enthesitis scores  $\pm$  SD were  $7.54 \pm 4.99$  for patients and  $3.63 \pm 3.03$  for controls ( $P < .001$ ). No statistically significant correlation was found between the MASEI score and familial Mediterranean fever duration or colchicine treatment duration. There was no difference between the MASEI score and the presence or absence of arthritic involvement among the patients. The area under the receiver operating characteristic curve was 0.74 (95% confidence interval, 0.649-0.839). When analyzed by sex, men with familial Mediterranean fever had significantly higher MASEI scores than women ( $P < .05$ ).

**CONCLUSIONS:** This study showed significant enthesopathy in patients with familial Mediterranean fever. The findings support the hypothesis that familial Mediterranean fever and spondyloarthropathy may have common inflammatory mechanisms and suggest that the MASEI scoring system can be incorporated into clinical protocols for studying patients with familial Mediterranean fever in daily practice.

Autoinflammatory skin disorders in inflammatory bowel diseases, pyoderma gangrenosum and Sweet's syndrome: a comprehensive review and disease classification criteria.

Marzano AV(1), Ishak RS, Saibeni S, Crosti C, Meroni PL, Cugno M.

Author information:

(1)Unità Operativa di Dermatologia, Dipartimento di Fisiopatologia Medico-Chirurgica e dei Trapianti, Fondazione IRCCS Ca' Granda, Ospedale Maggiore Policlinico, Università degli Studi di Milano, Milan, Italy.

Comment in

Am J Gastroenterol. 2015 Dec;110(12):1739-40.

Pyoderma gangrenosum (PG) and Sweet's syndrome (SS) are skin diseases usually presenting with recurrent ulcers and erythematous plaques, respectively. The accumulation of neutrophils in the skin, characteristic of these conditions, led to coin the term of neutrophilic dermatoses to define them. Recently, neutrophilic dermatoses have been included in the group of autoinflammatory diseases, which classically comprises genetically determined forms due to mutations of genes regulating the innate immune response. Both PG and SS are frequently associated with inflammatory bowel diseases (IBDs); however, IBD patients develop PG in 1-3 % of cases, whereas SS is rarer. Clinically, PG presents with deep erythematous-to-violaceous painful ulcers with well-defined borders; bullous, pustular, and vegetative variants can also occur. SS is characterized by the abrupt onset of fever, peripheral neutrophilia, tender erythematous skin lesions, and a diffuse neutrophilic dermal infiltrate. It is also known as acute febrile neutrophilic dermatosis. Treatment of PG involves a combination of wound care, topical medications, antibiotics for secondary infections, and treatment of the underlying IBD. Topical therapies include corticosteroids and the calcineurin inhibitor tacrolimus. The most frequently used systemic medications are corticosteroids and cyclosporine, in monotherapy or in combination. Dapsone, azathioprine, cyclophosphamide, methotrexate, intravenous immunoglobulins, mycophenolate mofetil, and plasmapheresis are considered second-line agents. Hyperbaric oxygen, as supportive therapy, can be added. Anti-TNF- $\alpha$  agents such as etanercept, infliximab, and adalimumab are used in refractory cases. SS is usually responsive to oral corticosteroids, and the above-mentioned immunosuppressants should be considered in resistant or highly

relapsing cases.

Enthesopathy in patients with familial Mediterranean fever: increased prevalence in M694 V variant.

Tufan A(1), Mercan R, Tezcan ME, Kaya A, Bitik B, Ozturk MA, Haznedaroglu S, Goker B.

Author information:

(1)Division of Rheumatology, Department of Internal Medicine, Faculty of Medicine, Gazi University, Ankara, Turkey. dratufan@hotmail.com

Enthesopathy is pathology of bony insertions of tendons, ligaments or joint capsules. It is a frequent finding in rheumatic diseases, like ankylosing spondylitis (AS) and Behçet's disease. Musculoskeletal complaints are common in patients with familial Mediterranean fever (FMF), and these could be a clinical manifestation of enthesopathy. Hence, we investigated the possible association between FMF and enthesopathy. Fifty-six patients with FMF and 11 patients with FMF-associated spondyloarthropathy (FMFS) were enrolled. Forty-seven healthy individuals and 36 patients with AS formed the healthy and diseased control groups. Musculoskeletal complaints were meticulously questioned, and all patients underwent a detailed physical and ultrasonographic (US) examination of the lower limbs. US scorings of enthesopathy was performed according to the Glasgow Ultrasound Enthesitis Scoring System (GUESS). Demographic data, disease characteristics, MEFV genotypes and HLA B27 results were retrieved from the medical records. Patient-reported pain and physical examination findings consistent with enthesopathy were frequent in all groups with the highest prevalence in the FMFS group. Heel was the most common region affected in all patient groups. FMF patients harboring M694 V variant had higher GUESS scores compared to patients with other variants ( $2.78 \pm 2.43$  vs.  $1.37 \pm 1.67$ ,  $p = 0.026$ ). There was no statistically significant difference in the mean  $\pm$  SD GUESS scores between healthy subjects and those FMF patients with genetic variants

other than M694 V ( $1.38 \pm 1.42$  vs.  $1.37 \pm 1.67$ ,  $p > 0.05$ ). Enthesopathy may not be a feature of general FMF population; rather, it might be specifically associated with the presence of M694 V variant. Our results further support the previous evidence regarding M694 V mutation and spondyloarthropathy association.

2488. Peptides. 2013 Apr;42:97-100. doi: 10.1016/j.peptides.2012.12.013. Epub 2013 Jan 16.

Thr21Met (T21M) but not Ser89Asn (S89N) polymorphisms of the urotensin-II (UTS-II) gene are associated with Behcet's disease (BD).

Oztuzcu S(1), Ulasli M, Pehlivan Y, Cevik MÖ, Cengiz B, Gogebakan B, Igci YZ, Okumuş S, Arslan A, Onat AM.

Author information:

(1)Department of Medical Biology, Faculty of Medicine, University of Gaziantep, Gaziantep, Turkey. serdaroztuzcu@gmail.com

Behcet's disease (BD) is multisystemic vasculitis or chronic inflammation that may lead to various autoimmune and autoinflammatory syndromes. Exact etiopathogenesis of BD has not been clarified yet. Urotensin II (UTS-II) is predominantly a vasoactive peptide and Thr21Met polymorphism in UTS-II gene was proved to be increasing in some autoimmune diseases. Considering these, our objective was to evaluate whether two UTS-II gene polymorphisms (Thr21Met and Ser89Asn) were responsible in genetic susceptibility to BD in a Turkish population. A total of 198 patients with BD and 275 healthy controls were enrolled. We analyzed the genotype and allele frequencies of two UTS-II gene polymorphisms, Thr21Met and Ser89Asn, in BD patients and in controls. We found that Thr21Met but not Ser89Asn polymorphisms of the UTS-II gene were markedly associated with the risk of developing BD ( $p < 0.0001$ ). The Met21Met genotype was less common among BD patients (6.1% in patients vs. 17.1% in controls;  $p < 0.0001$ ). There was also an increase in the 21Thr allele (54.8% in BD patients vs. 43.8% in controls) and a decrease in 21Met allele frequencies (45.2% in controls vs. 56.2% in patients) in the BD groups ( $p < 0.0044$ ). To the best of our knowledge, for the first time in the literature, our study claims that there is an association between Thr21Met, and

not between Ser89Asn polymorphisms in the UTS-II gene and BD. These results put a new player to the field of undiscovered pathogenesis of BD and hopefully provide new insights to the treatment options.

Unexplained recurrent fever: when is autoinflammation the explanation?

Kallinich T(1), Gattorno M, Grattan CE, de Koning HD, Traidl-Hoffmann C, Feist E, Krause K, Lipsker D, Navarini AA, Maurer M, Lachmann HJ, Simon A.

Author information:

(1)Autoinflammation Reference Center Charité (ARC(2)), Charité University Medicine Berlin, Berlin, Germany. [tilmann.kallinich@charite.de](mailto:tilmann.kallinich@charite.de)

Recurrent fever can be the sole or leading manifestation of a variety of diseases including malignancies, autoimmune diseases and infections. Because the differential diagnoses are manifold, no formal guidelines for the approach of patients with recurrent fever exists. The newly recognized group of autoinflammatory diseases are often accompanied by repetitive fever attacks. As these episodes are frequently associated by a variety of divergent presentations, the differentiation of other causes for febrile illnesses can be difficult. In this article, we first review disease entities, which frequently present with the symptom of recurrent fever. In a next step, we summarize their characteristic pattern of disease presentation. Finally, we analyse key features of autoinflammatory diseases, which are helpful to distinguish this group of diseases from the other causes of recurrent fever. Recognizing these symptom patterns can provide the crucial clues and, thus, lead to the initiation of targeted specific diagnostic tests and therapies.

Rare MEFV variants are not associated with risk to develop multiple sclerosis and severity of disease.

Pauwels I(1), Cosemans L, Boonen S, Dubois B, Goris A.

Author information:

(1)Department of Neurosciences, Laboratory for Neuroimmunology, Section of Experimental Neurology, KU Leuven, Belgium.

**BACKGROUND:** Recent studies suggest an association between rare variants in Mediterranean fever (MEFV), the gene underlying the auto-inflammatory disorder Familial Mediterranean Fever (FMF), the risk to develop multiple sclerosis (MS) and severity of MS.

**OBJECTIVE:** The objective of this study is to investigate these findings in a Belgian MS population and to test for association with additional clinical parameters such as treatment response.

**METHODS:** MEFV was sequenced in a cohort of MS patients (N=94) suffering from auto-inflammatory symptoms, systemic side-effects upon interferon-beta (IFN- $\beta$ ) treatment, or patients in whom glatiramer acetate was started as first choice due to severe fatigue. Five rare non-synonymous variants were detected in this cohort and subsequently genotyped in 915 MS patients and 763 healthy controls.

**RESULTS:** We observed no association between these alleles and susceptibility to MS (p-value=0.99) or disease severity (p-value=0.78). However, we did observe a correlation between carrying an MEFV variant and the development of systemic side-effects upon IFN- $\beta$  treatment (p-value=0.022).

**CONCLUSION:** In contrast to recent smaller studies, we did not find an association between carrying a rare variant in the MEFV gene and the risk to develop MS or disease severity. However, carrying rare variants in MEFV was associated with the development of severe systemic side-effects upon IFN- $\beta$  treatment.

The genetics of Henoch-Schönlein purpura: a systematic review and meta-analysis.

He X(1), Yu C, Zhao P, Ding Y, Liang X, Zhao Y, Yue X, Wu Y, Yin W.

Author information:

(1)Wuhan Children's Hospital, No. 100 Hongkong Rd, Jiangnan District, 430016  
Wuhan, People's Republic of China. hxljm07@hotmail.com

Henoch-Schönlein purpura (HSP) is the most common form of systemic vasculitis of unknown etiology. This study aimed at reviewing published studies investigating the association of genetic polymorphisms with HSP and its severity. We systematically reviewed all published data on genetic risk factors for HSP by searching MEDLINE. We also performed a meta-analysis of association studies of HLA-DRB1-01, 07, and 11, angiotensin I-converting enzyme (ACE) insertion/deletion (I/D) polymorphism. We identified 45 studies investigating polymorphisms in 39 genes in association with HSP and/or its severity. Most of these genes are involved in immunological and/or inflammatory responses or vasomotor regulation. Most results were negative. The most convincing finding is the association of HLA-DRB1 01, 07, and 11 with HSP susceptibility. The overall odds ratios (ORs) for the three loci were significant for HSP: HLA-DRB1 01 (OR = 1.805, 95 % CI 1.259-2.588,  $p = 0.0012$ ); HLA-DRB1 07 (OR = 0.671, 95 % CI 0.469-0.961,  $p = 0.058$ ); HLA-DRB1 11 (OR = 2.001, 95 % CI 1.50-2.67,  $p = 0.027$ ). Genetic regulation of endothelial function, such as polymorphisms in genes coding rennin-angiotensin system (RAS) components, endothelial nitric oxide synthases, Inter-Cellular Adhesion Molecule 1, and vascular endothelial growth factor, could also confer effect on HSP. In addition, MEFV, whose mutations cause familial Mediterranean fever, could be an important candidate gene for HSP. Further large studies are required to investigate the association between genetic polymorphisms and HSP. Alternative approaches, such as genome-wide association study, are necessary to help to identify genetic risks for HSP.

Symptoms related to tumor necrosis factor receptor 1-associated periodic syndrome, multiple sclerosis, and severe rheumatoid arthritis in patients carrying the TNF receptor superfamily 1A D12E/p.Asp41Glu mutation.

Havla J(1), Lohse P, Gerdes LA, Hohlfeld R, Kümpfel T.

Author information:

(1)Institute of Clinical Neuroimmunology and the Department of Clinical Chemistry, Ludwig-Maximilians University, Munich, Germany.

**OBJECTIVE:** Tumor necrosis factor (TNF) receptor 1-associated periodic syndrome (TRAPS) is an autoinflammatory disorder caused by autosomal dominantly inherited mutations in the TNF receptor superfamily 1A (TNFRSF1A) gene. The D12E substitution has been described only once to date, in a 4-year-old boy with fever.

**METHODS:** For DNA sequence analysis of the TNFRSF1A gene, genomic DNA was isolated, amplified by PCR, purified, and sequenced.

**RESULTS:** We describe 3 families (8 subjects) with the TNFRSF1A D12E substitution and TRAPS-related symptoms, in 4 cases associated with the autoimmune diseases multiple sclerosis and rheumatoid arthritis.

**CONCLUSION:** The clinical phenotype might be associated with the TNFRSF1A D12E mutation. There is a close pathophysiological relationship between TNF signaling and autoimmune disorders.

IL-1 $\beta$  biological treatment of familial Mediterranean fever.

Soriano A(1), Verecchia E, Afeltra A, Landolfi R, Manna R.

Author information:

(1)Periodic Fever Research Centre-National Reference Centre for FMF, Catholic University of the Sacred Heart, Rome, Italy.

Familial Mediterranean fever (FMF) is a recessive, autosomal, auto-inflammatory disorder characterised by brief, recurring, self-limited episodes of fever and serositis resulting in abdominal, chest, joint and muscular pain; it is the most common of the periodic hereditary fevers and mostly affects Mediterranean populations. Daily administration of colchicine, a tricyclic alkaloid with anti-microtubule and anti-inflammatory properties, prevents the recurrence of FMF attacks and the development of secondary (AA) amyloidosis, the major long-term complication of FMF. Colchicine is generally safe and well-tolerated; nevertheless, 5-10 % of FMF patients do not respond to conventional treatment, while another 2-5 % of patients are colchicine-intolerant because of toxicity issues, leading physicians to search for alternative therapeutic strategies. Recent new insights into the mechanisms of auto-inflammation add further proof to the efficacy of IL-1 targeting drugs in colchicine non-responder/intolerant FMF patients. A systematic study of relevant literature through PubMed/Medline was performed in order to identify publications reporting IL-1 $\beta$  biological treatment of FMF. Treatment methods, comorbidities, clinical response and side effects in literature case reports were analysed, as well as recent advances in the pathogenesis of auto-inflammation mechanisms in FMF and the causes of colchicine resistance or toxicity in common clinical practice. The paradigmatic experience of an FMF patient with severe FMF mutations (M694V/M694V) suffering from colchicine toxicity and successfully treated with anakinra is also reported. The present data show that anti-IL-1 $\beta$  biological treatment is actually a therapeutic option for FMF patients unresponsive or intolerant to colchicine or in FMF patients with concomitant vasculitis.

Autoinflammatory diseases (AIDs) and autoimmune diseases (ADs) are characterized by an aberrant chronic activation of the immune system which causes tissue inflammation and damage in genetically predisposed individuals. Pathogenetic mechanisms underlying this damage differ between these two types of diseases; in AIDs, the innate immune system is directly responsible for tissue inflammation, while in ADs it works by activating the adaptive immune system, which becomes the main effector of the inflammatory process. Despite the fact that AIDs have only been recently defined, they are older than ADs. The innate immune system is found in plants and animals, and it developed earlier than the adaptive immune system, which first appeared in jawed vertebrates. According to genetic background and clinical, serological, and radiological findings, AIDs and ADs might be considered as a single spectrum of disorders, with a wide range of manifestations. Indeed, autoinflammatory-like diseases have been reported in simple organisms such as *Drosophila melanogaster* and *Caenorhabditis elegans*. We analyzed here the main pathogenetic and clinical features of these two groups of diseases mostly dealing with their similarities and differences.

Auto-inflammatory diseases were first described more than 10 years ago as inherited disorders, characterized by recurrent flares of inflammation due to an abnormality in the innate immune system. The understanding of the underlying pathogenic mechanisms of these disorders, and especially the fact that they are mediated by IL-1 secretion by stimulated monocytes/macrophages, facilitated significant progress in patient management. IL-1 inhibitors are especially effective, and indeed, a brief and complete response to IL-1 inhibition is probably one of the best signs of auto-inflammation. Cutaneous manifestations are frequent in the monogenic auto-inflammatory syndromes, and a careful analysis of those findings reveals that they are almost always the consequence of neutrophilic skin infiltration. The neutrophilic dermatoses are, therefore, the cutaneous manifestations of those disorders. Even when the neutrophilic dermatoses occur outside the setting of genetically determined auto-inflammatory disorders, they probably also result from auto-inflammatory mechanisms. The distinction between auto-inflammation and autoimmunity is essential for the proper treatment of the patients. Auto-inflammation will almost always respond to IL-1 inhibition, while immunosuppressors will not be beneficial. The aim of the current paper is to review these two sub-groups of inflammatory diseases, focusing on their cutaneous manifestations, and highlighting the connection between these syndromes and inflammation in general.

Skin diseases have been the focus of many innovations in the last decade. These innovations are mainly in the classification of skin diseases (primarily due to the dramatic development of research into the genetics of skin diseases, but not only because of this element), a new understanding of the processes underlying various diseases, improvements in diagnosis and innovations in drug treatment. In the current issue of "Harefuah", we review some advances in the field of skin diseases discovered in recent years. We review psoriasis as a multi-system disease, describe new insights into polyarteritis nodosa, parapsoriasis, autoinflammatory syndromes, and pustular psoriasis of pregnancy (impetigo herpetiformis). We also describe the new immunotherapy for metastatic melanoma. Dermatology also has new technological developments, especially the in vivo reflected mode confocal laser microscopy. We describe in detail the use of this technique in dermatology.

Author information:

(1)Department of Otolaryngology, Cumhuriyet University Medical School, Sivas, Turkey.

Familial Mediterranean fever (FMF) is a common and well-understood hereditary periodic fever syndrome. Hereditary periodic fever syndromes include a group of

multisystem diseases characterized by recurrent fever attacks with inflammation affecting skin, joints, and some other tissues. These are FMF, tumor necrosis factor receptor, tumor necrosis factor receptor associated periodic syndrome, hyperimmunoglobulinemia D syndrome, Muckle-Wells syndrome, and familial cold urticaria. In literature, it is determined that some of these diseases cause hearing loss. In light of the foregoing, we thought that FMF patients may have the same type of subclinical hearing loss and, therefore, the hearing ability of these patients was evaluated with otoacoustic emission and high frequency audiometry tests.

Decidualization renders the endometrium transiently receptive to an implanting blastocyst although the underlying mechanisms remain incompletely understood. Here we show that human endometrial stromal cells (HESCs) rapidly release IL-33, a key regulator of innate immune responses, upon decidualization. In parallel, differentiating HESCs upregulate the IL-33 transmembrane receptor ST2L and other pro-inflammatory mediators before mounting a profound anti-inflammatory response that includes downregulation of ST2L and increased expression of the soluble decoy receptor sST2. We demonstrate that HESCs secrete factors permissive of embryo implantation in mice only during the pro-inflammatory phase of the decidual process. IL-33 knockdown in undifferentiated HESCs was sufficient to abrogate this pro-inflammatory decidual response. Further, sequential activation of the IL-33/ST2L/sST2 axis was disordered in decidualizing HESCs from women with recurrent pregnancy loss. Signals from these cultures prolonged the implantation window but also caused subsequent pregnancy failure in mice. Thus, IL-33/ST2 activation in HESCs drives an autoinflammatory response that controls the temporal expression of receptivity genes. Failure to constrain this response predisposes to miscarriage by allowing out-of-phase implantation in an unsupportive uterine environment.

Pharmacokinetics of colchicine in pediatric and adult patients with familial Mediterranean fever.

Berkun Y, Wason S, Brik R, Butbul Y, Ben-Chetrit E, Hashkes PJ, Livneh A, Ozen S, Ozdogan H, Faulkner R, Davis MW.

This study sought to determine the appropriate starting dose of colchicine in children aged 2 to 4 years with familial Mediterranean fever (FMF) based on steady-state pharmacokinetics in pediatric patients with FMF from 2 to less than 16 years and adult patients with FMF from 16 to 65 years. Outpatients received colchicine for 90 days starting with a fixed dose for 14 days (blood sampling days 14 and 15). After starting doses of colchicine (0.6 mg/day [2 to less than 4 years], 0.9 mg/day [from 4 to less than 6 years], 0.9 mg/day [from 6 to less than

12 years], 1.2 mg/day [from 12 to less than 16 years], and 1.2 mg/day [from 16 to less than 65 years]), the observed steady-state pharmacokinetic parameters were comparable across age groups, despite the higher doses of colchicine on a mg/kg/day basis in the younger age groups. An exception occurred with once-daily colchicine, whereby mean C<sub>max</sub> for colchicine was higher in patients 4 to less than 6 years (9.4 ng/mL) compared with the younger and older age groups (6.1-6.7 ng/mL). Mean AUC<sub>0-24h</sub> values in children 2 to less than 4, 6 to less than 12, and 12 to less than 16 years were similar to those in adults. However, mean AUC<sub>0-24h</sub> values in children 4 to less than 6 years were 25 percent higher than those observed in adults. The results show that the recommended starting dose for children 2-4 years and 4-6 years should be 0.6 mg/day (half the US adult dose). Children aged 6 to less than 12 years should receive 0.9 mg/day (i.e. three-quarters of the US adult dose). The safety of colchicine in children 2 to less than 4 years was comparable to that in older children and adults.

Gut microbiota and the immune system: an intimate partnership in health and disease.

Iebba V, Nicoletti M, Schippa S.

In recent years there have been increased rates of autoimmune diseases, possibly associated to altered intestinal microflora. In this brief review article, after a description of the structure and function of the gut microbiota organ and its cross-talk with the human host, we give a report on findings indicating how the host immune system responds to bacterial colonization of the gastrointestinal tract. The disturbances in the bacterial microbiota will result in the deregulation of adaptive immune cells, which may underlie autoimmune disorders. The mammalian immune system, which seems to be designed to control microorganisms, could be instead influenced by microorganisms, as suggested in recent literature. Alterations in both the structure and function of intestinal microbiota could be one of the common causative triggers of autoimmune and/or autoinflammatory disorders.

Association of missense mutations of Mediterranean fever (MEFV) gene with multiple sclerosis in Turkish population.

Yigit S(1), Karakus N, Kurt SG, Ates O.

Author information:

(1)Department of Medical Biology, Faculty of Medicine, Gaziosmanpasa University, 60100 Tokat, Turkey. yigit.serbulent@gmail.com

Genetic risk factors are known to contribute to the etiology of multiple sclerosis (MS). Patients with familial Mediterranean fever (FMF) have susceptibility to develop MS. Mediterranean fever (MEFV) gene has already been identified as being responsible for FMF. The aim of this study was to explore the frequency of missense mutations of MEFV gene in a cohort of Turkish patients with MS. The study included 100 patients with MS and 160 healthy controls. Genomic DNA was isolated and genotyped using polymerase chain reaction and restriction fragment length polymorphism analyses for the five MEFV gene mutations (M694V, M680I, V726A, E148Q, and P369S). There were statistically significant differences of the MEFV gene mutation carrier rates and allele frequencies between MS patients and healthy controls ( $p = 0.0008$ , odds ratio (OR) 2.6, 95 % confidence interval (CI) 1.47-4.77 and  $p = 0.0002$ , OR 2.6, 95 % CI 1.55-4.48, respectively). The results of this study suggest that MEFV gene mutations are positively associated with predisposition to develop MS.

Pyogenic Arthritis, Pyoderma Gangrenosum, and Acne Syndrome (PAPA syndrome) is an autoinflammatory disease caused by aberrant production of the proinflammatory cytokine interleukin-1. Mutations in the gene encoding proline serine threonine phosphatase-interacting protein-1 (PSTPIP1) have been linked to PAPA syndrome. PSTPIP1 is an adaptor protein that interacts with PYRIN, the protein encoded by the Mediterranean Fever (MEFV) gene whose mutations cause Familial Mediterranean Fever (FMF). However, the pathophysiological function of PSTPIP1 remains to be elucidated. We have generated mouse strains that either are PSTPIP1 deficient or ectopically express mutant PSTPIP1. Results from analyzing these mice suggested that PSTPIP1 is not an essential regulator of the Nlrp3, Aim2, or Nlrp4 inflammasomes. Although common features of human PAPA syndrome such as pyogenic arthritis and skin inflammation were not recapitulated in the mouse model, ectopic expression of the mutant but not the wild type PSTPIP1 in mice lead to partial embryonic lethality, growth retardation, and elevated level of circulating proinflammatory cytokines.

Fever is one of the critical symptoms of patients in pediatrics field. It indicates inflammatory focus somewhere in the body, and the major causes of fever are infectious diseases. Recent progresses of our knowledge about autoinflammatory syndrome promoted the investigation of the mechanism of fever, and suggested that the pro-inflammatory cytokines are the direct causative agents of fever. The basic science revealed that cooperation of IL-6 and IL-1 $\beta$  induces febrile response. Fever of unknown origin (FUO) remains a challenging problem. Rheumatic diseases, rare infectious diseases, and benign tumors and malignancies are diagnoses to be differentiated. FDG-PET is recently proved a valuable tool for the identification of the etiology in patients with FUO. Since the introduction of biological response modifiers into the treatment of patients with pediatric rheumatic diseases has shifted the therapeutic paradigm, a new concept that the blockade of a unique pro-inflammatory cytokine brings cessation of whole inflammatory responses affected tremendously the clinical medicine. A more investigation of inflammation and its pathophysiology will be needed in pediatric rheumatology.

[Familial Mediterranean fever with pulmonary manifestations alone; early diagnosis with genetic analysis].

[Article in Turkish]

Sever F(1), Sever M, Sanal S, Yalçın M, Berdeli A.

Author information:

(1)Department of Chest Diseases, Faculty of Medicine, Sifa University, Izmir, Turkey. fidanyildiz@yahoo.com

Painful pleural effusion and fever are the only presenting clinical features in 5-10% of patients with familial Mediterranean fever (FMF). We report the results of genetic analysis that have confirmed the diagnosis of FMF in six patients who presented with fever and pleuritic pain alone. At time of presentation, all six patients received antibiotic treatment for suspected infectious etiology following routine laboratory and microbiologic evaluation. Gene analysis was performed when other diagnostic studies had failed to uncover the etiology and patients did not respond to conventional treatment. Mutation analysis for MEFV gene performed from genomic DNA by the direct DNA sequence method. Half of the patients were male. Five were older than 50, one was 33 years old. All of the patients had fever and pleuritic pain; none had the typical abdominal symptoms. Erythrocyte sedimentation rates and C-reactive protein levels were high. Pericardial effusion was discovered in three patients. Genetic analysis confirmed; R202Q/R202R, E148V/E148E, R314R, E474E, Q476Q, D510D, E148Q/E148E heterozygote polymorphisms with and M694V/M694V mutations were determined on the MEFV gene. In five patients an improvement has been observed with colchicine therapy. In one patient steroid treatment was needed because of no response to colchicine and clinical deterioration. Rapid improvement was observed in this case with steroid therapy. But after cessation of steroid therapy new flare developed that responded to new colchicine therapy. In patients who present with pleuritic chest pain and fever without an identifiable etiology, genetic analysis help making the diagnosis of FMF, especially in certain ethnic populations where FMF is relevant. This should help patients receive specific treatment without unnecessary delay. Thus, by making early diagnosis and timely delivery of treatment, disease progression is delayed and development of secondary amyloidosis avoided.

Nonalcoholic fatty liver disease and familial Mediterranean fever: are they related?

Sarkis C(1), Caglar E, Ugurlu S, Cetinkaya E, Tekin N, Arslan M, Ozdemir S, Tuncer M.

Author information:

(1)Division of Gastroenterology, Department of Medicine, Balikesir University School of Medicine, Balikesir,Turkey.

**INTRODUCTION:** Familial Mediterranean fever (FMF) is a periodic febrile disease characterized by acute recurrent episodes of serositis. Liver disease is not considered a part of the spectrum of clinical manifestations of FMF.

**OBJECTIVE:** The purpose of this study was to characterize the nonalcoholic fatty liver disease (NAFLD) that could be associated with familial Mediterranean fever (FMF).

**METHODS:** Clinical findings and treatment information of the patients with FMF were obtained from outpatient files. Weight, height, hip and waist circumference, blood pressure, blood C-reactive protein (CRP), erythrocyte sedimentation rate (ESR), fibrinogen, glucose, low-density lipoprotein (LDL), high-density lipoprotein (HDL), triglycerides (TG), creatinine, alanine aminotransferase (ALT), and insulin levels were determined in all subjects, and additionally liver ultrasonography was performed for signs of hepatosteatosi.

**RESULTS:** Fifty-two age and gender matched patients with FMF, and 30 healthy controls were included in the study. The prevalence of metabolic syndrome in the patient group was determined to be significantly higher in the patient group compared to the healthy group. When FMF patients with and without hepatosteatosi were compared, the prevalence of metabolic syndrome was determined to be 6 vs. 3, respectively ( $p < 0.001$ ). Eleven patients with FMF were found to have grade 1-2 hepatosteatosi, and only 6 of healthy subjects had grade 1 hepatosteatosi ( $p = 0.901$ ).

**CONCLUSION:** When compared with healthy controls, we found the prevalence of NAFLD was not increased in patients with FMF.

[Therapeutic antibody: new opportunity for immunity and inflammatory diseases].

[Article in Chinese]

Sun W(1), Lin H, Hua F, Hu ZW.

Author information:

(1)Institute of Materia Medica, Chinese Academy of Medical Sciences & Peking Union Medical College, Beijing, China.

With the development of therapeutic antibodies over the past decade, they have become the treatment options for immunity and inflammation diseases. Major limitations of mouse antibodies as therapeutic agents - immunogenicity, lack of effectors' functions and short serum half-life -- were subsequently identified and largely overcome by the advent of humanized and fully human antibody technologies. The therapeutic antibodies for immunity and inflammatory diseases are primarily utilized in the treatment of allograft rejection, autoimmune disease, autoinflammatory syndromes, allergies and other chronic inflammation. The action mechanisms of therapeutic antibody include blocking ligands or receptors, regulating receptor activity, clearing the target cells or activating receptor. Strategies for generating the antibody drugs with high efficacy and low side effects can be realized by modulation of Fc-mediated activities and optimization of antigen-binding domains.

Although colchicine, a natural product, is one of the oldest drugs still currently available, its possible functions seem to be surprisingly not well-known. Beyond its present medicinal use (gout, familial Mediterranean fever, Behcet's disease, chondrocalcinosis and other crystal arthritis), numerous other conditions have been recently proposed for the use of this drug, including pericardial diseases. However, colchicine appears as a double-edged sword, with

underestimated toxicity and frequent side effects. In this review, we present the main pharmacologic features of this drug, with an emphasis on toxicity and highlight its possible applications in the cardiovascular field.

Author information:

(1)Department of Pediatrics, Elisabeth-Hospital Essen, Germany.

Kathi.Wasserscheid@gmx.de

**BACKGROUND:** Colchicine is used as an anti-inflammatory drug in the treatment of gout, familial Mediterranean fever, and Behçet disease. However, because of its potent inhibition of mitosis, adverse effects and symptoms of intoxication are frequent. Clinical manifestations of colchicine intoxication include abdominal cramps, diarrhea, and multiorgan failure including cardiovascular collapse with fatal outcome.

**OBJECTIVE:** We report here the case of a 14-year-old girl who ingested 12.5 mg (0.23 mg/kg body weight) colchicine in a suicide attempt.

**CASE REPORT:** Major complaints of this fully conscious patient at the time of presentation ~2 hours after ingestion of colchicine were nausea and impaired vision. Apart from a colchicine serum concentration of 16.2 ng/mL, no abnormalities were seen in the physical examination and blood tests.

Gastrointestinal decontamination by activated charcoal, repeated administrations of sodium sulfate (Glauber salt) and substitution of volume and electrolytes led to complete recovery.

AA amyloidosis complicating the hereditary periodic fever syndromes.

Lane T(1), Loeffler JM, Rowczenio DM, Gilbertson JA, Bybee A, Russell TL, Gillmore JD, Wechalekar AD, Hawkins PN, Lachmann HJ.

Author information:

(1)National Amyloidosis Centre, University College London Medical School, Royal Free Campus, Rowland Hill Street, London NW3 2PF, UK.

**OBJECTIVE:** AA amyloidosis is a life-threatening complication of the hereditary periodic fever syndromes (HPFS), which are otherwise often compatible with normal life expectancy. This study was undertaken to determine the characteristics, presentation, natural history, and response to treatment in 46 patients who had been referred for evaluation at the UK National Amyloidosis Centre.

**METHODS:** Disease activity was monitored by serial measurement of serum amyloid A. Renal function was assessed by measurement of serum creatinine and albumin levels, the estimated glomerular filtration rate, and proteinuria from 24-hour urine collections. The amyloid load was measured by serum amyloid P scintigraphy.

**RESULTS:** Twenty-four patients had familial Mediterranean fever, 12 patients had tumor necrosis factor receptor-associated periodic syndrome, 6 patients had cryopyrin-associated periodic syndromes, and 4 patients had mevalonate kinase deficiency. The median age at onset of HPFS was 5 years; median age at presentation with AA amyloidosis was 38 years. Diagnosis of an HPFS had not been considered prior to presentation with AA amyloidosis in 23 patients (50%). Eleven patients (24%) had end-stage renal failure (ESRF) at presentation; of these, 3 had received transplants prior to referral. A further 13 patients developed ESRF over the followup period, with 10 undergoing renal transplantation. The median time to progression to ESRF from onset of AA amyloidosis was 3.3 years (interquartile range [IQR] 2-8), with a median time to transplant of 4 years (IQR 3-6). Eleven patients (24%) died. The median survival in the entire cohort was 19 years from diagnosis of AA amyloidosis. Of the 37 patients who were treated successfully, or in whom at least partial suppression of the underlying HPFS was achieved, 17 (46%) showed amyloid regression, 14 (38%) showed a stable amyloid load, and 2 (5%) showed increased amyloid deposition over the followup period.

**CONCLUSION:** AA amyloidosis remains a challenging and serious late complication of HPFS; however, outcomes are excellent when HPFS is diagnosed early enough to allow effective treatment, thus preventing or retarding further amyloid

deposition and organ damage.

The angiotensin-converting enzyme gene insertion/deletion polymorphism in Indian patients with vitiligo: a case-control study and meta-analysis.

Patwardhan M(1), Pradhan V, Taylor LH, Thakkar V, Kharkar V, Khopkar U, Ghosh K, Gawkrödger DJ, Teare MD, Weetman AP, Kemp EH.

Author information:

(1)Department of Clinical and Experimental Immunology, National Institute of Immunohaematology, Indian Council of Medical Research, Mumbai 400012, India.

**BACKGROUND:** Vitiligo is a common, acquired, idiopathic depigmenting skin disorder. Although the exact pathogenesis remains unknown, genetic susceptibility and autoimmune responses play a role in vitiligo development. Previous studies have suggested that the D allele of the insertion/deletion (I/D) polymorphism of the angiotensin-converting enzyme (ACE) gene is associated with vitiligo in Indians and Koreans. Furthermore, significantly higher serum ACE levels have been demonstrated in patients with some autoimmune and autoinflammatory disorders.

**OBJECTIVES:** The objectives were to investigate any association between the ACE I/D polymorphism and vitiligo susceptibility in an Indian population, and to compare serum ACE levels in patients with vitiligo and healthy subjects.

**METHODS:** The ACE I/D genotypes of 79 patients with vitiligo and 100 normal individuals were determined by polymerase chain reaction amplification. A meta-analysis was done to compare the distribution of the ACE I/D alleles and genotypes in the current and three previous studies. Serum ACE levels were evaluated by enzyme-linked immunosorbent assay.

**RESULTS:** A significant increase in the frequency of the ACE I/D D allele was evident in patients with vitiligo in both the case-control study [ $P=0.005$ ; odds ratio (OR) 1.87; 95% confidence intervals (CI) 1.22-2.85] and the meta-analysis ( $P=0.044$ ; OR 1.44; 95% CI 1.01-2.06). Serum ACE levels were significantly

increased in patients with vitiligo compared with healthy subjects ( $P<0.0001$ ).

**CONCLUSIONS:** In agreement with earlier reports, the ACE I/D D allele is associated with vitiligo susceptibility in the Indian population. The significantly elevated serum ACE levels in our cohort of patients with vitiligo concur with those previously found in patients with some other autoimmune diseases.

**OBJECTIVE:** Colchicine is the mainstay treatment for Familial Mediterranean Fever (FMF). However 5% to 10% of the patients with FMF are unresponsive or intolerant to colchicine. Biologics are efficient in many rheumatic diseases, including rheumatoid arthritis, ankylosing spondylitis, psoriatic arthritis, cryopyrin-associated periodic syndromes. We performed a systematic review to analyze patients with FMF, including juvenile patients who received treatment with biologics.

**METHODS:** A MEDLINE search, including articles published in English language between 1990 and May 2012, was performed. Patients who had Mediterranean fever variants but could not be classified as FMF according to Tel-Hashomer criteria were excluded.

**RESULTS:** There is no controlled trial on the efficacy and safety of biologics in FMF. Fifty-nine (32 female and 27 male) patients with FMF who had been treated with biologics (infliximab, etanercept, adalimumab, anakinra, and canakinumab) were reported in 24 single reports and 7 case series. There were 16 children and

43 adults (7- to 68-year olds). Five patients were reported to have colchicine intolerance or had adverse events related to colchicine use, and the rest 54 were unresponsive to colchicine treatment.

**CONCLUSIONS:** The current data are limited to case reports, and it is difficult to obtain a quantitative evaluation of response to biologic treatments. However, on the basis of reported cases, biologic agents seem to be an alternative treatment for patients with FMF who are unresponsive or intolerant to colchicine therapy and seem to be safe. Controlled studies are needed to better evaluate the safety and efficacy of biologics in the treatment of patients with FMF.

P-wave duration and dispersion in children with uncomplicated familial Mediterranean fever.

Arslan D(1), Oran B, Yazılıtaş F, Peru H, Cimen D, Vatansev H.

Author information:

(1)Department of Pediatric Cardiology, Selcuk University Faculty of Medicine, 42080, Konya, Turkey, aminederya@hotmail.com.

**OBJECTIVES:** This was a prospective controlled study to determine the P-wave duration (Pdu) and P-wave dispersion (Pd) in patients with familial Mediterranean fever (FMF).

**METHODS:** The study group consisted of 26 children with uncomplicated FMF and 25 age- and sex-matched healthy controls. We performed electrocardiography (ECG) with Doppler echocardiography on patients and controls. All participants underwent 12-lead electrocardiography under strict standards. Pdu and Pd were computed from a randomly selected beat and from an averaged beat constructed from 12 beats, included in a 10-s ECG.

**RESULTS:** The left ventricle (LV) dimensions, LV ejection fraction (LVEF), and LV fractional shortening (LVFS) values, left atrium dimension, and aortic dimension were in normal range in both groups. There were significant differences between the groups regarding LV-isovolumic relaxation time (IRT), LV-isovolumic

contraction time (ICT), right ventricle (RV)-ICT, RV-IRT, and Pd (all  $p < 0.0001$ ). However, highly significant positive correlation was detected between LV-ICT, LV-IRT, RV-ICT, RV-IVT, C-reactive protein (CRP), and Pd ( $r = 0.505$ ,  $p < 0.0001$ ;  $r = 0.483$ ,  $p < 0.0001$ ;  $r = 0.433$ ,  $p = 0.001$ ;  $r = 0.421$ ,  $p = 0.001$ ;  $r = 0.452$ ,  $p = 0.001$ ;  $r = 0.478$ ,  $p < 0.0001$ , respectively).

**CONCLUSIONS:** Uncomplicated FMF children who are continuously treated with colchicine and do not develop amyloidosis have abnormal atrial dispersion and therefore seemingly have an increased electrocardiographic risk of atrial fibrillation.

arnd.giese@rub.de

We assessed quality of life (QOL) and disease activity in patients with Familial Mediterranean fever (FMF) of Turkish ancestry living in Germany or Turkey and conducted a correlation with FMF disease activity. 40 FMF patients in Turkey (TR), 40 FMF patients in Germany (G) and 40 healthy controls in Germany (C) were included. QOL was evaluated with the short form of the World Health Organisation Quality of Life scale (WHOQOL-BREF). FMF disease activity was examined with the Pras score. Mean age was TR  $30.5 \pm 10.6$ , G  $35.2 \pm 10.2$ , C  $34.6 \pm 10.7$ . Of the 120 participants, 77 were female. FMF patients in TR and G had a significantly decreased QOL physical health domain compared to controls (TR  $59.7 \pm 18.8$ , G  $60.4 \pm 19.4$ , C  $76.5 \pm 14.6$ ). Turkish FMF patients had a lower QOL environment domain compared to controls (TR  $62.3 \pm 17.5$ , G  $69.7 \pm 16.5$ , C  $72.3 \pm 13.5$ ). In the other

QOL domains, no significant differences were found. The differences in QOL were robust to a regression analysis. No significant correlation between QOL and FMF disease activity was found. German FMF patients had longer duration of disease, younger age at onset and longer delay from disease onset to colchicine treatment. A total of 5 of 40 German FMF patients were not taking colchicine (TR:0). Erythrocyte sedimentation rate was lowest in TR with significant difference between TR and G as well as G and C (TR  $13.2 \pm 10.3$ , G  $27.8 \pm 19.4$ , C  $16.3 \pm 12.8$  mm/h). C-reactive protein did not differ between TR and G. FMF has an important impact on QOL physical health domain. No correlation between FMF disease activity and the WHOQOL-BREF could be found.

FAPA syndrome (periodic fever, aphthous stomatitis, pharyngitis and adenitis) is a relatively new entity described in pediatric patients. In adults, reports of FAPA are limited to rare case reports. The differential diagnosis of FAPA in adults includes Behcet's syndrome, familial Mediterranean fever (FMF), Hyper IgD syndrome and juvenile rheumatoid arthritis (JRA), i.e., adult Still's disease. With FAPA syndrome, between episodes patients are completely asymptomatic and serologic inflammatory markers such as erythrocyte sedimentation rate (ESR),

C-reactive protein (CRP) and white blood cell (WBC) count are normal. The etiology of FAFA is unknown, but lack of secondary cases or clustering in close contacts, lack of seasonality, and the lack of progression for years argue against an infectious etiology. We describe an extremely rare case of an adult with a recurrent FUO with profuse night sweats and prominent chills due to FAPA syndrome.

The SAPHO syndrome and genetics - discoveries in need of replication.

Wollheim FA(1).

Author information:

(1)Department of Rheumatology, University of Lund, S-22185, Sweden.

frank.wollheim@med.lu.se.

SAPHO and its relative CMRO are uncommon but not rare chronic conditions with unknown etiology. Environmental factors, perhaps related to microorganisms, may be important triggers, but there is no support for a septic nature. The monogenic animal models called cmo and Lupo with autosomal recessive transmission have not been replicated in human disease. Interesting but unconfirmed studies indicate impaired p53 formation, increased IL-10 production and decreased capacity to mount ROS responses in different patients with SAPHO. There is more evidence supporting an autoinflammatory than an autoimmune pathogenesis of SAPHO. Susceptibility genes on chromosomes 1 and 18 need to be confirmed. More studies in larger numbers of patients are needed to confirm the often anecdotal observations reviewed here. It is hoped that this review may stimulate such work.

Uncontrolled inflammation is a feature of autoimmune diseases and autoinflammatory syndromes and may promote tumorigenesis. Thus, identifying molecules that regulate the signaling pathways triggering, mediating, and suppressing inflammation could be helpful in developing new therapeutic approaches for these debilitating diseases. In this review, we present new information on three molecules with important roles in controlling inflammation: MALT1, Ariadne-2, and acetylcholine. We summarize our current state of knowledge of how these molecules function, and how they are involved in pathways of NF- $\kappa$ B activation or vagal nerve stimulation associated with inflammation.

The role of inflammasome-derived IL-1 in driving IL-17 responses.

Mills KH(1), Dungan LS, Jones SA, Harris J.

Author information:

(1)Trinity Biomedical Sciences Institute, Trinity College Dublin, Dublin 2, Ireland. kingston.mills@tcd.ie

NLRs are members of the PRR family that sense microbial pathogens and mediate

host innate immune responses to infection. Certain NLRs can assemble into a multiprotein complex called the inflammasome, which activates caspase-1 required for the cleavage of immature forms of IL-1 $\beta$  and IL-18 into active, mature cytokines. The inflammasome is activated by conserved, exogenous molecules from microbes and nonmicrobial molecules, such as asbestos, alum, or silica, as well as by endogenous danger signals, such as ATP, amyloid- $\beta$ , and sodium urate crystals. Activation of the inflammasome is a critical event triggering IL-1-driven inflammation and is central to the pathology of autoinflammatory diseases, such as gout and MWS. Recent studies have also shown IL-1 or IL-18, in synergy with IL-23, can promote IL-17-production from Th17 cells and  $\gamma\delta$  T cells, and this process can be regulated by autophagy. IL-1-driven IL-17 production plays a critical role in host protective immunity to infection with fungi, bacteria, and certain viruses. However, Th17 cells and IL-17-secreting  $\gamma\delta$  T cells, activated by inflammasome-derived IL-1 or IL-18, have major pathogenic roles in many autoimmune diseases. Consequently, inflammasomes are now major drug targets for many autoimmune and chronic inflammatory diseases, as well as autoinflammatory diseases.

Adult onset Still's disease (ASD) is a systemic inflammatory disorder of unknown etiology. ASD is characterized by fever with unknown etiology, rash, arthritis, and involvement of several organ systems. FMF and TRAPS are two important autoinflammatory diseases which characterized with recurrent inflammatory

attacks. We aimed in this study to investigate the MEFV gene and TNFRSF1A gene variations in ASD. Twenty consecutive Turkish ASD patients (14 female and 6 male; mean age  $38.45 \pm 14$ ; mean disease duration  $3.3 \pm 2.3$ ; mean age of the disease onset  $35.1 \pm 14.4$ ) and 103 healthy controls of Turkish origin were analyzed. All ASD patients were genotyped for the 4 MEFV mutations (M694V, E148Q, V726A, M680I) and TNFRSF1A gene exon 2-3 and exon 4-5 by using sequence analysis. The healthy controls are genotyped using PCR-RFLP method for intron 4 variation. The results of MEFV gene mutations screening show an increase in the MEFV mutation rate in ASD group, but it was not significantly different ( $p = 0.442$ , OR 1.64, 95 % CI 0.409-6.589). T-C polymorphism (rs1800692) was the only variation in the intron 4 of TNFRSF1A gene that we observed at the ASD patients. The frequency of TT genotype was 15 %, TC: 45 %, and CC: 40 % in ASD patients and the frequencies were 22, 41, and 37 % in healthy controls, respectively. When we analyzed the allele difference between both groups, there was no difference ( $p = 0.54$ , OR 1.24, 0.619-2.496-2.654). The variations in MEFV may have role in ASD pathogenesis. Our findings suggest that there is no significant association between ASD and TNFRSF1A variations.

Phagocyte-derived S100 proteins in autoinflammation: putative role in pathogenesis and usefulness as biomarkers.

Kessel C(1), Holzinger D, Foell D.

Author information:

(1)Department of Pediatric Rheumatology and Immunology, University Children's Hospital, University of Muenster, Germany.

The cytoplasmic S100 proteins derived from cells of myeloid origin are promising new markers of (auto-)inflammation. S100A8/A9 and S100A12 are released from monocytes and granulocytes during activation of the innate immune system. Tissue and serum concentrations correlate to disease activity, both during local and systemic inflammation. In autoinflammatory diseases such as Familial

Mediterranean Fever (FMF) and Systemic onset Juvenile Idiopathic Arthritis (SJIA), a dysregulation of alternative secretory pathways may be involved in pathogenesis and lead to hypersecretion of S100 proteins. Since autoinflammatory diseases can be difficult to diagnose, phagocyte-derived S100 proteins are valid tools in the diagnosis of autoinflammatory diseases. In addition, they may help achieve a better understanding of the pathophysiology of autoinflammatory disorders including SJIA and FMF, and even provide novel therapeutic targets in the future.

Chronic recurrent multifocal osteomyelitis (CRMO): a longitudinal case series review.

Falip C(1), Alison M, Boutry N, Job-Deslandre C, Cotten A, Azoulay R, Adamsbaum C.

Author information:

(1)AP-HP, Pediatric Imaging Department, St. Vincent de Paul Hospital, Paris, France.

**BACKGROUND:** Chronic recurrent multifocal osteomyelitis (CRMO) is an autoinflammatory disorder that is currently diagnosed based on clinical, radiologic, pathological and longitudinal findings.

**OBJECTIVE:** To provide detailed descriptions of CRMO lesion patterns seen on radiographs and MRI and to suggest clinical use of whole-body MRI and propose noninvasive diagnostic strategy.

**MATERIALS AND METHODS:** Retrospective longitudinal study (1989-2010) of 31 children (22 girls, 9 boys) diagnosed with CRMO. Imaging data were evaluated by two pediatric radiologists.

**RESULTS:** Mean age at diagnosis was 11 years (3-17). A total of 108 lesions were investigated. The most common sites were the long bone metaphyses (56 lesions in

24 children) especially femoral and tibial (20/24); pelvis (10/31); spine (9/31); clavicle (6/31) and mandible (3/31). In long bones, the radiologic appearance was normal (22/56), mixed lytic and sclerotic (20/56), sclerotic (8/56) or lytic (6/56) often juxtaphyseal (36/56), with hyperostosis or periosteal thickening (10/56). Vertebral involvement was often multifocal (6/9). Medullary edema was seen on MRI (42) with epiphyseal (23/42) or soft-tissue (22/42) inflammation and juxtaphyseal nodule-like appearance (7/42). Whole-body MRI (15/31) was key in detecting subclinical lesions.

CONCLUSION: CRMO is a polymorphous disorder in which whole-body MRI is extremely useful for showing subclinical edema. Vertebral collapse requires long-term monitoring.

Recurrent fevers.

Isaacs D(1), Kesson A, Lester-Smith D, Chaitow J.

Author information:

(1)The Children's Hospital at Westmead, Westmead, New South Wales, Australia.  
david@chw.edu.au

An 11-year-old girl had four episodes of fever in a year, lasting 7-10 days and associated with headache and neck stiffness. She had a long history of recurrent urticaria, usually preceding the fevers. There was also a history of vague pains in her knees and in the small joints of her hands. Her serum C-reactive protein was moderately raised at 41 g/L (normal <8). Her rheumatologist felt the association of recurrent fevers that lasted 7 or more days with headaches, arthralgia and recurrent urticaria suggested one of the periodic fever syndromes. Genetic testing confirmed she had a gene mutation consistent with one of tumour necrosis factor receptor-associated periodic syndrome.

Author information:

(1)Department of Pediatric Sciences, Università Cattolica Sacro Cuore, Largo A. Gemelli, 8, 00168, Rome, Italy, a.stabile@rm.unicatt.it.

Comment in

*Rheumatol Int*. 2014 Mar;34(3):423-4.

In selected cases, childhood's recurrent fevers of unknown origin can be referred to systemic autoinflammatory diseases as mevalonate kinase deficiency (MKD), caused by mutations in the mevalonate kinase gene (MVK), previously named "hyper-IgD syndrome" due to its characteristic increase in serum IgD level. There is no clear evidence for studying MVK genotype in these patients. From a cohort of 305 children evaluated for recurrent fevers in our outpatient clinic during the decade 2001-2011, we have retrospectively selected 10 unrelated Italian children displaying febrile episodes, associated with recurrent inflammatory

signs (variably involving gastrointestinal tube, joints, lymph nodes, and skin) and persistently increased serum IgD levels. All these patients were examined for MVK genotype: only 2 presented bonafide MVK mutations, 5 showed the same S52N MVK polymorphism, while the remaining 3 had a wild-type MVK sequence. Clinical details of these patients have been reviewed through the critical analysis of their medical charts. Our report underscores the pitfalls of MKD diagnosis based on clinical grounds and IgD levels, emphasizing the uncertain contribution of MVK polymorphisms in the diagnostic assessment of the syndrome.

Association of the toll-like receptor 9 gene polymorphisms with Behcet's disease in a Japanese population.

Sakamoto N(1), Sekine H, Kobayashi H, Sato Y, Ohira H.

Author information:

(1)Department of Gastroenterology and Rheumatology, Fukushima Medical University School of Medicine.

Bacterial infection (i.e., *Streptococcus sanguinis*) has been suggested to be related to pathogenesis and/or symptom of Behcet's disease (BD). Toll-like receptor 9 (TLR9) plays an important role in both the innate and adaptive immune systems by recognizing a component of bacterial DNA (i.e., CpG-DNA). Previous studies have demonstrated that single nucleotide polymorphisms (SNPs) in TLR9 were associated with infectious and autoimmune/autoinflammatory diseases. In this study, we detected five SNPs with BD patients in a Japanese population. Allele frequency analysis of the three common SNPs (-1486: T/C (promoter region), 1174: A/G (intron 1), 2848: G/A (exon 2; Pro545Pro)) showed no statistically significant difference between the BD patients and the healthy controls. However, genotyping analysis revealed that the homozygous genotypes -1486CC and 1174GG were significantly more frequent in the BD patients compared to the healthy controls ( $P = 0.048$  and  $P = 0.027$ , respectively). The homozygous diplotype distribution C-G-A/C-G-A was significantly more frequent in the BD patients compared to the healthy controls ( $P = 0.041$ ). For reporter gene assay, the

plasmid construct carrying diplotype distribution C-G/C-G of the -1486T/C and 1174A/G SNPs showed significantly higher luciferase activity compared to the plasmid construct carrying diplotype distribution T-A/T-A ( $P = 0.019$ ). These results suggested an association of the homozygous genotypes and homozygous diplotype configuration of the TLR9 SNPs with susceptibility to BD in the Japanese population.

2527. Amyloid. 2013 Mar;20(1):56-7. doi: 10.3109/13506129.2012.746655. Epub 2012 Dec 14.

How nature preserves fetuses.

Adami F, Fedrigo M, Gervasi MT, Verga L, Coccato M, Lessi F, Angelini A, Daliento L.

We report on a young pregnant woman developing distal leg edema and hypoalbuminemia, who was lately diagnosed with AL amyloidosis. Fetal growth retardation led to a caesarian section in the 27th week of gestation. A live birth healthy female, 710 g weight, was admitted to the neonatal intensive care unit and survived. Thereafter the mother underwent specific chemotherapy achieving only a partial and transient response, and eventually died due to sepsis. Interestingly, amyloidotic material was found on the maternal but not on the fetal side of the placenta. Experimental data show suppression of AA amyloid formation during pregnancy and suggest a protective role of the placenta on the offspring. However, most reported cases deal with pregnant women diagnosed with AA amyloidosis associated with Familial Mediterranean Fever and describe growth retardation of the fetus, worsening renal function and preeclampsia. To the best of our knowledge, this is the first report of AL amyloidosis diagnosed in a pregnant woman. In our patient, as well as in the other reported cases, amyloidosis during pregnancy has been confirmed to be an ominous condition. Therefore mild leg edema and proteinuria during pregnancy, though a common finding, may not be innocent.

The role of IL-17-secreting mast cells in inflammatory joint disease.

Kenna TJ(1), Brown MA.

Author information:

(1)The University of Queensland Diamantina Institute, Level 4, R Wing, Princess Alexandra Hospital, Ipswich Road, Brisbane, QLD 4102, Australia.

The proinflammatory cytokine IL-17 has an important role in pathogenesis of several inflammatory diseases. In immune-mediated joint diseases, IL-17 can induce secretion of other proinflammatory cytokines such as IL-1, IL-6 and TNF, as well as matrix metalloproteinase enzymes, leading to inflammation, cartilage breakdown, osteoclastogenesis and bone erosion. In animal models of inflammatory arthritis, mice deficient in IL-17 are less susceptible to development of disease. The list of IL-17-secreting cells is rapidly growing, and mast cells have been suggested to be a dominant source of IL-17 in inflammatory joint disease. However, many other innate sources of IL-17 have been described in both inflammatory and autoinflammatory conditions, raising questions as to the role of mast cells in orchestrating joint inflammation. This article will critically assess the contribution of mast cells and other cell types to IL-17 production in the inflammatory milieu associated with inflammatory arthritis, understanding of which could facilitate targeted therapeutic approaches.

Phenotype 2 familial mediterranean fever: evaluation of 22 case series and review of the literature on phenotype 2 FMF.

Altunoğlu A(1), Erten Ş, Canoz MB, Yuksel A, Ceylan GG, Balci S, Dogan HT.

Author information:

(1)Department of Nephrology, Atatürk Education and Research Hospital, Ankara, Turkey.

Familial Mediterranean fever (FMF) is an autosomal recessive autoimmune disorder characterized by recurrent bouts of fever and serosal inflammation. FMF may be complicated by AA-type amyloidosis, worsening the prognosis, with associated renal failure in some patients. Complication rate varies with race, being as high as 60% in Turks and as low as 2% in Armenians. In a few cases of patients with FMF (phenotype 2), amyloid nephropathy may be the presenting manifestation. This study included 420 patients who were admitted to the Nephrology and Rheumatology Departments of Atatürk Education and Research Hospital with unexplained proteinuria/nephrotic syndrome. The initial screening test for amyloidosis was the presence of significant proteinuria (300 mg/24 h). All MEFV gene exons were screened for causative mutations by direct DNA sequencing to check for any mutations. There were 22 phenotype 2 FMF patients with 27 allelic variants. The most prevalent allelic variants were M694V (10/27, 37%) and E148Q (7/27, 26%). Phenotype 2 FMF is not as rare as it was thought before; this should be kept in mind for all patients with unexplained proteinuria and/or acute phase response in high-risk ethnic groups for FMF.

Genetic loss of murine pyrin, the Familial Mediterranean Fever protein, increases interleukin-1 $\beta$  levels.

Hesker PR(1), Nguyen M, Kovarova M, Ting JP, Koller BH.

Author information:

(1)Curriculum of Genetics and Molecular Biology, University of North Carolina, Chapel Hill, NC, USA.

Familial Mediterranean Fever (FMF) is an inherited autoinflammatory disorder characterized by unprovoked episodes of fever and inflammation. The associated gene, MEFV (Mediterranean Fever), is expressed primarily by cells of myeloid

lineage and encodes the protein pyrin/TRIM20/Marenostrin. The mechanism by which mutations in pyrin alter protein function to cause episodic inflammation is controversial. To address this question, we have generated a mouse line lacking the *Mefv* gene by removing a 21 kb fragment containing the entire *Mefv* locus. While the development of immune cell populations appears normal in these animals, we show enhanced interleukin (IL) 1 $\beta$  release by *Mefv*(-/-) macrophages in response to a spectrum of inflammatory stimuli, including stimuli dependent on IL-1 $\beta$  processing by the NLRP1b, NLRP3 and NLRC4 inflammasomes. Caspase-1 activity, however, did not change under identical conditions. These results are consistent with a model in which pyrin acts to limit the release of IL-1 $\beta$  generated by activation and assembly of inflammasomes in response to subclinical immune challenges.

Homeostatic tissue responses in skin biopsies from NOMID patients with constitutive overproduction of IL-1 $\beta$ .

Aubert P(1), Suárez-Fariñas M, Mitsui H, Johnson-Huang LM, Harden JL, Pierson KC, Dolan JG, Novitskaya I, Coats I, Estes J, Cowen EW, Plass N, Lee CC, Sun HW, Lowes MA, Goldbach-Mansky R.

Author information:

(1)Translational Autoinflammatory Disease Section NIAMS/NIH, Bethesda, MD, USA.

The autoinflammatory disorder, Neonatal-onset Multisystem Inflammatory Disease (NOMID) is the most severe phenotype of disorders caused by mutations in *CIAS1* that result in increased production and secretion of active IL-1 $\beta$ . NOMID patients present with systemic and organ-specific inflammation of the skin, central nervous system and bone, and respond dramatically to treatment with IL-1 blocking agents. We compared the cellular infiltrates and transcriptome of skin biopsies from patients with NOMID (n = 14) before treatment (lesional (LS) and non-lesional (pre-NL) skin) and after treatment (post-NL) with the IL-1 blocker anakinra (recombinant IL-1 receptor antagonist, Kineret<sup>®</sup>, Swedish Orphan

Biovitrum AB, SOBI), to normal skin (n = 5) to assess tissue responses in the context of untreated and treated disease. Abundant neutrophils distinguish LS skin from pre-NL and post-NL skin. CD11c(+) dermal dendritic cells and CD163(+) macrophages expressed activated caspase-1 and are a likely source of cutaneous IL-1 production. Treatment with anakinra led to the disappearance of neutrophils, but CD3(+) T cells and HLA-DR(+) cells remained elevated. Among the upregulated genes IL-6, IL-8, TNF, IL-17A, CCL20, and the neutrophil defensins DEFA1 and DEFA3 were differentially regulated in LS tissues (compared to normal skin). Important significantly downregulated pathways in LS skin included IL-1R/TLR signaling, type I and II cytokine receptor signaling, mitochondrial dysfunction, and antigen presentation. The differential expression and regulation of microRNAs and pathways involved in post-transcriptional modification were suggestive of epigenetic modification in the chronically inflamed tissue. Overall, the dysregulated genes and pathways suggest extensive "adaptive" mechanisms to control inflammation and maintain tissue homeostasis, likely triggered by chronic IL-1 release in the skin of patients with NOMID.

Microarray-based gene expression profiling in patients with cryopyrin-associated periodic syndromes defines a disease-related signature and IL-1-responsive transcripts.

Balow JE Jr(1), Ryan JG, Chae JJ, Booty MG, Bulua A, Stone D, Sun HW, Greene J, Barham B, Goldbach-Mansky R, Kastner DL, Aksentijevich I.

Author information:

(1)Inflammatory Disease Section, National Human Genome Research Institute (NHGRI), Bethesda, Maryland 20892-1820, USA.

OBJECTIVE: To analyse gene expression patterns and to define a specific gene expression signature in patients with the severe end of the spectrum of cryopyrin-associated periodic syndromes (CAPS). The molecular consequences of

interleukin 1 inhibition were examined by comparing gene expression patterns in 16 CAPS patients before and after treatment with anakinra.

**METHODS:** We collected peripheral blood mononuclear cells from 22 CAPS patients with active disease and from 14 healthy children. Transcripts that passed stringent filtering criteria ( $p$  values  $\leq$  false discovery rate 1%) were considered as differentially expressed genes (DEG). A set of DEG was validated by quantitative reverse transcription PCR and functional studies with primary cells from CAPS patients and healthy controls. We used 17 CAPS and 66 non-CAPS patient samples to create a set of gene expression models that differentiates CAPS patients from controls and from patients with other autoinflammatory conditions.

**RESULTS:** Many DEG include transcripts related to the regulation of innate and adaptive immune responses, oxidative stress, cell death, cell adhesion and motility. A set of gene expression-based models comprising the CAPS-specific gene expression signature correctly classified all 17 samples from an independent dataset. This classifier also correctly identified 15 of 16 post-anakinra CAPS samples despite the fact that these CAPS patients were in clinical remission.

**CONCLUSIONS:** We identified a gene expression signature that clearly distinguished CAPS patients from controls. A number of DEG were in common with other systemic inflammatory diseases such as systemic onset juvenile idiopathic arthritis. The CAPS-specific gene expression classifiers also suggest incomplete suppression of inflammation at low doses of anakinra.

Reduced expression of NLRP3 and MEFV in human ischemic heart tissue.

Hermansson C(1), Lundqvist A, Wasslavik C, Palmqvist L, Jeppsson A, Hultén LM.

Author information:

(1)Sahlgrenska Center for Cardiovascular and Metabolic Research, Wallenberg Laboratory, Department of Molecular and Clinical Medicine, Institute of Medicine, Sahlgrenska Academy, University of Gothenburg, Sahlgrenska University Hospital, Gothenburg, Sweden.

The innate immune system and, in particular, activation of the multi-protein complex known as the inflammasome complex are involved in ischemic injury in myocardial cells. The nucleotide-binding leucine-rich repeat-containing pyrin receptor 3 (NLRP3) inflammasome has been linked to inflammation and NLRP3 is especially important for increased inflammation in atherosclerosis, which may lead to myocardial infarction. Here we investigated how inflammasome molecules are affected in human ischemic heart tissue. Surprisingly the important member of the inflammasome complex, NLRP3, displayed markedly decreased levels in human ischemic heart tissue compared with non ischemic control heart tissue. However, subsequent gene analysis revealed mutations in NLRP3 in human ischemic heart tissues but not in non-ischemic control tissue. Gene polymorphisms in the NLRP3 inflammasome have been shown to be associated with increased IL-1 $\beta$  and IL-18 production and severe inflammation. The autoinflammatory disorder familial Mediterranean fever (FMF) is associated with decreased expression of the Mediterranean fever gene (MEFV) and increased inflammation. We also observed reduced expression of MEFV in ischemic versus non-ischemic heart tissue. Further analyses showed a mutation in MEFV in human ischemic heart tissue but not in non-ischemic control tissue. Our data show that defects in the inflammasome and associated proteins may be involved in promoting ischemic heart disease.

The expanded clinical profile and the efficacy of colchicine therapy in Egyptian children suffering from familial Mediterranean fever: a descriptive study.

Talaat HS(1), Mohamed MF, El Rifai NM, Gomaa MA.

Author information:

(1)Department of Pediatrics, Cairo University, Cairo, Egypt.

**BACKGROUND:** Familial Mediterranean fever (FMF) is an autosomal recessive disease characterized by self-limiting recurrent attacks of fever and serosal inflammation, leading to abdominal, thoracic or articular pain.

**OBJECTIVE:** To detect variable clinical presentations and genotypic distribution of different groups of FMF patients and the efficacy of colchicine therapy in treatment of these groups of FMF after one year.

**METHODS:** A cross-sectional study was conducted on 70 patients already diagnosed with FMF and following-up at the Rheumatology Clinic, Children's Hospital - Cairo University. Diagnosis of FMF was determined according to Tel Hashomer criteria for FMF. All patients were subjected to a questionnaire including detailed history with emphasis on clinical manifestations and colchicine dose to control attacks. Mutational analysis was performed for all study subjects covering 12 mutations in the MEFV gene: E148Q, P369S, F479L, M680I (G/C), M680I (G/A), I692del, M694V, M694I, K695R, V726A, A744S and R761H. Response to colchicine treatment was evaluated as complete, incomplete and unresponsive.

**RESULTS:** Out of the 70 patients- 40 males and 30 females- fever was the most common presenting feature, followed by abdominal pain, and arthritis; documented in 95.7%, 94.3%, and 77.1% of cases respectively. Mutational analysis detected gene mutation on both alleles in 20 patients (homozygotes), on only 1 allele in 40 patients (heterozygotes), and on none of the alleles (uncharacterized cases). Mild to moderate disease severity score (according to Tel Hashomer key to severity score) was detected in a significant proportion of heterozygotes and the uncharacterized group than the homozygotes. All patients received colchicine therapy; 22.9% of them showed complete response, 74.3% showed incomplete response and 2.9% showed no response to therapy. The colchicine dose needed to control attacks was significantly lower in heterozygotes than the homozygotes( $P=0.04$ ). Also patients' response to colchicine therapy was significantly better in the

heterozygous group( $P=0.023$ ).

CONCLUSION: Fever, abdominal pain and arthritis are the most common presenting features for homozygous, Heterozygous and uncharacterized patients. E148Q, V726A, and M680I were the most common mutations detected in the heterozygous group. Homozygosity were found for M680I, M694V, and M694I mutations in 13 patients (65% of homozygotes). Heterozygotes presenting with severe phenotype should be further analyzed for less common second MEFV mutation using gene sequencing. The colchicine dose required to control the attacks was significantly lower and patients' response to colchicine therapy was significantly better in the heterozygous group than homozygous group.

**OBJECTIVE:** Hyperactivation of innate immunity by Toll-like receptors (TLRs) can contribute to the development of autoinflammatory or autoimmune diseases. This study evaluated the activation of Tyro3, Axl, Mer (TAM) receptors, physiologic negative regulators of TLRs, by their agonists, growth arrest-specific protein 6 (GAS-6) and protein S, in the prevention of collagen-induced arthritis (CIA).

**METHODS:** Adenoviruses overexpressing GAS-6 and protein S were injected intravenously or intraarticularly into mice during CIA. Splenic T helper cell subsets from intravenously injected mice were studied by flow cytometry, and the knee joints of mice injected intravenously and intraarticularly were assessed histologically. Synovium from mice injected intraarticularly was evaluated for cytokine and suppressor of cytokine signaling (SOCS) expression.

**RESULTS:** Protein S significantly reduced ankle joint swelling when overexpressed systemically. Further analysis of knee joints revealed a moderate reduction in pathologic changes in the joint and a significant reduction in the number of splenic Th1 cells when protein S was overexpressed systemically. Local overexpression of GAS-6 decreased joint inflammation and joint pathology. Protein S treatment showed a similar trend of protection. Consistently, GAS-6 and protein S reduced cytokine production in the synovium. Moreover, levels of messenger RNA for interleukin-12 (IL-12) and IL-23 were reduced by GAS-6 and protein S treatment, with a corresponding decrease in the production of interferon- $\gamma$  and IL-17. TAM ligand overexpression was associated with an increase in SOCS-3 levels, which likely contributed to the amelioration of arthritis.

**CONCLUSION:** This study provides the first evidence that TAM receptor stimulation by GAS-6 and protein S can be used to ameliorate arthritis when applied systemically or locally. TAM receptor stimulation limits proinflammatory signaling and adaptive immunity. This pathway provides a novel strategy by which to combat rheumatoid arthritis.

Massive colchicine overdose with recovery.

Iosifina I(1), Lan J, Chin C, Werb R, Levin A.

Author information:

(1)Department of Medicine, University of British Columbia, Vancouver, B.C., Canada.

Colchicine is an active alkaloid that is commonly used for treatment of multiple diseases including gout, primary biliary cirrhosis and familial Mediterranean fever. Less commonly, it has been implicated in several fatal overdoses. Deaths from colchicine overdoses are usually due to multi-organ failure, whether directly from colchicine toxicity or due to ensuing sepsis. We report an extreme case of colchicine ingestion (1.38 mg/kg), which is the largest reported non-fatal colchicine overdose. The patient was a 47-year-old First Nations woman with a history of depression and no other comorbidities. Ingestion was intentional and initial presentation was within 2 h of ingestion, at which point she had normal clinical and laboratory parameters. Early implementation of a targeted therapeutic strategy directed at the predicted multi-organ failure which included aggressive use of a GI decontamination protocol, timely supportive measures including ventilator support and renal replacement therapy, as well as the utilization of broad-spectrum antibiotics and G-CSF for sepsis and leucopenia management, resulted in successful support and discharge of this patient off dialysis.

Familial Mediterranean Fever -- an increasingly important childhood disease in Sweden.

Wekell P(1), Friman V, Balci-Peynircioglu B, Yilmaz E, Fasth A, Berg S.

Author information:

(1)Department of Pediatrics, University of Gothenburg, Sweden.

**AIM:** To characterize Familial Mediterranean Fever (FMF) in western Sweden, focusing on genotype, clinical picture, prevalence and age of onset as well as time to diagnosis.

**METHODS:** Patients with autoinflammatory diseases are continuously registered at the five main hospitals in Western Sweden. Case records of patients with FMF were analysed retrospectively. Population data on immigration was retrieved from Statistics Sweden.

**RESULTS:** Until 2008, 37 patients with FMF were identified. The prevalence among inhabitants of Turkish, Lebanese, Syrian and Iranian origin was 173, 124, 86 and 17/100 000, respectively. Median age at first symptoms was 4 years (range 3 month-37 years) and at diagnosis 10 years (range 2-44 years). Median time from first symptoms to diagnosis was 4 years (range <1 year-34 years). Among 32 patients screened for twelve common mutations, 75% were homozygotes or compound heterozygotes, 16% were heterozygotes and in 9% no mutation was found. In our cohort the frequencies of symptoms were fever 100%, peritonitis 92%, pleuritis 22% and arthritis 11%.

**CONCLUSIONS:** The majority of patients with FMF present during childhood. The prevalence among immigrants in western Sweden is in the same range as in their country of origin. Time to diagnosis needs to be shortened by means of increased awareness of the disease.

Anti-cyclic citrullinated Peptide frequency in patients with chronic hepatitis C virus infection and effect of presence of systemic disease.

Albayrak A(1), Dursun H(2), Uyanik MH(3), Cerrah S(2).

Author information:

(1)Department of Infectious Diseases and Clinical Microbiology, Erzurum Region Education and Research Hospital, Erzurum, Turkey.

(2)Department of Internal Medicine, Division of Gastroenterology, Faculty of Medicine, Ataturk University, Erzurum, Turkey.

(3)Department of Microbiology, Faculty of Medicine, Ataturk University, Erzurum, Turkey.

**OBJECTIVE:** Patients with chronic hepatitis C virus (HCV) infection may show a variety of rheumatic symptoms and signs. Anti-cyclic citrullinated peptide (anti-CCP) is widely used as a marker, particularly for rheumatoid arthritis (RA), and may be positive in some diseases that also cause arthritis, such as systemic lupus erythematosus, familial Mediterranean fever, Behçet's disease, and psoriatic arthritis.

**MATERIALS AND METHODS:** Blood samples were obtained (in routine protocols) from 57 patients with chronic HCV infection from the Gastroenterology Clinic of Ataturk University and Infectious Disease Clinic of Erzurum Region Research and Education Hospital. Normal sera were obtained from volunteer blood donors at Ataturk University.

**RESULTS:** Anti-CCP antibodies were found in 5 chronic HCV patients with RA. The patient with the highest anti-CCP antibody level had RA. No patient in the control group was positive for anti-CCP antibodies.

**CONCLUSION:** Anti-cyclic citrullinated peptide (anti-CCP) antibodies should be measured frequently in patients with HCV and an additional systemic disease, such as end-stage chronic renal failure, chronic obstructive airway disease, and decompensated liver cirrhosis, to differentiate RA from non-RA arthropathy.

**Publisher:** Kronik hepatit C virüs (HCV) enfeksiyonu çeşitli romatolojik belirti ve semptomlarla seyredebilir. Anti-siklik sitrüllenmiş peptid (Anti-CCP) özellikle romatoid artrit (RA) tanısında yaygın şekilde kullanılan, ayrıca sistemik lupus eritematozus, ailevi akdeniz ateşi ve psöriatik artrit gibi artritlerle birlikte seyreden bazı hastalıklarda da pozitif olduğu gösterilmiş bir antikordur. Çalışmada Atatürk Üniversitesi Gastroenteroloji Kliniği ve Erzurum Bölge Eğitim ve Araştırma Hastanesi Enfeksiyon Hastalıkları Kliniği'nden 57 kronik HCV enfeksiyonlu hastadan rutin tetkikleri sırasında alınmış olan kanlar kullanıldı. Kontrol kanları Atatürk Üniversitesi kan vericilerinden alınan kanlardan toplandı. Kronik HCV enfeksiyonuna ilaveten RA tanısı da almış olan 5 hastanın tamamında Anti-CCP pozitif bulundu. Anti-CCP seviyesi en yüksek olan hasta da RA'li olan bir hasta idi. Kontrol grubundaki hastalardan hiçbirinde

Anti-CCP pozitif değildi. Kronik HCV'li hastalarda kronik böbrek yetmezliği, kronik obstruktif akciğer hastalığı veya dekompanse karaciğer sirozu gibi sistemik hastalıkların varlığında, Anti-CCP daha sık olarak görülebilmektedir. Ayrıca Anti-CCP pozitifliğinin, bu hasta grubunda RA ile non-RA artropati ayrımında da kullanılabileceği düşünülmektedir.

Activated phenotype of circulating neutrophils in familial Mediterranean fever.

Manukyan G(1), Petrek M, Kriegova E, Ghazaryan K, Fillerova R, Boyajyan A.

Author information:

(1)Group of Molecular and Cellular Immunology, Institute of Molecular Biology, National Academy of Sciences, 7 Hasratyan St., 0014 Yerevan, Armenia.  
gaya.manukyan@gmail.com

Familial Mediterranean fever (FMF) is autoinflammatory disorder, characterized by MEFV gene mutations and recurrent episodes of fever and serosal or synovial inflammation. Neutrophils are the predominant effector cells of acute inflammatory attacks in FMF; however pathogenic role and molecular phenotype of these cells remain largely unknown. To gain insight into the processes that contribute to the self-directed autoinflammation we characterized expression of a spectrum of genes involved in regulation of inflammation in unstimulated and LPS-activated neutrophils from FMF patients. Expression of 12 candidate immune genes encoding for inflammation-related molecules was assessed by quantitative RT-PCR in freshly isolated and LPS-stimulated peripheral polymorphonuclear neutrophils from fifteen FMF patients in attack-free period and ten healthy volunteers as controls. The relative expression was calculated using the second derivative method; the target gene expression was normalized to the expression of RPL32 gene. FMF neutrophils were characterized by up-regulated baseline gene expression of c-FOS (9.5-fold,  $p < 0.05$ ), IL-8 (12-fold,  $p < 0.05$ ), MMP9 (8-fold,  $p < 0.01$ ), TLR2 (7-fold,  $p < 0.05$ ) compared to the neutrophils from control subjects, a trend was also evident towards increased caspase-1 expression

(3-fold,  $p = 0.09$ ). Discriminant analysis clustered the patient and control subjects into two distinct groups (Wilks's  $\lambda = 0.165$ ,  $p = 0.042$ ). Further, LPS-induced alterations of expression profiles were shared between FMF and healthy neutrophils, the profile consisting namely of up-regulated IL-1 $\beta$ , TLR4, IL-8, and TNFAIP6 transcripts. Present study demonstrates distinct expression patterns of pre-activated neutrophils during attack-free period of FMF when compared to neutrophils from healthy controls. Furthermore, our data emphasize the importance of host-derived ligands in activation of FMF neutrophils.

Pyoderma gangrenosum, acne and suppurative hidradenitis syndrome following bowel bypass surgery.

Marzano AV(1), Ishak RS, Colombo A, Caroli F, Crosti C.

Author information:

(1)UO Dermatologia, Fondazione IRCCS Ca' Granda, Ospedale Maggiore Policlinico, Dipartimento di Fisiopatologia Medico-Chirurgica e dei Trapianti, Università degli Studi di Milano, Milano, Italy. angelovalerio.marzano@policlinico.mi.it

The clinical triad of pyoderma gangrenosum (PG), acne and suppurative hidradenitis (PASH) has recently been described as a new disease entity within the spectrum of autoinflammatory syndromes, which are an emerging group of inflammatory diseases distinct from autoimmune, allergic and infectious disorders. PASH syndrome is similar to PAPA (pyogenic arthritis, acne and PG), but it differs in lacking the associated arthritis and on a genetic basis. PAPA syndrome is caused by mutations in a gene involved in the regulation of innate immune responses, the PSTPIP1, while no mutations have been detected to date in patients with PASH syndrome. We report a young male patient who developed coexisting disseminated PG, typical suppurative hidradenitis and acneiform eruption on the face, after he had undergone bowel bypass surgery for obesity. The cutaneous manifestations associated with bowel bypass syndrome often mimic PG

or other neutrophilic dermatoses, suggesting a pathogenesis related to neutrophil-mediated inflammation for this condition. This is the first report describing PASH syndrome after bariatric surgery, and we propose to include such neutrophilic dermatoses in the list of complications occurring after bowel bypass surgery. Extensive genetic studies may help to clarify the etiopathogenesis of PASH as well as of autoinflammatory diseases in general.

Strong induction of AIM2 expression in human epidermis in acute and chronic inflammatory skin conditions.

de Koning HD, Bergboer JG, van den Bogaard EH, van Vlijmen-Willems IM, Rodijk-Olthuis D, Simon A, Zeeuwen PL, Schalkwijk J.

Absent in melanoma 2 (AIM2) is a double-stranded DNA receptor, and its activation initiates an interleukin-1 beta processing inflammasome. AIM2 is implicated in host defense against several pathogens, but could hypothetically also contribute to autoinflammatory or autoimmune diseases, such as is the case for NLRP3. Using thoroughly characterised antibodies, we analysed AIM2 expression in human tissues and primary cells. A strong epidermal upregulation of AIM2 protein expression was observed in several acute and chronic inflammatory skin disorders, such as psoriasis, atopic dermatitis, venous ulcers, contact dermatitis, and experimental wounds. We also found AIM2 induction by interferon-gamma in submerged and three-dimensional in vitro models of human epidermis. Our data highlight the dynamics of epidermal AIM2 expression, showing Langerhans cell and melanocyte-restricted expression in normal epidermis but a pronounced induction in subpopulations of epidermal keratinocytes under inflammatory conditions.

Familial Mediterranean fever: the first adult case in Korea.

Lim AL(1), Jang HJ, Han JW, Song YK, Song WJ, Woo HJ, Jung YO, Kae SH, Lee J.

Author information:

(1)Department of Internal Medicine, Hallym University College of Medicine, Seoul, Korea.

Familial Mediterranean fever (FMF) is known to be a genetic disorder that prevalent among populations surrounding the Mediterranean Sea. Since Mediterranean fever gene (MEFV) was discovered at 1997, some cases have been reported in countries not related or close to this area like Japan. In addition it has been generally accepted that the clinical onset of FMF begins before 20 yr of age in most patients. Onset of the disease at an older age may occur but is rare. Adult-onset FMF may be a form of disease with distinct clinical, demographic and molecular characteristics. We describe a case of adult-onset FMF confirmed by DNA analysis of the MEFV gene in a Korean patient. A 32-yr-old man, who has no family history of FMF, presented with periodic fever, abdominal pain and vomiting. Though several various tests were thoroughly performed to evaluate the cause of his symptoms, there was no evidence of infectious, autoimmune or neoplastic diseases. Several gene analysis of periodic fever syndrome was finally performed and two point mutations (p.Leu110Pro, p.Glu148Gln) were identified. We confirmed the first adult case of FMF through detection of MEFV gene mutations in Korea and describe his clinical characteristics.

Association of inflammatory bowel disease with familial Mediterranean fever in

Turkish children.

bosporus2006@hotmail.com

**BACKGROUND AND AIMS:** Inflammatory bowel disease (IBD) and familial Mediterranean fever (FMF) share common clinical and biological features. The prevalence of other inflammatory diseases, including IBD, is increased in FMF. We investigated the presence of IBD accompanying FMF in patients who were being followed up with a diagnosis of FMF and the relation of IBD with the MEFV gene mutation.

**METHODS:** A total of 78 children with FMF were enrolled in the study. The patients were included in the study independent of the presence of complaints. Colonoscopy for IBD was performed if any of the following was present: blood mixed with mucus in the stool; chronic diarrhea (loose and frequent stools lasting >4 weeks); abdominal pain incompatible with FMF (localized in a certain part of the abdomen, not occurring during attacks, >3 days); and positive IgA and IgG anti-Saccharomyces cerevisiae antibodies and perinuclear antineutrophil cytoplasmic antibodies. MEFV gene mutations were analyzed in patients diagnosed as having IBD and FMF.

**RESULTS:** Of the 78 patients with a diagnosis of FMF, colonoscopy was performed and biopsy samples were taken in 20 patients (25.6%) who had abdominal pain incompatible with FMF, chronic diarrhea, bloody stools, and/or positive perinuclear anti-neutrophil cytoplasmic antibody or anti-Saccharomyces cerevisiae antibody. Histopathological examination resulted in a diagnosis of IBD in 12 of the 78 patients (15.4%). MEFV gene mutations were present in all 12 patients diagnosed as having IBD. We observed M694 V mutations in 5 of 12 patients (41.7%), M680I mutations in 3 (25%), K695R mutations in 3 (25%), and E148Q mutations in 1 (8.3%).

**CONCLUSIONS:** We found that the number of patients with FMF was higher than the number with IBD in the general population. When IBD accompanied FMF, the most common mutation was M694 V; however, the high rate (25%) of K695R mutation in our patients with FMF and IBD was not observed in previous studies.

The scintigraphic evaluation and genetic correlation of joint involvements in pediatric patients with familial Mediterranean fever.

Aydogan F(1), Tutanc M, Arica V, Arica S, Gunesacar R.

Author information:

(1)Department of Nuclear Medicine, Faculty of Medicine, Mustafa Kemal University, Hatay, Turkey. drfusunay@yahoo.com

**PURPOSE:** We aimed to evaluate the articular involvements in pediatric patients with familial Mediterranean fever (FMF) with joint symptoms by bone scintigraphy and to correlate the involved joints with the gene mutations.

**MATERIALS AND METHODS:** A total of 41 newly diagnosed patients in pediatric age group (28 girls and 13 boys; mean age  $9.14 \pm 2.91$  years) with joint involvement symptoms were included in this study. Scintigraphic images were obtained at 5th min (blood pool or early phase) and starting at 3 h (late phase) after (after tracer injection) intravenous administration of technetium-99m ( $^{99m}\text{Tc}$ )-methylenediphosphonate (MDP). Genomic DNA was isolated from leukocytes using standard salting out procedure. The sequencing data were analyzed.

**RESULTS:** Of the 41 patients, arthritis was found in 21 (51.2%) patients. Of the 21 patients, there was single joint involvement in 15 (71.4%) patients and

multiple joint involvement in six (28.6%) patients. The mean age of patients with joint involvement ( $8 \pm 2.3$  years) were considerably lower than the patients without joint involvement ( $10.35 \pm 3.04$  years), and this was statistically significant ( $p = 0.008$ ). The most commonly involved joints were ankles and knees. Multiple joint involvements were most frequently observed in the M694V and M694I gene mutations (16.7%).

**CONCLUSIONS:** We use and recommend the bone scintigraphy in patients with FMF to determine the presence and distribution of arthritis, since bone scintigraphy is inexpensive, noninvasive, easy-to-use, and also is more sensitive in the diagnosis and distribution of arthritis than conventional radiological methods and clinical examination.

Hepatic amyloidosis: morphologic spectrum of histopathological changes in AA and nonAA amyloidosis.

Sarsik B(1), Sen S, Kirdok FS, Akarca US, Toz H, Yilmaz F.

Author information:

(1)Department of Pathology, Ege University Faculty of Medicine, Izmir, Turkey.  
banu.sarsik@ege.edu.tr

In hepatic amyloidosis (HA), the relationships between the pattern and extent of amyloid deposition, morphologic changes, associated diseases and clinical data have not yet been demonstrated. In this study, we sought the correlation between the above mentioned parameters in HA. Liver biopsies of 34 HA were retrospectively analyzed for the type, distribution, and intensity of amyloid deposition and associated morphologic changes. AA and nonAA types were classified on the basis of immunohistochemistry. Follow-up clinical and laboratory findings were reviewed. Twenty-three out of 34 patients (67.6%) had AA, and 11 out of 34 patients (32.4%) had nonAA amyloidosis. The predominant localization pattern in AA amyloidosis was vascular (91.3%), and in nonAA amyloidosis it was mixed with other patterns (72.7%). We confirmed that nonAA amyloid involves the hepatic

artery, as well as the portal and central vein, but deposition occurred more frequently in the sinusoidal areas. We detected a portal stromal pattern only in cases of nonAA amyloidosis with a mixed pattern of amyloid deposition. The pattern of amyloid deposition in liver differs between the AA and nonAA type amyloidosis. The distribution of amyloid within the liver is not a reliable method for distinguishing AA from nonAA amyloidosis. However, the histological pattern provides strong clues as to the etiology of the amyloid deposits, and could provide information on the clinical status and prognosis of these patients.

No evidence for involvement of the toll-like receptor (TLR) 4 gene Asp299Gly and Thr399Ile polymorphisms in susceptibility to primary gouty arthritis.

Qing YF(1), Zhou JG, Li M, Xie WG, Huang CP, Zeng SP, Yin L.

Author information:

(1)Department of Rheumatology and Hematology, Institute of Rheumatology and Immunology, The Affiliated Hospital of North Sichuan Medical College, 63 Wenhua Road, Nanchong, 637000, Sichuan, China, qingyufengqq@163.com.

Previous studies demonstrated that toll-like receptor (TLR) 4 was involved in the development of autoinflammatory disease including gouty arthritis (GA). TLR4 functional gene Asp299Gly and Thr399Ile polymorphisms play a role in some autoinflammatory disease susceptibility. We undertook this study to analyze the association between the genetic polymorphisms within TLR4 gene and the susceptibility to GA in Chinese Han people. Two functional variants, Asp299Gly and Thr399Ile, in the TLR4 gene were genotyped using 5' exonuclease TaqMan technology from 218 male GA patients and 226 ethnically matched controls. None polymorphisms of Asp299Gly and Thr399Ile were detected in all GA cases and controls, which indicates that there is no evidence for involvement of the TLR4 gene Asp299Gly and Thr399Ile polymorphisms in susceptibility to primary GA in the

Chinese Han population. Further studies with extended single nucleotide polymorphisms should be performed.

Autoantibodies are not associated with familial mediterranean fever.

Guler E(1), Kaptanoglu E, Sahin O, Candan F, Hayta E, Elden H.

Author information:

(1)Kayseri Education and Research Hospital, Kayseri, Turkey.

**OBJECTIVE:** It has been suggested that Mediterranean fever (MEFV) gene mutations are also seen in certain autoimmune diseases and are related to severity of the disease activity. As most of the clinical symptoms of these inflammatory diseases are related to autoantibody positivity, we assessed autoantibody prevalence in patients with Familial Mediterranean fever (FMF) and investigated the relationship between clinical involvement of FMF and the autoantibodies. There are a few studies on this subject with conflicting results.

**PATIENTS AND METHODS:** Fifty patients with FMF without attack and 27 healthy controls were enrolled to the study. Clinical characteristics of the patient group were questioned. Rheumatoid factor (RF), anti-cyclic citrullinated peptide (anti-CCP) values, Fluorescent antinuclear antibody (ANA), extractable nuclear antigen (ENA) profile was studied in both groups.

**RESULTS:** No statistically significant difference was found in ANA, ENA profile, anti-CCP, and RF positivity between the groups ( $p>0.05$ ). There was no relationship between the autoantibodies and the clinical status in patients with FMF. MEFV gene mutations were identified in 98% of the FMF patients.

**CONCLUSION:** In conclusion, autoantibody positivity is similar to the healthy population in FMF. Although MEFV mutations affect clinical course in other autoantibody mediated diseases, it is not related to autoantibody formation in FMF.

Colchicine and NSAID combination causing acute kidney injury.

Chen HW(1), Chen KC, Chen JS.

Author information:

(1)Department of Internal Medicine, Tri-Service General Hospital, Taipei, Taiwan.

Colchicine is used mainly for the treatment of gout and familial mediterranean fever. The use of colchicine is limited by its toxicity, and colchicine overdose is associated with a high mortality rate. Herein, we are reporting a young man who presented to the emergency department after ingesting 13.5 mg of colchicine and 1200 mg of aceclofenac (non-steroid anti-inflammatory drug) for deliberate self harm. He developed acute kidney injury, metabolic acidosis, and bradycardia after admission. A combination effect of non-steroid anti-inflammatory drug and colchicines was responsible for this event.

2552. Clin Radiol. 2013 Apr;68(4):371-5. doi: 10.1016/j.crad.2012.08.030. Epub 2012 Nov 10.

Exertional muscle pain in familial Mediterranean fever patients evaluated by MRI and 31P magnetic resonance spectroscopy.

Kushnir T(1), Eshed I, Heled Y, Livneh A, Langevitz P, Ben Zvi I, Konen E, Lidar M.

Author information:

(1)Department of Diagnostic Imaging, The Sheba Medical Center, Tel Hashomer/Sackler School of Medicine, Tel Aviv University, Tel Aviv, Israel.

AIM: To evaluate the effect of physical activity on the structural, morphological, and metabolic characteristics of the gastrocnemius muscle in

familial Mediterranean fever (FMF) patients, utilizing quantitative (31)P magnetic resonance spectroscopy (MRS), in order to elucidate the mechanism of their exertional leg pain.

**MATERIALS AND METHODS:** Eleven FMF patients suffering from exertional leg pain (eight male, three female; mean age 33 years) and six healthy individuals (three male, three female; mean age 39 years) constituted the control group. All of the participants underwent magnetic resonance imaging (MRI) and non-selective (31)P MRS (3 T) of the leg muscles before and after graded exercise on a treadmill.

Phosphocreatine (PCr):inorganic phosphate (Pi), PCr:adenosine triphosphate (ATP) ratios and the intracellular pH of the leg muscles were measured using (31)P MRS.

**RESULTS:** For both groups, normal muscle mass with no signal alterations was observed on the MRI images after exercise. The normal range of pre- and post-exercise MRS muscle parameters was observed in both groups. However, the intracellular pH post-exercise, was significantly higher (less acidic) in the FMF group compared to the control group [pH (FMF) =  $7.03 \pm 0.02$ ; pH (control)  $7.00 \pm 0.02$ ;  $p < 0.0006$ ].

**CONCLUSIONS:** The finding of a less prominent, post-exercise acidification of the gastrocnemius muscle in this FMF patient group suggests a forme fruste of glycogenosis. This preliminary observation should be further investigated in a future, larger-scale study.

The calcium-sensing receptor regulates the NLRP3 inflammasome through Ca<sup>2+</sup> and cAMP.

Comment in

Nat Rev Immunol. 2013 Jan;13(1):1.

Mutations in the gene encoding NLRP3 cause a spectrum of autoinflammatory diseases known as cryopyrin-associated periodic syndromes (CAPS). NLRP3 is a key component of one of several distinct cytoplasmic multiprotein complexes (inflammasomes) that mediate the maturation of the proinflammatory cytokine interleukin-1 $\beta$  (IL-1 $\beta$ ) by activating caspase-1. Although several models for inflammasome activation, such as K(+) efflux, generation of reactive oxygen species and lysosomal destabilization, have been proposed, the precise molecular mechanism of NLRP3 inflammasome activation, as well as the mechanism by which CAPS-associated mutations activate NLRP3, remain to be elucidated. Here we show that the murine calcium-sensing receptor (CASR) activates the NLRP3 inflammasome, mediated by increased intracellular Ca(2+) and decreased cellular cyclic AMP (cAMP). Ca(2+) or other CASR agonists activate the NLRP3 inflammasome in the absence of exogenous ATP, whereas knockdown of CASR reduces inflammasome activation in response to known NLRP3 activators. CASR activates the NLRP3 inflammasome through phospholipase C, which catalyses inositol-1,4,5-trisphosphate production and thereby induces release of Ca(2+) from endoplasmic reticulum stores. The increased cytoplasmic Ca(2+) promotes the assembly of inflammasome components, and intracellular Ca(2+) is required for spontaneous inflammasome activity in cells from patients with CAPS. CASR stimulation also results in reduced intracellular cAMP, which independently activates the NLRP3 inflammasome. cAMP binds to NLRP3 directly to inhibit inflammasome assembly, and downregulation of cAMP relieves this inhibition. The binding affinity of cAMP for CAPS-associated mutant NLRP3 is substantially lower than for wild-type NLRP3, and the uncontrolled mature IL-1 $\beta$  production from CAPS patients' peripheral blood mononuclear cells is attenuated by increasing cAMP. Taken together, these findings indicate that Ca(2+) and cAMP are two key molecular regulators of the NLRP3 inflammasome that have critical roles in the molecular pathogenesis of CAPS.

Behçet's disease (BD) is now mentioned in the latest Chapel Hill nomenclature of vasculitides and is classified under the variable vessel vasculitides (VVV).

Pathogenetically, a new classification among the so-called mixed-pattern diseases between classical polygenic autoinflammatory disorders and autoimmune diseases is being discussed. The genetic association with HLA-B51 is undisputed and an association with HLA-A26 as well as with polymorphisms in the IL-10 and IL23R-IL12RB2 genes have recently been described. Increasingly, a participation of IL-17 in the pathogenesis of BD is assumed. Therapeutically, the EULAR recommendations are still applicable. Interferon-alpha can be discontinued for severe ocular BD in remission without further relapses. Infliximab can be switched to adalimumab effectively and recent case series show an efficacy of IL-1 antagonists, tocilizumab and rituximab for BD.

Targeting aberrant colon cancer-specific DNA methylation with lipoteichoic acid-deficient *Lactobacillus acidophilus*.

Lightfoot YL(1), Yang T, Sahay B, Mohamadzadeh M.

Author information:

(1)Department of Infectious Diseases and Pathology, Division of Hepatology/Gastroenterology and Nutrition, Department of Medicine, Cancer Genetic

Institute, University of Florida, Gainesville, FL, USA.

Pathogenic autoinflammatory responses triggered by dysregulated microbial interactions may lead to intestinal disorders and malignancies. Previously, we demonstrated that a lipoteichoic acid (LTA)-deficient *Lactobacillus acidophilus* strain, NCK2025, ameliorated inflammation-induced colitis, significantly reduced the number of polyps in a colonic polyposis cancer model and restored physiological homeostasis in both cases. Nonetheless, the regulatory signals delivered by NCK2025 to reprogram the gastrointestinal microenvironment, and thus resist colonic cancer progression, remain unknown. Accumulating evidence suggest that epigenetic changes, in the presence and absence of pathogenic inflammation, can result in colorectal cancer (CRC). To test possible epigenetic modifications induced by NCK2025, the expression of epigenetically regulated, CRC-associated genes was measured with and without bacterial treatment. In vivo and in vitro, NCK2025 enhanced the expression of tumor suppressor genes that may regulate CRC development. Therefore, differential epigenetic regulation of CRC-related genes by NCK2025 represents a potential therapy against colitis-associated and sporadic CRC.

Familial Mediterranean fever in Germany: clinical presentation and amyloidosis risk.

Ebrahimi-Fakhari D(1), Schönland SO, Hegenbart U, Lohse P, Beimler J, Wahlster L, Ho AD, Lorenz HM, Blank N.

Author information:

(1)Division of Rheumatology, Department of Medicine V, University of Heidelberg, Heidelberg, Germany.

OBJECTIVE: To characterize patients with familial Mediterranean fever (FMF) with and without AA amyloidosis living in Germany.

**METHOD:** Clinical and genetic data from 64 FMF patients were analysed for amyloidosis risk factors.

**RESULTS:** Fifty-five patients (85%) were of Turkish or Armenian origin. Thirty-one patients (48%) developed FMF symptoms before the age of 16 years. Sixteen patients (26%) became symptomatic after age 20. Symptoms reported were peritonitis (95%), fever (78%), pleuritis (59%), arthralgia (60%), arthritis (32%), erysipelas-like erythema (23%), and vasculitis (8%). FMF diagnosis was delayed for a median of 8.0 years. Genetic analysis confirmed M694V as the most prevalent Mediterranean fever (MEFV) gene mutation in 46 out of 59 patients (78%). M694V homozygosity was associated with an earlier FMF onset (median age 5.5 years,  $p = 0.0001$ ) and a higher prevalence of peritonitis ( $p = 0.007$ ) and pleuritis ( $p = 0.0007$ ) compared to patients without an M694V mutation. AA amyloidosis was detected in 16 patients (25%) at a median age of 36.5 years and tended to be associated with a higher age at disease onset ( $p = 0.062$ ) and a higher FMF activity score ( $p = 0.093$ ). AA amyloidosis was significantly associated with a higher age at FMF diagnosis ( $p = 0.0022$ ).

**CONCLUSIONS:** Clinical symptoms of FMF-affected migrants living in Germany resemble those observed in their home country. In particular, patients with an onset of FMF symptoms after age 20 and a later FMF diagnosis have a high risk of AA amyloidosis. Symptomatic patients who originate from countries with a higher FMF prevalence should be screened for FMF and proteinuria.

Autophagy contributes to inflammation in patients with TNFR-associated periodic syndrome (TRAPS).

Bachetti T(1), Chiesa S, Castagnola P, Bani D, Di Zanni E, Omenetti A, D'Ossualdo A, Fraldi A, Ballabio A, Ravazzolo R, Martini A, Gattorno M, Ceccherini I.

Author information:

Comment in

**OBJECTIVES:** Tumour necrosis factor (TNF) receptor-associated periodic syndrome (TRAPS) is caused by TNFRSF1A mutations, known to induce intracellular retention of the TNF $\alpha$  receptor 1 (TNFR1) protein, defective TNF $\alpha$ -induced apoptosis, and production of reactive oxygen species. As downregulation of autophagy, the main cellular pathway involved in insoluble aggregate elimination, has been observed to increase the inflammatory response, we investigated whether it plays a role in TRAPS pathogenesis.

**METHODS:** The possible link between TNFRSF1A mutations and inflammation in TRAPS was studied in HEK-293T cells, transfected with expression constructs for wild-type and mutant TNFR1 proteins, and in monocytes derived from patients with TRAPS, by investigating autophagy function, NF- $\kappa$ B activation and interleukin (IL)-1 $\beta$  secretion.

**RESULTS:** We found that autophagy is responsible for clearance of wild-type TNFR1, but when TNFR1 is mutated, the autophagy process is defective, probably accounting for mutant TNFR1 accumulation as well as TRAPS-associated induction of NF- $\kappa$ B activity and excessive IL-1 $\beta$  secretion, leading to chronic inflammation. Autophagy inhibition due to TNFR1 mutant proteins can be reversed, as demonstrated by the effects of the antibiotic geldanamycin, which was found to rescue the membrane localisation of mutant TNFR1 proteins, reduce their accumulation and counteract the increased inflammation by decreasing IL-1 $\beta$  secretion.

**CONCLUSIONS:** Autophagy appears to be an important mechanism in the pathogenesis of TRAPS, an observation that provides a rationale for the most effective therapy in this autoinflammatory disorder. Our findings also suggest that autophagy could be proposed as a novel therapeutic target for TRAPS and possibly other similar diseases.

migita@nmc.hosp.go.jp

Familial Mediterranean fever (FMF) is a hereditary autoinflammatory disease that is prevalent in Mediterranean populations. While it is considered a rare disease in the rest of world, a significant number of FMF patients have been reported in East Asia, including Japan. Our aim was to determine the prevalence of FMF in Japan and elucidate the clinical and genetic features of Japanese patients. A primary nationwide survey of FMF was conducted between January and December 2009. Hospitals specializing in pediatrics and hospitals with pediatric, internal medicine, and rheumatology/allergy departments were asked to report all patients with FMF during the survey year. The estimated total number of Japanese FMF patients was 292 (95% confidence interval, 187-398 people). We evaluated the clinical and genetic profiles of Japanese patients from the data obtained in a secondary survey of 134 FMF patients. High-grade fever was observed in 95.5%, chest pain (pleuritis symptoms) in 36.9%, abdominal pain (peritonitis symptoms) in 62.7%, and arthritis in 31.3%. Of the patients profiled, 25.4% of patients experienced their first attack before 10 years of age, 37.3% in their teens, and 37.3% after age 20 years. Colchicine was effective in 91.8% of patients at a relatively low dose (mean dose,  $0.89 \pm 0.45$  mg/d). AA amyloidosis was confirmed in 5 patients (3.7%). Of the 126 patients studied, 109 (86.5%) were positive for 1 or more genetic mutations and 17 (13.5%) had no mutation detected. Common Mediterranean fever gene (MEFV) mutations were E148Q/M694I (19.8%) and M694I/normal (12.7%). The differences in the prevalence of peritonitis, pleuritis, and a family history of FMF were statistically significant between FMF patients with MEFV exon 10 mutations compared with those without exon 10 mutations. In conclusion, a significant number of patients with FMF exist in Japan. Although Japanese patients with FMF are clinically or genetically different from Mediterranean patients, the delay in diagnosis is an issue that should be resolved.

Mevalonate kinase deficiency, a metabolic autoinflammatory disease.

van der Burgh R(1), Ter Haar NM, Boes ML, Frenkel J.

Author information:

(1)Center for Cellular and Molecular Intervention, Division of Pediatrics,  
University Medical Center Utrecht, The Netherlands.

Mevalonate kinase deficiency is a rare autosomal recessive inborn error of metabolism with an autoinflammatory phenotype. In this review we discuss its pathogenesis, clinical presentation and treatment. Mutations in both copies of the MVK-gene lead to a block in the mevalonate pathway. Interleukin-1 $\beta$  mediates the inflammatory phenotype. Shortage of a non-sterol isoprenoid product of the mevalonate pathway, Geranylgeranylpyrophosphate leads to aberrant activation of the small GTPase Rac1, and inflammasome activation. The clinical phenotype ranges widely, depending on the severity of the enzyme defect. All patients show recurrent fevers, lymphadenopathy and high acute phase proteins. Severely affected patients have antenatal disease onset, dysmorphic features, growth retardation, cognitive impairment and progressive ataxia. Diagnosis relies on mutation analysis of the MVK-gene. There is no evidence based therapy. IL-1 blockade is usually effective. Severe cases require allogeneic stem cell transplantation. Targeted therapies are needed.

The periprosthetic capsule and connective tissue diseases: a piece in the puzzle of autoimmune/autoinflammatory syndrome induced by adjuvants.

Bassetto F(1), Scarpa C, Vindigni V, Doria A.

Author information:

(1)Plastic Surgery Clinic, Padua University, Via Giustininani 2, Padua, Italy.

Breast prostheses have been criticized for being responsible for triggering systemic autoimmune disease. The presence of breast implants causes a natural foreign body reaction characterized by the infiltration of macrophages and T-cells. Using PubMed, Medline and eMedicine, we performed a systematic literature review on the stages of periprosthetic capsule formation and cells involved in order to understand which immunological pathways could be responsible for giving rise to, and the development of, connective tissue disease such as systemic sclerosis. We focused on the relationship between tissue growth factor- $\beta$ , interleukin (IL)-1, IL-6 and T helper 17 or T regulatory cells, as well as on their effects on the different steps of capsular tissue formation. A disturbance in the modulation of these key cytokines may be responsible, in susceptible individuals, for a perpetuation of the inflammatory reaction which can locally lead to capsular contracture and at the systemic level may contribute to triggering autoimmune diseases.

Comment in

Nat Immunol. 2012 Dec;13(12):1133-5.

We report the clinical description and molecular dissection of a new fatal human inherited disorder characterized by chronic autoinflammation, invasive bacterial infections and muscular amylopectinosis. Patients from two kindreds carried biallelic loss-of-expression and loss-of-function mutations in HOIL1 (RBCK1), a component of the linear ubiquitination chain assembly complex (LUBAC). These mutations resulted in impairment of LUBAC stability. NF- $\kappa$ B activation in response to interleukin 1 $\beta$  (IL-1 $\beta$ ) was compromised in the patients' fibroblasts. By contrast, the patients' mononuclear leukocytes, particularly monocytes, were hyper-responsive to IL-1 $\beta$ . The consequences of human HOIL-1 and LUBAC deficiencies for IL-1 $\beta$  responses thus differed between cell types, consistent with the unique association of autoinflammation and immunodeficiency in these patients. These data suggest that LUBAC regulates NF- $\kappa$ B-dependent IL-1 $\beta$  responses differently in different cell types.

(4)Department of Neurology, Cleveland Clinic, Cleveland, Ohio.

(5)Department of Rheumatic and Immunologic Diseases, Cleveland Clinic, Cleveland, Ohio.

**OBJECTIVES:** We sought to characterize a new category of autoinflammatory disease associated with nucleotide-binding oligomerization domain 2 (NOD2) gene mutations.

**METHODS:** A total of 22 patients were identified, inclusive of those reported previously. All had autoinflammatory phenotypes and NOD2 gene mutations that were prospectively studied between January 2009 and February 2012.

**RESULTS:** All 22 patients were non-Jewish whites (13 women and 9 men). The mean age at diagnosis was 40.1 years (range 17-72), with a mean disease duration of 4.7 years (range 1-13). Three female patients were siblings. Common clinical features were weight loss (13/22), episodic self-limiting fever (13/22), dermatitis (19/22), and inflammatory polyarthritis/polyarthralgia (20/22).

Gastrointestinal symptoms occurred in 13 patients, sicca-like symptoms in 9, and recurrent chest pain in 5. All patients carried the NOD2 gene mutations, with the intervening sequence 8(+158) variant in 21 and the R702W variant in 8.

**LIMITATIONS:** The NOD2 allelic frequency may need to be examined in a larger population with systemic autoimmune diseases.

**CONCLUSIONS:** The characteristic clinical phenotype, notably dermatitis, coupled with certain NOD2 variants constitutes a new autoinflammatory disease entity, which we have named as NOD2-associated autoinflammatory disease.

Small bowel MRI in adult patients: not just Crohn's disease-a tutorial.

Kavaliauskiene G(1), Ziech ML, Nio CY, Stoker J.

Author information:

(1)Department of Radiology, Academic Medical Center, Meibergdreef 9, 1105, AZ, Amsterdam, The Netherlands, giedre.kavaliauskiene@gmail.com.

**OBJECTIVES:** To provide an overview of less well-known small bowel and mesenteric diseases found at small bowel magnetic resonance (MR) enterography/enteroclysis and to review the imaging findings. MR enterography and enteroclysis are important techniques for evaluation of small bowel diseases. In most centres these techniques are primarily used in Crohn's disease, and most radiologists are familiar with these MRI findings. However, the knowledge of findings in other diseases is often sparse, including diseases that may cause similar clinical symptoms to those of Crohn's disease.

**METHODS:** We present a spectrum of less common and less well-known bowel and mesenteric diseases (e.g. internal hernia, intussusception, neuroendocrine tumour) from our small bowel MR database of over 2,000 cases.

**RESULTS:** These diseases can be found in patients referred for bowel obstruction, abdominal pain or rectal blood loss. Further, in patients with (or suspected to have) Crohn's disease, some of these diseases (e.g. neuroendocrine tumour, familial Mediterranean fever) may mislead radiologists to erroneously diagnose active Crohn's disease.

**CONCLUSION:** Radiologists should be familiar with diseases affecting the small bowel other than Crohn's disease, including diseases that may mimic Crohn's disease.

Toll-like receptors in gastrointestinal diseases.

Wagner H(1).

Author information:

(1)Institute of Med. Microbiology, Immunology and Hygiene, Technical University Munich, Munich, Germany. hermann.wagner @ mikrobio.med.tum.de

Innate immune cells - and many other cells - express evolutionarily conserved, germline-encoded receptors that recognize seemingly pathogen-derived ligands (also termed pathogen-associated molecular patterns), thereby allowing the host to perceive infection. Although they were the first to be discovered, Toll-like receptors (TLRs) are not the only pattern recognition receptors. TLRs are unlikely to discriminate between commensals and pathogens in the gut microbiota. There is, however, increasing evidence that TLRs shape intestinal function. In addition, certain bacteria appear to drive either Th1/Th17 proinflammatory immune responses, or T regulatory responses. Furthermore, TLRs appear to trigger 'sterile' autoinflammatory responses by sensing metabolically altered host (self) components.

IL-1 family cytokines trigger sterile inflammatory disease.

Lukens JR(1), Gross JM, Kanneganti TD.

Author information:

(1)Department of Immunology, St. Jude Children's Research Hospital Memphis, TN, USA.

Inflammation plays vital roles in protective responses against pathogens and tissue repair, however, improper resolution of inflammatory networks is centrally involved in the pathogenesis of many acute and chronic diseases. Extensive advances have been made in recent years to define the inflammatory processes that are required for pathogen clearance, however, in comparison, less is known about the regulation of inflammation in sterile settings. Over the past decade non-communicable chronic diseases that are potentiated by sterile inflammation have replaced infectious diseases as the major threat to global human health. Thus, improved understanding of the sterile inflammatory process has emerged as one of the most important areas of biomedical investigation during our time. In this review we highlight the central role that interleukin-1 family cytokines play in sterile inflammatory diseases.

Efficacy of anti-IL-1 treatment in Majeed syndrome.

Herlin T(1), Fiirgaard B, Bjerre M, Kerndrup G, Hasle H, Bing X, Ferguson PJ.

Author information:

(1)Department of Pediatrics, Aarhus University Hospital, Aarhus, Denmark.

**BACKGROUND AND OBJECTIVE:** Majeed syndrome is an autosomal recessive disorder characterised by the triad of chronic recurrent multifocal osteomyelitis, congenital dyserythropoietic anaemia and a neutrophilic dermatosis that is caused by mutations in LPIN2. Long-term outcome is poor. This is the first report detailing the treatment of Majeed syndrome with biological agents and demonstrates clinical improvement with IL-1blockade.

**METHODS:** We describe the clinical presentation, genetic analysis, cytokine profiles and response to biological therapy in two brothers with Majeed syndrome.

**RESULTS:** Both boys were homozygous for a novel 2-base pair deletion in LPIN2 (c.1312\_1313delCT; p.Leu438fs+16X), confirming the diagnosis. Their bone disease and anaemia were refractory to treatment with corticosteroids. Both siblings had

elevated proinflammatory cytokines in their serum, including tumour necrosis factor  $\alpha$  (TNF- $\alpha$ ), however a trial of the TNF inhibitor etanercept resulted in no improvement. IL-1 inhibition with either a recombinant IL-1 receptor antagonist (anakinra) or an anti-IL-1 $\beta$  antibody (canakinumab) resulted in dramatic clinical and laboratory improvement.

**CONCLUSIONS:** The differential response to treatment with TNF- $\alpha$  or IL-1 blocking agents sheds light into disease pathogenesis; it supports the hypothesis that Majeed syndrome is an IL-1 $\beta$  dependent autoinflammatory disorder, and further underscores the importance of IL-1 in sterile bone inflammation.

Sustained efficacy of the monoclonal anti-interleukin-1 beta antibody canakinumab in a 9-month trial in Schnitzler's syndrome.

de Koning HD(1), Schalkwijk J, van der Ven-Jongekrijg J, Stoffels M, van der Meer JW, Simon A.

Author information:

(1)Department of Dermatology, Radboud University Nijmegen Medical Centre, Nijmegen, The Netherlands. h.dekoning@derma.umcn.nl

**OBJECTIVES:** Schnitzler's syndrome is a chronic disabling autoinflammatory disorder, characterised by chronic urticaria, paraproteinemia and systemic inflammation. The interleukin (IL) 1 receptor antagonist anakinra is a very effective treatment, but requires daily injection and blocks both IL-1 $\alpha$  and IL-1 $\beta$ . Canakinumab is a selective human monoclonal anti-IL-1 $\beta$  antibody with a long half-life. We investigated the long-term efficacy and safety of canakinumab in Schnitzler's syndrome.

**METHODS:** In an open-label, single-treatment arm trial, eight patients with Schnitzler's syndrome received monthly injections with 150 mg canakinumab subcutaneously for 6 months, followed by a 3-month observation period. Primary outcome was complete or clinical remission at day 14. Secondary outcome measures

included inflammatory markers, quality of life, time to relapse, safety and tolerability.

**RESULTS:** After stopping anakinra, patients developed moderate to severe clinical symptoms. Canakinumab induced complete or clinical remission at day 14 in all eight patients. Median C-reactive protein concentrations decreased from 169 mg/l at baseline to less than 10 mg/l on day 14 and remained low or undetectable. One patient discontinued participation on day 39 because of return of symptoms while all others remained in complete or clinical remission during the 6-month treatment period. Relapse after last canakinumab dose occurred within 3 months in four patients. For two patients, remission continued several months post-study. Five patients reported at least one adverse event, predominantly mild upper respiratory tract infections. One patient died in a traffic accident.

**CONCLUSIONS:** In this 9-month study, monthly 150 mg canakinumab injection was an effective and well-tolerated treatment for Schnitzler's syndrome. Our data demonstrate that IL-1 $\beta$  plays a pivotal role in this disease. CLINICALTRIALS.GOV: NCT01276522.

Guidance on the use of canakinumab in patients with cryopyrin-associated periodic syndrome in Japan.

Yokota S(1), Nishikomori R, Takada H, Kikuchi M, Nozawa T, Kanetaka T, Kizawa T, Miyamae T, Mori M, Heike T, Hara T, Imagawa T.

Author information:

(1)Department of Pediatrics, Yokohama City University School of Medicine, 3-9, Fukuura, Kanazawa-ku, Yokohama 236-0004, Japan. syokota@med.yokohama-cu.ac.jp

Cryopyrin-associated periodic syndrome (CAPS) is an orphan disease with incidence of about one in 1,000,000 persons. This autoinflammatory disease develops in the neonatal period or early childhood, with various inflammatory symptoms occurring repeatedly throughout the patient's lifetime. It is caused by abnormality of the NLRP3 protein which mediates the intracellular signal transduction mechanism of

inflammatory processes, resulting in continuous overproduction of interleukin (IL)-1 $\beta$ , which induces chronic inflammation and progressive tissue damage. Definitive diagnosis of CAPS is difficult, and treatment has also been difficult because of a lack of effective medications in Japan. Clinical studies of human anti-human IL-1 $\beta$  monoclonal antibody (canakinumab) treatment were conducted in Japan, and approval was granted for therapeutic use of canakinumab for CAPS in September 2011. Similar to other biological drugs, canakinumab is clinically highly effective. However, sufficient attention to the method of use and adverse drug reactions is necessary. This guidance describes the use of canakinumab in Japan for CAPS in relation to exclusion criteria, method of use, evaluation criteria, and adverse drug reactions.

Suppurative necrotizing granulomatous lymphadenitis in adult-onset Still's disease: a case report.

Assimakopoulos SF(1), Karamouzou V, Papakonstantinou C, Zolota V, Labropoulou-Karatza C, Gogos C.

Author information:

(1)Department of Internal Medicine, University Hospital of Patras, Rion-Patras, 26504, Greece. sassim@upatras.gr.

**INTRODUCTION:** Lymphadenopathy is found in about 65% of patients with adult-onset Still's disease and is histologically characterized by an intense, paracortical immunoblastic hyperplasia. Adult-onset Still's disease has not been previously described as an etiology of suppurative necrotizing granulomatous lymphadenitis.

**CASE PRESENTATION:** We describe a 27-year-old Greek man who manifested prolonged fever, abdominal pain, increased inflammatory markers, episodic skin rash and mesenteric lymphadenopathy histologically characterized by necrotizing granulomatous adenitis with central suppuration. Disease flares were characterized by systemic inflammatory response syndrome with immediate clinico-laboratory response to corticosteroids but the patient required prolonged administration of methylprednisolone at a dose of above 12mg/day for disease

control. After an extensive diagnostic work-up, which ruled out any infectious, malignant, rheumatic or autoinflammatory disease the patient was diagnosed as having adult-onset Still's disease. The patient is currently treated with 4mg of methylprednisolone, 100mg of anakinra daily and methotrexate 7.5mg for two consecutive days per week and exerts full disease remission for six months.

**CONCLUSION:** To the best of our knowledge this is the first report of suppurative necrotizing granulomatous lymphadenitis attributed to adult-onset Still's disease. This case indicates that the finding of a suppurative necrotizing granulomatous lymphadenitis should not deter the consideration of adult-onset Still's disease as a potential diagnosis in a compatible clinical context; however, the exclusion of other diagnoses is a prerequisite.

Pregnancy outcome in women with familial Mediterranean fever.

Nabil H(1), Zayed A, State O, Badawy A.

Author information:

(1)Department of Obstetrics and Gynecology, Mansoura University, Mansoura, Egypt.

This study comprised 74 infertile patients with familial Mediterranean fever (FMF), among which 26 women became pregnant. Pregnancies were followed according to the standard antenatal follow-up protocol of high-risk pregnancies. The principal outcome measures were the termination of pregnancy and its upshot. This study comprised 74 infertile patients with FMF. Of the cases, 12 (16.22%) had antiphospholipid syndrome (APS); 16 patients (21.62%) had a history of previous abdominal/pelvic surgery, which might have been contributing to delay of conception; 66 patients (89.18%) were on drug therapy by corticosteroids, colchicines and other agents. A total of 10/22 patients were delivered by caesarean section for complicated pregnancies. Six of the newborns were positive for the MEFV gene. Favourable pregnancy outcome occurs in patients with FMF treated with colchicine before and after pregnancy. Neonatal outcome was similar to that expected in the general population.

Erratum in

Ann Intern Med. 2014 Feb 18;160(4):291-2.

**BACKGROUND:** Currently, there is no proven alternative therapy for patients with familial Mediterranean fever (FMF) that is resistant to or intolerant of colchicine. Interleukin-1 is a key proinflammatory cytokine in FMF.

**OBJECTIVE:** To assess the efficacy and safety of riloncept, an interleukin-1 decoy receptor, in treating patients with colchicine-resistant or -intolerant FMF.

DESIGN: Randomized, double-blind, single-participant alternating treatment study. (ClinicalTrials.gov number: NCT00582907).

SETTING: 6 U.S. sites.

PATIENTS: Patients with FMF aged 4 years or older with 1 or more attacks per month.

INTERVENTION: One of 4 treatment sequences that each included two 3-month courses of rilonacept, 2.2 mg/kg (maximum, 160 mg) by weekly subcutaneous injection, and two 3-month courses of placebo.

MEASUREMENTS: Differences in the frequency of FMF attacks and adverse events between rilonacept and placebo.

RESULTS: 8 males and 6 females with a mean age of 24.4 years (SD, 11.8) were randomly assigned. Among 12 participants who completed 2 or more treatment courses, the rilonacept-placebo attack risk ratio was 0.59 (SD, 0.12) (equal-tail 95% credible interval, 0.39 to 0.85). The median number of attacks per month was 0.77 (0.18 and 1.20 attacks in the first and third quartiles, respectively) with rilonacept versus 2.00 (0.90 and 2.40, respectively) with placebo (median difference, -1.74 [95% CI, -3.4 to -0.1];  $P = 0.027$ ). There were more treatment courses of rilonacept without attacks (29% vs. 0%;  $P = 0.004$ ) and with a decrease in attacks of greater than 50% compared with the baseline rate during screening (75% vs. 35%;  $P = 0.006$ ) than with placebo. However, the duration of attacks did not differ between placebo and rilonacept (median difference, 1.2 days [-0.5 and 2.4 days in the first and third quartiles, respectively];  $P = 0.32$ ). Injection site reactions were more frequent with rilonacept (median difference, 0 events per patient treatment month [medians of -4 and 0 in the first and third quartiles, respectively];  $P = 0.047$ ), but no differences were seen in other adverse events.

LIMITATION: Small sample size, heterogeneity of FMF mutations, age, and participant indication (colchicine resistance or intolerance) were study limitations.

CONCLUSION: Rilonacept reduces the frequency of FMF attacks and seems to be a treatment option for patients with colchicine-resistant or -intolerant FMF.

## Oral manifestations of systemic autoimmune and inflammatory diseases: diagnosis and clinical management.

Mays JW(1), Sarmadi M, Moutsopoulos NM.

### Author information:

(1)Clinical Research Core, National Institute of Dental and Craniofacial Research, National Institutes of Health, Bethesda, MD 20892, USA.

**CONTEXT:** Systemic autoimmune and inflammatory diseases often manifest oral lesions in their earliest stages, and early diagnosis, which may be spurred by a dental examination, is key for improved outcomes. After systemic diagnosis, oral lesions benefit from specialized care by dentists in collaboration with the medical team. This review aims to educate dental clinicians about the most relevant systemic autoimmune and inflammatory conditions with accompanying oral lesions, their implications for health, and management strategies supported by the biomedical literature and clinical experience. Ulcerative conditions including Behcet and Crohn diseases are discussed, along with rheumatic conditions including Sjögren syndrome, lupus erythematosus, and rheumatoid arthritis.

**EVIDENCE ACQUISITION:** Evidence was accumulated through PubMed searches using pertinent keywords for each subsection. References were reviewed and original publications examined to verify the accuracy of the information. We focused on evidence included in current reviews and randomized trials. Recommendations were supported by multiple studies and consensus expert opinion.

**EVIDENCE SYNTHESIS:** Disease phenotypes described and clinical recommendations were synthesized from best-quality evidence available for each disease. Efforts were made to describe evidence selection within each disease section.

**CONCLUSIONS:** Dentists play an important role in the early detection and multidisciplinary medical management of complex autoimmune diseases. It is important to recognize prevalent medical and dental issues and special needs of patients with autoimmune conditions. The management of many inflammatory conditions is similar, and often begins with the use of topical steroids, analgesics, and antimicrobial treatments, in addition to careful attention to oral hygiene and appropriate fluoride usage. In this brief review, we aim to discuss the presentation/prevalence, diagnosis, and treatment of oral manifestations encountered in autoimmune, autoinflammatory and systemic chronic

inflammatory diseases. Systemic autoimmune conditions are estimated to affect 5% to 8% of Americans.(1) Oral manifestations are encountered with high frequency, and are often the first clinical signs or symptoms of the general disease. Optimal management of complex autoimmune diseases requires a multidisciplinary medical team including dentists to care for lesions of the oral cavity. The dental practitioner may be asked to play a primary role in the diagnosis of such conditions and to participate with other health professionals working together to achieve effective clinical management. To aid in this process, we discuss in this article the current general knowledge of systemic autoimmune conditions that present with prevalent oral manifestations. The focus is on the diagnosis and management of the oral component of each disease. Importantly, whereas the etiology and pathogenesis and systemic clinical presentation may vary, presentation in the oral cavity is often similar and many conditions involve oral ulcerations. For this reason, we discuss the differential diagnosis and management of the most common oral ulcerations in a general section and subsequently address individual conditions that present with oral ulcerations. Similarly, treatment of various autoimmune/inflammatory oral conditions is often common and involves modulation or suppression of the immune response locally and/or systemically and will be therefore addressed in a common section as well as individually for each disease when unique treatment regimens are recommended. We present here our general treatment recommendations based on clinical experience and literature review; however, it is critical that good clinical judgment and specifics of an individual case should determine the appropriate dental/oral medicine intervention for a specific patient.

Dapsone as an alternative therapy in children with familial mediterranean Fever.

Salehzadeh F(1), Jahangiri S, Mohammadi E.

Author information:

(1)Department of Pediatrics, Ardabil University of Medical Sciences, Ardebil,

Iran.

**OBJECTIVE:** Familial Mediterranean Fever is an hereditary autoinflammatory disease that presents with recurrent febrile attacks and poly serositis. Colchicine is the only known treatment in this disease. However, nearly 5-10% of patients are resistant to colchicines. There are many different modalities in colchicine resistant patients, biologic and immunosuppressive drugs being the known ones. We studied the efficacy of Dapsone as an anti inflammatory drug in children with FMF who did not tolerate colchicine well.

**METHODS:** This is a case series study in 10 patients who had FMF on the base of Tel-Hashomer criteria and did not tolerate colchicine or did not respond to it well. Patients took 2mg/kg dapsone in single dose, during 6 months.

**FINDINGS:** In four patients episodic attacks returned after 27 days, so the drug was discontinued. One patient refused to continue the study; in five patients dapsone was taken in average for 8 months and 6 days, at least for 6 months. These five patients had no episodes of attack during the following observation.

**CONCLUSION:** Dapsone could control episodic attacks of FMF in 50% of cases. It might be considered as an alternative therapy in FMF cases not responding to colchicine.

**OBJECTIVES:** Familial Mediterranean fever (FMF) is an autoinflammatory disease characterized by recurrent attacks of fever and polyserositis and an autosomal

recessive inheritance mode. Up to 15 % of FMF patients are reported to experience perimenstrual attacks. Primary dysmenorrhea could be an incomplete abdominal attack, or patients with dysmenorrhea may have increased frequency of MEFV gene mutation carriage. Therefore, we aimed to evaluate the frequency of MEFV gene mutations in patients with dysmenorrhea.

**METHODS:** Eighty-four patients with primary dysmenorrhea attending consecutively to our gynecology department and 73 healthy female controls selected from hospital staff were included in the study, and MEFV gene mutations were analyzed.

**RESULTS:** The prevalence of total allelic variants was significantly increased in dysmenorrhea patients ( $p = 0.015$ ); analysis of individual variant rates revealed a significant increase in the frequency of MEFV gene mutations in dysmenorrhea patients compared with the control group ( $p = 0.036$ ).

**CONCLUSION:** Gynecologists and primary care physicians must be aware of FMF in the differential diagnosis of dysmenorrhea.

Comment in

*Pediatr Cardiol.* 2013 Jun;34(5):1293-4.

Pericarditis may recur in up to 30 % of adult patients, but recurrent pericarditis is a rare disease in childhood. The etiology of the initial attack and the causes of recurrences often remain unknown. Recurrent pericarditis is accompanied by a high morbidity rate and may represent a challenge to the clinician due to problems in management. Therapeutic strategies are not specific

and include nonsteroidal antiinflammatory drugs, corticosteroids, immunosuppressive drugs, colchicine, and pericardiectomy. Controlled trials have demonstrated that colchicine can reduce the recurrent rate of pericarditis, whereas early corticosteroid therapy promotes recurrences. Anakinra, a recombinant human interleukin-1 $\beta$  receptor antagonist, is a promising new biologic agent for the treatment of autoinflammatory diseases such as cryopyrinopathies, tumor necrosis factor receptor-associated periodic syndrome, and hyperimmunoglobulinemia D with periodic fever syndrome. This report describes an 11-year-old boy successfully treated with anakinra for a steroid-dependent recurrent pericarditis unresponsive to conventional treatment.

Author information:

(1)Center of Excellence for Biodiversity, Faculty of Natural Sciences, University of Tabriz, Tabriz, Iran. jabbarpour@tabrizu.ac.ir

Familial Mediterranean fever (FMF) is an autosomal recessive disorder characterized by intermittent episodes of fever with serositis, arthritis, or erisiplemia. Plasminogen activator inhibitor 1 (PAI-1) is a key element in the inhibition of fibrinolysis by inactivating tissue-type and urokinase-type plasminogen activators. We evaluated the association of PAI-1 -675 4G/5G polymorphism with the severity of FMF disease. For this purpose, 89 FMF patients with M694V homozygous mutation and 95 healthy controls from Iranian Azeri Turks were selected. Detection of this polymorphism was performed by polymerase chain reaction using allele-specific primers. No significant association was found between patients and control group. However, these data showed that FMF patients with M694V homozygous mutation carrying 4G/4G genotype have a reduced risk for development of pleuritis (odds ratios (OR) 0.36; 95 % confidence intervals (CI)

0.5-0.85; P value = 0.007) compared with 5G/5G homozygotes who have increased risk for development of amyloidosis (OR = 2.46; 95 %CI = 1.29-4.72; P value = 0.001), pleuritis (OR = 2.55; 95 %CI = 1.31-4.99; P value = 0.001), and fever (OR = 4.68; 95 %CI = 2.04-10.96; P value = 0.000). Furthermore, the allelic frequency of the 4G among the patients with pleuritis was significantly low (OR = 0.5, 95 % CI = 0.27-0.92, P value = 0.008).CONCLUSION: Our data suggest a protective role for the 4G allele against pleuritis in FMF patients with M694V homozygous mutation in this cohort. More evaluation of this polymorphism may be important and require further studies.

Behçet's disease is a systemic disorder with the histopathological correlate of leukocytoclastic vasculitis. Pathogenetically, besides a strong genetic component participation of the innate immune system and an autoinflammatory component are discussed. The disease is most common in countries along the former silk route but in Germany the disease is rare (prevalence approximately 0.6/100,000). Oral aphthous ulcers are the main symptom, followed by skin manifestations, genital ulcers and oligoarthritis of large joints. Severe manifestations, threatening quality of life and even life itself, are the gastrointestinal manifestations which often perforate, arterial, mainly pulmonary arterial aneurysms which cause life-threatening bleeding, CNS manifestations and ocular disease, which with occlusive retinal vasculitis often leads to blindness. For milder manifestations

low-dose steroids and colchicine are used, for moderate manifestations such as arthritis or ocular disease not immediately threatening visual acuity, azathioprin or cyclosporin A are combined with steroids. For severe manifestations, interferon-alpha, TNF-antagonists or cytotoxic drugs are recommended. Interleukin 1 (IL-1) antagonists are currently being examined in clinical studies.

(1)Department of Clinical Immunology, St. James's University Hospital, Leeds, UK.  
s.savic@leeds.ac.uk

The term 'autoinflammatory disease' was first proposed in 1999 to encompass some of the distinct clinicopathologic features of a group of monogenic conditions, characterised by recurrent episodes of inflammation, without high-titre autoantibodies or antigen-specific T cells. It was subsequently observed that several of these conditions were caused by mutations in proteins involved in the innate immune response, including, among others, components of the NLRP3 inflammasome, cytokine receptors (tumour necrosis factor receptor 1 (TNFR1)) and receptor antagonists (interleukin 1 receptor antagonist (IL-1RA)). More recently, additional mechanisms linking innate immune-mediated inflammation with a variety of cellular processes, including protein misfolding, oxidative stress and mitochondrial dysfunction, have been recognised to play a role in the pathogenesis of some monogenic autoinflammatory conditions, and also in more common diseases such as type 2 diabetes (T2D), previously perceived as a metabolic disorder, but reclassified as a chronic inflammatory condition. NLRP3 inflammasome activation is induced by islet amyloid polypeptides (IAPPs) in T2D and this condition may, in future, be more commonly treated with targeted

anti-cytokine therapies. Caspase 1 activation and release of IL-1 $\beta$ /IL-1 family members is central to the pathogenesis of many autoinflammatory syndromes, as evidenced by the effectiveness of anti-IL-1 biologics in treating these disorders. However, many patients continue to experience symptoms of chronic inflammation, and it will be necessary to translate discoveries on the immunopathology of these conditions into more effective therapies. For example, in tumour necrosis factor receptor-associated periodic fever syndrome (TRAPS), the pathogenesis may vary with each mutation and therefore future approaches to treatment of individual patients will require a more tailored approach based on genetic and functional studies.

Familial Mediterranean fever (FMF), inherited in an autosomal recessive manner, is a systemic auto-inflammatory disorder characterized by recurrent attacks of fever with peritonitis, pleuritis, synovitis and erysipeloid rash. The marenostin-encoding fever (MEFV) gene, located on chromosome 16p13.3, is the only gene in which mutations are currently known to cause FMF. To correlate specific genotypes with adverse phenotypes of affected populations residing in the Western United States, a retrospective case series review was conducted of all MEFV gene mutation testing completed at UCLA Clinical Molecular Diagnostic Laboratory between February 2002 and February 2012, followed by clinical chart review of all subjects who either have a single or double mutation. All 12 common

mutations in the MEFV gene were analyzed and the M694V variant was found to be associated with an adverse FMF clinical outcome in the Armenian-American population, manifested by earlier onset of disease, increased severity of disease, and renal amyloidosis.

Author information:

(1)Department of Medical Biology and Genetics, Faculty of Medicine, Inonu University, Malatya, Turkey. elif.yesilada@inonu.edu.tr

Familial Mediterranean fever (FMF) is an autosomal recessive disorder characterized by recurrent attacks of fever and serositis. Mutations in the Mediterranean fever gene (MEFV) localized on the short arm of chromosome 16 cause FMF. Over 90 MEFV missense/nonsense mutations have been identified so far in FMF patients, mostly in the 10th exon of the gene. In this study, the molecular test results of 891 patients identified as having FMF clinical symptoms referred to Molecular Genetics Laboratory of the Department of Medical Biology and Genetics, Faculty of Medicine, Inonu University, Malatya/Turkey were retrospectively evaluated. Patients were referred by their physicians for MEFV mutation detection. The DNA fragments including hot spots within the coding sequences of the MEFV gene were amplified by PCR using genomic DNA and analyzed by pyrosequencing technique. Of the 891 patients investigated, 420 (47.13%) had at least one mutation. The most frequent mutation was E148Q, followed by M694V, M680I (G/C), P369S, V726A, R761H, A744S, M694I, K695R and F479L mutations. In addition, a novel missense mutation (M694K) was reported in seven members of a

family in the course of mutation screening of patients.

Long-term efficacy and safety profile of rilonacept in the treatment of cryopyrin-associated periodic syndromes: results of a 72-week open-label extension study.

Hoffman HM(1), Throne ML, Amar NJ, Cartwright RC, Kivitz AJ, Soo Y, Weinstein SP.

Author information:

(1)University of California-San Diego, La Jolla, USA. hahoffman@ucsd.edu

**BACKGROUND:** Cryopyrin-associated periodic syndromes (CAPS) are rare, inherited autoinflammatory disorders associated with considerable hardship to patients. The interleukin-1 inhibitor rilonacept has been shown to be well-tolerated and effective in preventing CAPS symptoms in 2 pivotal studies.

**OBJECTIVE:** In this study, the long-term effects of rilonacept for improvement in CAPS symptoms and its safety and tolerability were evaluated during extended treatment.

**METHODS:** Patients with CAPS entered a 72-week open-label extension (OLE) following 2 sequential placebo-controlled Phase III studies (n = 44), or entered directly into the OLE (n = 57). Adults received weekly subcutaneous rilonacept 160 mg, and pediatric patients received subcutaneous rilonacept 2.2 mg/kg, up to 160 mg/week. Safety was evaluated in all patients, and efficacy was evaluated using a validated composite key symptom score in 56 patients.

**RESULTS:** After rilonacept treatment for 72 to 96 weeks mean key symptom score at OLE Week 72 was reduced from 2.6 to 0, and the mean number of multisymptom flare days was reduced from 7.3 (34.8% of days) at baseline to 0.6 (2.9% of days) at end point. Elevated levels of inflammatory markers (eg, high sensitivity-C reactive protein and serum amyloid A, were normalized. Adverse events were generally mild to moderate, the most common being injection site reactions and

upper respiratory tract infections. The incidence of these events was similar to or lower than the rate reported in the pivotal studies.

**CONCLUSIONS:** Long-term treatment with rilonacept of up to 96 weeks resulted in improvements in clinical signs and symptoms of CAPS and normalized biomarkers of inflammation. Rilonacept exhibited a generally favorable safety and tolerability profile in adult and pediatric patients with CAPS throughout the extended treatment period. ClinicalTrials.gov identifier: NCT 00288704.

Familial Mediterranean fever in siblings.

Özçakar ZB(1), Erdogan BD, Elhan AH, Yalçinkaya F.

Author information:

(1)Department of Pediatric Nephrology and Department of Biostatistics, Ankara University School of Medicine, Ankara, Turkey.

**OBJECTIVE:** Genetic and environmental factors have been implicated in disease severity and development of amyloidosis in familial Mediterranean fever (FMF). We investigated similarities in clinical characteristics, disease severity, and treatment response within siblings with FMF.

**METHODS:** The study group consisted of 2 or more siblings who were followed in our center with the diagnosis of FMF. Siblings were evaluated for demographic data, clinical and laboratory disease features, genetic analysis of MEFV mutations, and disease severity score. The intraclass correlation coefficient (ICC), which can be interpreted as the expected correlation between 2 siblings, was used to reflect within-family similarity.

**RESULTS:** The study included 67 pediatric patients from 31 different families. When we investigated the similarity of siblings after adjusting for genetic effects, we found very low ICC with  $p > 0.05$  in the majority of clinical features, disease severity, and colchicine dosages. However, age at disease onset, age at onset of therapy, attack-free acute-phase reactant levels, and

presence of amyloidosis were found to be similar within siblings (relatively high ICC with  $p < 0.05$ ).

**CONCLUSION:** Siblings with FMF had different clinical findings and disease severity. They had similar amyloidogenic potential, proven by both similar presence of amyloid and increased levels of acute-phase reactants between attacks. Our findings strongly support that genetic factors may be more dominant in the development of amyloidosis.

2585. J Clin Immunol. 2013 Feb;33(2):325-34. doi: 10.1007/s10875-012-9805-x. Epub 2012 Sep 27.

In vitro analysis of the functional effects of an NLRP3 G809S variant with the co-existence of MEFV haplotype variants in atypical autoinflammatory syndrome.

Kubota K(1), Ohnishi H, Teramoto T, Matsui E, Murase K, Kanoh H, Kato Z, Kaneko H, Seishima M, Kondo N.

Author information:

(1)Department of Pediatrics, Graduate School of Medicine, Gifu University, 1-1 Yanagido, Gifu, 501-1194, Japan.

**PURPOSE:** Hereditary periodic fever syndromes have been considered monogenic diseases. However, some recent reports have described patients with co-existence of recurrent fever responsible genes. This study assessed whether a rare variant, found in Japanese children showing atypical autoinflammatory syndrome, located in the leucine-rich repeat domain of Nod-like receptor family, pyrin domain containing 3 (NLRP3) with co-existence of Mediterranean fever (MEFV) haplotype variants may contribute to a proinflammatory phenotype using a systematic approach.

**METHODS:** Cytokine production in serum or from peripheral blood monocytes was measured by ELISA. DNA sequence analysis of genes including NLRP3, MEFV, mevalonate kinase (MVK), and tumor necrosis factor receptor superfamily, member 1A (TNFRSF1A) were performed on patient samples. In vitro functional assays determined the effects of the NLRP3 variants and pyrin using NF- $\kappa$ B activation and speck formation assays.

**RESULTS:** A heterozygous genetic variant of NLRP3, G809S, was found in samples from both patients. Additionally the previously reported heterozygous MEFV variants (P369S-R408Q or E148Q-P369S-R408Q) were also detected in both patients. Serum IL-1ra and sTNFR1 levels increased in the attack phase of the disease in both patients. The production levels of IL-1 $\beta$  from monocytes isolated from both cases were elevated following LPS and IFN- $\gamma$  stimulation. The NLRP3 G809S variant demonstrated no increase of NF- $\kappa$ B activity following monosodium urate stimulation, whereas it significantly increased speck formation by interacting with apoptosis-associated speck-like protein with caspase recruitment domain.

**CONCLUSIONS:** The phenotype of atypical autoinflammatory disease in patients could be modified by a synergistic effect with two other variants of autoinflammatory-associated genes.

Therapeutic approach to patients with familial Mediterranean fever-related amyloidosis resistant to colchicine.

Korkmaz C(1).

Author information:

(1)Division of Rheumatology, Department of Internal Medicine, Eskişehir Osmangazi University, School of Medicine, Eskişehir, Turkey. ckorkmaz@ogu.edu.tr

The frequency of FMF-related amyloidosis has been decreased by colchicine use over the past few decades. However, the beneficial effect of colchicine may differ in accordance with nephropathic stages. When used in proper doses and with compliance, colchicine is very effective in preclinical and proteinuric stages of FMF-related amyloidosis. Even so, a large number of patients with nephrotic range proteinuria, despite compliance and an ideal dose of colchicine, may still progress to end-stage renal failure (ESRF). We do not know exactly what we can do with such patients. This paper discusses the therapeutic approach to patients with FMF-related amyloidosis.

2587. Clin Chim Acta. 2012 Dec 24;414:36-40. doi: 10.1016/j.cca.2012.07.019. Epub 2012 Aug 7.

Association between sequence variations of the Mediterranean fever gene and fibromyalgia syndrome in a cohort of Turkish patients.

Karakus N(1), Yigit S, Inanir A, Inanir S, Toprak H, Okan S.

Author information:

(1)Faculty of Medicine, Department of Medical Biology, Ondokuz Mayıs University, Samsun, Turkey.

**OBJECTIVE:** Fibromyalgia syndrome (FMS) is a common chronic widespread pain syndrome mainly affecting women. Genetic risk factors are known to contribute to the etiology of the syndrome. Clinical features show that FMS and familial Mediterranean fever (FMF) have some overlapping symptoms. Mediterranean fever (MEFV) gene has already been identified as being responsible for FMF. The aim of this study was to explore the frequency and clinical significance of missense mutations and a common polymorphism of MEFV gene in a cohort of Turkish patients with FMS.

**METHODS:** The study included 187 patients with FMS and 190 healthy controls. Genomic DNA was isolated and genotyped using polymerase chain reaction (PCR) and restriction fragment length polymorphism (RFLP) analyses for the five MEFV gene mutations (M694V, M680I, V726A, E148Q and P369S) and one polymorphism (R202Q).

**RESULTS:** There were statistically significant differences of the MEFV gene mutation carrier rates and allele frequencies between FMS patients and healthy controls ( $p=0.002$ , OR: 2.3, 95% CI: 1.35-4.16 and  $p=0.003$ , OR: 2.2, 95% CI: 1.28-3.75, respectively). There was also a significant difference between MEFV mutation carriers and non-carriers with respect to the clinical characteristic of morning fatigue ( $p=0.045$ ). The genotype and allele frequencies of R202Q polymorphism of MEFV gene showed statistically significant differences between FMS patients and healthy controls ( $p<0.0001$  and  $p<0.0001$ , respectively) and especially the homozygous AA genotype was significantly higher in FMS patients than in healthy controls ( $p=0.0003$ ; OR: 7.43, 95% CI: 2.14-39.75). While 13 of the 44 FMS patients with MEFV mutation had R202Q polymorphism, none of the 22 controls with MEFV mutation had R202Q polymorphism. Stratification analysis

according to clinical features for this disease reveals that morning fatigue and irritable bowel syndrome had associations with R202Q polymorphism ( $p=0.022$  and  $p=0.031$  respectively).

**CONCLUSION:** The results of this study suggest that MEFV gene mutations and polymorphism are positively associated with predisposition to develop FMS. Further studies with larger populations will be required to confirm these findings.

FMF - clinical features, new treatments and the role of genetic modifiers: a critical digest of the 2010-2012 literature.

Berkun Y(1), Eisenstein E, Ben-Chetrit E.

Author information:

(1)Department of Pediatrics, Hadassah-Hebrew University Medical Center, Mount Scopus, Israel.

The last two years have been marked by many studies trying to better characterize the clinical features of FMF in children and proposal of new treatment for those who are resistant to colchicine. In addition, many studies tried to address the potential effect of genetic modifiers on FMF and the potential effect of MEFV mutations on other inflammatory diseases. The main points arose from these studies include a breakthrough in the therapeutic approach for FMF and the lack of consistency regarding the reciprocal effect of MEFV mutations on other diseases and the effect of genetic modifiers on FMF. The highlights of these studies, their potential clinical implications and the unmet needs, which are still to be addressed, are summarised in this review.

Concomitance of Gitelman syndrome and familial Mediterranean fever: a rare case presentation.

Erten S(1), Ceylan GG, Altunoğlu A.

Author information:

(1)Department of Rheumatology, Ankara Ataturk Education and Training Hospital, Ankara, Turkey.

We report a case that has Gitelman syndrome (GS) and familial Mediterranean fever (FMF) presenting with recurrent arthritis of right knee and heel pain.

Investigations showed hypokalemia and hypomagnesemia with urinary magnesium wasting. Genetic analysis revealed the presence of heterozygous E148Q mutation in the MEFV gene. Management with potassium, magnesium supplements, spironolactone for GS, and colchicine for FMF resulted in a significant improvement in symptoms.

To the best of our knowledge, this is the first report of association between GS and FMF. Further studies are needed to identify if there is an association between these two diseases and the genes responsible for these diseases.

Neurological complications of Behçet's syndrome.

Kidd D(1).

Author information:

(1)Department of Clinical Neurosciences, Royal Free Hospital, London NW3 2QG, UK.  
d.kidd@ucl.ac.uk

Behçet's syndrome is an autoinflammatory disease of uncertain cause characterized by mucous membrane ulceration, arthritis and inflammation within most tissues.

Its prevalence differs throughout different populations, but neurological complications arise in 10 % of all those affected. The majority develop inflammation within the central nervous system which may remit but may also progressively worsen without treatment. This article reviews the epidemiology, clinical characteristics, natural history and management of the disorders, and emphasizes recent considerable advances in our understanding of the various treatments which may be beneficial across the spectrum of disease types.

Periodic fever, aphthous stomatitis, pharyngitis, cervical adenitis syndrome is linked to dysregulated monocyte IL-1 $\beta$  production.

Kolly L(1), Busso N, von Scheven-Gete A, Bagnoud N, Moix I, Holzinger D, Simon G, Ives A, Guarda G, So A, Morris MA, Hofer M.

Author information:

(1)Rheumatology Service, DAL, Lausanne University Hospital, University of Lausanne, Lausanne, Switzerland.

**BACKGROUND:** The exact pathogenesis of the pediatric disorder periodic fever, aphthous stomatitis, pharyngitis, cervical adenitis (PFAPA) syndrome is unknown.

**OBJECTIVES:** We hypothesized that PFAPA might be due to dysregulated monocyte IL-1 $\beta$  production linked to genetic variants in proinflammatory genes.

**METHODS:** Fifteen patients with PFAPA syndrome were studied during and outside a febrile episode. Hematologic profile, inflammatory markers, and cytokine levels were measured in the blood. The capacity of LPS-stimulated PBMCs and monocytes to secrete IL-1 $\beta$  was assessed by using ELISA, and active IL-1 $\beta$  secretion was visualized by means of Western blotting. Real-time quantitative PCR was performed to assess cytokine gene expression. DNA was screened for variants of the MEFV, TNFRSF1A, MVK, and NLRP3 genes in a total of 57 patients with PFAPA syndrome.

**RESULTS:** During a febrile attack, patients with PFAPA syndrome revealed significantly increased neutrophil counts, erythrocyte sedimentation rates, and C-reactive protein, serum amyloid A, myeloid-related protein 8/14, and S100A12

levels compared with those seen outside attacks. Stimulated PBMCs secreted significantly more IL-1 $\beta$  during an attack (during a febrile episode, 575  $\pm$  88 pg/mL; outside a febrile episode, 235  $\pm$  56 pg/mL;  $P < .001$ ), and this was in the mature active p17 form. IL-1 $\beta$  secretion was inhibited by ZYVAD, a caspase inhibitor. Similar results were found for stimulated monocytes (during a febrile episode, 743  $\pm$  183 pg/mL; outside a febrile episode, 227  $\pm$  92 pg/mL;  $P < .05$ ). Genotyping identified variants in 15 of 57 patients, with 12 NLRP3 variants, 1 TNFRSF1A variant, 4 MEFV variants, and 1 MVK variant.

**CONCLUSION:** Our data strongly suggest that IL-1 $\beta$  monocyte production is dysregulated in patients with PFAPA syndrome. Approximately 20% of them were found to have NLRP3 variants, suggesting that inflammasome-related genes might be involved in this autoinflammatory syndrome.

Whole-exome sequencing was performed in a family affected by dominantly inherited inflammatory disease characterized by recurrent blistering skin lesions, bronchiolitis, arthralgia, ocular inflammation, enterocolitis, absence of autoantibodies, and mild immunodeficiency. Exome data from three samples, including the affected father and daughter and unaffected mother, were filtered

for the exclusion of reported variants, along with benign variants, as determined by PolyPhen-2. A total of eight transcripts were identified as possible candidate genes. We confirmed a variant, c.2120C>A (p.Ser707Tyr), within PLCG2 as the only de novo variant that was present in two affected family members and not present in four unaffected members. PLCG2 encodes phospholipase C $\gamma$ 2 (PLC $\gamma$ 2), an enzyme with a critical regulatory role in various immune and inflammatory pathways. The p.Ser707Tyr substitution is located in an autoinhibitory SH2 domain that is crucial for PLC $\gamma$ 2 activation. Overexpression of the altered p.Ser707Tyr protein and ex vivo experiments using affected individuals' leukocytes showed clearly enhanced PLC $\gamma$ 2 activity, suggesting increased intracellular signaling in the PLC $\gamma$ 2-mediated pathway. Recently, our laboratory identified in individuals with cold-induced urticaria and immune dysregulation PLCG2 exon-skipping mutations resulting in protein products with constitutive phospholipase activity but with reduced intracellular signaling at physiological temperatures. In contrast, the p.Ser707Tyr substitution in PLC $\gamma$ 2 causes a distinct inflammatory phenotype that is not provoked by cold temperatures and that has different end-organ involvement and increased intracellular signaling at physiological temperatures. Our results highlight the utility of exome-sequencing technology in finding causal mutations in nuclear families with dominantly inherited traits otherwise intractable by linkage analysis.

[Muckle-Wells syndrome caused by a new cryopyrin mutation: effective treatment with interleukin-1 antagonist].

[Article in Russian]

Rameev VV, Kozlovskaja LV, Bogdanova MV.

A significant progress in the field of molecular-biological investigations

resulted in definition of a new group of systemic diseases referred to as autoinflammatory. This group comprises familial periodic fevers: periodic disease (mediterranean fever), Muckle-Wells syndrome, others cryopyrinopathy, TRAPS-syndrome. As shown by case reports, Muckle-Wells syndrome is not a rare disease, its sporadic forms are encountered as well as a less severe variant of cryopyrinopathy - nonallergic cold urticaria. Awareness of the physicians in respect of this pathology is essential especially because early diagnosis enables control of this disease with use of biological preparations the spectrum of which tends to expansion. Moreover, arrest of inflammation is necessary for prevention of development and progression of such prognostically poor complication as AA-amyloidosis.

[Serum levels of myeloid-related protein MRP 8/14 (calprotectin) in Armenian patients with familial mediterranean fever].

[Article in Russian]

Dzhndoian ZT.

AIM: The determination of serum myeloid-related protein MRP 8/14 (calprotectin) in Armenian patients with FMF before and after treatment with colchicine (including colchicine-resistant patients who don't respond to 2 mg of colchicine; t patients who don't respond to 1,5 mg of colchicine, and also responders to different dose of colchicine) and estimation of the response to antiinflammatory therapy.

MATERIAL AND METHODS: MRP 8/14 serum levels were measured in 80 FMF patients before and after treatment with colchicine and in healthy individuals (n = 11) and patients with rheumatoid arthritis RA (n=11) as a control group. Serum MRP 8/14 concentration was measured by ELISA (Enzyme Linked-Immuno-Sorbent-Assay) method using "Buhlmann" kit (Switzerland) in the laboratory with modern equipment.

RESULTS: Serum MRP 8/14 concentrations were within a normal ranges in healthy individuals and elevated in patients with FMF and RA. MRP 8/14 serum levels in

FMF patients were higher than in RA patients. Serum MRP 8/14 concentrations in FMF patients before colchicines therapy were higher than after treatment.

CONCLUSION: The findings of our study indicate that myeloid-related protein MRP 8/14 is a very sensitive marker of the disease activity and response to antiinflammatory therapy in FMF.

Familial Mediterranean fever with onset at 66 years of age.

Inoue K(1), Torii K, Yoda A, Kadota K, Nakamichi S, Obata Y, Nishino T, Migita K, Kawakami A, Ozono Y.

Author information:

(1)Department of General Medicine, Nagasaki University School of Medicine, Japan.  
inoway77@gmail.com

The patient was a 68-year-old woman who had experienced recurrent febrile episodes since 66 years of age. Despite various examinations and treatments, the etiology remained unclear. Further examinations following another referral failed to uncover the cause. Therefore, despite her age, it was presumed that she had familial Mediterranean fever. An analysis of the familial Mediterranean fever (MEFV) gene detected heterozygous L110P, E148Q, and R202Q mutations. No further febrile episodes occurred after colchicine treatment was initiated. Familial Mediterranean fever presenting in patients in their sixties is extremely rare.

The prevalences [correction] and patient characteristics of primary immunodeficiency diseases in Turkey--two centers study.

Kilic SS(1), Ozel M, Hafizoglu D, Karaca NE, Aksu G, Kutukculer N.

Author information:

(1)Department of Pediatric Immunology, Uludag University School of Medicine, Görükle, Bursa, Turkey, 16059. sebnemkl@uludag.edu.tr

**PURPOSE:** Primary immunodeficiency diseases (PIDs) are inherited disorders of the immune system resulting in increased susceptibility to unusual infections and predisposition to autoimmunity and malignancies. The European Society for Immunodeficiencies (ESID) has developed an internet-based database for clinical and research data on patients with PID. This study aimed to provide a minimum estimate of the prevalence of each disorder and to determine the clinical characteristics and outcomes of patients with PID in Turkey.

**METHODS:** Clinical features of 1435 patients with primary immunodeficiency disorders are registered in ESID Online Patient Registry by the Pediatric Immunology Departments of the Medical Faculties of Uludag University and Ege University Between 2004 and 2010. These two centers are the major contributors reporting PID patients to ESID database from Turkey.

**RESULTS:** Predominantly antibody immunodeficiency (73.5 %) was the most common category followed by autoinflammatory disorders (13.3 %), other well defined immunodeficiencies (5.5 %), congenital defects of phagocyte number, function or both 3.5 %), combined T and B cell immunodeficiencies (2 %), defects in innate immunity (1 %), and diseases of immune dysregulation (0.7 %). Patients between 0 and 18 years of age constituted 94 % of total and the mean age was  $9.2 \pm 6$  years. The consanguinity rate within the registered patients was 14.3 % (188 of 1130 patients). The prevalence of all PID cases ascertained from the registry was 30.5/100.000. The major cause of the mortality was severe infection which was seen in forty-two of seventy five deceased patients. The highest mortality was observed in patients with severe combined immunodeficiencies and ataxia-telangiectasia.

**CONCLUSION:** Promoting the awareness of PID among the medical professionals and the general public is required if premature death and serious morbidity occurs due to late diagnosis of the wider spectrum of PID are to be avoided.

**OBJECTIVE:** Pseudotumor cerebri (PTC) is a clinical condition characterized by signs and symptoms of increased intracranial pressure, such as headache and papilledema. Our aim was to investigate the etiological and clinical features of pseudotumor cerebri (PTC) in children.

**MATERIALS AND METHOD:** We performed a comprehensive analysis of epidemiology, diagnostic work-up, therapy, and clinical follow-up in 42 consecutive patients.

**RESULTS:** Totally 42 patients diagnosed with PTC [27 (64.3%) females and 15 (35.7%) males] were included in the study. The average age of the symptoms onset was  $10.79 \pm 3.43$  years (range from 12 months to 17 years). Obesity was found in eleven (26.2%) of them. Two of the patients had familial mediterranean fever, two of them had posttraumatic PTC. The following diseases were one patient, respectively; mycophenolate mofetil-induced PTC, hypervitaminosis A induced PTC, corticosteroid induced withdrawal due to nephritic syndrome, use of oral contraceptives, Guillain-Barre syndrome, urinary tract infection, varicella-zoster virus infection and dural venous sinus thrombosis associated with otitis media. The most common symptom was headache, recorded in 76.2% of the patients. All patients were treated medically. Three patients in our group also required a ventriculoperitoneal shunt.

**CONCLUSION:** Pseudotumor cerebri is an avoidable cause of visual loss, both in adults and children. Pre-pubertal obese girls are more common. Medical therapy appeared to be successful in treating pediatric PTC in most patients.

Nevertheless, despite adequate treatment, children can rarely experience loss of visual field and acuity; thus, prompt diagnosis and management are important.

Comment in

Bratisl Lek Listy. 2013;114(11):668.

**OBJECTIVES:** In this study, alterations in antioxidant enzyme activities and malondialdehyde (MDA) levels in the serum samples of patients with familial Mediterranean fever (FMF), an autosomal recessive disease characterized by recurrent episodes of peritonitis, pleuritis, arthritis and fever, were investigated and compared with those of age- and sex-matched healthy controls.

**METHODS:** Twenty-five patients with FMF undergoing colchicine therapy at doses of 1-1.5 mg and 25 age- and sex-matched healthy controls were included in the study. In the patients with FMF and control subjects, the erythrocyte sedimentation rate (ESR) and C-reactive protein (CRP) level were measured. Cu/Zn-superoxide dismutase (Cu/Zn-SOD), paraoxonase-1 (PON-1) and arylesterase (ARE) enzyme activities and MDA levels as a production of lipid peroxidation were evaluated using the appropriate methods.

**RESULTS:** No statistically significant differences in the serum levels of ESR, CRP, Cu/Zn-SOD, MDA and PON-1 between the groups were observed ( $p>0.05$ ). Serum ARE activity was significantly decreased in the patients with FMF compared with the control subjects ( $p<0.01$ ).

**CONCLUSION:** In conclusion, some abnormalities in the antioxidant defense system and lipid peroxidation may be observed in FMF patients during attack-free periods. However, further long-term studies on the subject are needed to explore altered lipid peroxidation and antioxidant defense mechanisms in patients with

FMF (Tab. 1, Fig. 1, Ref. 35).

How not to miss autoinflammatory diseases masquerading as urticaria.

Krause K(1), Grattan CE, Bindslev-Jensen C, Gattorno M, Kallinich T, de Koning HD, Lachmann HJ, Lipsker D, Navarini AA, Simon A, Traidl-Hoffmann C, Maurer M.

Author information:

(1)Autoinflammation Reference Center Charité, Charité-Universitätsmedizin Berlin, Berlin, Germany.

Urticarial skin reactions are one of the most frequent problems seen by allergists and clinical immunologists in daily practice. The most common reason for recurrent wheals is spontaneous urticaria. There are, however, several less common diseases that present with urticarial rash, such as urticarial vasculitis and autoinflammatory disorders. The latter include cryopyrin-associated periodic syndrome and Schnitzler's syndrome, both rare and disabling conditions mediated by increased interleukin-1 secretion. Apart from the urticarial rash, patients are suffering from a variety of systemic symptoms including recurrent fever attacks, arthralgia or arthritis and fatigue. Autoinflammatory diseases are often associated with a diagnostic delay of many years and do not respond to antihistamines and other treatments of urticaria. Also, the chronic inflammation may lead to long-term complications such as amyloidosis. It is therefore important not to miss these diseases when diagnosing and treating patients with chronic recurrent urticarial rash. Here, we present clinical clues and tips that can help to identify autoinflammatory disorders in patients presenting with chronic urticarial rash and discuss their clinical picture and management.

Inflammasomes and their roles in health and disease.

Lamkanfi M(1), Dixit VM.

Author information:

(1)Department of Biochemistry, Ghent University, Ghent 9000, Belgium.

Inflammasomes are a set of intracellular protein complexes that enable autocatalytic activation of inflammatory caspases, which drive host and immune responses by releasing cytokines and alarmins into circulation and by inducing pyroptosis, a proinflammatory cell death mode. The inflammasome type mediating these responses varies with the microbial pathogen or stress factor that poses a threat to the organism. Since the discovery that polymorphisms in inflammasome genes are linked to common autoimmune diseases and less frequent periodic fever syndromes, inflammasome signaling has been dissected at the molecular level. In this review, we present recently gained insight on the distinct inflammasome types, their activation and effector mechanisms, and their modulation by microbial virulence factors. In addition, we discuss recently gained knowledge on the role of deregulated inflammasome activity in human autoinflammatory, autoimmune, and infectious diseases.

Optical projection tomography reveals dynamics of HEV growth after immunization with protein plus CFA and features shared with HEVs in acute autoinflammatory lymphadenopathy.

Kumar V(1), Chyou S, Stein JV, Lu TT.

Author information:

(1)Autoimmunity and Inflammation Program and Pediatric Rheumatology, Hospital for Special Surgery New York, NY, USA.

The vascular-stromal compartment of lymph nodes is important for lymph node function, and high endothelial venules (HEVs) play a critical role in controlling the entry of recirculating lymphocytes. In autoimmune and autoinflammatory diseases, lymph node swelling is often accompanied by apparent HEV expansion and, potentially, targeting HEV expansion could be used therapeutically to limit autoimmunity. In previous studies using mostly flow cytometry analysis, we defined three differentially regulated phases of lymph node vascular-stromal growth: initiation, expansion, and the re-establishment of vascular quiescence and stabilization. In this study, we use optical projection tomography to better understand the morphologic aspects of HEV growth upon immunization with ovalbumin/CFA (OVA/CFA). We find HEV elongation as well as modest arborization during the initiation phase, increased arborization during the expansion phase, and, finally, vessel narrowing during the re-establishment of vascular quiescence and stabilization. We also examine acutely enlarged autoinflammatory lymph nodes induced by regulatory T cell depletion and show that HEVs are expanded and morphologically similar to the expanded HEVs in OVA/CFA-stimulated lymph nodes. These results reinforce the idea of differentially regulated, distinct phases of vascular-stromal growth after immunization and suggest that insights gained from studying immunization-induced lymph node vascular growth may help to understand how the lymph node vascular-stromal compartment could be therapeutically targeted

in autoimmune and autoinflammatory diseases.

Common Mediterranean fever (MEFV) gene mutations associated with ankylosing spondylitis in Turkish population.

Yigit S(1), Inanir A, Karakus N, Kesici E, Bozkurt N.

Author information:

(1)Department of Medical Biology, Faculty of Medicine, Gaziosmanpasa University, Tokat, Turkey.

Ankylosing spondylitis (AS) is a common inflammatory rheumatic disease. Mediterranean fever (MEFV) gene, which has already been identified as being responsible for familial Mediterranean fever (FMF), is also a suspicious gene for AS because of the clinical association of these two diseases. The aim of this study was to explore the frequency and clinical significance of MEFV gene mutations (M694V, M680I, V726A, E148Q and P369S) in a cohort of Turkish patients with AS. Genomic DNAs of 103 AS patients and 120 controls were isolated and

genotyped using polymerase chain reaction (PCR) and restriction fragment length polymorphism (RFLP) methods. There was a statistically significant difference of the MEFV gene mutation carrier rates between AS patients and healthy controls ( $p=0.004$ , OR: 2.5, 95% CI: 1.32-4.76). This association was also observed in allele frequencies ( $p=0.005$ , OR: 2.3, 95% CI: 1.27-4.2). A relatively higher frequency was observed for M694V mutation in AS patients than controls (10.7% versus 4.2% ,  $p=0.060$ ). There were no significant differences between MEFV mutation carriers and non-carriers with respect to the clinical and demographic characteristics. The results of this study suggest that MEFV gene mutations are positively associated with a predisposition to develop AS.

Author information:

(1)Department of Plastic Surgery, School of Medicine, University of Tor Vergata, Rome, Italy.

Secondary amyloidosis is associated with a variety of chronic inflammatory diseases such as rheumatoid arthritis, ankylosing spondylitis, familial Mediterranean fever, osteomyelitis, inflammatory bowel diseases and infective or neoplastic conditions. Few cases of secondary amyloidosis complicating psoriasis have been reported. We describe a 58-year-old patient with secondary amyloidosis, psoriasis, an associated symbrachydactyly of the hand and a transverse deficiency of the foot. To the best of our knowledge, no case of this association has been previously reported.

The frequency of MEFV gene mutation in patients admitted to hospital with preliminary diagnosis of familial mediterranean fever who undergone a prior appendectomy.

Yolbas I(1), Ozen F, Kocak N, Kelekci S, Gunes A, Yel S.

Author information:

(1)Department of Pediatrics, Dicle University, School of Medicine, Diyarbakir, Turkey. ilyasyolbas@hotmail.com

**OBJECTIVES:** Familial mediterranean fever (FMF) is an autosomal recessive disease characterized by recurrent and self-limiting fever, peritonitis, arthritis, synovitis, pleuritis, carditis, and erysipelas-like lesions. The aim of this study was to investigate the frequency of the MEFV gene mutation in patients who admitted to hospital with preliminary diagnosis FMF and who had undergone a prior appendectomy.

**PATIENTS AND METHODS:** We retrospectively reviewed the files of 52 patients between the ages of 7-18 who admitted to hospital with preliminary diagnosis of FMF and who had undergone a prior appendectomy. Age, gender and the MEFV gene mutations were included in the data. The 12 known, common MEFV gene mutations [E148Q, P369S, F479L, M6801 (G/C), M6801 (G/A), 1692del, M694V, M694I, K695R, V726A, A744S, R761H] were investigated in the patients.

**RESULTS:** Of these 52 cases, 29 (55.8%) were female and 23 (44.2%) were male. Their mean age was 12.1 +/- 3.1 years (range 7-18 yr). MEFV gene mutation was detected in 31/52 cases (59.6%). In this study was found an high frequency of the MEFV gene mutation in patients admitted to hospital with a preliminary diagnosis FMF who had undergone a prior appendectomy. MEFV gene mutations were M694V 16/41 (39%), E148Q 13/41 (31%), M6801 6/41 (15%), V726A 4/41 (10%) and R761H 2/41 (5%). Other genes mutations were F479L, M6801 (G/A), 1692del, M694I, K695R and A744S.

**CONCLUSION:** There are too much indications of unnecessary appendectomy in MEFV gene mutation carriers. In MEFV gene mutation carriers the frequency of appendicitis can be higher than the normal population. A more detailed and extensive study should be done about it.

Exertional leg pain as a manifestation of occult spondyloarthropathy in familial Mediterranean fever: an MRI evaluation.

Eshed I(1), Kushnir T, Livneh A, Langevitz P, Ben-Zvi I, Konen E, Lidar M.

Author information:

(1)Department of Diagnostic Imaging, Sheba Medical Center, Tel Hashomer, Tel Aviv, Israel. irished@gmail.com

**OBJECTIVES:** Familial Mediterranean fever (FMF) is characterized by recurrent episodes of fever, peritonitis, arthritis, and pleuritis, caused by neutrophil-induced sterile serositis. Another clinical manifestation in patients with FMF is exertional leg and ankle pain that appears after minor exercise, for which the underlying mechanism is obscure. The purpose of the current study was to feature distal leg changes in FMF patients complaining of exertional leg pain, using magnetic resonance imaging (MRI).

**METHODS:** Eleven patients with FMF who suffer from exertional leg pain (eight males, three females; mean age 33 years) and six unaffected controls (three males, three females; mean age 39 years) underwent MRI (3 T) of the ankle, including conventional T1 and T2 with fat saturation sequences, before and after graded exercise on a treadmill. Clinical and genetic data and sacroiliac radiographs were obtained.

**RESULTS:** Ten patients (91%) with FMF but none of the control group had signs compatible with enthesitis of the Achilles tendon, long plantar ligament, or the plantar fascia (including enthesophytes, erosions, and bone marrow oedema). Nine patients (80%) had radiographic signs of sacroiliitis on the pelvic radiograph.

**CONCLUSIONS:** Exertional leg pain in FMF patients, shown to be associated with signs of enthesopathy on imaging, may be included within the spectrum of spondyloarthropathy.

The dual roles of inflammatory cytokines and chemokines in the regulation of autoimmune diseases and their clinical implications.

Shachar I(1), Karin N.

Author information:

(1)Department of Immunology, The Weizmann Institute of Science, Rehovot, Israel.  
idit.shachar@weizmann.ac.il

Cytokines and chemokines are secreted, small cell-signaling protein molecules, whose receptors are expressed on immune cells. These factors play a critical role in immune cell differentiation, migration, and polarization into functional subtypes and in directing their biological functions. Much attention has been devoted to exploring the role of key inflammatory cytokines and promigratory chemokines in autoimmune, autoinflammatory, and allergic diseases, leading to development of therapeutic strategies that are based on their targeted neutralization. Recent studies, including those coming from our groups, show that several major proinflammatory cytokines and chemokines, including IFN- $\gamma$ , IL-2, CCL2, and CXCL12, may also function as anti-inflammatory mediators and therefore, may have potential as anti-inflammatory drugs. Likewise, major anti-inflammatory mediators, such as TGF- $\beta$ , may under certain conditions, in combination with other cytokines, exhibit proinflammatory function and direct the polarization of the highly inflammatory CD4(+) Th17 cells. We show here that the biological function of pro- and anti-inflammatory cytokines is dependent on three key parameters: the local concentration of a given cytokine, the stage of disease in which it is administered, and its combination with other cytokines. The therapeutic implications of these findings are discussed, including two very recent studies summarizing clinical trials, in which low-dose administration of IL-2 was used to successfully suppress HCV and GVHD.

## High Frequency of Inherited Variants in the MEFV Gene in Acute Lymphocytic Leukemia.

Sayan O, Kilicaslan E, Celik S, Tangi F, Erikci AA, Ipcioglu O, Sanisoglu YS, Nalbant S, Oktenli C.

In the present study, we aimed to determine the frequency of inherited variants in the MEFV (Mediterranean FeVer), the gene responsible for familial Mediterranean fever (FMF), gene in patients with acute lymphocytic leukemia (ALL). The eight MEFV gene variants (M694I, M694V, M680I (G/C-A), V726A, R761H, E148Q and P369S) were detected in 36 patients with ALL and 65 healthy controls; none had own and/or family history compatible with FMF. We identified 11 heterozygous inherited variants in the MEFV gene in both ALL patients and controls. The mean overall frequency of inherited variants in the MEFV gene rate was higher in ALL patients than healthy controls ( $P = 0.040$ ). It is interesting to note that M680I/0 is predominant variant in patients with ALL. In addition, E148Q variant frequency was also significantly higher in the patient group than the controls ( $P = 0.012$ ). In conclusion, overall frequency of inherited variants in the MEFV gene was found to be higher in patients with ALL. Based on the present data, it is difficult to reach a definitive conclusion regarding the possibility that inherited variants in the MEFV gene could represent a causative role in ALL. However, the data of our study may provide some new insights in understanding of individual genetic differences in susceptibility to these neoplasms. Further investigations are needed to determine the actual role of inherited variants in the MEFV gene in pathogenesis of ALL.

Deficiency of the IL-1 receptor antagonist (DIRA) is a recently described rare autoinflammatory disease, caused by loss of function mutations in IL1RN leading to the unopposed activation of the IL-1 pathway. We describe a novel nonsense mutation in the IL1RN gene, associated with early intrauterine onset, death and multiorgan involvement in a prematurely born baby. The protein prediction model indicated that the novel Q119X mutation would result in a nonfunctional protein by impairing the ability of the IL-1Ra to bind and antagonize signaling through the IL-1R. Since the disorder may mimic severe bacterial infections and the treatment with anakinra is life saving, we intend to raise awareness of the syndrome and the possibility of a founder mutation that may lead to the diagnosis of additional cases in Turkey. The clinical suspicion of DIRA is critical to avoid improper management of the patients with antibiotics alone and death from multiorgan failure.

Attenuated TLR4/MAPK signaling in monocytes from patients with CRMO results in impaired IL-10 expression.

Hofmann SR(1), Morbach H, Schwarz T, Rösen-Wolff A, Girschick HJ, Hedrich CM.

Author information:

(1)Klinik und Poliklinik für Kinder- und Jugendmedizin, Universitätsklinikum Carl Gustav Carus, Technische Universität Dresden, Fetscherstr. 74, D-01307 Dresden, Germany.

Chronic recurrent multifocal osteomyelitis (CRMO) is an autoinflammatory bone disorder of unknown origin. We previously demonstrated that monocytes from CRMO patients fail to express the immune-modulatory cytokine interleukin-10 (IL-10) in a chromatin dependent manner. Here, we demonstrate that attenuated extracellular-signal regulated kinase (ERK)1 and 2 signaling in response to TLR4 activation results in failure to induce IL-10 expression in monocytes from CRMO patients. Attenuated ERK1/2 activation results in 1) reduced levels of Sp-1, a transcription factor that induces IL-10 expression in monocytes, and 2) impaired H3S10 phosphorylation of the IL10 promoter, an activating epigenetic mark. The pro-inflammatory cytokines tumor necrosis factor (TNF) $\alpha$  and IL-6 are not negatively affected, resulting in an imbalance towards pro-inflammatory cytokines. Thus, impaired ERK1/2 signaling with subsequently reduced Sp-1 expression and H3S10 phosphorylation of the IL10 promoter may centrally contribute to the pathophysiology of CRMO.

Mean platelet volume and  $\beta$ -thromboglobulin levels in familial Mediterranean fever: effect of colchicine use?

Abanonu GB(1), Daskin A, Akdogan MF, Uyar S, Demirtunc R.

Author information:

(1)Department of Internal Medicine, Haydarpasa Numune Training and Research Hospital, Istanbul, Turkey. babacangul@hotmail.com

**BACKGROUND:** Many studies have shown that subclinical inflammation persisted during remission period of Familial Mediterranean Fever (FMF) patients but long term effects of subclinical inflammation in these patients aren't clearly known. Besides, a few of the recent studies revealed that risk of atherosclerosis had increased in FMF patients.  $\beta$ -Thromboglobulin ( $\beta$ -TG) is considered as a sensitive marker of platelet activation. In this study Mean Platelet Volume (MPV) and  $\beta$ -TG

levels were evaluated in FMF patients.

**METHODS:** Following the Local Ethics Committee's consent, 25 FMF patients were included in the study. Twenty eight age and sex matched healthy volunteers were recruited as a control group. Lipid profile, inflammatory parameters, hemogram,  $\beta$ -TG, MPV were assessed. Statistical analysis was performed with SPSS for Windows 16.00.

**RESULTS:** Group I consisted of 25 FMF cases (16 females, 9 males; mean age:  $35.72 \pm 12.34$  years), Group II consisted of 28 cases (22 females, 6 males; mean age  $31.78 \pm 10.31$  years). There was no statistically significant difference between the groups in terms of age and gender distribution, smoking status, total cholesterol, triglyceride, LDL and MPV ( $p > 0.05$ ). HDL levels were found to be statistically lower in Group I ( $p: 0.04$ ). Median  $\beta$ -TG levels was significantly higher in Group II than Group I (129.50 (range: 372.00) ng/mL versus 104.00 (range: 212.80) ng/mL respectively;  $p: 0.03$ ).

**CONCLUSION:** In this study MPV and  $\beta$ -TG were evaluated for FMF cases and healthy controls,  $\beta$ -TG levels were found significantly lower among patients; we hypothesized that this difference may have resulted from the effect of colchicine use on platelet functions.

[Palindromic rheumatism].

[Article in French]

Vayssade M(1), Tatar Z, Soubrier M.

Author information:

(1)Service de rhumatologie, hôpital Gabriel-Montpied, CHU de Clermont-Ferrand, 58, boulevard Montalembert, BP 69, 63003 Clermont-Ferrand cedex 1, France.

Palindromic rheumatism is characterized by episodes of arthritis or para-arthritis leaving no residual or radiographic changes. Several diseases should be ruled out in the differential diagnosis. Evolution to rheumatoid arthritis is common, especially in patient with positive rheumatoid factor and anticitrullinated peptides. In seronegative patients, palindromic rheumatism could be part of the spectrum of autoinflammatory diseases because of a high frequency of MEFV mutations. Treatment remains discussed. The use of antimalarials could delay the development of rheumatoid arthritis or another connective tissue disease.

**PURPOSE:** To evaluate the positivity rate of temporal artery biopsies (TAB) performed in suspects of giant cell arteritis (GCA) and to study the epidemiological and clinical factors associated to the biopsy result.

**METHODS:** A retrospective, multicenter, case-control study was performed, including three hundred and thirty-five patients who underwent TAB for a suspicion of GCA from 2001 to 2010. Clinical, epidemiological and pathology data were recovered from the patients' clinical records. Histologic diagnosis of GCA

was made when active inflammation or giant cells were found in the arterial wall.

**RESULTS:** Eighty-one biopsies (24.2%) were considered positive for GCA. Clinical factors independently associated to TAB result in a logistic regression analysis were temporal cutaneous hyperalgesia (OR = 10.8;  $p < 0.001$ ), jaw claudication (OR = 4.6;  $p = 0.001$ ), recent-onset headache (OR = 4.4;  $p = 0.001$ ), decreased temporal pulse (OR = 2.8;  $p = 0.02$ ), pain and stiffness in neck and shoulders (OR = 2.3;  $p = 0.05$ ), unintentional weight loss (OR = 1.33;  $p = 0.003$ ) and age (OR = 1.085;  $p = 0.004$ ). Other factors such as length of the surgical specimen (OR = 1.079;  $p = 0.028$ ) and erythrocyte sedimentation rate (OR = 1.042;  $p < 0.001$ ) were also statistically significant. The model was accurate (C-index = 0.921), reliable (pHosmer-Lemeshow = 0.733) and consistent in the bootstrap sensitivity analysis. No significant association was detected between TAB result and number of days of previous systemic corticosteroid treatment ( $p = 0.146$ ). However, an association was observed between TAB result and the total accumulated dose of previous systemic corticotherapy ( $p = 0.043$ ).

**CONCLUSIONS:** Exhaustive anamnesis and clinical examination remain of paramount importance in the diagnosis of GCA. To improve the yield of TAB, it should be performed specially in older patients with GCA-compatible clinic. TAB could be avoided in patients with an isolated elevation of acute phase reactants, without GCA-compatible clinic.

# Long-term clinical course of patients carrying the Q703K mutation in the NLRP3 gene: a case series.

Vitale A(1), Lucherini OM, Galeazzi M, Frediani B, Cantarini L.

## Author information:

(1)Interdepartmental Research Centre of Systemic Autoimmune and Autoinflammatory Diseases, Unit of Rheumatology, Policlinico Le Scotte, University of Siena, Siena, Italy.

**BACKGROUND:** Cryopyrin-associated periodic syndromes (CAPS) comprise a spectrum of apparently distinct, rare, autosomal dominant autoinflammatory disorders of increasing severity caused by NLRP3 gene mutations. The Q703K allele is a variant of unknown pathogenetic significance, and has been considered to be both a clinically unremarkable polymorphism and a low- penetrance mutation.

**OBJECTIVES:** To analyse the long-term clinical course in a cohort of patients presenting with periodic fever attacks and carrying the Q703K mutation in the NLRP3 gene.

**METHODS:** Seven Caucasian patients (mean age  $37.3 \pm 8.5$  years, 2 males and 5 females) were identified as carriers of the Q703K mutation among 71 patients with CAPS-like symptoms.

**RESULTS:** The mean age at disease onset was  $25.58 \pm 16.08$  years and the mean disease duration was  $12.28 \pm 8.36$ . The mean number of febrile episodes was  $7.56 \pm 6.48$  and the mean duration of fever attacks was  $6.66 \pm 4.71$  days. Six out of 7 patients had a low grade fever, while 1 patient had no fever episodes. All patients were characterised by symptoms consistent with recurrent inflammatory syndrome. Six patients out of 7 presented skin lesions, 4/7 arthralgia, 4/7 myalgia, 4/7 conjunctivitis, 3/7 headache. All patients also complained of severe fatigue. In 4/7 patients symptoms were triggered or worsened by generalised cold exposure.

**CONCLUSIONS:** We suggest that patients carrying the low-penetrance Q703K mutation in the NLRP3 gene may present with FCAS-like symptoms. However, given the high frequency of healthy carriers, the role of additional, still unknown genetic and/or environmental modifiers is conceivable.

Serum leptin, resistin, visfatin and adiponectin levels in tumor necrosis factor receptor-associated periodic syndrome (TRAPS).

Cantarini L(1), Obici L, Simonini G, Cimaz R, Bacarelli MR, Merlini G, Vitale A, Lucherini OM, Brizi MG, Galeazzi M, Fioravanti A.

Author information:

(1)Interdepartmental Research Center of Systemic Autoimmune and Autoinflammatory Diseases, Rheumatology Unit, Policlinico Le Scotte, University of Siena, 53100 Siena, Italy. cantariniluca@hotmail.com

**OBJECTIVES:** The aims of our study were to evaluate serum leptin, resistin, visfatin and adiponectin levels in patients with tumour necrosis factor receptor-associated periodic syndrome (TRAPS), in comparison to healthy controls, and to correlate their levels to parameters of disease activity and/or severity.

**METHODS:** Serum leptin, resistin, visfatin and adiponectin levels were obtained from 14 TRAPS patients carrying mutations involving cysteine residues, from 16 TRAPS patients carrying other mutations, and from 16 healthy controls.

Demographic, clinical and laboratory parameters, including amyloidosis were entered for each patient. Comparisons between groups as well as reciprocal comparisons have been evaluated.

**RESULTS:** Serum leptin, resistin, visfatin and adiponectin did not significantly differ among the 3 groups. Patients carrying cysteine residues mutations showed lower visfatin serum levels than patients carrying other mutations ( $p<0.02$ ).

Serum leptin significantly correlated with the number of attacks/year (multiple  $R=0.32$ , multiple adjusted  $R^2=0.19$ ,  $p<0.03$ ). Serum adiponectin levels significantly correlated with the presence of amyloidosis (multiple  $R=0.79$ , multiple adjusted  $R^2=0.57$ ,  $p<0.03$ ). Adiponectin values were a significant predictor for amyloidosis (AUC 0.75, 95 CI: 0.56-0.94,  $p<0.03$ ), with a predicting cut-off value set at 23.16 pg/ml, the predictive positive value was 53.8%.

Visfatin serum levels resulted respectively related to leptin ( $r_s=0.42$ ,  $r^2=0.18$ ,  $p<0.02$ ) and to resistin ( $r_s=0.57$ ,  $r^2=0.32$ ,  $p<0.01$ ) serum levels; whilst leptin and resistin serum levels did not reciprocally correlate.

**CONCLUSIONS:** Although a prospective design study and larger cohort are mandatory, adipokines serum levels and their correlations with parameters of disease activity and/or severity seem to show a baseline pattern in TRAPS patients.

Apoptosis-associated speck-like protein containing a CARD (ASC) expression profiles in familial Mediterranean fever (FMF) patients with different MEFV mutation patterns.

Nalbantoglu S(1), Tanyolac B, Berdeli A.

Author information:

(1)Faculty of Medicine, Children's Hospital, Molecular Medicine Laboratory, Ege University, Bornova, Izmir, Turkey. nalbantoglusunem@gmail.com

**OBJECTIVES:** The inflammasome complex and the inflammatory pathway have been implicated in the pathogenesis of the most common autoinflammatory disorder, familial Mediterranean fever (FMF). Pyrin, the protein product of the FMF gene MEFV, interacts with the inflammasome complex adaptor protein ASC/PYCARD (apoptosis-associated speck-like protein with a CARD). Pyrin and ASC can both function as either inducers or suppressors of the cellular inflammatory response. We aimed to characterize ASC-induced gene expression profiles in FMF patients with different MEFV mutation patterns.

**METHODS:** A total of 165 Caucasian patients with clinical and molecular FMF diagnoses were enrolled in the study. ASC gene expression was quantified by real-time quantitative reverse transcriptase polymerase chain reaction (qRT-PCR).

**RESULTS:** ASC mRNA expression was increased in the MEFV mutation-positive group

compared to the mutation-negative group ( $p = 0.001$ ). The fold changes of ASC expression in the M694V homozygous ( $p = 0.02$ ), M694V heterozygous ( $p = 0.012$ ), compound heterozygous ( $p = 0.002$ ), and R202Q/P369S/R408Q ( $p = 0.00$ ) groups relative to the MEFV mutation-negative group were +2.4, +2.7, +3, and +3.4, respectively. qRT-PCR did not reveal a significant difference in ASC mRNA expression levels among the MEFV mutation-positive groups ( $p > 0.05$ ).

CONCLUSION: ASC mRNA expression was up-regulated in patients carrying MEFV mutations independent of mutation type. There was no significant relationship between specific MEFV genotypes and the level of ASC expression in the patient group analysed. Thus, the findings of this work may suggest a crucial relationship between mutant MEFV/pyrin and remarkable ASC up-regulation in FMF inflammation.

Ocular manifestations of the autoinflammatory syndromes.

Tarabishy AB(1), Hise AG, Traboulsi EI.

Author information:

(1)Cole Eye Institute, Cleveland Clinic Foundation, Cleveland, OH 44195, USA.

The autoinflammatory syndromes are rare inherited disorders characterized by recurrent attacks of multi-system inflammation caused by genetic mutations that result in abnormal upregulation of key innate immune mediators. The term autoinflammatory syndromes includes a broad variety of disorders, including cryopyrin-associated periodic syndromes (CAPS) such as neonatal onset multisystem inflammatory disease (NOMID), familial cold autoinflammatory syndrome (FCAS), Muckle-Wells syndrome (MWS), periodic fever syndromes, including familial Mediterranean fever (FMF), TNF receptor-1 associated periodic syndrome (TRAPS), and Blau syndrome. Ocular manifestations are frequent and diverse in affected patients, and visual impairment and blindness are not uncommon sequelae of chronic active disease. Novel therapeutic interventions targeting specific pathophysiologic mechanisms have been extremely promising in the treatment of

these disorders. The purpose of this article is to provide a review of these disorders with a focus on pathogenesis, clinical manifestations, ophthalmologic involvement, and available treatment options.

Early-onset chronic inflammatory disease associated with maternal microchimerism.

Ishikawa T(1), Sakurai Y, Takeda T, Suzuki H.

Author information:

(1)Department of Pediatrics, Nara City Hospital, Nara 630-8305, Japan.

Maternal microchimerism (mMc) refers to the presence of a small population of cells originating from the mother. Whether mMc leads to autoimmune responses in children remains controversial. We describe here an 11-year-old boy with persistent fever and elevated levels of C-reactive protein from infancy onward. During infancy, the patient presented with high fever, skin rashes, and hepatic dysfunction. Careful examination including a liver biopsy failed to reveal the cause. At 4 years old, petechiae developed associated with thrombocytopenia and positive anti-dsDNA autoantibodies. Steroid pulse therapy was effective, but the effect of low-dose prednisone was insufficient. At age 9, an extensive differential diagnosis was considered especially for infantile onset autoinflammatory disorders but failed to make a definitive diagnosis. On admission, the patient exhibited short stature, hepatosplenomegaly, generalized superficial lymphadenopathy, and rashes. Laboratory findings revealed anemia, elevated levels of inflammation markers, and hypergammaglobulinemia. Serum complement levels were normal. Serum levels of IL-6 and B-cell activating factor were elevated. Viral infections were not identified. Although HLA typing revealed no noninherited maternal antigens in lymphocytes, female cells were demonstrated in the patient's skin and lymph nodes, suggesting that maternal microchimerism might be involved in the pathogenesis of fever without source in infants.

PSTPIP2 deficiency in mice causes osteopenia and increased differentiation of multipotent myeloid precursors into osteoclasts.

Chitu V(1), Nacu V, Charles JF, Henne WM, McMahon HT, Nandi S, Ketchum H, Harris R, Nakamura MC, Stanley ER.

Author information:

(1)Department of Developmental and Molecular Biology, Albert Einstein College of Medicine, Bronx, NY 10461, USA. violeta.chitu@einstein.yu.edu

Missense mutations that reduce or abrogate myeloid cell expression of the F-BAR domain protein, proline serine threonine phosphatase-interacting protein 2 (PSTPIP2), lead to autoinflammatory disease involving extramedullary hematopoiesis, skin and bone lesions. However, little is known about how PSTPIP2 regulates osteoclast development. Here we examined how PSTPIP2 deficiency causes osteopenia and bone lesions, using the mouse PSTPIP2 mutations, cmo, which fails to express PSTPIP2 and Lupo, in which PSTPIP2 is dysfunctional. In both models, serum levels of the pro-osteoclastogenic factor, MIP-1 $\alpha$ , were elevated and CSF-1 receptor (CSF-1R)-dependent production of MIP-1 $\alpha$  by macrophages was increased. Treatment of cmo mice with a dual specificity CSF-1R and c-Kit inhibitor, PLX3397, decreased circulating MIP-1 $\alpha$  and ameliorated the extramedullary hematopoiesis, inflammation, and osteopenia, demonstrating that aberrant myelopoiesis drives disease. Purified osteoclast precursors from PSTPIP2-deficient mice exhibit increased osteoclastogenesis in vitro and were used to probe the structural requirements for PSTPIP2 suppression of osteoclast development. PSTPIP2 tyrosine phosphorylation and a functional F-BAR domain were essential for PSTPIP2 inhibition of TRAP expression and osteoclast precursor fusion, whereas interaction with PEST-type phosphatases was only required for suppression of TRAP expression. Thus, PSTPIP2 acts as a negative feedback regulator of CSF-1R signaling to suppress inflammation and osteoclastogenesis.

Analysis of cytotoxic T lymphocyte antigen-4 (CTLA-4) promoter -318C/T and +49A/G gene polymorphisms in Turkish patients with familial Mediterranean fever.

Gunesacar R(1), Erken E, Dinkci S.

Author information:

(1)Department of Medical Biology and Genetics, Faculty of Medicine, Kahramanmaras Sutcu Imam University, Kahramanmaras, Turkey. rgunesacar@hotmail.com

Either the role of the adaptive immune system or the interaction between innate and adaptive immune systems in familial Mediterranean fever (FMF) is not clear so far. So, we planned to search for the interaction between the innate and adaptive immune systems in the pathogenesis of FMF by investigating polymorphism for CTLA-4 gene, which plays a role in controlling antigen presentation to T cells. We also aimed to investigate whether there is an association between -318C/T and +49A/G polymorphisms in the CTLA-4 gene and the main clinical features of the disease. 75 FMF patients and 179 controls were studied. Polymorphism was detected by the PCR-RFLP technique. The CT genotype and T allele frequencies of the -318C/T polymorphism and the haplotype frequency for the -318T/+49A in the CTLA-4 gene were higher in the FMF (21.3, 21.3, and 10.7 %) when compared with the controls (10.6, 10.6, and 5.3 %;  $P = 0.029$ ,  $0.044$ , and  $0.029$ ). However, these differences did not reach a statistically significant level after the Bonferroni correction. A significant linkage disequilibrium was found between the -318C/T and +49A/G polymorphisms in the CTLA-4 gene ( $D' = 0.997$ ,  $r(2) = 0.027$ ,  $P = 0.0002$ ). Genotype and carrier frequencies of the CTLA-4 gene +49A/G polymorphism were not significantly different between FMF patients and healthy controls. No association was found between the studied polymorphisms and the main clinical features of the disease. Our findings suggest that although not statistically significant, higher frequencies of CTLA-4 gene -318CT genotype, T allele, and -318T/+49A haplotype in FMF patients may be related to the non-autoimmune pathogenesis of FMF.

Tumor necrosis factor receptor-associated periodic syndrome (TRAPS) is characterized by periodic fever, cutaneous rash, conjunctivitis, lymphadenopathy, abdominal pain, myalgia, and arthralgia. It is a rare autosomal dominant disease and strongly associated with heterozygous mutations in the tumor necrosis factor (TNF) receptor super family 1A (TNFRSF1A) gene. It is believed to be more common in Western countries than in Asian countries. Here, we present the case of a 14-year-old girl with periodic fever and abdominal pain with elevation of inflammatory markers for 2 years. After extensive work-up of infectious etiology with negative results, the diagnosis of TRAPS was made although no gene mutations were identified in the TNFRSF1A gene, MVK gene, and NALP3/CIAS1 gene. She had partial clinical response to corticosteroids and immunomodulatory agents. However, the treatment response to TNF- $\alpha$  inhibitor etanercept was dramatic. She has remained symptom free under regular weekly to biweekly etanercept treatment for 2 years. We also reviewed the related literature and summarized the data of 10 Asian cases of TRAPS.

Decreased prevalence of atopic features in patients with psoriatic arthritis, but not in psoriasis vulgaris.

Hajdarbegovic E(1), Nijsten T, Westgeest A, Habraken F, Hollestein L, Thio B.

Author information:

(1)Department of Dermatology and Venerology, Erasmus Medical Center, Rotterdam, The Netherlands. e.hajdarbegovic@erasmusmc.nl

**BACKGROUND:** The prevalence of atopic disorders is reduced in patients with various autoinflammatory diseases but, to our knowledge, this association has not been studied in psoriasis vulgaris or psoriatic arthritis (PSA).

**OBJECTIVE:** Prevalence of hay fever, asthma, and sensitization to common aeroallergens was compared in patients with psoriasis vulgaris to patients with PSA and control subjects; we also investigated whether atopy influences the arthritis activity and severity scores in patients with PSA.

**METHODS:** In a cross-sectional cohort study design, the differences in patient-reported lifetime prevalence of atopic disorders and serum IgE directed against common aeroallergens were compared. The effect of atopy on arthritis severity was assessed using the 28-joint Disease Activity Score and Health Assessment Questionnaire. Logistic regression models were used to calculate crude and adjusted odds ratios with 95% confidence intervals (CI) for presence of atopy.

**RESULTS:** A total of 168 patients with PSA, 133 patients with psoriasis vulgaris, and 147 control subjects were included. The lifetime prevalence of hay fever did not differ across groups. Patients with PSA were less likely to have had asthma than control subjects (adjusted odds ratio 0.20; 95% CI 0.04-0.92) and they were less likely to be sensitized (adjusted odds ratio 0.50; 95% CI 0.25-0.99). Health Assessment Questionnaire-visual analog scales for pain and for patient global score were significantly reduced by sensitization to common aeroallergens (beta-coefficients -0.54 [95% CI -0.84 to -0.25] and -18.4 [95% CI -28.5 to -8.25], respectively.)

LIMITATIONS: This was a cross-sectional, small-numbered study.

CONCLUSION: Atopy may protect against development of PSA and diminish its severity.

Tumor necrosis factor receptor-associated periodic syndrome (TRAPS) in Japan: a review of the literature.

Washio M(1), Nakano T, Kawaguchi Y, Takagi K, Kiyohara C, Tsukamoto H, Tokunaga S, Horiuchi T.

Author information:

washio@st-mary.ac.jp

Erratum in

*Mod Rheumatol*. 2013 Mar;23(2):218.

Tumor necrosis factor receptor-associated periodic syndrome (TRAPS) is a dominantly inherited autoinflammatory syndrome that is characterized by recurrent episodes of fever attacks associated with rashes, abdominal pain, myalgia, conjunctivitis, chest pain, and arthralgia. Some patients have severe abdominal pain leading to abdominal surgery. Most reported cases of TRAPS involve patients of European ancestry, but there have been nine reports of patients with TRAPS in Japan. Here, we review these nine case reports. Reported TNFRSF1A gene mutations in these nine index patients were C70S, T61I, C70G, C30Y, C30R, N101K, and N25D. Fever (100 %) was seen in all 23 cases. Most patients developed rash (erythema) (84.6 %) and arthralgia (73.3 %), and half suffered from myalgia (54.5 %) and abdominal pain (50.0 %). Although one-half of the patients suffered from abdominal pain, none underwent surgery. In contrast, only a small percentage of

patients suffered from chest pain (20.0 %), conjunctivitis (20.0 %), and headache (10.0 %). Almost all cases (95.7 %) concerned patients whose relatives suffered from periodic fever. These findings suggest that the clinical features of Japanese TRAPS patients may be milder than those of patients in Western countries.

Effect of cyclosporine on the pharmacokinetics of colchicine in healthy subjects.

Wason S(1), Digiacinto JL, Davis MW.

Author information:

(1)URL Pharma, Inc, Philadelphia, PA 19111, USA. swason@urlpharma.com

**OBJECTIVE:** Colchicine and cyclosporine are often administered together, particularly in patients who have undergone solid-organ transplantation. However, the potential for drug-drug interactions between these agents resulting in colchicine toxicity is high.

**METHODS:** This study sought to determine the effect of cyclosporine (100-mg capsule) on the pharmacokinetics of the US Food and Drug Administration-approved formulation of colchicine (0.6-mg tablet) after single oral-dose administration in 24 healthy subjects under fasted conditions in a phase 1, single-sequence, 2-period drug-drug interaction trial.

**RESULTS:** Coadministration of cyclosporine increased colchicine maximum observed plasma concentration, area under the plasma concentration-time curve to the last measurable time point, and area under the plasma concentration-time curve to time infinity on average by 224%, 216%, and 215% (ie, almost doubled), respectively, and decreased colchicine oral clearance on average by 72% (from 48.24 to 13.42 L/h), indicating substantially higher colchicine exposures when combined with cyclosporine, compared with colchicine alone.

**CONCLUSION:** The dose of colchicine should be reduced by  $\geq 50\%$  when colchicine and cyclosporine are administered concurrently for treatment and prophylaxis of gout flares or treatment of patients with familial Mediterranean fever. Health care professionals should be vigilant for potential adverse events during

colchicine/cyclosporine coadministration, notably in patients who have undergone solid-organ transplantation.

Juvenile spondyloarthropathies.

Scofield RH(1), Sestak AL.

Author information:

(1)Arthritis & Clinical Immunology Program, Oklahoma Medical Research Foundation (RHS, ALS), Oklahoma City, OK, USA. [hal-scofield@omrf.ouhsc.edu](mailto:hal-scofield@omrf.ouhsc.edu)

Spondyloarthropathy (or spondyloarthritis) can begin in childhood (defined as individuals less than 16 years of age). These diseases are distinct in childhood, when compared with adult-onset disease. Because of overlapping features, especially sacroiliac joint involvement, diagnostic difficulty may arise from Behcet's disease, as well as familial Mediterranean fever. Despite advances in diagnostic techniques such as magnetic resonance imaging, the diagnosis of juvenile spondyloarthropathy may still be delayed many years from the onset of symptoms. Treatment of juvenile spondyloarthropathy has advanced rapidly in the last several years, with increasing evidence that agents targeting tumor necrosis factor are effective. These agents also have serious complications, including induction of other autoimmune diseases.

Comment in

Clin Genet. 2013 Jun;83(6):582-3.

Fabry disease (FD) is an underdiagnosed pathology due to its symptomatology that overlaps with various systemic and rheumatic disorders, including familial Mediterranean fever (FMF). We examined the Mediterranean fever (MEFV) and  $\alpha$ -galactosidase A (GLA) genes, whose mutations are responsible for FMF and FD, respectively, in 42 unrelated patients diagnosed with FMF, which revealed significant ambiguity regarding some of the symptoms which are also present in FD. The objective of this study was to determine the spectrum of mutations present in these genes, in order to identify cases of mistaken diagnosis of FMF and/or missed diagnosis of FD. Ten out of 42 patients had one mutation in homozygosis or two different mutations in heterozygosis in the MEFV gene; 20/42 had a single heterozygous mutation, and 12/42 did not have genetic alterations in MEFV. The analysis of the GLA gene conducted on all the samples revealed that three subjects, and some members of their families, had two different exonic mutations associated with FD. Family studies allowed us to identify eight other cases of FD, bringing the total undiagnosed subjects to 11/53. Analyzing the MEFV and GLA genes in patients with clinical diagnoses of FMF proved to be

fundamentally important for the reduction of diagnostic errors.

Immunoregulation by naturally occurring and disease-associated autoantibodies : binding to cytokines and their role in regulation of T-cell responses.

Nielsen CH(1), Bendtzen K.

Author information:

(1)Institute for Inflammation Research, Department of Rheumatology, Copenhagen University Hospital, Rigshospitalet, Copenhagen, Denmark.

claus.henrik.nielsen@rh.regionh.dk

The role of naturally occurring autoantibodies (NAbs) in homeostasis and in disease manifestations is poorly understood. In the present chapter, we review how NAbs may interfere with the cytokine network and how NAbs, through formation of complement-activating immune complexes with soluble self-antigens, may promote the uptake and presentation of self-molecules by antigen-presenting cells. Both naturally occurring and disease-associated autoantibodies against a variety of cytokines have been reported, including NAbs against interleukin (IL)-1 $\alpha$ , IL-6, IL-8, IL-10, granulocyte-macrophage colony-stimulating factor, interferon (IFN)- $\alpha$ , IFN- $\beta$ , IFN- $\gamma$ , macrophage chemotactic protein-1 and IL-21. NAbs against a variety of other self-antigens have also been reported, and using thyroglobulin as an example we discuss how NAbs are capable of promoting uptake of immune complexes via complement receptors and Fc-receptors on antigen-presenting cells and thereby regulate T-cell activity. Knowledge of the influence of NAbs against cytokines on immune homeostasis is likely to have wide-ranging implications both in understanding pathogenesis and in treatment of many immunoinflammatory disorders, including a number of autoimmune and autoinflammatory diseases.

Familial Mediterranean fever in Germany: epidemiological, clinical, and genetic characteristics of a pediatric population.

Lainka E(1), Bielak M, Lohse P, Timmann C, Stojanov S, von Kries R, Niehues T, Neudorf U.

Author information:

(1)Department of Paediatric Rheumatology, Children's Hospital, University Duisburg-Essen, Hufelandstr. 55, 45122, Essen, Germany. elke.lainka@uni-due.de

Familial Mediterranean fever (FMF) is an autoinflammatory disease and belongs to the heterogeneous group of hereditary recurrent fever syndromes (HRFs). AIMS: The aims of the study were to determine the incidence of FMF in Germany and to describe the spectrum of pyrin mutations and the clinical characteristics in children. A prospective surveillance of children with HRF including FMF was conducted in Germany during a time period of 3 years by the German paediatric surveillance unit for rare paediatric diseases (ESPED). Monthly inquiries were sent to 370 children's hospitals (Clinic-ESPED, n1) and to 23 laboratories (Laboratory-ESPED, n2). Inclusion criteria were children  $\leq 16$  years of age, disease-associated pyrin mutations, and more than three self-limiting episodes of fever  $>38.5^{\circ}\text{C}$  with increased inflammation markers. In n1, 122 patients with FMF and 225 pyrin mutations were identified. Ninety-two of 122 (75 %) children were of Turkish origin. The minimum incidence of FMF was estimated to be 3 (95 % CI: 2.48-3.54) per 10(6) person-years in the whole children population and 55 (95 % CI: 46-66) per 10(6) person-years in Turkish children living in Germany. N1 U n2 amounted to 593 asymptomatic and symptomatic carriers of 895 mutations (overlap of 73 cases with 134 mutations). p.Met694Val (45 %), p.Met680Ile (14 %), p.Val726Ala (12 %), and p.Glu148Gln (11.5 %) were the most common pyrin mutations.

CONCLUSIONS: Despite FMF being the most frequent of the HRFs, its incidence in Germany is low. Twenty-five to 50 FMF patients  $\leq 16$  years are newly diagnosed per year. The disease is most commonly observed in individuals of Turkish ancestry.

Canakinumab in Schnitzler syndrome.

Vanderschueren S(1), Knockaert D.

Author information:

(1)Clinical Department of General Internal Medicine and The Research Department of Microbiology and Immunology, Laboratory for Clinical Infectious and Immunological Disorders, University Hospital Leuven, Leuven, Belgium.  
steven.vanderschueren@uzleuven.be

**OBJECTIVES:** Daily injections of anakinra, an interleukin-1-receptor antagonist, have been reported to control effectively the symptoms and signs of Schnitzler syndrome, a rare acquired autoinflammatory disorder, presenting in adulthood by intermittent fever, urticarial rash, and paraproteinemia, usually IgM.

Canakinumab, a fully human interleukin-1 $\beta$  monoclonal antibody, approved for the cryoporin-associated periodic syndrome, may offer a practical advantage because its half-life of  $\sim$ 28 days may allow less frequent dosing. The present trial was designed to test canakinumab in patients with Schnitzler syndrome.

**METHODS:** A patient with Schnitzler syndrome was treated with canakinumab, 150 mg subcutaneously injection every 8 weeks for 6 consecutive months. Injections were resumed in case of a flare following discontinuation.

**RESULTS:** Canakinumab induced a swift and sustained clinical response, with disappearance of fever and arthralgias, near abolishment of fatigue and rash, and substantial reduction of C-reactive protein levels. Interruption of canakinumab after four 8-weekly injections led to a flare 10 weeks after the last administration, which was countered as soon as canakinumab injections were resumed. The patient remained in complete remission. Canakinumab was well tolerated. No injection site reactions, other adverse events, or laboratory abnormalities were observed.

**CONCLUSIONS:** Canakinumab has potential for the treatment of Schnitzler syndrome (ClinicalTrials.gov.number, NCT01245127).

An atypical familial Mediterranean fever patient who developed ulcers in the terminal ileum and recurrent abscess-like lesions in multiple organs.

Takahashi T(1), Tsukuda H, Itoh H, Kimura H, Yoshimoto M, Tsujisaki M.

Author information:

(1)Department of Hematology and Gastroenterology, Tenshi Hospital, Japan.  
tohrut@cocoa.ocn.ne.jp

We herein describe the case of a 25-year-old woman who suffered from atypical familial Mediterranean fever for more than a decade. She presented with a periodic fever, abdominal pain and persistent ulcers in the terminal ileum. Colchicine was effective, and familial Mediterranean fever was diagnosed. A genetic study showed a heterozygous E148Q mutation in the MEFV gene. Multiple, recurrent, abscess-like lesions developed asynchronously in the spleen, liver, and a lung. Infliximab was administered when colchicine treatment became ineffective. However, infliximab treatment soon became ineffective, probably because antibodies were generated against it. Therefore, etanercept treatment was started, and the patient showed an immediate response.

Author information:

(1)Department of Medicine F, Soroka University Medical Center and Faculty of

Health Sciences, Ben-Gurion University of the Negev, Beer Sheva, Israel.  
lbarski@bgu.ac.il

**BACKGROUND:** Establishing the etiology of a large pericardial effusion is of crucial importance since it is likely the result of a serious underlying disease. However, there is a paucity of literature on the diagnostic management of patients with large hemorrhagic effusions.

**OBJECTIVES:** To analyze the management of patients with large hemorrhagic pericardial effusion.

**METHODS:** We reviewed seven cases of large hemorrhagic pericardial effusions hospitalized in Soroka University Medical Center in 2010.

**RESULTS:** All seven patients underwent a comprehensive evaluation followed by pericardiocentesis. Six of the seven cases demonstrated echocardiographic signs of tamponade. Large amounts of hemorrhagic pericardial effusion (> 600 ml) were aspirated from each patient. A pericardial window was performed in two of the seven patients. The causes for the hemorrhagic effusions were malignancy, streptococcal infection, familial Mediterranean fever exacerbation, and idiopathic. Four patients completely recovered. The condition of one patient improved after initiation of chemotherapy for lung cancer, and two patients with progressive malignancies passed away shortly after discharge. Two cases of massive pulmonary embolism were diagnosed and resolved spontaneously without anticoagulation therapy after the effusion was treated.

**CONCLUSIONS:** All cases of pericardial effusion resolved after rapid diagnosis and initiation of specific treatment. Pulmonary embolism in situ may be a complication of large pericardial effusions that does not require anticoagulation treatment after the effusion resolves.

The role of interleukin-1 in allergy-related disorders.

Krause K(1), Metz M, Makris M, Zuberbier T, Maurer M.

Author information:

(1)Autoinflammation Reference Center Charité, Charité - Universitätsmedizin Berlin, Berlin, Germany.

**PURPOSE OF REVIEW:** Interleukin-1 $\beta$  (IL-1 $\beta$ ) is a potent proinflammatory cytokine, which is involved in many inflammatory conditions including autoinflammatory and allergic disorders. This review provides insights into recent advances of our understanding of the pathogenesis of IL-1 $\beta$ -associated allergy-related disorders.

**RECENT FINDINGS:** In autoinflammatory as well as allergic diseases such as contact hypersensitivity, atopic dermatitis and bronchial asthma, dysfunctional inflammasome processing has been demonstrated to account for IL-1 $\beta$ -induced inflammation. IL-1-neutralizing drugs have been shown to completely suppress or markedly reduce inflammatory responses in clinical studies and experimental models of urticarial autoinflammatory diseases as well as common allergic disorders.

**SUMMARY:** The recent findings support a crucial role for IL-1 $\beta$  and inflammasome components in a variety of allergy-related disorders.

Novel mutations causing hyperimmunoglobulin D and periodic fever syndrome.

Sinha A(1), Waterham HR, Sreedhar KV, Jain V.

Author information:

(1)Department of Pediatrics, All India Institute of Medical Sciences, New Delhi, India.

Hyperimmunoglobulin D and periodic fever syndrome (HIDS) is a rare, hereditary autoinflammatory condition characterized by recurrent inflammatory episodes. We report a 9-year-old boy, diagnosed with HIDS due to two novel mutations, c.62C>T (p.Ala21Val) and c.372-6T>C (probable splicing defect), in the mevalonate kinase (MVK) gene. The pathogenicity of these mutations was confirmed by measurement of low MVK enzyme activity in cultured primary skin fibroblasts of the patient. The symptoms have been refractory to therapy with steroids and non steroidal anti inflammatory drugs. This report expands the genetic and ethnic spectrum of HIDS.

Blau syndrome, clinical and genetic aspects.

Sfriso P(1), Caso F, Tognon S, Galozzi P, Gava A, Punzi L.

Author information:

(1)Rheumatology Unit, Department of Medicine, University of Padova, Padova, Italy. paolo.sfriso@unipd.it

Blau syndrome (BS) is a rare autosomal dominant, autoinflammatory syndrome characterized by the clinical triad of granulomatous recurrent uveitis, dermatitis and symmetric arthritis. The gene responsible for BS has been identified in the caspase recruitment domain gene CARD15/NOD2. In the majority of patients, the disease is characterized by early onset, usually before 3-4 years of age. The manifestations at disease onset are usually represented by articular and cutaneous involvement signs, generally followed later by ocular manifestations which are often the most relevant morbidity of BS. In some cases the presence of fever is also observed; atypical cases of BS have been reported with cardiovascular, neurological, renal, intestinal and other organ involvement. The rarity and the variations in the severity and evolution of its expressions do not permit sufficient data about optimal treatment for patients with BS. The first step of therapy is represented by the use of corticosteroids and successively, in case of unsatisfactory response, by additional treatment with immunosuppressive agents. The results with biologic anti-cytokine agents, such as anti-TNF $\alpha$  and anti-IL1 $\beta$ , are different, particularly with regard to ocular morbidity. Clinical and genetic aspects of the familial and the sporadic form of BS will be discussed and focused on. A description of a case study of an Italian family is also included.

Gout as autoinflammatory disease: new mechanisms for more appropriated treatment targets.

Punzi L(1), Scanu A, Ramonda R, Oliviero F.

Author information:

(1)Rheumatology Unit, Department of Medicine DIMED, University of Padova, Italy.  
punzireu@unipd.it

Gout is probably one of the oldest diseases affecting men. This is not surprising especially for the active role that innate immunity seems to play in its pathogenesis. It is fascinating to observe as this ancestral mechanism of defense feels that microcrystals are a danger, quite similar to infectious agents. New advances have revealed that at the base of the powerful inflammatory reaction stimulated by monosodium urate crystals there are many complexes cellular mechanisms, mainly involving inflammasome and toll-like receptors. Subsequently, there is an early increase of proinflammatory cytokines responsible for the acute attack, followed in few days by their reduction along with an increase of anti-inflammatory cytokines, probably main actors of the resolution phase. New targets have also been identified for the reduction of hyperuricemia, the prerequisite of gout, in order to prevent new attacks and the deposition of urate crystals in and around the joints. All these aspects, leading to deeper insight, have suggested new treatments, some of which are already available while others are likely to become available in the near future.

## Recurrent pericarditis: autoimmune or autoinflammatory?

Maestroni S(1), Di Corato PR, Cumetti D, Chiara DB, Ghidoni S, Prisacaru L, Cantarini L, Imazio M, Penco S, Pedrotti P, Caforio AL, Doria A, Brucato A.

### Author information:

smaestroni@ospedaliriuniti.bergamo.it

Idiopathic recurrent acute pericarditis (IRAP) represents the most troublesome complication of acute pericarditis and occurs in up to 20-50% of patients. It is generally idiopathic or postcardiac injury. IRAP is a disease of suspected immune-mediated pathogenesis. On the other hand, it has been suggested that some of these patients might have an atypical or subclinical form of an autoinflammatory disease, e.g. genetic disorders characterized by primary dysfunction of the innate immune system and caused by mutations of genes involved in the inflammatory response. We found that IRAP patients were negative for mutations associated with familial Mediterranean fever, but 6% (8/131 patients) carry a mutation in the TNFRSF1A gene, encoding the receptor for tumor necrosis factor- $\alpha$ . C-reactive protein (CRP) may be useful to follow the disease activity and guide the appropriate length of therapy, with continuation of the attack doses of the drugs until CRP normalization, at which time tapering may be considered. IRAP often needs a multidrug therapy: NSAIDs or aspirin at high dosages every 6-8h, corticosteroids only rarely, at low dosages and with a very gradual tapering (months) and colchicine at low dosages if tolerated. Anakinra could be a solution for patients who do not tolerate other therapies.

Incomplete response to colchicine in M694V homozygote FMF patients.

Lidar M(1), Yonath H, Shechter N, Sikron F, Sadetzki S, Langevitz P, Livneh A, Pras E.

Author information:

(1)Department of Medicine F, Sheba Medical Center, Israel.

**BACKGROUND:** Previous studies have shown that with prophylactic colchicine 65% of the patients suffering from Familial Mediterranean fever (FMF) will show a complete response, 30% a partial response and about 5% will show minimum or no response. These studies were performed before the isolation of the disease gene.

Genotyping enables us to study the response rates according to specific mutations. We have witnessed a large number of M694V homozygotes who do not respond well to colchicine despite being treated with maximal sustained doses.

**AIM:** To assess the response rates to colchicine in M694V homozygote FMF patients in comparison to other prevalent genotypes.

**METHODS:** We conducted a telephonic survey which included 112 FMF patients: 40 M694V homozygotes, and 2 comparison groups of 41 M694V/V726A compound heterozygotes and 31 V726A homozygotes. The questionnaire included demographic, social and clinical features, colchicine dose, response rates and reported side effects.

**RESULTS:** M694 homozygotes showed a more severe disease, and were treated with higher doses of colchicine (average dose  $1.98 \pm 0.56$  compared to  $1.47 \pm 0.58$ ,  $p=0.0001$  and  $1.13 \pm 0.41$ ,  $p<0.001$  in the M694V/V726A compound heterozygotes and the V726A homozygotes, respectively); Colchicine related side effects were noted in 40% of the M694V homozygotes. The average rate of attacks in treated M694V homozygotes ( $0.70 \pm 1.06$ ) was higher compared to the two other groups ( $0.14 \pm 0.26$ ,  $p=0.002$  and  $0.08 \pm 0.20$ ,  $p=0.0009$ , respectively) and only 25% of them reported no attacks in the last year. None of the patients who took part in this study had amyloidosis. Side effects limiting the dose of colchicine were noted in 40% of the M694V homozygotes.

**CONCLUSIONS:** Despite receiving higher doses of colchicine the prevalence of complete responders among M694V homozygotes is much lower than previously appreciated. The results highlight the need for additional treatment modalities for these patients.

Tumour necrosis factor receptor-associated periodic syndrome (TRAPS): state of the art and future perspectives.

Cantarini L(1), Lucherini OM, Muscari I, Frediani B, Galeazzi M, Brizi MG, Simonini G, Cimaz R.

Tumor necrosis factor (TNF) receptor-associated periodic syndrome (TRAPS) is an autosomal dominant autoinflammatory disorder characterized by periodic fever episodes, arthralgia, myalgia, abdominal pain, serositis, and skin rash. TRAPS is caused by mutations in the gene encoding the TNF Receptor Super Family 1A (TNFRSF1A) on chromosome 12p13. The identification of TNFRSF1A mutations as the genetic cause of TRAPS coincided with the wider use of biological agents in medicine and raised the possibility that blocking TNF could potentially represent the primary therapeutic goal in TRAPS, thus disclosing new treatment choices for this complex disease. Anti-TNF therapy in TRAPS has been based on etanercept, a recombinant human TNFR (p75)-Fc fusion protein comprising two receptors linked by an IgG(1) Fc fragment. However a decrease in responsiveness to etanercept over time has been described, and it may be due to a non-specific action of etanercept in TRAPS; its efficacy may reflect 'generic' anti-inflammatory properties. Long-term adherence to etanercept is poor and a significant number of patients need to switch to anti-interleukin (IL)-1 $\beta$  therapy. In fact, the IL-1 receptor antagonist anakinra has recently been shown to prevent disease relapses both in the short- and in the long-term, and to induce a prompt and stable disease remission.

Biologic drugs in autoinflammatory syndromes.

Caorsi R(1), Federici S, Gattorno M.

Author information:

(1)Department of Paediatrics, University of Genoa, Pediatria II, Reumatologia, IRCCS G. Gaslini, Genoa, Italy.

**PURPOSE OF THE REVIEW:** Inherited autoinflammatory syndromes are conditions caused by mutations of proteins playing a pivotal role in the regulation of the innate immunity leading to an uncontrolled inflammation. The understanding of the molecular pathways involved in these disorders has shed a new light on the pattern of activation and maintenance of the inflammatory response and disclosed new molecular therapeutic targets. In this review we give a start of the art of the use of biologics in these disorders.

**MAIN TOPICS:** The dramatic response to anti IL-1 drugs in cryopyrin-associated periodic syndromes represents the brightest example of the possibility to completely dampen inflammation in these severe disorders with the selective blockade of a single pivotal cytokine. Periodic fevers are characterized by recurrent episodes of fever, usually treated with on demand steroids. However the increasing frequency of fever episodes or the development of a chronic disease course may require a continuous long-term treatment, with anti-TNF or IL-1 blockers in mevalonate kinase deficiency and TNF-receptor associated periodic syndrome. Anti-IL-1 treatment is also effective in FMF patients resistant or partially responsive to colchicine. The deficiency of the interleukin-1-receptor antagonist (DIRA) is caused by mutations in the gene encoding for the interleukin-1 receptor antagonist (IL-1Ra). In this case the recombinant IL-1Ra (anakinra) is the treatment of choice. Due to their extreme rarity the response to the available biologic drugs in other autoinflammatory diseases is still largely anecdotal.

Systemic juvenile idiopathic arthritis.

Martini A(1).

Author information:

(1)Dipartimento di Pediatria, Università di Genova, Pediatria II e Reumatologia, Istituto G Gaslini, Genova, Italy. albertomartini@ospedale-gaslini.ge.it

Systemic juvenile idiopathic arthritis (sJIA) sets well apart from all the other forms of JIA. Several observations show that sJIA is etiopathogenically different from all the other forms of JIA and has a prominent autoinflammatory component. A major role in the pathogenesis is played by two proinflammatory cytokines, interleukin-6 and interleukin-1. The specific inhibition of these two cytokines is going to change not only the therapeutic approach to the disease but also, presumably, its long term prognosis.

Autoinflammatory diseases: how to put the fire inside the body out?

Doria A(1), Dayer JM, Punzi L.

Author information:

(1)Division of Rheumatology, Department of Medicine, University of Padova, Padova, Italy. adoria@unipd.it

Autoinflammatory diseases (AIDs) are a group of distinct hereditary disorders characterized by unexplained, recurrent episodes of fever and severe inflammation, most commonly involving skin, joints, gut, and eyes. Mutations in inflammasome-related proteins, particularly in NOD-like receptor (NLR) genes, have been strongly associated with the occurrence of AIDs. However, new genes and dysfunctional proteins have recently been identified and the spectrum of AIDs is ever-expanding. In fact, it has been suggested to encompass other disorders which share some clinical features with AIDs, but are not clearly familial, or are not characterized by fever as a prominent symptom, or are polygenic. In this issue of Autoimmunity Reviews some novel and burning aspects of AIDs were covered and the relationship between AIDs and autoimmune diseases was discussed.

Peking University Institute of Nephrology, Key Laboratory of Renal Disease, Ministry of Health of China, Key Laboratory of Chronic Kidney Disease Prevention and Treatment (Peking University), Ministry of Education, Beijing, China.

Autophagy is now emerging as a spotlight in trafficking events that activate innate and adaptive immunity. It facilitates innate pathogen detection and antigen presentation, as well as pathogen clearance and lymphocyte homeostasis. In this review, we first summarize new insights into its functions in immunity, which underlie its associations with autoimmunity. As some lines of evidence are emerging to support its role in autoimmune and autoinflammatory diseases, we further discuss whether and how it affects autoimmune diseases including systemic lupus erythematosus, rheumatoid arthritis, diabetes mellitus and multiple sclerosis, as well as autoinflammatory diseases, such as Crohn disease and vitiligo.

As soon as autoinflammatory diseases (AIDs) emerged as new entities, they have been linked to the well known world of autoimmunity. In fact, AIDs and systemic autoimmune diseases (ADs), share some characteristics: they start with the prefix "auto" to define a pathological process directed against self; they are systemic diseases, frequently involving musculoskeletal system; both include monogenic and polygenic diseases. From the pathogenetic point of view, they are characterized by a chronic activation of immune system, which eventually leads to tissue

inflammation in genetically predisposed individuals. Nevertheless, the specific effectors of the damage are different in the two groups of diseases: in AIDs the innate immune system directly causes tissue inflammation, whereas in ADs the innate immune system activates the adaptive immune system which, in turn, is responsible for the inflammatory process. Mutations in inflammasome-related proteins, particularly in NOD-like receptor (NLR) genes, have been strongly associated to the occurrence of AIDs, whereas the link between inflammasome and ADs is less clear. However, a role for this multiprotein-complex in some ADs can be postulated, since a wide spectrum of endogenous danger signals can activate NLRs and inflammasome products, including IL-1 $\beta$ , can activate adaptive immunity. An association between single nucleotide polymorphisms (SNPs) localized in the inflammasome gene NLRP1 and systemic lupus erythematosus has recently been reported. AIDs and ADs are currently subdivided into two different groups, but looking at their similarities they might be considered as a single group of diseases with a large immune pathological and clinical spectrum which includes at one end pure ADs and at the other end pure AIDs.

Familial Mediterranean fever: new phenotypes.

Soriano A(1), Manna R.

Author information:

(1)Periodic Fever Research Centre, National Reference Centre for FMF, Catholic University of the Sacred Heart, Rome, Italy.

Familial Mediterranean fever (FMF) is an inherited autosomal recessive disorder, ethnically restricted and commonly found among individuals of Mediterranean descent, caused by MEditerranean FeVer gene (MEFV) mutations on chromosome 16. It is the most frequent periodic febrile syndrome among the autoinflammatory syndromes. Clinically, FMF can be distinguished into three phenotypes: type 1,

which is commonly associated with recurrent short episodes of inflammation and serositis, including fever, peritonitis, synovitis, pleuritis, but also pericarditis, orchitis or meningitis episodes; type 2, characterized by the evidence of reactive amyloid-associated (AA) amyloidosis, the most severe complication of FMF, as the first clinical manifestation of the disease in an otherwise asymptomatic individual; type 3, referred to the 'silent' homozygous or compound heterozygote state, in which two MEFV mutations are detected without signs or symptoms of FMF nor of AA amyloidosis. In the recent years it has been observed that also heterozygous mutation carriers can suffer from a mild or incomplete form of FMF, named 'FMF-like' disease. The influence of other modifiers genes and/or environmental factors can contribute to the variable penetrance and to the phenotypic variability of FMF. The insight into complex clinical and genetic cases will provide adjunctive details for the comprehension of the mechanisms of this kaleidoscopic disease.

Periodic fevers with aphthous stomatitis, pharyngitis, and adenitis (PFAPA).

Vigo G(1), Zulian F.

Author information:

(1)Pediatric Rheumatology Unit, Department of Pediatrics, University of Padua, Italy.

PFAPA syndrome (acronym of periodic fever, aphthous stomatitis, pharyngitis and cervical adenitis) is the most common cause of periodic fever in childhood. Nowadays, it is considered part of the wide family of the autoinflammatory diseases, but a genetic or molecular marker hasn't been identified yet, therefore, its etiology is still unknown. Diagnosis is essentially based on clinical criteria but, especially in younger children, it is sometimes difficult to differentiate it from other hereditary periodic fever syndromes. Fever attacks

in PFAPA have a spontaneous resolution and in a high rate of patients the syndrome ends spontaneously over time. Treatment is still a matter of debate. Usually a single administration of oral corticosteroids aborts attacks. Tonsillectomy may be an alternative option but its role remains to be clarified.

New genetic interpretation of old diseases.

Touitou I(1).

Author information:

(1)UMAI, Laboratoire de Génétique, CHRU Montpellier, Université Montpellier 1, UM1, INSERM U844, France. Isabelle.touitou@inserm.fr

The title of this section, "New genetic interpretation of old diseases," perfectly reflects the unique history of our understanding of autoinflammatory diseases (AIDs). Indeed, the main clinical feature of most AIDs is the recurrent fever, a symptom that has been extensively documented for centuries. However, the first clear description of a patient suffering from the AID prototype, familial Mediterranean fever (FMF), has only been reported in 1908, although dating studies have shown that ancestral mutations appeared in biblical times. FMF and 11 other AID genes were identified between 1997 and 2011. The patient's care has dramatically benefited from the elucidation of the molecular defect underlying similar diseases of the innate immune system. However, accumulation of present and future sequence data let us anticipate that interpretation of genetic diagnosis will be increasingly difficult.

Amyloidosis in autoinflammatory syndromes.

Obici L(1), Merlini G.

Author information:

(1)Amyloidosis Research and Treatment Centre, Biotechnology Research Laboratories, Fondazione IRCCS Policlinico San Matteo, Italy.

AA amyloidosis may still dramatically impact on the outcome of patients with autoinflammatory diseases, particularly when diagnosis is delayed. Clinicians should maintain a high level of attention to identify early this severe complication. Initial signs mostly reflect kidney damage, with proteinuria, with or without renal failure, being the more frequent presenting feature. If SAA levels are not rapidly normalized, progression toward end-stage kidney disease and dialysis invariably occurs. Over time, multiple organ failure, including heart, autonomic and adrenal insufficiency usually complicates the disease course. Limited tools are still available to predict the occurrence of AA, therefore close monitoring of at risk patients is required to detect promptly the "early red flags" through periodic search for preclinical amyloid deposits and regular assessment of proteinuria and SAA concentration. Effective control of the underlying inflammatory process may halt disease progression and even reverse damage. Anti-cytokine agents are becoming the mainstay of therapy to prevent and treat AA, including patients with FMF that do not respond or do not tolerate adequate colchicine dosages. Renal transplantation can be considered in selected patients progressing to end-stage kidney disease. Novel treatments are under development, targeting key molecular events in the fibrillogenesis process.

The diagnostic evaluation of patients with potential adult-onset autoinflammatory disorders: our experience and review of the literature.

Muscari I(1), Iacoponi F, Cantarini L, Lucherini OM, Simonini G, Brizi MG, Vitale A, Frediani B, Cimaz R, Galeazzi M.

Author information:

Hereditary periodic fever syndromes (HPFSs) are a group of inherited disorders of the innate immune system caused by mutations of genes involved in the regulation or activation of the inflammatory response, which belong to the category of autoinflammatory disorders. Most HPFs typically have an onset in pediatric age, while a limited number of patients experience disease onset during adulthood. The relative rarity and lack of information on adult-onset autoinflammatory diseases make it likely that genetic testing is often inconclusive. Recently, we have identified a set of variables related to the probability of detecting gene mutations in MEFV, responsible for familial Mediterranean fever, and TNFRSF1A, responsible for tumor necrosis factor receptor-associated periodic syndrome. In addition, we have proposed a diagnostic score for identifying those patients at high risk of carrying mutations in these genes. However, before the score can be recommended for application, further evaluation by means of longitudinal studies on different ethnicities and different populations deriving from other geographical areas is needed in order to definitively verify both its sensitivity and its specificity. The present manuscript offers our suggestions on how to establish a differential diagnosis for adult-onset HPFs, as well as a review of the literature, and we also provide a score revision available online.

[The role of aldosterone and IL-6 in the pathogenesis of inflammation in familial Mediterranean fever].

[Article in Russian]

Dzhndoian ZT, Martirosian NG.

The aim of the article was to study the role of aldosterone and IL-6 - in the pathogenesis of familial Mediterranean fever (FMF). The hypersecretion of IL-6 and "the syndrome of aldosterone excess" in patients with FMF was revealed. The hyperactivity of the inflammatory process in FMF is one of the phenotypic factors of defective gene expression in FMF. In the course of the development of familial Mediterranean fever in presence of amyloidosis, the inhibition of mineralocorticoid function, and constantly elevated IL-6 levels, which gradually progresses bringing to an exhaustion of that function and to the dissociation of the adaptative-regulatory homeostasis. The given introduction enlarges view points of pathogenesis of FMF and confirms the multifactorial nature of FMF, in the development of which besides the genetic factors, has a great role of phenotypic factors, as well. From the phenotypic factors is hyperaldosteronemia, hyperinterleukinemia-6, which reacts with defective gene and promotes its expression, and brings to the development of FMF attacks.

Redox control of NLRP3 inflammasome activation in health and disease.

Rubartelli A(1).

Author information:

(1)Cell Biology Unit, IRCCS AOU San Martino, IST Istituto Nazionale per la Ricerca sul Cancro, Genova, Italy. anna.rubartelli@istge.it

Shifts in the redox balance between ROS and antioxidants regulate innate immunity at various levels. Changes in the redox microenvironment modulate the activation

potential of the NLRP3 inflammasome, a signaling platform that activates caspase-1, allowing the maturation of IL-1 $\beta$ . However, a clear definition of the underlying mechanism is missing. In this essay, I review the most-credited theories on inflammasome activation. In particular, I will focus on the redox-mediated mechanisms that regulate the assembly of NLRP3 inflammasome and discuss how aberrations in them are implicated in the pathogenesis of autoinflammatory diseases.

Treating inflammation by blocking interleukin-1 in a broad spectrum of diseases.

Dinarello CA(1), Simon A, van der Meer JW.

Author information:

(1)Department of Medicine, University of Colorado Denver, Aurora, Colorado 80045, USA. cdinare333@aol.com

Interleukin-1 (IL-1) is a highly active pro-inflammatory cytokine that lowers pain thresholds and damages tissues. Monotherapy blocking IL-1 activity in autoinflammatory syndromes results in a rapid and sustained reduction in disease severity, including reversal of inflammation-mediated loss of sight, hearing and organ function. This approach can therefore be effective in treating common conditions such as post-infarction heart failure, and trials targeting a broad spectrum of new indications are underway. So far, three IL-1-targeted agents have been approved: the IL-1 receptor antagonist anakinra, the soluble decoy receptor rilonacept and the neutralizing monoclonal anti-IL-1 $\beta$  antibody canakinumab. In addition, a monoclonal antibody directed against the IL-1 receptor and a neutralizing anti-IL-1 $\alpha$  antibody are in clinical trials.

Revisiting secondary amyloidosis for an inadequately investigated feature: dyslipidemia.

Piskinpasa S(1), Akoglu H, Koc E, Dogru F, Coskun EY, Turgut D, Ozkayar N, Ozturk R, Odabas AR, Dede F.

Author information:

(1)Department of Nephrology, Ankara Numune Research and Educational Hospital, Ankara, Turkey. svppasa@yahoo.com

Secondary amyloidosis is the most frequent form of the systemic amyloidosis around the world. Data on frequency and nature of dyslipidemia in patients with secondary amyloidosis are not conclusive. We evaluated the lipid abnormalities and their association with clinical and laboratory characteristics of the patients with secondary amyloidosis. The reports of the kidney biopsies performed in our hospital were reviewed. Clinical and laboratory data of the patients with biopsy-proven secondary amyloidosis were analyzed retrospectively. A total of 102 patients were diagnosed as having secondary amyloidosis. Familial Mediterranean fever was the leading cause of secondary amyloidosis accounting for 42.2 % of the cases. The most frequent indication for kidney biopsy was the nephrotic range proteinuria. The most common clinical and laboratory characteristics at the time of the diagnosis were edema, proteinuria and impaired renal function. The frequency of the nephrotic range proteinuria and microscopic hematuria were 75.5 and 18.6 %, respectively. Dyslipidemia was found in 88 % of the cases. Serum lipids significantly correlated with estimated glomerular filtration rate (eGFR), but not with serum albumin or urine protein levels. We demonstrated that majority of the patients with secondary amyloidosis had serum lipid abnormalities. Dyslipidemia was closely associated with GFR in a manner that patients with advanced stage kidney disease had lower serum lipid levels.

Author information:

(1)Faculty of Medicine, Department of Internal Medicine, Harran University, Şanlıurfa, Turkey. turgayulas@yahoo.com

Familial Mediterranean fever is an autosomal recessive disorder characterized by paroxysmal episodes of fever and serosal inflammation. The classical presentation is fever and severe recurrent abdominal pain due to serositis that lasts for one to three days and the resolves spontaneously. Between the episodes patients are asymptomatic. Ninety-five percent of patients with familial mediterranean fever have painful episodes localized to the abdomen, which is usually the dominant manifestation of the disease. Herein, we present a case of 34-year-old man with incomplete abdominal pain episode of familial mediterranean fever limited to the epigastrium and had no cardinal symptoms of this disease. The diagnosis was made by genetic screening. Successful treatment response was achieved by colchicine.

Periodic fever as the manifestation of primary Sjogren's syndrome: a case report and literature review.

Wang HC(1), Chang K, Lin CY, Chen YH, Lu PL.

Author information:

(1)Department of Internal Medicine, Kaohsiung Medical University Hospital, Kaohsiung Medical University, No. 100, Tzyou 1st Road 807, Kaohsiung, Taiwan, China.

A 56-year-old male had periodic fever for 5 years and suffered from auditory hallucination and hearing impairment for 3 years. Xerostomia, xerophthalmia, elevated anti-SSA/Ro titer, positive Schirmer's test, and lymphocyte infiltrate of mucoserous gland in lip biopsy of this case confirmed the diagnosis of primary Sjogren's syndrome (pSS). We review literature for fever and neuropsychiatric involvement in pSS case series. Though fever is present in 6-41 % pSS cases, periodic fever has not been reported. Auditory hallucination was rare in cases

with pSS. The literature review alerts clinicians that fever and neurological manifestations were not uncommon in pSS cases.

(1)Department of Medicine, Section of Nephrology, The University of Texas Southwestern Medical Center, Dallas, TX, USA.

AA amyloidosis is a disorder characterized by the abnormal formation, accumulation and systemic deposition of fibrillary material that frequently involves the kidney. Recurrent AA amyloidosis in the renal allograft has been documented in patients with tuberculosis, familial Mediterranean fever, ankylosing spondylitis, chronic pyelonephritis and rheumatoid arthritis. De novo AA amyloidosis is rarely described. We report two cases of AA amyloidosis in the renal allograft. Our first case is a 47-year-old male with a history of ankylosing spondylitis who developed end-stage renal disease reportedly from tubulointerstitial nephritis from non-steroidal anti-inflammatory agent use. A biopsy was never performed. One year after transplantation, AA amyloidosis was identified in the femoral head and 8 years post-transplantation, AA amyloidosis was identified in the renal allograft. He was treated with colchicine and adalimumab and has stable renal function at 1 year-follow-up. Our second case is a 57-year-old male with a long history of intravenous drug use and hepatitis C infection who developed end-stage kidney disease due to AA amyloidosis. Our second patient's course was complicated by renal adenovirus, pulmonary aspergillosis and hepatitis C with AA amyloidosis subsequently being identified in the allograft 2.5 years post-transplantation. Renal allograft function remains stable 4-years post-transplantation. These reports describe clinical and pathologic features of two cases of AA amyloidosis presenting with proteinuria and focal involvement of the renal allograft.

Monogenic causes of inflammatory disease in rheumatology.

Verbsky JW(1).

Author information:

(1)Department of Pediatrics, Division of Rheumatology, Medical College of Wisconsin, Milwaukee, Wisconsin, USA. jverbsky@mcw.edu

**PURPOSE OF REVIEW:** To review the single-gene defects that can mimic rheumatologic diseases.

**RECENT FINDINGS:** Monogenic disorders can cause a variety of diseases that may be seen by a rheumatologist. Many of these illnesses present with recurrent episodes of arthritis, rash, fever and inflammation, and serositis. Recent discoveries have defined inflammatory diseases due to mutations in the IL-1 and IL-36 receptor antagonists, as well as the immunoproteasome. Further study of well defined monogenic causes of inflammatory diseases, such as FMF, PAPA, TRAPS, and HIDS, has elucidated the pathophysiology of these diseases leading to targeted immunotherapy with anticytokine biological medications.

**SUMMARY:** A rheumatologist should be aware of the genetic causes of inflammatory disease mimics. This will not only help with the prognosis of these diseases, but also help to guide therapy to prevent long-term complications associated with these disorders.

TNF receptor-associated periodic syndrome (TRAPS) is caused by mutations of TNFRSF1A gene and characterized by recurrent febrile episodes of prolonged duration and initial good response to steroids. Etanercept, a TNF blocker, has been used as a putative molecular-targeted agent for TRAPS, with some patients showing limited efficacy. Here, we report a patient with TRAPS who recovered from steroid dependency by etanercept and kept remission with a reduced dose of etanercept. The pathophysiology of TRAPS still remains to be elucidated and several hypotheses have been proposed. In the most recent hypothesis, the concerted action of wild-type and mutant TNF receptors plays an important role in provoking enhanced inflammation in TRAPS. The excellent response to etanercept in our patient suggested that there is heterogeneity in TRAPS patients in terms of the contribution of normal TNF signaling to autoinflammation.

[Celiac disease is a 33-year-old man with periodic disease].

[Article in Russian]

Krums LM, Golovanova EV, Khomeriki SG, Varlamicheva AA, Dorofeev AS.

The article presents a clinical case of a 33-year-old Armenian man, who suffered from two rare diseases: Familial Mediterranean fever and celiac. The diagnosis of Familial Mediterranean fever: abdominal-feverish form, is confirmed by genetic markers. The morphological study of duodenal mucosa's specimens confirms the

celiac.

Lighting the fires within: the cell biology of autoinflammatory diseases.

Park H(1), Bourla AB, Kastner DL, Colbert RA, Siegel RM.

Author information:

(1)Immunoregulation Section, Autoimmunity Branch, National Institute of Arthritis and Musculoskeletal and Skin Diseases (NIAMS), National Institutes of Health (NIH), Bethesda, Maryland, USA.

Autoinflammatory diseases are characterized by seemingly unprovoked pathological activation of the innate immune system in the absence of autoantibodies or autoreactive T cells. Discovery of the causative mutations underlying several monogenic autoinflammatory diseases has identified key regulators of innate immune responses. Recent studies have highlighted the role of misfolding, oligomerization and abnormal trafficking of pathogenic mutant proteins in triggering autoinflammation, and suggest that more common rheumatic diseases may have an autoinflammatory component. This coincides with recent discoveries of new links between endoplasmic reticulum stress and inflammatory signalling pathways, which support the emerging view that autoinflammatory diseases may be due to pathological dysregulation of stress-sensing pathways that normally function in host defence.

Blau syndrome/early-onset sarcoidosis (Blau/EOS) is an autoinflammatory disease characterized by granulomatous arthritis, uveitis, and skin rash. It has been shown that gain-of-function NOD2 mutations cause Blau/EOS. In this paper, we describe a patient with a gain-of-function NOD2 mutation who developed infantile Takayasu arteritis, which is rare in Blau/EOS, but who has not yet had significant granulomatous changes in joints, eyes, or skin. We suspect that this case is an unusual phenotype of Blau/EOS.

The factors considered as trigger for the attacks in patients with familial Mediterranean fever.

Karadag O(1), Tufan A, Yazisiz V, Ureten K, Yilmaz S, Cinar M, Akdogan A, Erdem H, Ozturk MA, Pay S, Dinc A.

Author information:

(1)Division of Rheumatology, Gulhane School of Medicine, Ankara, Turkey.

Although the inflammatory cascade of familial Mediterranean fever (FMF) is partially understood, triggering factors of those attacks has not been studied well. It is supposed that physical stresses such as cold exposure, tiredness and emotional stresses could provoke attacks. This study is aimed to survey the factors regarded as triggering the attacks in patients with FMF and their relationship with MEFV gene mutations. Clinical findings and genetic mutations

(consist of M694V, M694I, M680I, V726A, E148Q) of patients were recorded. Patients were questioned about cold exposure, emotional stress, tiredness, long-lasting standing, long-duration travel, starvation, high intake of food, trauma, and infection as triggering factors for the attacks with both serositis and musculoskeletal pain. The study is comprised of 275 FMF patients (male/female: 177/98). The most common triggering factors for the attacks with serositis were cold exposure (59.3 %), emotional stress (49.8 %), tiredness (40.0 %) and menstruation (33.7 % in females). Long-lasting standing (78.8 %), long-duration travel (64.1 %) and tiredness (47.8 %) were the triggering factors for the attacks with musculoskeletal symptoms. The relationships between MEFV mutations and triggering factors were found as M694V allele with starvation, E148Q allele with high intake of food and V726A allele with long-duration travel. The attacks with serositis seem to be triggered by those factors to which whole body exposed, whereas the attacks with musculoskeletal complaints seem to be triggered by those factors to which regional or local part of body exposed. Since the number of alleles was small, a clear conclusion for a relationship between a particular gene variant and a specific trigger was not made.

**BACKGROUND:** Association of NOD2 (CARD15) gene mutations with inflammatory bowel diseases (IBD) is well known. We herein aimed to investigate the role of familial Mediterranean fever-associated MEFV variations in IBD patients as additional regional-specific risk factor.

**STUDY:** One hundred thirty-seven (78 female, 56.9%) IBD patients [62 Crohn's disease (CD), 75 ulcerative colitis (UC)] were enrolled into the study. The diagnosis of all patients was confirmed by colonoscopy, histopathology, and the clinical findings. One hundred one healthy donors' samples were used as healthy controls. All patients were genotyped for the most common E148Q, M608I, M694V, and V726A variations of the MEFV and R702W, G908R, and 1007fs of the NOD2.

**RESULTS:** The overall MEFV variation frequency was found to be higher in the IBD (25.5%) patients (28% in UC, 22.6% in CD) compared with controls (9.9%,  $P=0.006$ ). This association was stronger with the penetrant exon 10 variations (M694V, M680I, V726A; odds ratio =4.5,  $P=0.001$ ). Contribution of M694V was higher compared with the other variations (14.5% in CD, 17.3% in UC and 3% in controls, odds ratio =6.039, 95% confidence intervals, 1.7-20.7,  $P=0.002$ ). The overall frequency of 3 NOD2 variants in the IBD group was not different from that of controls.

**CONCLUSIONS:** The results of this study suggest that the MEFV variations may be an additional susceptibility factor for IBD in certain parts of the world where the carrier rate is high, and the genetic background of the IBD patients may show regional changes.

**OBJECTIVE:** It is known that clinical similarities between Behcet's disease and Familial Mediterranean Fever have led to the hypothesis of a common pathogenesis. Familial Mediterranean Fever is caused by MEFV gene mutations coding for pyrin. Therefore, we examined whether these pyrin mutations are also associated with Behcet's disease.

**METHODS:** Molecular testing for pyrin mutations was performed in 96 unrelated Greek patients with an established diagnosis of Behcets disease. The results were compared with an analysis for pyrin mutations in 140 unrelated healthy Greek controls.

**RESULTS:** We found no pyrin mutations among the Behcet cases tested; this result is comparable with the control group.

**CONCLUSIONS:** Pyrin gene mutations in Greek patients with Behcet's disease are not more common than those in the general population. This finding is not in agreement with the findings in other populations. It is suggested that screening for pyrin mutations not be included in the evaluation of Greeks suspected to have Behcet's disease.

Primary manifestation of an autoinflammatory systemic disease was found in a 15-year-old patient, which initially ran a fulminant course. The course was first controlled by therapy with steroids and cyclosporin A. In the course of the disease, the patient developed a therapy refractory polyarthritis, which failed to respond to a combination of disease-modifying antirheumatic drugs (DMARDs) and tumor necrosis factor (TNF) inhibitors. A good disease control could only be achieved with an interleukin 6 (IL-6) blockade and DMARDs.

TNFR1 signaling is associated with backbone conformational changes of receptor dimers consistent with overactivation in the R92Q TRAPS mutant.

Lewis AK(1), Valley CC, Sachs JN.

Author information:

(1)Department of Biomedical Engineering, University of Minnesota, Twin Cities, Minneapolis, MN 55455, USA.

The widely accepted model for tumor necrosis factor 1 (TNFR1) signaling is that ligand binding causes receptor trimerization, which triggers a reorganization of cytosolic domains and thus initiates intracellular signaling. This model of stoichiometrically driven receptor activation does not account for the occurrence of ligand independent signaling in overexpressed systems, nor does it explain the constitutive activity of the R92Q mutant associated with TRAPS. More recently, ligand binding has been shown to result in the formation of high molecular weight, oligomeric networks. Although the dimer, shown to be the preligand structure, is thought to remain present within ligand-receptor networks, it is unknown whether network formation or ligand-induced structural change to the dimer itself is the trigger for TNFR1 signaling. In the present study, we investigate the available crystal structures of TNFR1 to explore backbone

dynamics and infer conformational transitions associated with ligand binding. Using normal-mode analysis, we characterize the dynamic coupling between the TNFR1 ligand binding and membrane proximal domains and suggest a mechanism for ligand-induced activation. Furthermore, our data are supported experimentally by FRET showing that the constitutively active R92Q mutant adopts an altered conformation compared to wild-type. Collectively, our results suggest that the signaling competent architecture is the receptor dimer and that ligand binding modifies domain mobilities intrinsic to the receptor structure, allowing it to sample a separate, active conformation mediated by network formation.

A rare cause of massive ascites: familial Mediterranean fever.

Aslan M(1), Demir G, Esen R, Dülger AC, Beğenik H, Çelik Y, Küçükoğlu ME, Bahar K.

Author information:

(1)Department of Internal Medicine , Yüzüncü Yıl University, Medical Faculty, 65000 Van, Turkey. m.aslan301@mynet.com

Familial Mediterranean fever is an autosomal recessive disease characterized by recurrent fever and peritoneal and pleural inflammation. It is an inherited disorder commonly found in Armenians, Turks, Arabs, Balkans, and Jews originating from North African countries. A small amount of peritoneal fluid collection can be observed during peritoneal attacks in patients with Familial Mediterranean fever, but chronic ascites has been described rarely in these patients. A 42-year-old female patient was admitted to our clinic in June 2010 with fever, severe abdominal pain and abdominal distention that had continued for one month. There was no family history of periodic fevers or abdominal pain. We could not find any cause for ascites, including tuberculosis. A diagnosis of Familial Mediterranean fever was suspected based on the clinical findings and her family history. She was screened for mutations causing Familial Mediterranean fever, and when found to be homozygous for M694V, treatment with colchicine was initiated. After treatment, the amount of ascites decreased, and relief of symptoms was

confirmed during a follow-up. In conclusion, because Familial Mediterranean fever is common in our country, it should be considered in the differential diagnosis of patients with ascites of unknown etiology in populations where hereditary inflammatory disease is endemic.

An overview of interleukin-1 receptor antagonist, anakinra, in the treatment of cutaneous diseases.

Pazyar N(1), Feily A, Yaghoobi R.

Author information:

(1)Department of Dermatology, Jundishapur University of Medical Sciences, Ahvaz, Iran.

Interleukin (IL)-1 is a pivotal proinflammatory cytokine consisting of two molecular species, IL-1 $\alpha$  and IL-1 $\beta$ . Anakinra (Kineret), a recombinant human IL-1 receptor antagonist, is regarded as a biological agent which blocks the inflammatory effects of IL-1. The aim of this review was to search the literatures and summarizes in vivo, in vitro and human studies on anakinra uses in dermatological disorders. The results show that anakinra is currently used clinically for the treatment of a variety of skin conditions such as psoriasis, atopic dermatitis, photoaging, melanoma, Schnitzler syndrome, pyoderma gangraenosum, PAPA syndrome, hidradenitis suppurativa, lamellar ichthyosis, Sweet's syndrome, panniculitis, Muckle-Wells syndrome, familial Mediterranean fever, SAPHO syndrome and other disorders. Notably, anakinra is expensive to produce and administer. Injection is the route of therapy and allergic reaction is most possible.

Familial Mediterranean fever (FMF) is an inherited disease characterized by recurrent episodes of fever and serositis. FMF is caused by mutations in the MEFV gene that encodes pyrin/marenostrin. The 5 most frequent mutations are M694V, M694I, V726A, M680I and E148Q. Here, we reported 3 FMF patients, a sister and two brothers, who have the same M694V mutation with different clinical presentations. While the sister presented with abdominal pain, one of the brothers presented with erysipelas-like erythema and the other brother with bilateral sacroiliitis. Here, we report the different clinical courses of FMF in a family carrying the same M694V mutation.

Significance of MEFV gene R202Q polymorphism in Turkish familial Mediterranean fever patients.

Yigit S(1), Karakus N, Tasliyurt T, Kaya SU, Bozkurt N, Kisacik B.

Author information:

(1)Gaziosmanpasa University, Faculty of Medicine, Department of Medical Biology, Tokat, Turkey.

**OBJECTIVE:** Familial Mediterranean fever (FMF) is an autosomal recessive disorder characterized by recurrent attacks of fever and inflammation in the peritoneum, synovium, or pleura, accompanied by pain. The disease is associated with mutations in the Mediterranean fever (MEFV) gene, which encodes for the pyrin

protein. The aim of this study was to explore the frequency and clinical significance of the R202Q (c.605G>A) polymorphism in exon 2 of the MEFV gene in a cohort of Turkish patients with FMF.

**METHODS:** The study included 191 patients with FMF and 150 healthy controls. Genomic DNA was isolated and genotyped using polymerase chain reaction (PCR)-based restriction fragment length polymorphism (RFLP) assay for the MEFV gene R202Q polymorphism.

**RESULTS:** The genotype and allele frequencies of R202Q polymorphism showed a statistically significant difference between FMF patients and controls ( $p < 0.0001$  and  $p = 0.0004$ , respectively) and especially the homozygous AA genotype was significantly higher in FMF patients than healthy controls ( $p = 0.0002$ ; odds ratio = 6.27; 95% CI = 2.1-18.3). However no significant association was observed between clinical and demographic features of FMF patients and R202Q polymorphism.

**CONCLUSION:** The results of this study showed that there was a high association between MEFV gene R202Q polymorphism and FMF. R202Q polymorphism should be included in routine molecular diagnosis of FMF patients.

ishiguro.takashi@pref.saitama.lg.jp

A 32-year-old man presented to our hospital complaining of periodic fever and unilateral chest pain. We suspected that he had familial Mediterranean fever

because of his symptoms. Magnetic resonance imaging (MRI) showed an increased intensity within the anterior chest wall, which was consistent with the site of his pain. Genomic analysis showed the patient to be heterozygous for the E148Q/M694I mutation in the MEFV gene, and we diagnosed familial Mediterranean fever. The ability of MRI to detect inflammatory changes could provide useful additional information for evaluating thoracic symptoms in FMF patients, and the detection of inflammatory changes using MRI may aid in early diagnosis, thus contributing to early and adequate treatment.

Periodic fever associated with aphthous stomatitis, pharyngitis and cervical adenitis.

Kyvsgaard N(1), Mikkelsen T, Korsholm J, Veirum JE, Herlin T.

Author information:

(1)Department of Paediatrics, Aarhus University Hospital, Skejby, Aarhus N, Denmark. ninisoer@rm.dk

**INTRODUCTION:** The periodic fever, aphthous stomatitis, pharyngitis and cervical adenitis (PFAPA) syndrome is a non-hereditary idiopathic febrile syndrome belonging to the group of autoinflammatory diseases. PFAPA does not cause long-lasting sequelae. An early diagnosis provides treatment possibilities for the patient and comfort to the family.

**MATERIAL AND METHODS:** This study is a retrospective review of the medical records of patients diagnosed with PFAPA and admitted to our clinic from January 1999 to January 2010 (n = 31).

**RESULTS:** The study population (n = 31) consisted of 21 males and ten females: 30 Caucasians and 1 Asian. Normal growth was seen in 30 patients. The median age at onset was 33 months. The mean duration of fever episodes was 4.45 days (95% confidence interval (CI): 3.92-4.98 days), and the mean duration of intervals between fever episodes was 29.66 days (95% CI: 25.31-34.01 days). Concomitantly with the fever, all patients had characteristic symptoms. All patients were asymptomatic in between their fever episodes. Prodromal symptoms were seen in 12 patients. Oral prednisolone was used in 24 patients and caused immediate fever reduction in 87.5%. A reduction in the duration of the asymptomatic interval after treatment was seen in 75.0%. Tonsillectomy was performed in 20 of the 31 patients causing cessation of fever episodes in 70%. Fever episodes continued in 15%, and the postoperative status remained unknown in the last 15%. Spontaneous resolution was seen in four patients. The diagnostic delay had a median duration of 28 months (range 2-160 months).

**CONCLUSION:** The long diagnostic delay of PFAPA gives cause for concern and it indicates a need for greater awareness of the disease so that the diagnosis may be made earlier.

**FUNDING:** not relevant.

**OBJECTIVE:** To evaluate the response to treatment of autoinflammatory diseases from an international registry and an up-to-date literature review.

**METHODS:** The response to treatment was studied in a web-based registry in which clinical information on anonymised patients with autoinflammatory diseases was collected retrospectively as part of the Eurofever initiative. Participating hospitals included paediatric rheumatology centres of the Paediatric Rheumatology International Trial Organisation network and adult centres with a specific interest in autoinflammatory diseases. The following diseases were included: familial Mediterranean fever (FMF), cryopyrin-associated periodic syndromes (CAPS), tumour necrosis factor (TNF)-receptor associated periodic syndrome (TRAPS), mevalonate kinase deficiency (MKD), pyogenic arthritis pustulosis acne (PAPA) syndrome, deficiency of interleukin-1 receptor antagonist (DIRA), NLRP12-related periodic fever and periodic fever aphthosis pharyngitis adenitis (PFAPA) syndrome. Cases were independently validated by experts for each disease. A literature search regarding treatment of the abovementioned diseases was also performed using Medline and Embase.

**RESULTS:** 22 months from the beginning of the enrolment, complete information on 496 validated patients was available. Data from the registry in combination with evidence from the literature confirmed that colchicine is the treatment of choice

for FMF and IL-1 blockade for DIRA and CAPS. Corticosteroids on demand probably represent a valid therapeutic strategy for PFAPA, but also for MKD and TRAPS. Patients with poorly controlled MKD, TRAPS, PAPA or FMF may benefit from IL-1 blockade; anti-TNF treatment may represent a possible valuable alternative. CONCLUSIONS: In the absence of high-grade evidence, these results could serve as a basis for therapeutic guidelines and to identify candidate drugs for future therapeutic trials.

OBJECTIVES: Familial Mediterranean fever (FMF) is an autosomal-recessive disease characterized by recurrent attacks of fever with serositis. Differential diagnosis of a FMF abdominal attack with acute abdomen is difficult. Acute appendicitis is the most common cause of acute abdominal pain that requires surgical treatment. The aim of this study was to investigate frequency of FMF in patients with negative appendectomy.

METHODS: We assessed 278 patients (female/male 127/151) who were operated with preoperative diagnosis of acute appendicitis. In 250 of the patients, definitive diagnosis of acute appendicitis was established by histo-pathological examination. Patients with negative appendectomy were assessed for FMF by rheumatologist.

RESULTS: Negative appendectomy was detected in 28 patients (M/F 5/23, mean age  $25.3 \pm 8.4$  years). Negative appendectomy ratio was 10.1 %. Among 28 patients two had FMF (7.7 %).

CONCLUSIONS: FMF were established in 7.7 % of patients with negative appendectomy. Our study suggests patients having negative appendectomy should be evaluated for FMF. Further large sample studies are needed to define the real prevalence of FMF among negative appendectomy patients.

Pathogenetic overview of psoriatic disease.

Haroon M(1), Fitzgerald O.

Author information:

(1)St Vincent's University Hospital and Conway Institute, University College Dublin, Dublin, Ireland.

Psoriatic arthritis (PsA) is an inflammatory musculoskeletal disease with both autoimmune and autoinflammatory features. Evidence supports the distinct nature of PsA regarding its clinical, genetic, immunohistochemical, and imaging features. Such features can help to distinguish PsA from other common rheumatic diseases. Apart from peripheral joint involvement, the musculoskeletal lesions in PsA include enthesitis and involvement of the distal interphalangeal joint (frequently associated with nail involvement, dactylitis, and axial involvement). The traditional model of pathogenesis in PsA has identified it as an autoimmune disease; however, an alternative model classifies it as having autoinflammatory features. Similarly, there are important new genetic observations focusing on the HLA region, and genome-wide association that confirms the genetic heterogeneity of patients with psoriasis and patients with PsA. Newer imaging techniques have also provided a much more detailed characterization of tissue abnormalities, in particular highlighting the extent of new bone formation, which is quite distinct from rheumatoid arthritis.

The spectrum of adipose tissue diseases ranges from obesity to lipodystrophy, and is accompanied by insulin resistance syndrome, which promotes the occurrence of type 2 diabetes, dyslipidemia and cardiovascular complications. Lipodystrophy refers to a group of rare diseases characterized by the generalized or partial absence of adipose tissue, and occurs with or without hypertrophy of adipose tissue in other sites. They are classified as being familial or acquired, and generalized or partial. The genetically determined partial forms usually occur as Dunnigan syndrome, which is a type of laminopathy that can also manifest as muscle, cardiac, neuropathic or progeroid involvement. Gene mutations encoding for PPAR-gamma, Akt2, CIDEA, perilipin and the ZMPSTE 24 enzyme are much more rare. The genetically determined generalized forms are also very rare and are linked to mutations of seipin AGPAT2, FBN1, which is accompanied by Marfan syndrome, or of BANF1, which is characterized by a progeroid syndrome without insulin resistance and with early bone complications. Glycosylation disorders are sometimes involved. Some genetically determined forms have recently been found to be due to autoinflammatory syndromes linked to a proteasome anomaly (PSMB8). They result in a lipodystrophy syndrome that occurs secondarily with fever, dermatosis and panniculitis. Then there are forms that are considered to be acquired. They may be iatrogenic (protease inhibitors in HIV patients, glucocorticosteroids, insulin, graft-versus-host disease, etc.), related to an immune system disease (sequelae of dermatopolymyositis, autoimmune polyendocrine syndromes, particularly associated with type 1 diabetes, Barraquer-Simons and Lawrence syndromes), which are promoted by anomalies of the complement system. Finally,

lipomatosis is currently classified as a painful form (adiposis dolorosa or Dercum's disease) or benign symmetric multiple form, also known as Launois-Bensaude syndrome or Madelung's disease, which are sometimes related to mitochondrial DNA mutations, but are usually promoted by alcohol. In addition to the medical management of metabolic syndrome and the sometimes surgical treatment of lipodystrophy, recombinant leptin provides hope for genetically determined lipodystrophy syndromes, whereas modifications in antiretroviral treatment and tesamorelin, a GHRH analog, is effective in the metabolic syndrome of HIV patients. Other therapeutic options will undoubtedly be developed, dependent on pathophysiological advances, which today tend to classify genetically determined lipodystrophy as being related to laminopathy or to lipid droplet disorders.

The limited role of interferon- $\gamma$  in systemic juvenile idiopathic arthritis cannot be explained by cellular hyporesponsiveness.

Sikora KA(1), Fall N, Thornton S, Grom AA.

Author information:

(1)Children's Hospital Medical Center, Cincinnati, Ohio, USA.

keith.sikora@cchmc.org

**OBJECTIVE:** Systemic juvenile idiopathic arthritis (JIA) is an autoinflammatory syndrome in which the myelomonocytic lineage appears to play a pivotal role. Inflammatory macrophages are driven by interferon- $\gamma$  (IFN $\gamma$ ), but studies have failed to demonstrate an IFN- induced gene signature in active systemic JIA. This study sought to characterize the status of an IFN-induced signature within affected tissue and to gauge the integrity of IFN signaling pathways within peripheral monocytes from patients with systemic JIA.

**METHODS:** Synovial tissue from 12 patients with active systemic JIA and 9 with active extended oligoarticular JIA was assessed by real-time polymerase chain reaction to quantify IFN-induced chemokine gene expression. Peripheral monocytes

from 3 patients with inactive systemic JIA receiving anti-interleukin-1 $\beta$  (anti-IL-1 $\beta$ ) therapy, 5 patients with active systemic JIA, and 8 healthy controls were incubated with or without IFN $\gamma$  to gauge changes in gene expression and to measure phosphorylated STAT-1 (pSTAT-1) levels.

RESULTS: IFN-induced chemokine gene expression in synovium was constrained in active systemic JIA compared to the known IFN-mediated extended oligoarticular subtype. In unstimulated peripheral monocytes, IFN-induced gene expression was similar between the groups, except that lower levels of STAT1, MIG, and PIAS were observed in patients with active disease, while higher levels of PIAS1 were observed in patients with inactive disease. Basal pSTAT-1 levels in monocytes tended to be higher in systemic JIA patients compared to healthy controls, with the highest levels seen in those with inactive disease. Upon stimulation of monocytes, the fold increase in gene expression was roughly equal between groups, except for a greater increase in STAT1 in patients with inactive systemic JIA compared to controls, and a greater increase in IRF1 in those with active compared to inactive disease. Upon stimulation, the fold increase in pSTAT-1 was highest in monocytes from patients with inactive systemic JIA.

CONCLUSION: Monocytes in patients with active systemic JIA retain the ability to respond to IFN $\gamma$ , suggesting that the lack of an IFN-induced gene signature in patients with active disease reflects a limited in vivo exposure to IFN $\gamma$ . In patients with inactive systemic JIA who received treatment with anti-IL-1 $\beta$ , hyperresponsiveness to IFN $\gamma$  was observed.

Biologic agents in the treatment of urticaria.

Kaplan AP(1).

Author information:

(1)Department of Medicine, Division of Pulmonary and Critical Care Medicine, Allergy and Clinical Immunology, Medical University of South Carolina,

Charleston, 29425, USA. kaplana@musc.edu

Numerous controlled studies as well as case reports have demonstrated that Omalizumab can be employed successfully in approximately 75 % of patients with chronic spontaneous urticaria, leading to a dramatic decrement in symptoms with very few side effects. No other drug currently available is comparable, and the success rate in patients resistant to antihistamines is no different. In the U.S., Phase I and Phase II trials are complete and we await the results of a Phase III multicenter study, with a view to eventual submission to the Food and Drug Administration in the U.S. and to comparable agencies abroad seeking approval for this indication. Omalizumab is currently marketed for the treatment of severe allergic asthma. Case reports suggest efficacy in difficult cases of physical urticaria, but no controlled trials have been done. Other agents require further evaluation for possible efficacy in the treatment of chronic spontaneous urticaria, including antibody to CD20, a B-lymphocyte cell surface marker, anti-TNF $\alpha$ , and anti-Interleukin 1. Thus far, targeting TNF $\alpha$  has been disappointing for this indication, while targeting Interleukin 1 has dramatically ameliorated autoinflammatory disorders with urticaria or urticaria-vasculitic-like lesions such as cold-induced autoinflammatory syndrome, Muckle-Wells syndrome, and Schnitzler syndrome.

OBJECTIVE: To identify any adverse effects of colchicine in a pediatric patients with familial Mediterranean fever (FMF).

**STUDY DESIGN:** Clinical presentation, Mediterranean fever gene genotype, disease duration, colchicine dose, laboratory tests, and reported adverse effects in children with FMF were analyzed.

**RESULTS:** Of the 153 patients with FMF, 22 (14.4%) developed diarrhea during a follow-up of 4 years; the colchicine dose was reduced to control this symptom in only 4 patients. In 18 (11.8%) patients, a mild transitory increase of transaminases (45-158 IU/L) was found during a follow-up of 1 year. Blood cell counts and kidney function tests were normal in all patients. No correlation was found between the adverse effects and patient's age, disease onset, treatment duration, or any of the clinical characteristics of the disease.

**CONCLUSION:** Colchicine is a safe drug in the treatment of children with FMF, even in infancy. The only significant adverse effects are diarrhea (in a small number of patients), which can be controlled by a decrease in the colchicine dose and transitory elevation of transaminases.

**OBJECTIVES:** Familial Mediterranean fever (FMF) is one of the most serious inherited inflammatory disorders among Jewish, Armenian, Turkish and Arab populations. The imbalance between pro- and anti-inflammatory cytokines may play a role in its etiology. We have investigated whether tumor necrosis factor- $\alpha$  (TNF- $\alpha$ ) and plasminogen activator inhibitor 1 (PAI-1) gene polymorphisms are associated with FMF and evaluated the relationship between these polymorphisms

and genotypic manifestation of FMF.

**METHODS:** We investigated single nucleotide polymorphisms of the TNF- $\alpha$  promoter at positions -308 G/A and the PAI-1 4G/5G gene polymorphism in peripheral blood leukocytes collected from 177 individuals with FMF with different genotype combinations. All of the polymorphisms of TNF- $\alpha$  and PAI-1 were detected by PCR and restriction fragment length polymorphism analysis.

**RESULTS:** There were no association between the TNF- $\alpha$ /308 genotypes and mutations in FMF. In contrast, the PAI-1 4G/5G gene polymorphism may have a significant effect in FMF disease.

**CONCLUSIONS:** Screening with PAI-1 gene polymorphism tests may be beneficial for tracing future FMF patients. However, further investigations are needed to reach a conclusion on the association between PAI-1 polymorphisms and FMF.

Critical role for calcium mobilization in activation of the NLRP3 inflammasome.

Murakami T(1), Ockinger J, Yu J, Byles V, McColl A, Hofer AM, Horng T.

Author information:

(1)Department of Genetics and Complex Diseases, Harvard School of Public Health, Boston, MA 02115, USA.

The NLRP3 (nucleotide-binding domain, leucine-rich-repeat-containing family, pyrin domain-containing 3) inflammasome mediates production of inflammatory mediators, such as IL-1 $\beta$  and IL-18, and as such is implicated in a variety of inflammatory processes, including infection, sepsis, autoinflammatory diseases, and metabolic diseases. The proximal steps in NLRP3 inflammasome activation are not well understood. Here we elucidate a critical role for Ca(2+) mobilization in activation of the NLRP3 inflammasome by multiple stimuli. We demonstrate that blocking Ca(2+) mobilization inhibits assembly and activation of the NLRP3 inflammasome complex, and that during ATP stimulation Ca(2+) signaling is pivotal in promoting mitochondrial damage. C/EPB homologous protein, a transcription factor that can modulate Ca(2+) release from the endoplasmic reticulum, amplifies

NLRP3 inflammasome activation, thus linking endoplasmic reticulum stress to activation of the NLRP3 inflammasome. Our findings support a model for NLRP3 inflammasome activation by Ca(2+)-mediated mitochondrial damage.

MEFV which encodes pyrin, cause familial Mediterranean fever (FMF), the most common auto-inflammatory disease. Pyrin is believed to be a regulator of inflammation, though the nature of this regulatory activity remains to be identified. Prophylactic treatment with colchicine, a microtubule toxin, has had a remarkable effect on disease progression and outcome. It has been thought that, inhibition of microtubule polymerization is the main mechanism of action of colchicine. But, the exact cellular mechanism explaining the efficacy of colchicine in suppressing FMF attacks is still unclear. Given the ability of colchicine treatment to be considered as a differential diagnosis criteria of FMF, we hypothesized that colchicine may have a specific effect on pyrin and pyrin interacting proteins. This study showed that colchicine prevents reticulated fibrils formed by PSTPIP1 filaments and reduces ASC speck rates in transfected cells. We further noted that, colchicine down-regulates MEFV expression in THP-1 cells. We also observed that colchicine causes re-organization of actin cytoskeleton in THP-1 cells. Pyrin is an actin-binding protein that specifically localizes with polymerizing actin filaments. Thus, MEFV expression might be affected by re-organization of actin cytoskeleton. The data presented here reveal an important connection between colchicine and pyrin which might explain the remarkable efficacy of colchicine in preventing FMF attacks.

Mevalonate kinase deficiency: disclosing the role of mevalonate pathway modulation in inflammation.

Marcuzzi A(1), Crovella S, Monasta L, Vecchi Brumatti L, Gattorno M, Frenkel J.

Author information:

(1)Institute for Maternal and Child Health – IRCCS “Burlo Garofolo” – Trieste, Italy.

Inflammation is a highly regulated process involved both in the response to pathogens as well as in tissue homeostasis. In recent years, a complex network of proteins in charge of inflammation control has been revealed by the study of hereditary periodic fever syndromes. Most of these proteins belong to a few families and share the capability of sensing pathogen-associated and damage-associated molecular patterns. By interacting with each other, these proteins participate in the assembly of molecular platforms, called inflammasomes, which ultimately lead to the activation of cytokines, to the transcription of inflammatory genes or to the induction of cell apoptosis. Among hereditary periodic fever syndromes, mevalonate kinase deficiency (MKD) is the sole in which the phenotype did not directly associate with a deficiency of these proteins, but with a metabolic defect of the mevalonate pathway, highlighting the importance of this metabolic pathway in the inflammation control. Noteworthy, drugs acting on this pathway can greatly influence the inflammatory response. The modulation of inflammation by mevalonate pathway is of interest, since it may involve mechanisms not directly referable to inflammasomes. MKD provides a model to study these mechanisms and possibly to develop new classes of anti-inflammatory drugs.

Author information:

(1)Center for iPS Cell Research and Application, Kyoto University, Kyoto, Japan.

Chronic infantile neurologic cutaneous and articular (CINCA) syndrome is an IL-1-driven autoinflammatory disorder caused mainly by NLRP3 mutations. The pathogenesis of CINCA syndrome patients who carry NLRP3 mutations as somatic mosaicism has not been precisely described because of the difficulty in separating individual cells based on the presence or absence of the mutation. Here we report the generation of NLRP3-mutant and nonmutant-induced pluripotent stem cell (iPSC) lines from 2 CINCA syndrome patients with somatic mosaicism, and describe their differentiation into macrophages (iPS-MPs). We found that mutant cells are predominantly responsible for the pathogenesis in these mosaic patients because only mutant iPS-MPs showed the disease relevant phenotype of abnormal IL-1 $\beta$  secretion. We also confirmed that the existing anti-inflammatory compounds inhibited the abnormal IL-1 $\beta$  secretion, indicating that mutant iPS-MPs are applicable for drug screening for CINCA syndrome and other NLRP3-related inflammatory conditions. Our results illustrate that patient-derived iPSCs are useful for dissecting somatic mosaicism and that NLRP3-mutant iPSCs can provide a valuable platform for drug discovery for multiple NLRP3-related disorders.

Does mean platelet volume influence the attack or attack-free period in the patients with Familial Mediterranean fever?

Sahin S(1), Senel S, Ataseven H, Yalcin I.

Author information:

(1)Department of Internal Medicine, Medicine Faculty, Gaziosmanpasa University, Tokat, Turkey. drsafaksahin@gmail.com

Familial Mediterranean fever (FMF) is an autosomal recessive hereditary disease which is characterized by recurrent attacks of fever and peritonitis, pleuritis, arthritis, or erysipelas-like skin disease. Mean platelet volume (MPV) is a sign of platelet activation. There are limited studies in the literature about MPV levels in FMF patients. We aimed to investigate MPV levels during the attack period (group 1) and attack-free periods (group 2) in FMF patients, and to compare them with healthy controls (group 3). The study consisted of the data of: 60 group 1 patients, 120 group 2 patients, and 75 group 3 patients. Erythrocyte sedimentation rate, C-reactive protein, white blood cell count, platelet count, and MPV levels were retrospectively recorded from patient files. Statistical analyses showed that MPV was significantly lower in FMF patients both in group 1 and group 2 than in group 3 ( $p = 0.004$ ,  $p = 0.002$ , respectively); however, there was no difference among group 1 and group 2 in patients with FMF ( $p = 0.279$ ). The mean platelet count of group 1 was higher than that of group 3 ( $p = 0.010$ ). In conclusion, this study results suggested that MPV level did not increase on the contrary, it decreased in patients with FMF both in group 1 and/or group 2 when compared to group 3. It was concluded that the lower MPV level was an expected result of secondary thrombocytosis in FMF patients.

The autoinflammatory diseases.

Federici S(1), Caorsi R, Gattorno M.

Author information:

(1)UO Pediatria II - Reumatologia, Ospedale G. Gaslini, Genova, Italy.

The monogenic autoinflammatory syndromes are conditions caused by mutations of genes coding for proteins that play a pivotal role in the regulation of the inflammatory response. Due to their genetic nature, most of these disorders have an early onset. Clinically they are characterised by recurrent flares of systemic inflammation presenting most of the time as sudden fever episodes associated with elevation of acute phase reactants and with a number of clinical manifestations such as rash, serositis, lymphadenopathy and arthritis. Symptom-free intervals are characterised by complete wellbeing, normal growth and complete normalisation of acute phase reactants. Familial Mediterranean fever (FMF), mevalonate-kinase deficiency (MKD) and tumour necrosis factor (TNF) receptor-associated periodic syndrome (TRAPS) are the three monogenic disorders subsumed under the term periodic fevers, while a systemic inflammation dominated by a characteristic urticarial rash associated with a number of other clinical manifestations is typical of familial cold autoinflammatory syndrome (FCAS), Muckle-Wells syndrome (MWS) and chronic infantile neurological cutaneous and articular syndrome (CINCA). These diseases represent the clinical spectrum of different mutations of a gene named cold-induced autoinflammatory syndrome 1 (CIAS-1, or NLRP3) coding for a protein called cryopyrin. Hence these disorders are also known as cryopyrin-associated periodic syndromes (CAPS). Other conditions are characterised by typical granulomatous formations (granulomatous disorders). Blau's syndrome (familial juvenile systemic granulomatosis) presents with non-caseating granulomatous inflammation affecting the joint, skin, and uveal tract (the triad of arthritis, dermatitis and uveitis) and is associated with mutations of the NACHT domain of the gene CARD15 (or NOD2).

The impact of familial Mediterranean fever on women's health.

Dotters-Katz S(1), Kuller J, Price T.

Author information:

(1)Duke University, Durham, NC, USA. sarah.dotters-katz@duke.edu

Familial Mediterranean fever (FMF) is the most common hereditary recurrent febrile disorder, characterized by the sudden onset of high fever and severe abdominal pain. The implications of this disorder on a woman's health are significant and not well known among obstetrician/gynecologists. The goal of this review is to familiarize providers caring for women on the ramifications of FMF on different aspects of a woman's life, including puberty, fertility, pregnancy, and menopause, as well as to help them to diagnose and manage FMF when these patients become pregnant.

**BACKGROUND AND OBJECTIVES:** Familial Mediterranean fever (FMF) is an autosomal recessive disorder caused by mutations in MEFV gene, which encodes pyrin. FMF is

especially prevalent among Turks, Armenians, non-Ashkenazi Jews, and Arabs. The aim of this study was to determine the frequency and spectrum of 12 MEFV mutations of these patients and any genotype-phenotype correlation in this large Turkish group.

**DESIGN AND SETTING:** A retrospective study at Erciyes University Medical Faculty, from January 2007 to June 2009.

**PATIENTS AND METHODS:** We enrolled 446 Turkish FMF patients and identified the known 12 MEFV mutations with clinical investigations. DNA was amplified by PCR and subjected to reverse hybridization for the detection of MEFV gene mutations.

**RESULTS:** Among the 446 patients, 103 (46.6%) had a heterozygous genotype, 44 (19.9%) had a homozygous genotype, and 74 (33.49%) had a compound heterozygous genotype. The most common mutation detected was heterozygote M694V (46/221). Of the included 446 patients, 218 (48.87%) were male and 228 (51.12%) were female. High parental consanguinity rates affect FMF development. The clinical spectrum varied with different mutation profiles.

**CONCLUSIONS:** This study plays an important role in detecting the distribution of MEFV mutations and determining clinical approaches among Turk FMF patients. Also, we seemed to detect a distinctive clinical picture, specifically a lower frequency of amyloidosis.

NOMID: the radiographic and MRI features and review of literature.

Zaki FM(1), Sridharan R, Pei TS, Ibrahim S, Ping TS.

Author information:

(1)Department of Radiology, Universiti Kebangsaan Malaysia Medical Center (UKMMC), Malaysia.

Neonatal onset multisystem inflammatory disease (NOMID) is a rare autoinflammatory disorder, which manifests early in infancy. We describe a case of a 10-year-old boy who has been unwell since infancy. He presented with

urticarial rash, intermittent fever and hepatosplenomegaly followed by progressive arthropathy. His joint symptoms started at two years of age, which progressively involved multiple joints, resulting in bone and joint deformities. A series of joint radiographs demonstrated bizarre enlarging physeal mass with heterogenous calcification. Magnetic resonance imaging (MRI) of the involved right ankle and knee showed characteristic thickened and calcified physeal lesions, which enhanced post-gadolinium. This debilitating disease is also known to involve the central nervous system and eyes. This case report aims to highlight the conventional radiographic and magnetic resonance imaging (MRI) findings of this physeal abnormality in NOMID syndrome.

Update: Cytokine Dysregulation in Chronic Nonbacterial Osteomyelitis (CNO).

Hofmann SR(1), Roesen-Wolff A, Hahn G, Hedrich CM.

Author information:

(1)Department of Pediatrics, University Hospital Carl Gustav Carus, Fetscherstra ß e 74, 01307 Dresden, Germany.

Chronic nonbacterial osteomyelitis (CNO) with its most severe form chronic recurrent multifocal osteomyelitis (CRMO) is a non-bacterial osteitis of yet unknown origin. Secondary to the absence of both high-titer autoantibodies and autoreactive T lymphocytes, and the association with other autoimmune diseases, it was recently reclassified as an autoinflammatory disorder of the musculoskeletal system. Since its etiology is largely unknown, the diagnosis is based on clinical criteria, and treatment is empiric and not always successful. In this paper, we summarize recent advances in the understanding of possible etiopathogenetic mechanisms in CNO.

2700. Ann Rheum Dis. 2012 Dec;71(12):2035-43. doi: 10.1136/annrheumdis-2011-201197. Epub 2012 Jun 7.

Involvement of X-box binding protein 1 and reactive oxygen species pathways in the pathogenesis of tumour necrosis factor receptor-associated periodic syndrome.

Dickie LJ(1), Aziz AM, Savic S, Lucherini OM, Cantarini L, Geiler J, Wong CH, Coughlan R, Lane T, Lachmann HJ, Hawkins PN, Robinson PA, Emery P, McGonagle D, McDermott MF.

Author information:

(1)Experimental Rheumatology, National Institute for Health Research–Leeds Musculoskeletal Biomedical Research Unit, Leeds Institute of Molecular Medicine, Leeds, West Yorkshire, UK.

**OBJECTIVES:** To investigate convergence of endoplasmic reticulum stress pathways and enhanced reactive oxygen species (ROS) production, due to intracellular retention of mutant tumour necrosis factor receptor 1 (TNFR1), as a disease mechanism in TNFR-associated periodic syndrome (TRAPS).

**METHODS:** Peripheral blood mononuclear cells from patients with TRAPS (n=16) and healthy controls (HC) (n=22) were studied alongside HEK293T cells expressing wild type-TNFR1 or TRAPS-associated mutations. Unfolded protein response (UPR)-associated proteins (protein kinase-like endoplasmic reticulum kinase, PERK), phosphorylated-PERK (p-PERK), phosphorylated inositol-requiring enzyme 1 $\alpha$  (p-IRE1 $\alpha$ ) and spliced X-box binding protein 1 (sXBP1)) were measured by flow cytometry. XBP1 splicing and UPR-associated transcript expression were assessed by reverse transcription PCR/quantitative real-time PCR. ROS levels were measured using CM-H(2)DCFDA and MitoSOX Red in patients' monocytes or HEK293T cells by flow cytometry.

**RESULTS:** Mutant TNFR1-expressing HEK293T cells had increased TNFR1 expression associated with intracellular aggregation. TRAPS patients had increased sXBP1 transcripts (p<0.01) compared with HC. Raised p-PERK protein was seen, indicative of an UPR, but other UPR-associated transcripts were normal. Increased ROS levels were observed in TRAPS monocytes compared with HCs (p<0.02); these increased further upon IL-6 stimulation (p<0.01). Lipopolysaccharide-stimulated peripheral blood mononuclear cells of patients with TRAPS, but not HCs, demonstrated increased sXBP1 levels (p<0.01), which were reduced by antioxidant treatment

( $p < 0.05$ ).

**CONCLUSIONS:** Patients with TRAPS have evidence of increased sXBP1 and PERK expression but without other signs of classical UPR, and also with high ROS generation that may contribute to the pro-inflammatory state associated with TRAPS. The authors propose a non-traditional XBP1 pathway with enhanced sXBP1 as a novel disease-contributing mechanism in TRAPS.

(1)Department of Rheumatology, Tel Aviv Sourasky Medical Center, Tel Aviv, Israel. [uria@tasmc.health.gov.il](mailto:uria@tasmc.health.gov.il)

Monogenic periodic fever syndromes are characterized by recurrent episodes of fever, accompanied by localized inflammatory manifestations. Among them, familial

Mediterranean fever (FMF) is the most studied and is by far the most prevalent periodic fever syndrome in Israel. We present a diagnostic workup of a patient suffering from a periodic fever syndrome, initially thought to be FMF and characterized by attacks of fever, severe abdominal pain, a migratory erythematous rash and conjunctivitis. The development of periorbital edema presenting as diplopia led to consideration of tumor necrosis factor receptor-1-associated periodic syndrome (TRAPS). Genetic tests confirmed the diagnosis. This case should alert us that even in Israel, a patient with periodic fever not fully consistent with the typical features of FMF, should be evaluated for other periodic fever syndromes.

QT variability in amyloidosis of familial Mediterranean fever.

Nussinovitch U(1), Ben-Zvi I, Livneh A.

Author information:

(1)Israel Naval Medical Institute, Israel Defense Forces Medical Corps, Haifa, Israel.

**BACKGROUND:** The association between familial Mediterranean fever (FMF) and increased risk for ventricular arrhythmias is controversial, and data on this subject are meager.

**OBJECTIVES:** To evaluate QT variability index (QTVI) and other repolarization markers associated with arrhythmogenicity in patients with amyloidosis of FMF.

**METHODS:** The study group comprised 12 FMF patients with amyloidosis, and 14 age and gender-matched healthy subjects served as the control group. QT measurements were conducted according to accepted procedure, using computerized software for recording and analysis.

**RESULTS:** No differences were found in clinical and demographic parameters in the study and control groups, except for hypertension which was more common in the FMF amyloidosis group. QTc and power spectral analysis of QT variability parameters were similar in both groups. Nevertheless, QTVI values in FMF amyloidosis patients were significantly higher than in healthy individuals (-1.02

+/- 0.38, vs. -1.36 +/- 0.32 respectively,  $P = 0.02$ ).

**CONCLUSIONS:** Compared with healthy controls, amyloidosis of FMF is associated with increased QTVI. It remains unknown whether this finding is solely amyloidosis related and whether it has any prognostic significance.

Risk factors for amyloidosis and impact of kidney transplantation on the course of familial Mediterranean fever.

Ben-Zvi I(1), Danilesko I, Yahalom G, Kukuy O, Rahamimov R, Livneh A, Kivity S.

Author information:

(1)Rheumatology Unit, Zabłudowicz Center of Autoimmune Disease, Tel Hashomer, Israel.

**BACKGROUND:** Amyloidosis of familial Mediterranean fever (FMF) may lead to end-stage renal failure, culminating in kidney transplantation in some patients.

**OBJECTIVES:** To assess demographic, clinical and genetic risk factors for the development of FMF amyloidosis in a subset of kidney-transplanted patients and to evaluate the impact of transplantation on the FMF course.

**METHODS:** Demographic, clinical and genetic data were abstracted from the files, interviews and examinations of 16 kidney-transplanted FMF amyloidosis patients and compared with the data of 18 FMF patients without amyloidosis.

**RESULTS:** Age at disease onset and clinical severity of the FMF amyloidosis patients prior to transplantation were similar to FMF patients without amyloidosis. Compliance with colchicine treatment, however, was much lower (50% vs. 98%). Posttransplantation, FMF amyloidosis patients experienced fewer of the typical serosal attacks than did their counterparts (mean 2214 days since last attack vs. 143 days). Patients with FMF amyloidosis carried only M694V mutations in the FMF gene, while FMF without amyloidosis featured other mutations as well.

**CONCLUSIONS:** Compliance with treatment and genetic makeup but not severity of FMF constitutes major risk factors for the development of amyloidosis in FMF.

Transplantation seems to prevent FMF attacks. The protective role of immunosuppressive therapy cannot be excluded.

Behçet syndrome: is it one condition?

Yazici H(1), Ugurlu S, Seyahi E.

Author information:

(1)Department of Medicine, Division of Rheumatology, Cerrahpaşa Medical School, University of Istanbul, Safa sok. 17/7 Kadikoy, Istanbul, 34710, Turkey.

hasan@yazici.net

Behçet's syndrome (BS) is a disease of unknown etiology, and as such, there have been efforts to classify BS within the popular nosological identities of the times such as seronegative spondarthritides, autoimmune, and more recently autoinflammatory diseases. Current evidence suggests that BS does not easily fit into any one of these lumps, while on occasion, it might be impossible to tell BS from Crohn's disease, especially when the main clinical presentation is intestinal ulceration. There are distinct regional differences in disease expression of BS with fewer cases of intestinal disease in the Mediterranean basin and less severe eye disease and less frequent skin pathergy among patients

reported from northern Europe or America. The clustering of symptoms, especially with the recently described increased frequency of the acne/arthritis cluster in familial cases, suggests that more than one pathological pathway is involved in what we call BS today. Supportive evidence for this contention also comes from the observations that (a) the genetic component is very complex with perhaps different genetic modes of inheritance in the adult and in the pediatric patients; and (b) there are differing organ responses to one same drug. For example, the anti-TNF agents successfully control the oral ulcers while they have no effect on the pathergy reaction.

Infliximab therapy for familial Mediterranean fever-related amyloidosis: case series with long term follow-up.

Özçakar ZB(1), Yüksel S, Ekim M, Yalçinkaya F.

Author information:

(1)Department of Pediatric Nephrology, Ankara University School of Medicine, Ankara, Turkey.

Familial Mediterranean fever (FMF) is an autosomal recessive disease characterized by recurrent self-limited attacks of fever and polyserositis. Reactive amyloid A amyloidosis is the most devastating complication of FMF, and amyloidosis continues to occur in the colchicine era in untreated and noncompliant patients. Unfortunately, there is no proven effective treatment for established amyloidosis. In this report, we present four FMF-related amyloidosis patients that were treated with long term infliximab therapy with the longest duration of follow-up, together with the literature review. Infliximab was very effective in controlling gastrointestinal system findings and protracted arthritis, and it also had a favorable impact on the clinical findings of nephrotic syndrome in these patients. In conclusion, by controlling debilitating complaints of amyloidosis with infliximab, quality of life increases in these patients, and they get rid of recurrent hospitalizations and return to school or

work.

Diffuse amyloid deposition in thyroid gland: a cause for concern in familial Mediterranean fever.

Turhan İyidir Ö(1), Altay M, Konca Degertekin C, Altınova A, Karakoç A, Ayvaz G, Arslan M, Öneç K, Arınsoy T, Cesur N, Gönül İl.

Author information:

(1)Department of Endocrinology and Metabolism, Gazi University Faculty of Medicine, Ankara, Turkey.

Thyroid gland is among the many organs that could be infiltrated in systemic amyloidosis. However, diffuse infiltration of the thyroid gland secondary to systemic amyloidosis associated with Familial Mediterranean fever (FMF) is rare. Here, we present a 49-year-old woman diagnosed with FMF and systemic amyloidosis, who had a large goiter and multiple nodules that developed slowly through the years and was complicated by tracheal compression symptoms and a mild thyroid dysfunction. Multiple fine needle aspiration biopsies of the nodules and the thyroid parenchyma revealed amyloid deposits. We would like to point out that amyloidosis may have a significant impact on the thyroid gland and fine needle aspiration biopsy is a valuable tool for diagnosis.

Guidelines for the genetic diagnosis of hereditary recurrent fevers.

Shinar Y(1), Obici L, Aksentijevich I, Bennetts B, Austrup F, Ceccherini I, Costa JM, De Leener A, Gattorno M, Kania U, Kone-Paut I, Lezer S, Livneh A, Moix I, Nishikomori R, Ozen S, Phylactou L, Risom L, Rowczenio D, Sarkisian T, van Gijn ME, Witsch-Baumgartner M, Morris M, Hoffman HM, Touitou I; European Molecular Genetics Quality Network.

Author information:

(1)Unité médicale des maladies autoinflammatoires, CHRU Montpellier, INSERM U844, Université UM1, Montpellier, France.

Hereditary recurrent fevers (HRFs) are a group of monogenic autoinflammatory diseases characterised by recurrent bouts of fever and serosal inflammation that are caused by pathogenic variants in genes important for the regulation of innate immunity. Discovery of the molecular defects responsible for these diseases has initiated genetic diagnostics in many countries around the world, including the Middle East, Europe, USA, Japan and Australia. However, diverse testing methods and reporting practices are employed and there is a clear need for consensus guidelines for HRF genetic testing. Draft guidelines were prepared based on current practice deduced from previous HRF external quality assurance schemes and data from the literature. The draft document was disseminated through the European Molecular Genetics Quality Network for broader consultation and amendment. A workshop was held in Bruges (Belgium) on 18 and 19 September 2011 to ratify the draft and obtain a final consensus document. An agreed set of best practice guidelines was proposed for genetic diagnostic testing of HRFs, for reporting the genetic results and for defining their clinical significance.

C-reactive protein and procalcitonin during febrile attacks in PFAPA syndrome.

Yazgan H(1), Keleş E, Yazgan Z, Gebeşçe A, Demirdöven M.

Author information:

(1)Dept of Pediatrics, Sema Hospital, Turkey. hyazgan@semahastanesi.com.tr

**OBJECTIVES:** To assess the levels of procalcitonin (PCT) and C-reactive protein (CRP) in children diagnosed with PFAPA (periodic fever, aphthous stomatitis, pharyngitis, and cervical adenitis) during their febrile attacks.

**METHODS:** 23 patients with diagnosis of PFAPA included into the study prospectively during a three years period. In these patients, CRP and PCT values

were recorded during 78 febrile episodes. Furthermore, 20 patients with diagnosis of pneumonia were chosen as a control group and their CRP and PCT values were measured. Normal reference values for CRP and PCT were 0-10 mg/L and 0-0.5 ng/mL, respectively.

RESULTS: Mean CRP and PCT values of patients with PFAPA were  $94.8 \pm 71.6$  mg/L and  $0.29 \pm 0.14$  ng/mL, respectively. In control group, mean CRP value was  $153.2 \pm 26$  mg/L and PCT was  $1.59 \pm 0.53$  ng/mL. CRP and PCT were high in control group. CRP was detected high and PCT was normal in PFAPA. Compared to control group, in PFAPA group, CRP values were not significantly ( $p > 0.05$ ) and PCT values were significantly lower ( $p < 0.001$ ).

CONCLUSION: During febrile episodes in the patients with diagnosis of PFAPA, CRP values were substantially elevated, whereas PCT values were within normal levels. Concomitant assessment of CRP and PCT in addition to clinical diagnostic criteria may be of help in making diagnosis and distinguishing febrile attacks from infections. However, studies in larger groups are required.

Interleukin-1, inflammasomes, autoinflammation and the skin.

Contassot E(1), Beer HD, French LE.

Author information:

(1)Department of Dermatology, Zurich University Hospital, Zürich, Switzerland.

Interleukin 1, one of the first cytokines discovered in the 1980s, and a potent mediator of fever, pain and inflammation, is at present experiencing a revival in biology and medicine. Whereas the mechanism of activation and secretion of interleukin 1 $\beta$ , which critically regulates the function of this molecule, has remained mysterious for some 30 years following its discovery, the identification of a new cytoplasmic complex of proteins regulating IL-1 $\beta$  activation and secretion has carried our understanding of the role of IL1 in biology and disease one big step further. The inflammasomes, recently identified innate immune complexes that sense intracellular danger- (e.g. uric acid, ATP, cytoplasmic DNA) or pathogen-associated molecular patterns (e.g. muramyl dipeptide, flagellin, anthrax lethal toxin), are now known to be responsible for triggering inflammation in response to several molecular patterns, including, for example, uric acid, a danger-associated molecular pattern and trigger of gout. Dysregulation of inflammasome function is however also the cause of a family of genetic autoinflammatory diseases known as cryopyrin-associated periodic syndromes (CAPS) characterised by recurrent episodes of fever, urticarial-like skin lesions, systemic inflammation and arthritis. In mouse models recapitulating mutations observed in CAPS, neutrophilic inflammation of the skin is a cardinal feature, in a manner similar to several autoinflammatory diseases with skin involvement such as PAPA (pyoderma gangrenosum, acne and pyogenic arthritis) and Schnitzler's syndrome, in which IL-1 $\beta$  very probably plays a pathogenic role. In this article the role of the inflammasome in IL-1 biology, autoinflammation and disease is reviewed, together with new avenues for the therapy of these diseases.

AA amyloidosis: basic knowledge, unmet needs and future treatments.

Obici L(1), Merlini G.

Author information:

(1) Amyloidosis Research and Treatment Centre, Biotechnology Research Laboratories, Fondazione IRCCS Policlinico San Matteo, Pavia, Italy.  
l.obici@smatteo.pv.it

Systemic AA amyloidosis is a long-term complication of several chronic inflammatory disorders, including rheumatoid arthritis, ankylosing spondylitis, autoinflammatory syndromes, Crohn's disease, malignancies and conditions predisposing to recurrent infections. Organ damage results from the extracellular deposition of proteolytic fragments of the acute-phase reactant serum amyloid A (SAA) as amyloid fibrils. A sustained high concentration of SAA is the prerequisite for developing AA amyloidosis. However, only a minority of patients with long-standing inflammation actually presents with this complication, pointing to the existence of disease-modifying factors, the best characterised of which being SAA1 genotype. The kidneys, liver and spleen are the main target organs of AA amyloid deposits. In more than 90% of patients proteinuria, nephrotic syndrome and/or renal dysfunction dominate the clinical picture at onset. If not effectively treated, this disease invariably leads to end stage kidney disease and renal replacement therapy, that are still associated with a poor outcome. Although the incidence of AA in rheumatoid arthritis and other chronic arthritides has continuously decreased over the past ten years, thanks to the increasing availability of more effective anti-inflammatory and immunosuppressive therapies, AA remains a life-threatening disease with several areas of uncertainty and unmet needs, deserving continuous efforts at prevention and effective treatment. The deeper understanding of the molecular mechanisms of amyloid formation and regression is now driving the development of novel treatments targeting different steps in the amyloidogenic cascade. These therapies will hopefully improve the quality of life and outcome of these patients in a near future.

Spontaneous inflammatory pain model from a mouse line with N-ethyl-N-nitrosourea mutagenesis.

Chen TC(1), Wu JJ, Chang WP, Hsu PN, Hsieh ST, Shyu BC.

Author information:

(1)Institute of Biomedical Sciences, Academia Sinica, Taipei, 11529, Taiwan, Republic of China.

**BACKGROUND:** N-ethyl-N-nitrosourea mutagenesis was used to induce a point mutation in C57BL/6 J mice. Pain-related phenotype screening was performed in 915 G3 mice. We report the detection of a heritable recessive mutant in meiotic recombinant N1F1 mice that caused an abnormal pain sensitivity phenotype with spontaneous skin inflammation in the paws and ears.

**METHODS:** We investigated abnormal sensory processing, neuronal peptides, and behavioral responses after the induction of autoinflammatory disease.

Single-nucleotide polymorphism (SNP) markers and polymerase chain reaction product sequencing were used to identify the mutation site.

**RESULTS:** All affected mice developed paw inflammation at 4-8 weeks. Histological examinations revealed hyperplasia of the epidermis in the inflamed paws and increased macrophage expression in the spleen and paw tissues. Mechanical and thermal nociceptive response thresholds were reduced in the affected mice.

Locomotor activity was decreased in affected mice with inflamed hindpaws, and this reduction was attributable to the avoidance of contact of the affected paw with the floor. Motor strength and daily activity in the home cage in the affected mice did not show any significant changes. Although Fos immunoreactivity was normal in the dorsal horn of affected mice, calcitonin gene-related peptide immunoreactivity significantly increased in the deep layer of the dorsal horn.

The number of microglia increased in the spinal cord, hippocampus, and cerebral cortex in affected mice, and the proliferation of microglia was maintained for a couple of months. Two hundred eighty-five SNP markers were used to reveal the affected gene locus, which was found on the distal part of chromosome 18. A point mutation was detected at A to G in exon 8 of the *pstpip2* gene, resulting in a conserved tyrosine residue at amino acid 180 replaced by cysteine (Y180 C).

**CONCLUSIONS:** The data provide definitive evidence that a mutation in *pstpip2* causes autoinflammatory disease in an N-ethyl-N-nitrosourea mutagenesis mouse model. Thus, our *pstpip2* mutant mice provide a new model for investigating the

potential mechanisms of inflammatory pain.

The role of SH3BP2 in the pathophysiology of cherubism.

Reichenberger EJ(1), Levine MA, Olsen BR, Papadaki ME, Lietman SA.

Author information:

(1)Department of Reconstructive Sciences, Center for Regenerative Medicine and Skeletal Development, University of Connecticut Health Center, Farmington, CT, USA. reichenberger@uchc.edu

Cherubism is a rare bone dysplasia that is characterized by symmetrical bone resorption limited to the jaws. Bone lesions are filled with soft fibrous giant cell-rich tissue that can expand and cause severe facial deformity. The disorder typically begins in children at ages of 2-5 years and the bone resorption and facial swelling continues until puberty; in most cases the lesions regress spontaneously thereafter. Most patients with cherubism have germline mutations in the gene encoding SH3BP2, an adapter protein involved in adaptive and innate immune response signaling. A mouse model carrying a Pro416Arg mutation in SH3BP2 develops osteopenia and expansile lytic lesions in bone and some soft tissue organs. In this review we discuss the genetics of cherubism, the biological functions of SH3BP2 and the analysis of the mouse model. The data suggest that the underlying cause for cherubism is a systemic autoinflammatory response to physiologic challenges despite the localized appearance of bone resorption and fibrous expansion to the jaws in humans.

Sustained remission of multicentric Castleman disease in children treated with tocilizumab, an anti-interleukin-6 receptor antibody.

Galeotti C(1), Boucheron A, Guillaume S, Koné-Paut I.

Author information:

(1)Department of Pediatrics, Pediatric Rheumatology, National Referral Centre of Auto-Inflammatory Diseases, CEREMAI, CHU de Bicêtre, le Kremlin Bicêtre, France. caroline.galeotti@gmail.com

Multicentric Castleman Disease (MCD) is an idiopathic lymphoproliferative disorder, reported exceptionally in children and generally believed to be an autoinflammatory disease resulting in an increase of interleukin-6 secretion. Previous studies in adult patients suggested a beneficial role of the anti-interleukin-6 receptor antibody tocilizumab on the clinical and biologic disease manifestations of MCD. Here, we describe the efficacy and safety of tocilizumab in two children with MCD, which was diagnosed on the basis of clinical and histologic findings. In both cases, tocilizumab was administered intravenously at a dose of 8 mg/kg every 2 weeks. The tocilizumab treatment alleviated fever and restored growth rate in both patients. The patients' hypergammaglobulinemia, high C-reactive protein, and high erythrocyte sedimentation rates normalized simultaneously. Nevertheless, splenomegaly persisted in the first patient, and a secondary hepatic node appeared in the second patient. The side effects, essentially sustained thrombocytopenia, were mild in both cases. For the first patient, following an initial 10-month period, the interval between infusions was increased. This patient benefited from sustained remission for a period of 3 years. Tocilizumab was effective and safe in these two children with MCD.

Infections and vaccines in the etiology of antiphospholipid syndrome.

Cruz-Tapias P(1), Blank M, Anaya JM, Shoenfeld Y.

Author information:

(1)Zabludowitz Center for Autoimmune Diseases, Sheba Medical Center affiliated to Sackler Faculty of Medicine, Tel-Aviv University, Israel.

PURPOSE OF REVIEW: To present scientific evidence supporting the infectious origin for the antiphospholipid syndrome (APS) by molecular mimicry between pathogens, infection and vaccination with  $\beta$ 2-glycoprotein I ( $\beta$ 2-GPI) molecule.

RECENT FINDINGS: APS is characterized by the presence of pathogenic autoantibodies against  $\beta$ 2-GPI. The infection etiology of APS was well established. Likewise, a link between vaccination such as tetanus toxoid may trigger antibodies targeting tetanus toxoid and  $\beta$ 2-GPI, due to molecular mimicry between the two molecules. During the years, the pathogenic potential of anti-tetanus toxoid antibodies cross reactive with  $\beta$ 2-GPI were found to be pathogenic in animal models, inducing experimental APS.

SUMMARY: Accumulated evidence supports that the presence of anti- $\beta$ 2-GPI antibodies is associated with a history of infections and the main mechanism to explain this correlation is molecular mimicry. The relationship between tetanus toxoid vaccination and APS reveals a novel view on the autoimmune/autoinflammatory syndrome induced by adjuvants (ASIA).

Frequency of alterations in the MEFV gene and clinical signs in familial Mediterranean fever in Central Anatolia, Turkey.

Ceylan GG(1), Ceylan C, Ozturk E.

Author information:

(1)Department of Medical Genetics, Ankara Ataturk Education and Training Hospital, Ankara, Turkey. nil\_vey@yahoo.com

Familial Mediterranean fever is a recessive autoinflammatory disease that is

frequent in Armenians, Jews, Arabs, and Turks. The MEFV gene is responsible for this disease. We looked for MEFV gene variations (polymorphism and mutations) in a population that resides in Central Anatolia, Turkey. DNA was extracted from peripheral blood leukocytes of 802 familial Mediterranean fever patients. The DNA sequence data were examined for approximately 150 different mutations and polymorphisms, including single nucleotide polymorphisms in different exons of the MEFV gene. The male:female ratio of these patients was 1.44:1. Mutations were detected in 48.1% of the patients; 7.5% were homozygous, 11.1% were compound heterozygous and 31.5% had only one identifiable mutant allele. No mutations were detected in 51.9% of the patients. The main clinical characteristics of the patients were: abdominal pain in 20.6%, arthritis in 22.9% and amyloidosis in 4.6%. Sixty-six percent of patients had a family history of familial Mediterranean fever; 19.4% of the patients were found to have parental consanguinity. We conclude that the genetics of familial Mediterranean fever is more complex than has previously been reported; heterozygous patients presenting a severe phenotype should be further analyzed for less common secondary MEFV mutations, using gene sequencing.

Is Still's Disease an Autoinflammatory Syndrome?

Rossi-Semerano L(1), Koné-Paut I.

Author information:

(1)Department of Paediatrics and Paediatric Rheumatology, Bicêtre Hospital, National Reference Centre for Autoinflammatory Diseases, 78 rue du Général Leclerc, Le Kremlin Bicêtre, 94270 Paris, France.

Systemic juvenile idiopathic arthritis (sJIA), formerly called Still's disease, is officially classified as a subset of juvenile idiopathic arthritis (JIA). Beside arthritis, it is characterized by prominent systemic features and a marked inflammatory response. Even if it is still included in the group of juvenile arthritides, sJIA is set apart from all the other forms of JIA. This disorder has markedly distinct clinical and laboratory features suggesting a different

pathogenesis. sJIA does not show any association with HLA genes or with autoantibodies and is characterised by an uncontrolled activation of phagocytes with hypersecretion of IL-1 and IL-6. Based on clinical and laboratory features, as well as on new acquisitions on the pathogenesis, it seems evident that sJIA is an autoinflammatory disease related to abnormality in innate immune system. The new insights on the pathogenesis of sJIA have therefore dramatically changed the approach to treatment, with the development of targeted treatments (anti-IL-1 and anti-IL-6 agents) more effective and safer than earlier medications.

Anti-Interleukin-1 Agents in Adult Onset Still's Disease.

Giampietro C(1), Fautrel B.

Author information:

(1)Department of Internal Medicine, University of L'Aquila, L'Aquila, Italy.

Interleukin 1 $\beta$  (IL-1 $\beta$ ) is emerging as a master mediator of adult onset Still's disease (AOSD) pathogenesis. This pleiotropic cytokine, whose expression is under the control of the inflammasome pathway, has a wide type of effects. As a key mediator of innate immunity is a potent pyrogen and facilitates neutrophilic proliferation and diapedesis into the inflamed tissues, which are key AOSD manifestations. The study of proinflammatory cytokines profiles in sera and pathological tissues of AOSD patients has shown elevated levels of IL-1 $\beta$ , these levels being highly correlated with disease activity and severity. These experimental evidences and the analogy with other autoinflammatory diseases that share with AOSD clinical and biological characteristics have suggested the blockade of IL-1 $\beta$  as a possible new therapeutic option for the AOSD, especially in conventional therapy resistant cases. Anakinra, the first anti-IL-1 agent put on the market, has demonstrated capable to induce a rapid response sustained over time, especially in systemic forms, where anti-TNF $\alpha$  failed to control symptoms. While a growing number of evidences supports the utilisation of anakinra in AOSD, a new generation of anti-IL1 $\beta$  antagonists is developing. Canakinumab and

rilonacept, thanks to their higher affinity and longer half-life, could improve the management of this invalidating disease.

Case study: chronic recurrent multifocal osteomyelitis in the femoral diaphysis of a young female.

Quon JS(1), Dzus AK, Leswick DA.

Author information:

(1)Department of Medical Imaging, Ottawa Hospital, University of Ottawa, Civic Campus, Ottawa, ON, Canada K1N 6N5.

Chronic recurrent multifocal osteomyelitis (CRMO) is relatively uncommon. Even though the name suggests it is the result of infection, this is not likely the case. Instead it is more likely the result of genetic, autoimmune, or autoinflammatory causes. Although CRMO has a benign course and responds well to anti-inflammatory medications, it can have a very aggressive clinical and imaging presentation overlapping with infectious osteomyelitis and malignancy. Therefore, radiologists and clinicians need to be aware of its clinical and imaging presentation to avoid morbidity associated with more aggressive treatment. We present the case of a ten-year-old female with CRMO as a solitary expansile-mixed lytic and sclerotic lesion in the distal femoral diaphysis. The diaphyseal location and mixed lytic and sclerotic appearance are less common and have an aggressive imaging appearance. We also review the pathophysiology, imaging findings, and therapeutic approach to this uncommon but clinically important condition.

Tumor necrosis factor- $\alpha$  gene polymorphisms in FMF and their association with amyloidosis.

Bonyadi M(1), Bahrami S, Jahanafrooz Z, Dastgiri S.

Author information:

(1)Center of Excellence for Biodiversity, University of Tabriz, Tabriz, Iran.

jabbarpour@tabrizu.ac.ir

Familial Mediterranean fever (FMF) is an autosomal recessive disorder characterized by periodic provocative attacks of fever with peritonitis, pleuritis, arthritis, or erisiplemia. Tumor necrosis factor- $\alpha$  (TNF- $\alpha$ ) plays an important role in the regulation of the immune response as a part of the cytokine network, including activation of macrophages and apoptosis. We investigated the possible association of TNF- $\alpha$  promoter -1031T/C and -308G/A polymorphisms in 86 FMF patients carrying M694 V homozygous mutation and 100 matched healthy controls both from Iranian Azeri Turks. Our data showed that patients with TNF- $\alpha$  -308 GG are more susceptible to the development of amyloidosis and arthritis (P value <.05). These data also showed that the frequency of TNF- $\alpha$  -308 A allele is considerably low among patients with amyloidosis, and it may have protective role among them (odds ratio [OR] = 0.083,  $\chi^2(2)$  = 5.46, P value = .003). Further evaluation of this polymorphism may be important and need further studies.

Efficacy and safety of the interleukin-1 antagonist rilonacept in Schnitzler syndrome: an open-label study.

Krause K(1), Weller K, Stefaniak R, Wittkowski H, Altrichter S, Siebenhaar F, Zuberbier T, Maurer M.

Author information:

(1)Department of Dermatology and Allergy, Allergie-Centrum-Charité, Charité - Universitätsmedizin Berlin, Berlin, Germany.

**BACKGROUND:** Schnitzler syndrome (SchS) is a rare disease with suspected autoinflammatory background that shares several clinical symptoms, including urticarial rash, fever episodes, arthralgia, and bone and muscle pain with cryopyrin-associated periodic syndromes (CAPS). Cryopyrin-associated periodic syndromes respond to treatment with interleukin-1 antagonists, and single case reports of Schnitzler syndrome have shown improvement following treatment with the interleukin-1 blocker anakinra. This study evaluated the effects of the interleukin-1 antagonist rilonacept on the clinical signs and symptoms of SchS.

**METHODS:** Eight patients with SchS were included in this prospective, single-center, open-label study. After a 3-week baseline, patients received a subcutaneous loading dose of rilonacept 320 mg followed by weekly subcutaneous doses of 160 mg for up to 1 year. Efficacy was determined by patient-based daily health assessment forms, physician's global assessment (PGA), and measurement of inflammatory markers including C-reactive protein (CRP), serum amyloid A (SAA), and S100 calcium-binding protein A12 (S100A12).

**RESULTS:** Treatment with rilonacept resulted in a rapid clinical response as demonstrated by significant reductions in daily health assessment scores and PGA scores compared with baseline levels ( $P < 0.05$ ). These effects, which were accompanied by reductions in CRP and SAA, continued over the treatment duration. Rilonacept treatment was well tolerated. There were no treatment-related severe adverse events and no clinically significant changes in laboratory safety parameters.

**CONCLUSION:** Rilonacept was effective and well tolerated in patients with SchS and may represent a promising potential therapeutic option.

Clinical impact of MEFV mutations in children with periodic fever in a prevalent

western European Caucasian population.

Federici S(1), Calcagno G, Finetti M, Gallizzi R, Meini A, Vitale A, Caroli F, Cattalini M, Caorsi R, Zulian F, Tommasini A, Insalaco A, Sormani MP, Baldi M, Ceccherini I, Martini A, Gattorno M.

Author information:

(1)UO Pediatria II Reumatologia, Istituto G Gaslini, Genova, Italy.

**OBJECTIVE:** To evaluate the actual impact of MEFV mutations on clinical manifestations associated with fever attacks in Caucasian children with periodic fever.

**METHODS:** 113 children carrying MEFV mutations (44 with mutations in two alleles, 69 heterozygous) and 205 children negative for mutations in genes associated with periodic fevers were analysed. The following groups of patients were considered: patients carrying two high penetrance mutations (M694V, M694I, M680I); one high, one low penetrance mutation; two low penetrance mutations; one high penetrance mutation; one low penetrance mutation; genetically negative patients.

**RESULTS:** Patients with two MEFV mutations displayed a shorter duration of fever attacks and higher prevalence of a positive family history than patients carrying one MEFV mutation and genetically negative patients. Severe abdominal pain, chest pain and pleurisy were also more frequent in patients with two MEFV mutations compared with children with one MEFV mutation and genetically negative patients. Conversely, a higher frequency of exudative and erythematous pharyngitis, enlargement of cervical lymph nodes, aphthous stomatitis and non-specific skin rash was observed in genetically negative patients and, to a lesser extent, in patients with one MEFV mutation. The frequency of 'familial Mediterranean fever (FMF)-like symptoms' decreases from patients carrying two high penetrance mutations towards patients with a single low penetrance mutation with an opposite trend for 'periodic fever, aphthous stomatitis, pharyngitis, adenitis-like symptoms'.

**CONCLUSIONS:** This clinical observation supports recent findings contrasting the notion of FMF being a pure autosomal recessive disorder associated with recurrence of mutations leading to loss of protein function. A dosage effect could be invoked, giving rise to symptom onset even in the presence of one wild-type allele.

Myocardial infarction in patients with familial Mediterranean fever and cardiac lesions.

Ambartsymian SV.

The investigation of relatively rare affections in familial Mediterranean fever--cardiac and lung lesions and pathogenesis of myocardium infarction in background of cardiac lesions is actual. Clinical-morphological analysis of 68 autopsy cases was done. The investigation data observes that cardiac amyloidosis as a dominated morphological manifestation in FMF can leads to heart failure and death. Macroscopically cardiac lesions as a cardiomegaly was observe. The morphological manifestation of cardiac affections in FMF was amyloidosis of the vessels and myocardium stroma. Amyloidosis of the heart valves leads to deformity and clinical-morphological picture of heart defect perform. The large amyloid areas of myocardium leading to the heart insufficiency according to clinical and instrumental data as pseudoinfarctions were manifested. Myocardium infarction develops in background of cardiac lesions in FMF--amyloid angiopathias, which were more expressed in arteriolar walls, with narrowing or obstructing of lumina, and accompanied with them--coronary vasculitis. The main predisposing pathogenic factors for myocardial infarction can be atherosclerotic changes of the vessels also, which were complicated by amyloid depositions of the vascular walls. Cardiac failure can develop before renal amyloidosis and uremia.

Morphological aspects of the familial Mediterranean fever.

Ambartsymian SV.

The study of clinical and morphological features of multiple organ lesions in familial Mediterranean fever (FMF) is important for identification of main

morphologic lesions in thanatogenesis in parallel with the clinical manifestations. Clinical-morphological analysis of 200 patients with FMF and 60 dead from complications of FMF without renal transplantation were done. It was established that renal affection was observed in all patients, who died from complications of FMF, but the severity and nature of the observed changes were different. The kidney affections in investigated material in 3 groups were classified: amyloidosis, nonamyloid affections and glomerulitis accompanied with amyloidosis. Cardiopathic amyloidosis we established in thanatogenesis of FMF manifested with heart failure. The secondary polyorganial amyloidosis in FMF resulting in polyorganial failure revealed. The lung amyloidosis was accompanied with cardiac. Kidney affections were manifested with nonamyloid nephropathias manifested with intracapillary mesangioproliferative or extracapillary productive glomerulonephritis, besides amyloidosis. Amyloidosis of the heart, lungs, adrenals can significantly prevail to kidney damage and be expressed at the forefront of thanatogenesis.

Erratum in

J Clin Immunol. 2012 Oct;32(5):933-5.

**OBJECTIVE:** To evaluate the prevalence of genetic defects in clinically suspected autoinflammatory syndromes (AIS) in a Brazilian multicenter study.

**METHODS:** The study included 102 patients with a clinical diagnosis of Cryopyrin

Associated Periodic Syndromes (CAPS), TNF Receptor Associated Periodic Syndrome (TRAPS), Familial Mediterranean Fever (FMF), Mevalonate Kinase Deficiency (MKD) and Pediatric Granulomatous Arthritis (PGA). One of the five AIS-related genes (NLRP3, TNFRSF1A, MEFV, MVK and NOD2) was evaluated in each patient by direct DNA sequencing, based on the most probable clinical suspect.

RESULTS: Clinical diagnoses of the 102 patients were: CAPS (n = 28), TRAPS (n = 31), FMF (n = 17), MKD (n = 17) and PGA (n = 9). Of them, 27/102 (26 %) had a confirmed genetic diagnosis: 6/28 (21 %) CAPS patients, 7/31 (23 %) TRAPS, 3/17 (18 %) FMF, 3/17 (18 %) MKD and 8/9 (89 %) PGA.

CONCLUSION: We have found that approximately one third of the Brazilian patients with a clinical suspicion of AIS have a confirmed genetic diagnosis.

Subfertility in women with familial Mediterranean fever.

Zayed A(1), Nabil H, State O, Badawy A.

Author information:

(1)Department of Obstetrics & Gynecology, Mansoura University, Mansoura, Egypt.

AIM: The aim of this study was to examine the causes and different modalities used for management of subfertile patients with familial Mediterranean fever (FMF).

MATERIAL AND METHODS: The study comprised of 74 infertile women with FMF. All patients were diagnosed as having FMF. All patients underwent a full infertility work-up. They were scheduled to expectant treatment, ovulation induction and timed intercourse, intrauterine insemination or intracytoplasmic sperm injection.

RESULTS: Anovulation was reported in 18 patients (24.32%). Anovulation was due to polycystic ovary syndrome in 12 (16.22%) cases and due to other causes in six patients (8.11%). Excessive clear peritoneal fluid was present in 56 (57.67%) and male-factor infertility was present in 14 couples (18.91%). Ovulation induction and timed intercourse was adopted for a maximum of six cycles and intrauterine insemination for three cycles. In vitro fertilization/intracytoplasmic sperm

injection was needed in six cases using standard long agonist protocol.

Twenty-six women became pregnant.

**CONCLUSION:** The causes of infertility in patients with FMF are not different from those expected in the general population. Treatment of the problem should be causal, adopting the conventional lines of treatment up to in vitro fertilization/intracytoplasmic sperm injection when appropriate. Colchicine is the treatment of choice and it is important to use it in its proper doses to control the disease.

Renal transplantation in patients with familial Mediterranean fever.

Erdem E(1), Karatas A, Kaya C, Dilek M, Yakupoglu YK, Arık N, Akpolat T.

Author information:

(1)Department of Nephrology, Faculty of Medicine, Ondokuz Mayıs University, Samsun 55139, Turkey. emredlk@yahoo.com

Amyloidosis is the most common and devastating complication of familial Mediterranean fever (FMF). Renal transplantation is the choice of treatment of in most end-stage renal disease (ESRD). We report our experience on the outcomes in eight patients who underwent renal transplantation for ESRD due to FMF secondary to amyloidosis, and we provide a discussion on the current evidence on this topic of study. The clinical charts of eight renal transplant patients (seven male, one female) who underwent ESRD due to FMF-related amyloidosis were investigated. Five patients underwent living-donor renal transplantation and three patients underwent deceased-donor renal transplant. The mean follow-up period was 35 months (range 3-72). All patients were on triple immunosuppressive treatment and received colchicine. All allografts are currently functioning well with a mean serum creatinine level of 1.4 (range 0.7-2.6) mg/dL. Posttransplantation

complications included acute rejection (n = 4), chronic rejection (n = 1), severe gastroenteritis (n = 2), and erythrocytosis (n = 5). None of the patients had proteinuria. During follow-up, we did not observe clinically severe FMF attack, septicemia, rhabdomyolysis, symptoms related to vasculitis, and clinical neuropathy. The clinical outcome of the patients in this cohort was similar to that of other renal transplant patients with ESRD due to other causes. This study shows favorable prognosis of eight ESRD patients due to amyloidosis caused by FMF after renal transplantation. Renal transplantation is a safe procedure for ESRD patients having amyloidosis due to FMF. Regular use of colchicine after transplantation should be mentioned.

Autoinflammatory syndromes.

Hashkes PJ(1), Toker O.

Author information:

(1)Pediatric Rheumatology Unit, Department of Pediatrics, Shaare Zedek Medical Center, PO Box 3235, Jerusalem 91031, Israel. hashkesp@szmc.org.il

There has been an expansion of the autoinflammatory syndromes due to the discovery of new diseases related to mutations in genes regulating the innate immune system and the knowledge gained from these diseases as applied to more common nongenetic inflammatory conditions. Autoinflammatory syndromes are characterized by unprovoked (or triggered by minor events) recurrent episodes of systemic inflammation involving various body systems, which are often accompanied by fever. Inflammation is mediated by polymorphonuclear and macrophage cells through cytokines, particularly interleukin-1. This article reviews the clinical approach to patients with suspected autoinflammatory syndromes, several of the main and new (mostly genetics) syndromes, advances in treatment, and prognosis.

Principles of inflammation for the pediatrician.

Omenetti A(1), Chiesa S, Gattorno M.

Author information:

(1)UO Pediatria II, G. Gaslini Institute, Largo G. Gaslini 5, 16147 Genova, Italy.

The immune system consists of 2 branches: innate and adaptive. The former represents the first line of host defense during infection and plays a key role in the early recognition and protection against invading pathogens. The latter orchestrates elimination of pathogens in the late phase of infection and leads to the generation of immunologic memory. Innate and adaptive immunity should not be considered separate compartments. Innate and adaptive immune responses represent an integrated system of host defense. The authors review the mechanisms driving the induction and perpetuation of the inflammatory responses observed during pathogen-associated, autoimmune, and autoinflammatory diseases.

z.adam@fnbrno.cz

We describe a case of an Erdheim-Chester disease patient. First line chemotherapy treatment with 2-chlorodeoxyadenosine did not reduce fluorodeoxyglucose accumulation in pathological lesions. The patient had continuously increased CRP values of 17-20 mg/l. The disease continued to cause subfebrile temperatures and significant fatigue that made the patient to spend most of the daytime in bed. To manage the permanently increased inflammation markers, we decided to start treatment with anakinra, successfully used in some other autoinflammatory diseases (e.g. Schnitzler syndrome). We have now been able to evaluate the first 6 months of treatment. Daily subcutaneous administration of anakinra (Kineret<sup>TM</sup> 100 mg daily) led to normalization of CRP values, cessation of subfebrile temperatures and, importantly, significant reduction of fatigue. Time periods the patient was able to spend out of the bed increased significantly. Consequent to the reduced fatigue, the patient was able to perform basic household tasks he was unable to undertake without treatment. After 3 months of treatment, fatigue of the same intensity returned following a short interruption of therapy. The CRP values went up again to 12 mg/l. CRP value returned back to norm and fatigue ceased after re-initiation of daily Kineret injections. Objective treatment response was assessed by measuring the degree of fluorodeoxyglucose accumulation in pathological bone lesions. PET-CT was performed before and 3 and 6 months after anakinra initiation. Intensity of accumulation did not change significantly after the first 3 months of therapy but decreased after 6 month therapy. Follow up CT of abdominal cavity was performed at the end of the 6th month of treatment. Presented CT images from before and 6 months after the treatment evidence an obvious reduction in fibroid changes in the retroperitoneum. Daily administration of anakinra to a patient with active Erdheim-Chester disease significantly reduced intensity of fatigue and improved quality of life, led to a reduction in inflammatory markers and regression in retroperitoneal fibrotization.

laurence.feldmeyer@chuv.ch

Hereditary periodic fever syndromes, also called autoinflammatory syndromes, are characterized by relapsing fever and additional manifestations such as skin rashes, mucosal manifestations, or arthralgias. Some of these disorders present without fever but with the associated systemic manifestations. The responsible mutated genes have been identified for most of these disorders, which lead to the induction of the uncontrolled and excessive production of interleukin-1beta (IL-1beta). The inhibition of IL-1beta through IL-1 receptor antagonist or monoclonal antibody against IL-1beta is used with success in most of these diseases. In case of TNF-receptor associated periodic syndrome (TRAPS) and paediatric granulomatous arthritis (PGA), TNF-antagonists may also be used; in familial Mediterranean fever (FMF) colchicine remains the first choice.

TRIM28 prevents autoinflammatory T cell development in vivo.

Chikuma S(1), Suita N, Okazaki IM, Shibayama S, Honjo T.

Author information:

(1)Department of Immunology and Genomic Medicine, Graduate School of Medicine, Kyoto University, Kyoto, Japan.

TRIM28 is a component of heterochromatin complexes whose function in the immune system is unknown. By studying mice with conditional T cell-specific deletion of TRIM28 (CKO mice), we found that TRIM28 was phosphorylated after stimulation via

the T cell antigen receptor (TCR) and was involved in the global regulation of CD4(+) T cells. The CKO mice had a spontaneous autoimmune phenotype that was due in part to early lymphopenia associated with a defect in the production of interleukin 2 (IL-2) as well as incomplete cell-cycle progression of their T cells. In addition, CKO T cells showed derepression of the cytokine TGF- $\beta$ 3, which resulted in an altered cytokine balance; this caused the accumulation of autoreactive cells of the T(H)17 subset of helper T cells and of Foxp3(+) T cells. Notably, CKO Foxp3(+) T cells were unable to prevent the autoimmune phenotype in vivo. Our results show critical roles for TRIM28 in both T cell activation and T cell tolerance.

Familial Mediterranean fever: risk factors, causes of death, and prognosis in the colchicine era.

Akar S(1), Yuksel F, Tunca M, Soysal O, Solmaz D, Gerdan V, Celik A, Sen G, Onen F, Akkoc N.

Author information:

(1)Division of Rheumatology, Department of Internal Medicine, Dokuz Eylul University School of Medicine, Izmir, Turkey. [servet.akar@deu.edu.tr](mailto:servet.akar@deu.edu.tr)

We assessed the risk factors and causes of death in patients with familial Mediterranean fever (FMF) in an era when colchicine is the standard therapy for all patients. This study included all FMF patients who had presented to any of the internal medicine, rheumatology, or nephrology clinics at Dokuz Eylul University Hospital between 1992 and 2009. Of the 650 patients with FMF identified, 587 (90.3%) had either a face-to-face (n = 380) or telephone (n = 193) interview, or were confirmed as deceased. A structured questionnaire was used to obtain socioeconomic and demographic data, presenting and cumulative clinical features, and disease severity scores. During the follow-up period mortality was analyzed by calculating age- and sex-standardized mortality ratio (SMR) according to the mortality statistics of the Turkish population. Factors predictive of mortality were evaluated using Kaplan-Meier and Cox proportional hazard models. Sixty-three

(9.7%) patients whose initial demographic and major clinical characteristics were similar to the rest of the group could not be contacted during the study period. Most (94.2%) patients were on colchicine at the time of the study. Thirty-seven (6.3%) patients had biopsy-verified amyloidosis, and 44 (7.5%) had renal disease. During a median follow-up of 6 years, 14 patients (9 women) died, and amyloidosis and its related complications were the leading causes of death in 7 patients. Univariate analysis revealed that increasing age, coronary heart disease, hypertension, renal disease, and amyloidosis were associated with mortality. However, Cox regression analysis showed amyloidosis as the only significant predictor of mortality ( $p < 0.001$ ). The overall patient survival rate was not significantly different from the age- and sex-matched Turkish general population (SMR, 1.48; 95% confidence interval, 0.817-2.49). Our findings suggest that although the survival of FMF patients in the colchicine era is comparable to that of the general population, renal involvement still predicts mortality.

Autoinflammatory grey matter lesions in humans: cortical encephalitis, clinical disorders, experimental models.

Junker A(1), Brück W.

Author information:

(1)Department of Neuropathology, University Medical Center, Georg August University Göttingen, Göttingen, Germany. andreas.junker@med.unigoettingen.de

**PURPOSE OF REVIEW:** In recent years, evidence has accumulated that grey matter abnormalities are common in many inflammatory central nervous system (CNS) disorders, such as multiple sclerosis (MS), which is by far the most frequent autoimmune-mediated CNS disease.

**RECENT FINDINGS:** A recent study described comprehensively the pathology of grey matter lesions in early MS. In this study, cortical demyelination together with inflammation was frequently observed in early MS cases. This study and others serve as a basis for a model of the development of cortical MS lesions in which several consecutive events may be involved. After the activation of T cells,

which may open the blood-brain barrier, the humoral immune system may mediate the inflammatory process. The inflammation may become chronic through the involvement of activated glial cells and the persistence of immune cells in the meninges. Apart from MS, other grey matter CNS disorders exist in which antibodies against neuronal structures contribute to pathophysiological events such as in limbic encephalitis. Humoral and adaptive immunity mediates the pathophysiology of Rasmussen encephalitis.

**SUMMARY:** This review focuses on the difference between inflammatory grey matter and white matter lesions. New insights into inflammatory grey matter lesions in MS and other CNS inflammatory processes such as limbic encephalitis are discussed.

Familial Mediterranean fever (FMF) is a chronic inflammatory disease, characterized by recurrent fever and polyserositis (pleuritis and/or peritonitis). The most important complication of FMF is amyloidosis, which causes chronic renal failure. Colchicine is the most effective treatment in acute attacks and amyloidosis development. However, the majority of patients with

amyloidosis have a relentless progression to end-stage renal disease despite initiation of colchicine treatment. We present the case of a 38-year-old man with FMF-associated chronic renal failure due to systemic amyloidosis. The patient suffered from periodic fever and renal insufficiency, and was admitted to our hospital. Laboratory examination revealed an inflammatory reaction, renal dysfunction (serum creatinine 2.5 mg/dl), and proteinuria. Renal biopsy revealed segmental mesangial AA amyloid deposits in several glomeruli and the walls of several vessels. Genetic analysis showed that the patient was heterozygous for the MEFV gene (E148Q/M694I). Thus, he was diagnosed with FMF, and colchicine treatment was initiated. He remained almost attack free, with decreasing serum creatinine levels (1.6 mg/dl) and diminishing urinary protein excretion. In conclusion, renal amyloidosis is the most important long-term complication of FMF, and treatment with colchicine is effective for preventing progression. Therefore, colchicine treatment should be initiated as early as possible after the diagnosis of FMF.

Familial Mediterranean fever (FMF) is an autosomal recessive disease affecting populations surrounding the Mediterranean area. In this case report, we report a Japanese female patient with polymyositis (PM) who presented with periodic fever. Genetic analysis revealed that she had compound heterozygous mutations in exon 2 of the MEFV gene (L110P/E148Q/R202Q). Treatment with colchicines (1.0 mg/day)

successfully eliminated febrile attack and normalized the elevated levels of neutrophil CD64 expression, leading to the diagnosis of FMF. The association of FMF and PM has not previously been reported, so we discuss this rare association.

The objective of this study was to assess the prevalence of the Mediterranean FeVer (MEFV) gene mutations in systemic lupus erythematosus (SLE) patients and their effect on organ involvement, as well as disease activity and severity. The frequencies of three familial Mediterranean fever-related MEFV gene mutations (M694V, V726A and E148Q) were investigated in 70 SLE patients. Organ involvement, Systemic Lupus International Collaborating Clinics/American College of Rheumatology (SLICC/ACR) damage index and Systemic Lupus Erythematosus Disease Activity Index (SLEDAI) scores were correlated with mutation carriage. Eleven of 70 patients (15.7%) were found to carry an MEFV mutation. A single patient harbored two mutations, E148Q and V726A, without overt familial Mediterranean fever while the rest were heterozygous carriers. Four of the 11 carried an M694V mutation, four carried V726A and two carried E148Q. The majority of MEFV mutation carriers were Sephardic while non-carriers were mainly of Ashkenazi origin (72.7% vs. 45.7% and 47.4% vs. 9.1%, respectively,  $p = 0.02$ ). SLE onset was significantly earlier in MEFV carriers ( $27.6 \pm 9.7$  vs.  $38.2 \pm 15.5$  years, in carriers vs. non-carriers,  $p = 0.02$ ). Hematologic and serologic parameters were comparable among mutation carriers and non-carriers. Febrile episodes were more common among MEFV mutation carriers (45.4% vs. 15.2%,  $p = 0.035$ ) and there was a trend for excess episodes of pleuritis as well (54.5% vs. 23.7%,  $p = 0.06$  in

carriers vs. non-carriers, respectively). The frequency of secondary anti-phospholipid antibody syndrome was equivalent among the groups. Conversely, compound urinary abnormalities and renal failure was not observed among MEFV carriers yet was present in 33.4% and 18.6% of non-carriers ( $p = 0.027$  and  $0.19$ , respectively). SLICC damage index and SLEDAI activity index did not differ significantly between the groups. MEFV mutation carriage appears to modify the SLE disease phenotype in that it contributes to an excess of inflammatory manifestations such as fever and pleuritis on the one hand, while thwarting more severe renal involvement on the other.

Author information:

(1)VCU Pauley Heart Center, Virginia Commonwealth University, 1200 E. Broad St. 10th floor, Richmond, VA 23298, USA. stoldo2@vcu.edu

**PURPOSE:** Acute myocardial infarction (AMI) drives an intense inflammatory response that contributes to infarct healing and cardiac remodeling. Recently, different studies have identified a role of interleukin-1 (IL-1) in the development of adverse cardiac remodeling. However, in animal models of AMI IL-1 has been shown to be cardioprotective in preconditioning, raising the question of clinical safety of therapeutic IL-1 blockade for autoinflammatory diseases or for the prevention or the treatment of AMI. In this study we proposed to evaluate the effects of pretreatment with recombinant human interleukin-1 receptor antagonist (rhIL-1Ra) on ischemia reperfusion (I/R) injury to the heart.

**METHODS:** RhIL-1Ra was given 4 h or 30 min before the surgical induction of I/R. Left ventricular ejection fraction(LVEF) and infarct size were assessed to determine the effects of the drug pretreatment compared to vehicle treated mice.

**RESULTS:** RhIL-1Ra, given 4 h or 30 min before the onset of the ischemia, showed

marked cardioprotection though preservation of the LVEF (no change vs sham operated mice) and the reduction of the infarct size (-40 % vs vehicle-treated mice). No differences were observed between the two groups of rhIL-1Ra treatment. CONCLUSIONS: IL-1 blockade therapies using rhIL-1Ra prior the onset of AMI protects the myocardium and preserves cardiac function.

[Cryopyrin-associated periodic syndrome].

[Article in German]

Kümmerle-Deschner JB(1).

Author information:

(1)Klinik für Kinder- und Jugendmedizin, Abteilung für pädiatrische Rheumatologie, Autoinflammation Reference Center Tübingen, Universitätsklinikum Tübingen, Hoppe-Seyler-Str. 1, 72076, Tübingen, Deutschland.  
kuemmerle.deschner@uni-tuebingen.de

The cryopyrin-associated periodic syndrome is a very rare disease. It is estimated that there are 1-2 cases out of 1 million inhabitants in the USA and 1/360,000 in France. However, many patients are diagnosed very late or not at all. Therefore the real prevalence is likely to be higher. CAPS encompasses the three entities familial cold autoinflammatory syndrome (FCAS), the Muckle-Wells syndrome and the neonatal-onset multisystem inflammatory disease (NOMID)/chronic infantile neurologic cutaneous and articular (CINCA) syndrome. They have in common a causative mutation in the NLRP3-gene. The altered gene product cryopyrin leads to activation of the inflammasome which in turn is responsible for excessive production of IL-1 $\beta$ . IL-1 $\beta$  causes the inflammatory manifestations in CAPS. These appear as systemic inflammation including fever, headache or fatigue, rash, eye disease, progressive sensorineural hearing loss, musculoskeletal manifestations and CNS symptoms (NOMID/CINCA only). With the advent of the IL-1 inhibitors anakinra, rilonacept and canakinumab for the first time safe and effective therapeutic options are available for this devastating disease. To

prevent severe and possible life-threatening disease sequelae, early and correct diagnosis and immediate initiation of therapy are mandatory.

[Schnitzler syndrome].

[Article in German]

Loock J(1).

Author information:

(1)Klinikum Bad Bramstedt, Bad Bramstedt, Deutschland. jloock@schoen-kliniken.de

Schnitzler syndrome is a rare systemic inflammatory disease characterized by the presence of chronic urticarial skin rash and a monoclonal immunoglobulin M (IgM) gammopathy, combined with further, variable disease symptoms. The term refers to a young disease entity which has recently gained increasing acknowledgement and attention, also due to the availability of interleukin-1 (IL-1) blockade as an effective therapeutic option. Insights into the pathophysiology of the disease have resulted in the assumption of Schnitzler syndrome being a special form of an autoinflammatory disease with late onset or an acquired genesis. This article provides an overview on the clinical appearance, current knowledge of pathophysiology and available therapeutic options.

The spectrum of disease manifestations in patients with common variable immunodeficiency disorders and partial antibody deficiency in a university hospital.

Maarschalk-Ellerbroek LJ(1), Hoepelman AI, van Montfrans JM, Ellerbroek PM.

Author information:

(1)Department of Internal Medicine and Infectious Diseases, University Medical Centre Utrecht, P.O. Box 85500, 3508 GA, Utrecht, the Netherlands.  
l.j.maarschalk-ellerbroek@umcutrecht.nl

**BACKGROUND:** Common variable immunodeficiency disorders (CVIDs) represents a heterogeneous disease spectrum that includes recurrent infections and complications such as autoimmunity, inflammatory organ disease and an increased risk of cancer. A diagnostic delay is common in CVIDs patients.

**PURPOSE:** To determine the spectrum of clinical manifestations, immunological characteristics, and the time to diagnosis of 61 adult CVIDs and 18 patients with a partial antibody deficiency (SADNI and IgG subclass deficiency).

**METHODS:** A retrospective cohort study was performed in patients who met the ESID/PAGID for CVIDs, IgG subclass deficiency and SADNI. Medical records were reviewed to obtain patient demographics, clinical and laboratory data.

**RESULTS:** Infections were the main presentation of all antibody deficient patients and the number of patients with infections declined during IgG therapy. The development of bronchiectasis continued despite IgG therapy, as well as the development of autoinflammatory conditions. Non-infectious disease complications

were present in 30% of CVIDs patients at the time of diagnosis and this increased to 51% during follow up despite IgG therapy. The most common complications were autoimmunity or lymphoproliferative disease. The median time to diagnosis was 10 years and in the patients with non-infectious complications the time to diagnosis was considerably longer when compared to the group of patients without complications (17.6 vs. 10.2 years,  $p = 0.026$ ).

**CONCLUSION:** In contrast to the partial antibody deficiencies we found a considerable delay in the diagnosis of CVIDs, especially in those patients who were dominated by non-infectious complications, and thus increased awareness would be beneficial. Pulmonary and other complications may continue despite adequate IgG replacement therapy suggesting other causes responsible for these complications.

Normal QT dispersion in colchicine-resistant familial Mediterranean fever (FMF).

Nussinovitch U(1), Livneh A, Volovitz B, Nussinovitch M, Ben-Zvi I, Lidar M, Nussinovitch N.

Author information:

(1)Israel Naval Medical Institute, IDF Medical Corps, Haifa, Israel.

The association between familial Mediterranean fever (FMF) and subclinical cardiac disease remains controversial. The aim of the current study was to evaluate whether FMF patients, who do not respond to colchicine treatment, and thereby endure persistent inflammation, have increased QT dispersion (QTd) values. Twenty-two FMF patients and 22 age- and sex-matched control subjects were included in the study. Repolarization and QT dispersion parameters were computed from 12-lead ECG recording using designated computer software, and results of five beats were subsequently averaged. Both FMF patients and controls had similar comorbidities, similar values of average QT, average corrected QT interval length, average QTd interval, average QT corrected dispersion, QT dispersion

ratio, JT dispersion (JTd), and JT corrected dispersion. In conclusion, FMF patients who were unresponsive to colchicine treatment and did not develop amyloidosis had normal QTd and JTd parameters, indicating a non-increased risk for repolarization-associated ventricular arrhythmias.

Current challenges in the diagnosis and management of fever.

Sherman JM(1), Sood SK.

Author information:

(1)Department of Pediatric Emergency Medicine, Cohen Children's Medical Center of New York, USA.

**PURPOSE OF REVIEW:** We review recommendations from recent publications on the management of fever with antipyretics, the classification and diagnosis of fevers of unknown origin (FUO), and the evaluation of fever in infants under 90 days of age.

**RECENT FINDINGS:** Anxiety about fever persists in the population, while the toxicity of antipyretics is an increasing concern. The numerous opportunities for overdosing with antipyretics have been emphasized by the American Academy of Pediatrics (AAP). The practice of alternating acetaminophen and ibuprofen has limited value. Nonclassic FUO and pseudo-FUO are as important to consider as true FUO, and clinicians should become familiar with the variety of periodic fever syndromes. The clinical utility of low-risk criteria to identify febrile infants at low risk for serious bacterial infection (SBI) was demonstrated in a systematic review of studies.

**SUMMARY:** Pediatricians should spend more time educating parents about fever and antipyretic use. Not all persistent fever is FUO, and testing should be targeted to the child's clinical condition. Existing low-risk criteria should be used to identify febrile infants who can be managed without extensive work-up and antibiotics. Adherence to evidence-based recommendations will lessen the morbidity and mortality associated with febrile illnesses in children.

tu-anh.tran@bct.aphp.fr

**OBJECTIVES:** Muckle-Wells syndrome (MWS) is a rare autoinflammatory disorder associated with NLRP3 gene mutations, which cause excessive caspase-1 activation and processing of interleukin (IL)-1 $\beta$  and IL-18. Here we investigated whether MWS disease may be associated with impaired fertility in male patients.

**METHODS:** Medical records of all male MWS patients with NLRP3 mutations followed in our tertiary center for inherited autoinflammatory diseases were reviewed retrospectively for data indicating fertility problems.

**RESULTS:** Six of 9 patients were unable to have children despite regular sexual activity during at least 2 years; 3 succeeded in having children through in vitro fertilization. Infertility was the main reason for divorce in 1 patient.

Spermogram analyses were available in 8 of the 9 patients. Oligozoospermia was observed in 5 patients and azoospermia in 3 patients. In 2 patients, treatment with IL-1-targeting drugs for 6 and 12 months, respectively, had a moderate or no effect on spermatozoa counts. In 2 patients testosterone levels were low and testosterone treatment significantly increased spermatozoa counts in 1 of them.

**CONCLUSIONS:** MWS may be associated with subfertility and infertility in male patients. Consequently, sexual health and fertility should be assessed systematically in adolescent and adult male patients. Additional studies are required to establish the frequency of subfertility in male MWS patients, to understand when subfertility occurs in the disease natural history, and, finally, to investigate whether early management with IL-1-targeting drugs, or testosterone treatment or early sperm cryo-conservation may help to allow

procreation.

A 38-year-old woman presented with 2 days history of left-flank pain. She had similar episodes of abdominal pain as well as chest pain several times, but symptoms disappeared spontaneously. Each time she developed pain, there was no fever. After ruling out common causes of recurrent abdominal pain, familial Mediterranean fever (FMF) was considered as a potential diagnosis. Genetic tests revealed multiple heterozygote mutations, which may be associated with FMF. Patients with Mediterranean fever mutations may present with atypical presentations without fever, like in this case. Astute clinical suspicion is required to make an accurate diagnosis.

Plasmablast frequency and trafficking receptor expression are altered in pediatric ulcerative colitis.

Tarltan NJ(1), Green CM, Lazarus NH, Rott L, Wong AP, Abramson ON, Bremer M, Butcher EC, Abramson T.

Author information:

(1)San José State University, Department of Biology, San Jose, California, USA.

**BACKGROUND:** The incidence of pediatric ulcerative colitis (UC), a chronic autoinflammatory disease of the colon, is on the rise. Although an increased infiltration of B cells from the peripheral blood into the colon occurs in UC, B-cell trafficking is understudied. We hypothesized that the frequency of circulating plasmablasts (PBs) and their trafficking receptor (TR) expression may be indicative of the location and degree of pathology in pediatric UC.

**METHODS:** We conducted multicolor flow cytometry analyses of circulating IgA(+/-) PBs and IgA(+) memory B cells (MBCs) in pediatric UC patients with remission, mild, moderate, and severe state of disease (n = 12), and healthy pediatric (n = 2) and adult donors (n = 11).

**RESULTS:** Compared to healthy donors the average frequency of PBs among total

peripheral blood lymphocytes is increased 30-fold during severe UC activity, and positively correlates with Pediatric Ulcerative Colitis Activity Index score, C-reactive protein level, and erythrocyte sedimentation rate. A greater percent of PBs in severe patients express the gut-homing receptors  $\alpha 4\beta 7$  and CCR10, and the inflammatory homing molecule P-selectin ligand (P-sel lig). The percent of IgA(+) MBCs expressing  $\alpha 4\beta 7$ , however, is reduced. Furthermore, expression of the small intestine TR CCR9 is decreased on  $\alpha 4\beta 7$ (high) PBs, and on  $\alpha 4\beta 7$ (high)/CCR10(high) PBs and MBCs in these patients, consistent with preferential cell targeting to the colon.

CONCLUSIONS: Peripheral blood PBs with a colon-homing phenotype ( $\alpha 4\beta 7$ /CCR10/P-sel lig) are elevated in children with severe UC. Screening this B-cell subset may provide a complementary approach in monitoring disease activity or therapeutic efficacy in pediatric UC.

Pathogenesis of spondyloarthritis: autoimmune or autoinflammatory?

Ambarus C(1), Yeremenko N, Tak PP, Baeten D.

Author information:

(1)Department of Clinical Immunology and Rheumatology, Academic Medical Center/University of Amsterdam, Amsterdam, The Netherlands.

PURPOSE OF REVIEW: Spondyloarthritis (SpA) is a chronic immune-mediated inflammatory disease of unknown origin. Here we aim to review whether SpA is driven by T-cell and/or B-cell autoreactivity or by abnormal innate immune responses.

RECENT FINDINGS: SpA does not share genetic risk factors, female predominance, presence of disease-specific autoantibodies and response to T-cell or B-cell-targeted therapies with prototypical autoimmune diseases like rheumatoid arthritis (RA) and systemic lupus erythematosus (SLE). Growing evidence indicates

that increased responsiveness of innate immune cells such as macrophages, mast cells and neutrophils drives inflammation in SpA. The altered innate immune response may be related to nonantigen-presenting functions of HLA-B27, including the induction of an unfolded protein response, and can be triggered by bacterial and mechanical stress. Innate immune cells appear to be the main producers of both pro-inflammatory (tumor necrosis factor, IL-1, IL-23, IL-17) and anti-inflammatory (IL-10) cytokines in SpA.

SUMMARY: The predominance of myeloid above lymphoid alterations suggests an autoinflammatory rather than autoimmune origin of inflammation in SpA. Therefore, targeting innate cells or their inflammatory mediators may be more effective than T-cell or B-cell-directed therapies.

Concurrent protracted febrile myalgia syndrome in a child with diabetic ketoacidosis.

Demir K(1), Carman KB, Kasap B.

Author information:

(1)Division of Pediatric Endocrinology, Children's Hospital, Gaziantep, Turkey.  
korcandemir@gmail.com

Familial Mediterranean Fever (FMF), characterized by recurrent attacks of inflammation in predominantly serosal and synovial membranes, is caused by MEFV gene mutations resulting in abnormal pyrin. Protracted febrile myalgia syndrome (PFMS), a kind of vasculitis requiring corticosteroid treatment, is associated with M694V mutation of MEFV gene. Here, we report a case where the patient developed PFMS leading to the diagnosis of FMF concurrently at the time of treatment for diabetic ketoacidosis (DKA) of new-onset type 1 diabetes mellitus and discuss the possible mechanisms of simultaneous DKA and FMF-associated PFMS. DKA-associated cytokine release may be a predisposing factor or trigger for FMF-associated PFMS.

Hypophysitis induced by monoclonal antibodies to cytotoxic T lymphocyte antigen 4: challenges from a new cause of a rare disease.

Torino F(1), Barnabei A, De Vecchis L, Salvatori R, Corsello SM.

Author information:

(1)Department of Internal Medicine, University of Rome Tor Vergata, Rome, Italy.

Specific human monoclonal antibodies antagonize cytotoxic T-lymphocyte antigen 4 (anti-CTLA-4 mAbs), a negative regulator of the immune system, inducing unrestrained T-cell activation. In patients with advanced or metastatic melanoma, one of these agents, ipilimumab, produced considerable disease control rates and, for the first time, a clear improvement in overall survival outcomes. However, accumulating clinical experience with anti-CTLA-4 mAbs identified a novel syndrome of autoimmune and autoinflammatory side effects, designated as "immune-related adverse events," including mainly rash, colitis, and hepatitis. Autoimmune hypophysitis has emerged as a distinctive side effect induced by anti-CTLA-4 mAbs. This condition may be life threatening because of adrenal insufficiency if not promptly recognized, but it may easily be diagnosed and treated if clinically suspected. Hypopituitarism caused by these agents is rarely reversible and prolonged or life-long substitutive hormonal treatment is often required. The precise mechanism of injury to the pituitary triggered by anti-CTLA-4 mAbs is yet to be fully elucidated.

We describe a 3-month-old infant who presented to our institution with interleukin (IL)-1 receptor antagonist deficiency (DIRA), which consists of neutrophilic pustular dermatosis, periostitis, aseptic multifocal osteomyelitis, and persistently high acute-phase reactants. Skin findings promptly improved upon initiation of treatment with anakinra (recombinant human IL-1 receptor antagonist), and the bony lesions and systemic inflammation resolved with continued therapy.

**OBJECTIVE:** To assess whether systemic autoimmune diseases are a risk group for coeliac disease and if there is a systemic autoimmune diseases-associated enteropathy.

**METHODS:** 183 patients with systemic autoimmune diseases were included. Duodenal biopsy was carried out on patients with positive coeliac genetics (HLA-DQ2-DQ8) and/or serology and/or symptoms of the coeliac disease spectrum. When enteropathy was found, causes, including gluten sensitivity, were investigated and categorized according to a sequentially applied treatment. Results were analysed with Chi-square or Fisher exact tests.

**RESULTS:** The prevalence of coeliac disease with atrophy was 0.55% (1 of 183 patients). Thirty-eight of the 109 patients (34.8%) who underwent duodenal biopsy had lymphocytic enteropathy (8 infectious, 5 due to gluten sensitive enteropathy, 5 HLA-DQ2/DQ8 who did not accept gluten-free diet and 20 of unknown aetiology). Lymphocytic enteropathy was unrelated to disease activity or immunosuppressants. HLA-DQ2 was more frequent in connective tissue disease (41.5%) compared with systemic vasculitis and autoinflammatory diseases (17.9%) ( $p=0.02$ ), whereas a lower percentage of lymphocytic enteropathy was observed in the former (20.2% vs. 41.6%). Lymphocytic enteropathy was clinically irrelevant in cases with no definite aetiology.

**DISCUSSION:** One third of systemic autoimmune diseases patients had enteropathy of uncertain clinical meaning in the majority of cases, which was rarely due to gluten sensitive enteropathy.

High frequency of inherited variants in the MEFV gene in patients with hematologic neoplasms: a genetic susceptibility?

Oktenli C(1), Celik S.

Author information:

(1)Department of Internal Medicine and Geriatrics, Anadolu Medical Center, 41400 Kocaeli, Turkey. cagatay.oktenli@anadolusaglik.org

Familial Mediterranean fever is an autosomal recessive disease occurring in populations originating from the Mediterranean basin. This autoinflammatory syndrome is caused by mutations in the Mediterranean FeVer (MEFV) gene. MEFV encodes a 781 amino acid protein known as pyrin. Pyrin is an important modulator of apoptosis, inflammation, and cytokine processing. In more recent pilot studies, inherited variant analysis of the MEFV gene in patients with hematologic neoplasm showed an unexpectedly high frequency of these variants in the gene. Here, we summarize the current state of knowledge of the relationship between inherited variants in the MEFV gene and hematologic neoplasms. Although no single

underlying defect could be targeted in all hematologic neoplasms, it will be important to fully exploit the mechanisms underlying the neoplasm promoting role of inherited variants in MEFV. However, it is unclear how inherited variants in the MEFV gene are associated with tumor susceptibility or promotion in hematologic neoplasms. Further investigations are needed to determine the actual role of the MEFV gene in pathogenesis of these neoplasms.

Prevalence and significance of the MEFV gene mutations in childhood Henoch-Schönlein purpura without FMF symptoms.

Dogan CS(1), Akman S, Koyun M, Bilgen T, Comak E, Gokceoglu AU.

Author information:

(1)Pediatric Rheumatology Unit, Department of Pediatrics, School of Medicine, Akdeniz University, 07070 Antalya, Turkey. d.caglaserpil@yahoo.com

Familial Mediterranean fever (FMF) has been reported more frequently in patients presenting with Henoch-Schönlein purpura (HSP) than in the general population. But, there is no clear knowledge about MEFV mutations in patients with HSP. We investigated the prevalence of MEFV mutations in children with HSP and without FMF whether these mutations have any effect on the disease course or complications. A total of 76 children with HSP who had no typical symptoms of FMF were screened for the mutations in exon 2 and exon 10 of the MEFV gene. Eleven of 76 patients (14.4 %) were heterozygous (E148Q in 5, M694V in 4, M680I in 1, E148V in 1), 5 (6.6 %) were homozygous (M694V/M694V in 4, V726A/V726A in 1), and 2 (2.6 %) were compound heterozygous (E148Q/M694V mutations in 1 and L110P/E148Q mutations in 1). Altogether, 7 patients carried 2 mutated MEFV alleles (9.2 %), which was higher than that observed in the general Turkish population (1 %). No significant differences in joint, gastrointestinal, renal involvement, or subcutaneous edema, and also acute phase reactants including leukocyte count, erythrocyte sedimentation rate, and serum C-reactive protein concentration were found between the groups. The prevalence of the two allele-MEFV mutations in

patients with HSP was found higher than that of the general population. However, it seems that MEFV gene mutations may not have any effect on the clinical presentation of HSP.

Nakajo-Nishimura syndrome: an autoinflammatory disorder showing pernio-like rashes and progressive partial lipodystrophy.

Kanazawa N(1).

Author information:

(1)Department of Dermatology, Wakayama Medical University, Wakayama, Japan.  
nkanazaw@wakayama-med.ac.jp

Nakajo-Nishimura syndrome (ORPHA2615; also registered as Nakajo syndrome in OMIM#256040) is a distinct inherited inflammatory and wasting disease, originally reported from Japan. This disease usually begins in early infancy with a pernio-like rash, especially in winter. The patients develop periodic high fever and nodular erythema-like eruptions, and gradually progress lipomuscular atrophy in the upper body, mainly the face and the upper extremities, to show the characteristic thin facial appearance and long clubbed fingers with joint contractures. So far about 30 cases have been reported from Kansai, especially Wakayama and Osaka, Tohoku and Kanto areas. At present, about 10 cases are confirmed to be alive only in the Kansai area, including one infant case in Wakayama. However, more cases are expected to be added in the near future. Although cause of the disease has long been undefined, a homozygous mutation of the PSMB8 gene, which encodes the  $\beta 5i$  subunit of immunoproteasome, has been identified to be responsible in 2011. By analyses of the patients-derived cells and tissues, it has been suggested that accumulation of ubiquitinated and oxidated proteins due to immunoproteasome dysfunction causes hyperactivation of p38 mitogen-activated protein kinase and interleukin-6 overproduction. Since similar diseases with PSMB8 mutations have recently been reported from Europe and the United States, it is becoming clear that Nakajo-Nishimura syndrome and

related disorders form proteasome disability syndromes, a new category of autoinflammatory diseases distributed globally.

[Colchicine has no negative effect on fertility and pregnancy].

[Article in Dutch]

Both T(1), van Laar JA, Bonte-Mineur F, van Hagen PM, van Daele PL.

Author information:

(1)Erasmus MC, afd. Interne Geneeskunde, Rotterdam, the Netherlands.

**OBJECTIVE:** To inventorise the possible development of infertility and pregnancy complications in patients with Familial Mediterranean Fever (FMF), on treatment with colchicine.

**DESIGN:** Systematic review.

**METHOD:** PubMed was searched for articles in English, describing the effects of colchicine on fertility and pregnancy in animals or humans.

**RESULTS:** We found 73 articles, 13 of which matched the inclusion criteria. We selected another 12 articles via cross references and after evaluation by the co-authors. From these articles it appeared that colchicine inhibits the clinical symptoms of FMF and the development of amyloid deposits. No statistically significant effect was found of colchicine treatment on semen quality or hormone levels. Treatment with colchicine during pregnancy did not lead to severe complications. Both male and female patients who were treated with colchicine had a better prospect of maintaining fertility, compared with patients without this treatment.

**CONCLUSION:** According to the literature selected, colchicine use has no demonstrable negative effect on fertility. If untreated, FMF itself can lead to amyloid deposits in the testis and ovary, resulting in infertility. Patients with FMF may safely continue to use colchicine throughout the reproductive phase of their life.

Interleukin 1 receptor antagonist deficiency presenting as infantile pustulosis mimicking infantile pustular psoriasis.

Minkis K(1), Aksentijevich I, Goldbach-Mansky R, Magro C, Scott R, Davis JG, Sardana N, Herzog R.

Author information:

(1)Department of Dermatology, Weill Medical College of Cornell University, 505 E 70th St, New York, NY 10065, USA.

**BACKGROUND:** Deficiency of interleukin 1 receptor antagonist (DIRA) is a recently described autoinflammatory syndrome of skin and bone caused by recessive mutations in the gene encoding the interleukin 1 receptor antagonist. Few studies have been published about this debilitating condition. Early identification is critical for targeted lifesaving intervention.

**OBSERVATIONS:** A male infant, born to nonconsanguineous Puerto Rican parents, was referred for management of a pustular eruption diagnosed as pustular psoriasis. At 2 months of age, the infant developed a pustular eruption. After extensive evaluation, he was confirmed to be homozygous for a 175-kb genomic deletion on chromosome 2 that includes the IL1RN gene, commonly found in Puerto Ricans. Therapy with anakinra was initiated, with rapid clearance of skin lesions and resolution of systemic inflammation.

**CONCLUSIONS:** Recent identification of DIRA as a disease entity, compounded by the limited number of reported cases, makes early identification difficult. It is critical to consider this entity in the differential diagnosis of infantile pustulosis. Targeted therapy with the recombinant human interleukin 1 receptor antagonist anakinra can be lifesaving if initiated early. A high carrier frequency of the 175-kb DIRA-associated genomic deletion in the Puerto Rican population strongly supports testing infants presenting with unexplained pustulosis in patients from this geographic region.

Sensing and reacting to microbes through the inflammasomes.

Franchi L(1), Muñoz-Planillo R, Núñez G.

Author information:

(1)Department of Pathology and Comprehensive Cancer Center, University of Michigan, Ann Arbor, Michigan, USA.

Inflammasomes are multiprotein complexes that activate caspase-1, which leads to maturation of the proinflammatory cytokines interleukin 1 $\beta$  (IL-1 $\beta$ ) and IL-18 and the induction of pyroptosis. Members of the Nod-like receptor (NLR) family, including NLRP1, NLRP3 and NLRC4, and the cytosolic receptor AIM2 are critical components of inflammasomes and link microbial and endogenous danger signals to the activation of caspase-1. In response to microbial infection, activation of the inflammasomes contributes to host protection by inducing immune responses that limit microbial invasion, but deregulated activation of inflammasomes is associated with autoinflammatory syndromes and other pathologies. Thus, understanding inflammasome pathways may provide insight into the mechanisms of host defense against microbes and the development of inflammatory disorders.

Neurologic and other systemic manifestations in FMF: published and own experience.

Feld O(1), Yahalom G, Livneh A.

Author information:

(1)FMF Clinic and Department of Medicine F, Sheba Medical Center, Ramat Gan, Tel-Hashomer 52621, Israel. Feld.family@gmail.com

**OBJECTIVE:** Familial Mediterranean fever (FMF) is an autosomal recessive autoinflammatory disease, presenting with recurrent episodes of fever and polyserositis. Neurologic involvement in FMF is rare and usually considered

fortuitous. The aim of this article is to review the spectrum of possible neurologic manifestations, which can be encountered in FMF patients, and to establish their relation to FMF.

**METHODS:** We reviewed the literature based on Pubmed search to find neurologic manifestations, which were reported in FMF patients. To that we added our own experience on the subject, abstracted from our computerised FMF registry of 12000 FMF patients of the National FMF Center and the computerised database of Sheba Medical Center.

**RESULTS:** A wide range of neurologic manifestations involving FMF patients was noted. A large part of these manifestations could be directly related to FMF, its complications, associated diseases and treatment adverse effects. The remaining were incidental, or of uncertain association to FMF.

**CONCLUSION:** A physician, taking care of an FMF patient, can face various neurologic manifestations and should be aware of their origin. The current chapter provides an insight to this association of FMF.

Mycophenolate mofetil and erythromycin for bullous lupus erythematosus of

childhood.

Pehr K(1).

Author information:

(1)McGill University-SMBD Jewish General Hospital, Montreal, QC, Canada.

**BACKGROUND:** Bullous lupus erythematosus is a rare disease that is extremely rare in childhood (with only seven previous reports) and difficult to control.

**OBJECTIVE:** Herein is presented the youngest patient reported with this condition, and a novel, safe, and effective treatment regimen is described.

**METHODS:** Through study, perseverance, serendipity, and creativity, a safe and effective regimen was developed.

**RESULTS:** The combination of mycophenolate mofetil and erythromycin (plus sun protection) was found to be efficacious.

**CONCLUSION:** It is proposed that the two medications act synergistically, with the "antibiotic" acting as a antiinflammatory agent, but at a different point in the inflammatory cascade than mycophenolate mofetil. This suggests the approach of using common, inexpensive, and benign antibiotics to potentiate, and perhaps decrease the use of, immunomodulatory agents in autoimmune and autoinflammatory diseases.

Frequency of juvenile fibromyalgia syndrome in children with familial Mediterranean fever: effects on depression and quality of life.

Alayli G(1), Durmus D, Ozkaya O, Sen HE, Genc G, Kuru O.

Author information:

(1)Department of Physical Medicine and Rehabilitation, Ondokuz Mayis University, Medical Faculty, Samsun, Turkey. alayli70@yahoo.com

**OBJECTIVES:** To determine the prevalence of juvenile fibromyalgia syndrome (JFMS) in children with familial Mediterranean fever (FMF) and to evaluate quality of

life (QoL) and depression.

**METHODS:** Ninety-one FMF patients (M/F: 44/47) who fulfilled the Livneh criteria and 60 healthy children (M/F: 27/33) were enrolled in the study. Yunus and Masi's criteria were used for diagnosis of JFMS. Depression was assessed with Children's Depression Inventory (CDI) and QoL was evaluated with child and parent reports of Paediatric Quality of Life Inventory 4.0 (PedsQL™).

**RESULTS:** While 20 (21.9%) of 91 FMF patients fulfilled JFMS criteria, 2 (3.3%) of the control group met the diagnostic criteria of JFMS ( $p=0.002$ ). PedsQL™ scores (child self-report and parent-report) of the FMF patients were significantly lower and the depression scores were significantly higher than the healthy controls ( $p<0.001$  for all). When the FMF patients were assigned to two groups as FMF with or without JFMS, patients with JFMS were found to have a higher depression score ( $p=0.007$ ) and child and parent reports of PedsQL™ 4.0 were lower in the children with JFMS than in the patients without JFMS ( $p=0.001$ ,  $p=0.003$ , respectively).

**CONCLUSIONS:** We have determined that JFMS frequency was higher in children with FMF and patients with FMF and JFMS had a poor QoL and were more susceptible to depression. FMF patients with widespread and persistent pain should be evaluated for JFMS in order to avoid unnecessary investigations and inappropriate treatment.

The possible underlying pathophysiological mechanisms for development of multiple sclerosis in familial Mediterranean fever.

Alpayci M(1), Bozan N, Erdem S, Gunes M, Erden M.

Author information:

(1)Bitlis State Hospital, Physical Medicine and Rehabilitation Department, Bitlis, Turkey. mahmutalpayci@gmail.com

Patients with familial Mediterranean fever (FMF) have a susceptibility to the development of multiple sclerosis (MS). Here, we will propose the possible

underlying pathophysiological mechanisms of this predisposition. Inflammation, disruption of blood-brain barrier (BBB), mitochondrial energy deficit, demyelination, and axonal damage, which play an important role in the pathogenesis of MS, may occur during the course of FMF. Most FMF patients have homozygous mutations in the MEFV gene that codes for the protein pyrin. Also, pyrin mutations were found about 3.5 times higher in the MS patients than the healthy control group. Pyrin is implicated in the maturation and secretion of the proinflammatory cytokine IL-1 $\beta$ . IL-1 $\beta$  is a major mediator of fever and systemic inflammation, and mononuclear cells from FMF patients release higher levels of IL-1 $\beta$ . Moreover, IL-1 plays a significant role in the regulation of the T-cells, and it is considered an essential cytokine for the Th cell differentiation that implicated in the MS pathogenesis. In addition, endothelial dysfunction and vasculitis in FMF may cause BBB breakdown that is the first step in the development of MS lesions. Apart from this, damage can occur in myelin and mitochondria proteins due to high body temperature that arises during the FMF attacks. Whereas the protein damage in myelin results in demyelination, and the protein damage in mitochondria causes lack of energy. Both situations play a part in the pathogenesis of MS. Due to mitochondrial energy deficit, remyelination may not be achieved, and therefore, axonal damage increases. Thus, at the end of these pathophysiological processes, MS findings may occur in the FMF patients especially with irregular use of colchicine.

Chicago, IL, USA. schaudhury@childrensmemorial.org

Mevalonic aciduria because of mutations of the gene for mevalonate kinase causes limited synthesis of isoprenoids, the effects of which are widespread. The outcome for affected children is poor. A child with severe multisystem manifestations underwent orthotopic liver transplantation at age 50 months for the indication of end-stage liver disease. This procedure corrected liver function and eliminated portal hypertension, and the patient showed substantial improvement in neurological function. However, autoinflammatory episodes continued unabated until hematopoietic stem cell transplantation was performed at 80 months. Through this complex therapy, the patient now enjoys a high quality of life without significant disability.

## Neonatal autoimmune diseases: a critical review.

Chang C(1).

### Author information:

(1)Division of Allergy, Asthma and Immunology, Thomas Jefferson University, Nemours/Al duPont Hospital for Children, Wilmington, DE 19803, USA.

cchang@nemours.org

Neonatal autoimmune diseases are distinctly rare. Most neonatal autoimmune diseases result from the transplacental transfer of maternal antibodies directed against fetal or neonatal antigens in various tissues. In neonatal lupus, the heart seems to be particularly susceptible. Primary autoimmunity in newborns, with the exception of familial autoinflammatory diseases, is virtually non-existent. The pathophysiologic basis for the development of neonatal autoimmunity is not entirely clear, but differences in the neonatal immune system compared with the adult immune system, as well as unique characteristics of target antigens in the newborn period may be important factors. Neonatal lupus is the most common presentation of autoimmunity in the newborn. But the characteristics defining neonatal lupus are not well defined and the presentation of neonatal lupus differs from that of classical lupus. Other neonatal autoimmune diseases involving the interaction between maternal antibodies and fetal/neonatal antigens include neonatal anti-phospholipid syndrome, Behcet's disease, neonatal autoimmune thyroid disease, neonatal polymyositis and dermatomyositis, neonatal scleroderma and neonatal type I diabetes mellitus. While autoantibodies have been detected in patients with neonatal autoimmune disease, the pathogenic role of autoantibodies has not been well defined. Other mechanisms may play a role in the development of neonatal autoimmunity, including fetal/maternal microchimerism and aberrant apoptosis of fetal cells. The autoinflammatory syndromes are a completely different category, but are also included in discussion of neonatal autoimmune diseases. The autoinflammatory syndromes include the cryopyrin associated periodic syndromes (CAPS) - familial cold autoinflammatory syndrome (FCAS), neonatal onset multisystem inflammatory disease (NOMID) and Muckle-Wells syndrome, which all share a common pathophysiologic mechanism.

Author information:

(1)Center for Autoimmune Diseases Research (CREA), School of Medicine and Health Sciences, Universidad del Rosario, Carrera 24 # 63-C-69, Bogotá, Colombia.

Polyautoimmunity is one of the major clinical characteristics of autoimmune diseases (ADs). The aim of this study was to investigate the prevalence of ADs in spondyloarthropathies (SpAs) and vice versa. This was a two-phase cross-sectional study. First, we examined the presence of ADs in a cohort of patients with SpAs (N = 148). Second, we searched for the presence of SpAs in a well-defined group of patients with ADs (N = 1077) including rheumatoid arthritis (RA), systemic lupus erythematosus (SLE), and Sjögren's syndrome (SS). Among patients with SpAs, ankylosing spondylitis was observed in the majority of them (55.6%). There were two patients presenting with SS in the SpA group (1.4%) and 5 patients with autoimmune thyroiditis (3.5%). The global prevalence of ADs in SpAs was 4.86%. In the ADs group, there were 5 patients with SpAs (0.46%). Our results suggest a lack of association between SpAs and ADs. Accordingly, SpAs might correspond more to autoinflammatory diseases rather than to ADs.

Intracellular inflammatory sensors for foreign invaders and substances of self-origin.

Jounai N(1), Kobiyama K, Takeshita F.

Author information:

(1)Department of Molecular Biodefense Research, Yokohama City University Graduate School of Medicine, Yokohama, Japan.

In order to survive, all organisms must recognize and eliminate foreign invaders such as infectious pathogens, chemicals, ultraviolet rays, metabolites and damaged or transformed self-tissues, as well as allogenic organs in cases of transplantation. Recent research in innate immunity has elucidated that there are versatile inflammatory sensors on spatiotemporal 'sentry duty' that recognize substances derived from both 'nonself' and 'self', e.g., Toll-like receptors, retinoic acid-inducible gene-I-like receptors, nucleotide oligomerization domain-like receptors and c-type lectin receptors. Having acquired high-level functions through the development of multiple molecules, higher organisms have established both extracellular and intracellular sensors that can discriminate danger-associated molecular patterns from promiscuous, but biologically similar, molecular patterns. In addition, 'loss-of-function' or 'gain-of-function' mutations in these inflammatory sensors have been linked (at least in part) with the etiology and severity of autoimmune diseases, autoinflammatory diseases and immunocompromised diseases in humans. Further studies focusing on the role of these inflammatory sensors in the development of immune disorders would highlight new avenues for the development of novel diagnostic and therapeutic applications with regard to these diseases.

Relationship between serum interleukin-1beta levels and acute phase response proteins in patients with familial Mediterranean fever.

Yildirim K(1), Uzkeser H, Keles M, Karatay S, Kiziltunc A, Kaya MD, Yildirim A.

Author information:

(1)Department of Physical Medicine and Rehabilitation, Ataturk University, Medical Faculty, Erzurum, Turkey.

**INTRODUCTION:** The aim of this study was to investigate whether serum levels of interleukin-1beta (IL-1beta) has any possible correlation on inflammatory parameters such as C-reactive protein (CRP), erythrocyte sedimentation rate (ESR) and fibrinogen concentration in patients with familial Mediterranean fever (FMF) patients during attack-free period.

**MATERIALS AND METHODS:** The serum levels of IL-1beta, as an indicator of cytokines status, and the acute phase response proteins, CRP, ESR and fibrinogen levels were evaluated in 35 attack-free patients with FMF and 25 healthy volunteers.

**RESULTS:** Serum IL-1beta levels were significantly higher in patients with FMF than control subjects ( $P = 0.018$ ). There was no statistically significant difference in the serum levels of ESR, CRP and fibrinogen between two groups ( $P = 0.181$ ,  $P = 0.816$ ,  $P = 0.686$ , respectively). There was a significant correlation between IL-1beta and CRP ( $r = 0.513$ ,  $P = 0.002$ ) values of FMF group.

**CONCLUSIONS:** In conclusion, our results confirm the presence of increased IL-1beta levels in FMF patients during attack-free period. Serum IL-1beta values seems to correlate with CRP levels. The elevation of IL-1beta levels may be

important in monitoring subclinical inflammation of attack free period in FMF patients.

Cryopyrin-associated periodic syndrome: a case report and review of the Japanese literature.

Aoyama K(1), Amano H, Takaoka Y, Nishikomori R, Ishikawa O.

Author information:

(1)Department of Dermatology, Gunma University Graduate School of Medicine, 3-39-22 Showa-machi, Maebashi, Gunma 371-8511, Japan. kumako@ac.auone-net.jp

Cryopyrin-associated periodic syndrome is an autoinflammatory syndrome caused by mutations of the CIAS1 gene (currently named NLRP3), and is characterized by periodic attacks of an urticaria-like rash, fever, head-ache, conjunctivitis and arthralgia. We report here a case of a 1-year-old boy with cryopyrin-associated periodic syndrome, which manifested as a recurrent skin rash in the postnatal period. Genetic analysis revealed a missense mutation of the CIAS1 gene in the mother and infant.

**OBJECTIVE:** To report on the demographic data from the first 18 months of enrollment to an international registry on autoinflammatory diseases in the context of the Eurofever project.

**METHODS:** A web-based registry collecting baseline and clinical information on autoinflammatory diseases and related conditions is available in the member area of the PRINTO web-site. Anonymised data were collected with standardised forms.

**RESULTS:** 1880 (M:F=916:964) individuals from 67 centers in 31 countries have been entered in the Eurofever registry. Most of the patients (1388; 74%), reside in western Europe, 294 (16%) in the eastern and southern Mediterranean region (Turkey, Israel, North Africa), 106 (6%) in eastern Europe, 54 in Asia, 27 in South America and 11 in Australia. In total 1049 patients with a clinical diagnosis of a monogenic autoinflammatory diseases have been enrolled; genetic analysis was performed in 993 patients (95%): 703 patients have genetically confirmed disease and 197 patients are heterozygous carriers of mutations in genes that are mutated in patients with recessively inherited autoinflammatory diseases. The median diagnosis delay was 7.3 years (range 0.3-76), with a clear reduction in patients born after the identification of the first gene associated with autoinflammatory diseases in 1997.

**CONCLUSIONS:** A shared online registry for patients with autoinflammatory diseases is available and enrollment is ongoing. Currently, there are data available for analysis on clinical presentation, disease course, and response to treatment, and to perform large scale comparative studies between different conditions.

Cryopyrin-associated periodic syndrome (CAPS) comprises a group of rare, but severe, autoinflammatory syndrome, and includes 3 distinct conditions, familial cold autoinflammatory syndrome (FCAS), Muckle-Wells syndrome (MWS), and neonatal-onset multisystem inflammatory disease (MONID). These syndromes are characterized by urticarial-like rash, periodic fever, central nervous system inflammation, an arthropathy, and the risk of amyloidosis. About 20% die by age 20 years in the most severe cases. The disease is associated with mutations in the NLRP3 gene that encodes for the protein cryopyrin, a component of the inflammasome complex that regulates the production and secretion of IL-1 $\beta$ . Canakinumab is a human IgG monoclonal antibody targeting IL-1 $\beta$ . The clinical trials of canakinumab for patients with CAPS in both western countries and Japan were well-tolerated in most patients, and provided significant advantages over existing competitive therapies. Although no serious adverse effects have been reported, the frequencies of common infectious diseases including nasopharyngitis, upper respiratory tract infections, and gastroenteritis were reported presumably due to the blockade of proinflammatory cytokine, IL-1 $\beta$ . For us pediatrician, it will be important to be more careful for infectious diseases to provide the maximum safety of canakinumab for these patients.

Inflammation-induced thrombosis: mechanisms, disease associations and management.

Aksu K(1), Donmez A, Keser G.

Author information:

(1)kenan.aksu@ege.edu.tr

Although inflammation-induced thrombosis is a well-known entity, its pathogenesis remains complicated. There are complex interactions between inflammation and hemostasis, involving proinflammatory cytokines, chemokines, adhesion molecules, tissue factor expression, platelet and endothelial activation, and microparticles. Inflammation increases procoagulant factors, and also inhibits natural anticoagulant pathways and fibrinolytic activity, causing a thrombotic tendency. Besides, chronic inflammation may cause endothelial damage, resulting in the loss of physiologic anticoagulant, antiaggregant and vasodilatory properties of endothelium. However, inflammation-induced venous thrombosis may develop even in the absence of vessel wall damage. On the other hand, coagulation also augments inflammation, causing a vicious cycle. This is mainly achieved by means of thrombin-induced secretion of proinflammatory cytokines and growth factors. Platelets may also trigger inflammation by activating the dendritic cells. There are many systemic inflammatory diseases characterized by thrombotic tendency, including Behçet disease (BD), antineutrophilic cytoplasmic antibody-associated vasculitides, Takayasu arteritis, rheumatoid arthritis, systemic lupus erythematosus, antiphospholipid syndrome, familial Mediterranean fever, thromboangiitis obliterans (TAO) and inflammatory bowel diseases. Inflammation-induced thrombosis may respond to immunosuppressive (IS) treatment, as in the case of BD. However effectiveness of this treatment can not be generalized to all other inflammatory diseases. For instance, IS agents do not have any beneficial role in the management of TAO. Heparin, antiplatelet agents such as aspirin and clopidogrel, colchicine and statins also have some antiinflammatory activity. However, decreased responsiveness to aspirin and clopidogrel treatments may be observed in inflammatory diseases, due to antiplatelet resistance caused by systemic inflammation. In the present review, we aimed to discuss the details of the complex crosstalk between inflammation and hemostasis in the context of available data. We also intended to overview the major inflammatory diseases with thrombotic tendency, as well as to discuss the general principles of the management of inflammation-induced thrombosis.

Frequency of inherited variants in the MEFV gene in myelodysplastic syndrome and acute myeloid leukemia.

Celik S(1), Oktenli C, Kilicaslan E, Tangi F, Sayan O, Ozari HO, Ipcioglu O, Sanisoglu YS, Terekeci MH, Erikci AA.

Author information:

(1)Division of Internal Medicine, GATA Haydarpasa Training Hospital, Istanbul, Turkey.

We investigated the frequency of inherited variants in the MEFV gene, which is mutated in familial Mediterranean fever (FMF), in patients with acute myeloid leukemia (AML) and myelodysplastic syndrome (MDS). Eight MEFV gene variants (M694I, M694V, M680I (G/C-A), V726A, R761H, E148Q and P369S) were analyzed in 33 MDS patients, 47 AML patients and 65 healthy controls; none had a history or family history compatible with FMF. We identified two homozygous (E148Q/E148Q), one compound heterozygous (M694V/E148Q) and five heterozygous inherited variants in the MEFV gene in AML patients. We also identified nine heterozygous variants in MDS patients, while we found 11 heterozygous variants in controls. The mean overall frequency of inherited variants in the MEFV gene rate was higher in MDS ( $\chi^2 = 4.241$ ;  $P = 0.039$ ) and AML ( $\chi^2 = 3.870$ ;  $P = 0.043$ ) patients than in healthy controls. In conclusion, this study reports high frequency of inherited variants in the MEFV gene in patients with MDS and AML. However, the hypothesis that MEFV is a cancer susceptibility gene at this point remains speculative. Additional evidence from future studies is needed to allow a more thorough evaluation of this hypothesis.

Familial Mediterranean fever-associated mutation pyrin E148Q as a potential risk factor for multiple sclerosis.

Kümpfel T(1), Gerdes LA, Wacker T, Blaschek A, Havla J, Krumbholz M, Pöhlmann W, Feneberg W, Hohlfeld R, Lohse P.

Author information:

(1)Institute of Clinical Neuroimmunology - Großhadern, Ludwig-Maximilians University of Munich, Germany. tania.kuempfel@med.uni-muenchen.de

**BACKGROUND:** Familial Mediterranean fever (FMF) is an inherited autoinflammatory disease caused by mutations in the MEFV gene and characterized by recurrent febrile polyserositis. A possible association of FMF and multiple sclerosis (MS) has been suggested in cohorts from Turkey and Israel.

**OBJECTIVE:** The objective of this study was to investigate the prevalence of MEFV mutations in subjects with MS and in controls in Germany.

**METHODS:** One-hundred and fifty seven MS patients with at least one symptom or without symptoms suggestive of FMF from our outpatient clinic were investigated for mutations in exons 2, 3, and 10 of the MEFV gene (group 1). 260 independent MS patients (group 2) and 400 unrelated Caucasian controls (group 3) were screened selectively for the low-penetrance pyrin mutations E148Q and K695R

**RESULTS:** In group 1, 19 MS patients (12.1%) tested positive for a mutation in the MEFV gene, mainly the E148Q (n=7) substitution. Fifteen of the 19 mutation-positive individuals reported at least one symptom suggestive of FMF. In three cases, we could identify additional family members with MS. In these

pedigrees, the E148Q exchange co-segregated with MS ( $p=0.026$ ). Frequencies of the pyrin E148Q and K695R mutations were not statistically different between MS group 2 and controls but they occurred with a surprisingly high frequency in the German population.

CONCLUSION: The MEFV gene appears to be another immunologically relevant gene locus which contributes to MS susceptibility. In particular, the pyrin E148Q mutation, which co-segregated with disease in three MS families, is a promising candidate risk factor for MS that should be further explored in larger studies.

Rare hereditary autoinflammatory disorders: towards an understanding of critical in vivo inflammatory pathways.

Kanazawa N(1).

Author information:

(1)Department of Dermatology, Wakayama Medical University, Wakayama 641-0012, Japan. nkanazaw@wakayama-med.ac.jp

Hereditary autoinflammatory syndromes are monogenic disorders with an inborn error of innate immunity, and include periodic fever syndromes such as familial Mediterranean fever (FMF), tumor necrosis factor receptor-associated periodic syndrome and cryopyrin-associated periodic syndromes (CAPS), pyogenic diseases such as pyogenic arthritis, pyoderma gangrenosum and acne syndrome (PAPAS), and granulomatous diseases such as Blau syndrome. By identifying the genetic abnormalities and subsequent analyses of the molecular mechanisms underlying these disorders, several critical in vivo pathways for inflammatory processes have been discovered. In this review, three categories of autoinflammatory disorders are discussed: inflammasomopathies, receptor antagonist deficiencies and proteasome disability syndromes. Inflammasomopathies are diseases with dysregulated NLRP3 inflammasome activation, and include CAPS with NLRP3, FMF with MEFV, and PAPAS with PSTPIP1 mutations. Analyses of these diseases have clarified some critical pathways regulating NLRP3 inflammasome signaling. Receptor

antagonist deficiencies include the newly defined deficiency for interleukin-1 receptor antagonist resulting in sterile multifocal osteomyelitis with periostosis and pustulosis, and deficiency for interleukin-36 receptor antagonist resulting in generalized pustular psoriasis. The identification of these genetic abnormalities has revealed a critical role for receptor antagonists of IL-1 family cytokines in regulating neutrophil activation/recruitment. Finally, proteasome disability syndromes with PSMB8 mutations include Nakajo-Nishimura syndrome and related disorders distributed globally. Analyses of these diseases have unexpectedly shown a critical role of the ubiquitin-proteasome system in the regulation or homeostasis of inflammation/metabolism. Since there still remain a number of predicted but undefined hereditary autoinflammatory syndromes, further clinical and genetic approaches are required to discover novel in vivo critical inflammatory pathways.

Cryopyrin-associated periodic syndromes (CAPS) are a group of rare autoinflammatory disorders; many cases of CAPS are caused by mutations in the NLRP3 gene. In these conditions, interleukin (IL)-1 is overproduced, and this overproduction plays a major role in disease onset and progression. CAPS include three variants, ranging in order of increasing severity from familial cold autoinflammatory syndrome, previously termed familial cold urticaria, through Muckle-Wells syndrome, to chronic infantile neurologic cutaneous articular syndrome, also known as neonatal onset multisystemic inflammatory disease.

Diagnosis of CAPS is initially based on clinical manifestations and medical history, and later confirmed genetically. CAPS should be suspected when characteristic skin lesions, typical periodic fever episodes, bone/joint manifestations, and CNS involvement are recognized. CAPS are life-long diseases, and early diagnosis and early treatment with IL-1-targeted therapies may improve prognosis.

Liver involvement in children with Familial Mediterranean fever.

Unal F(1), Cakir M, Baran M, Arıkan C, Yuksekkaya HA, Aydoğdu S.

Author information:

(1)Department of Pediatric Gastroenterology, Hepatology and Nutrition, Dörtçelik Pediatric Hospital, Bursa, Turkey.

AIM: Familial Mediterranean fever is characterised by recurrent, febrile, inflammatory attacks of the serosal membranes. Prolonged inflammatory response is triggered secondary to cytokine stimulation due to reduced activity of pyrin. Inflammatory cytokines play major role in the pathogenesis of acute liver injury; and chronic, recurrent cytokine production may cause chronic hepatitis/cirrhosis. We aimed to analyse liver involvement in children with Familial Mediterranean fever.

PATIENTS: The study included 58 patients with Familial Mediterranean fever. Patients with liver involvement were examined in detail.

RESULTS: Liver involvement was seen in 11 of 58 patients (18.9%). Two patients (3.4%) had abnormal liver enzymes during the diagnostic evaluation, whilst 9 patients (15.5%) were admitted with the features of liver diseases, and had final diagnosis of Familial Mediterranean fever (2 had Budd-Chiari syndrome, 5 had chronic hepatitis/cirrhosis, 2 had acute hepatitis). None of the demographic factors or laboratory findings was different between the patients with or without liver involvement M694V allele was more common in patients with liver involvement but did not reach significant difference (50% vs. 33.6%,  $p=0.21$ ). All the

patients showed clinical and laboratory improvement after colchicine.

**CONCLUSION:** Paediatric hepatologists must keep Familial Mediterranean fever in mind in the patients with cryptogenic hepatitis/cirrhosis especially in regions where hereditary inflammatory diseases are common.

Diagnosis of PFAPA syndrome applied to a cohort of 17 adults with unexplained recurrent fevers.

Cantarini L(1), Vitale A, Bartolomei B, Galeazzi M, Rigante D.

Author information:

(1)Interdepartmental Research Center of Systemic Autoimmune and Autoinflammatory Diseases, Unit of Rheumatology, Policlinico Le Scotte, University of Siena, Italy. cantariniluca@hotmail.com

**BACKGROUND:** The pathophysiology of PFAPA syndrome, mainly characterised by regularly recurring periodic fevers associated with aphthous stomatitis, pharyngitis and/or lymphadenitis, and mostly occurring in the paediatric setting, resembles an acquired autoinflammatory disease. The description of PFAPA syndrome in adult patients is largely increasing.

**OBJECTIVES:** To recognise PFAPA syndrome in a group of adult patients evaluated for recurrent fevers in our Rheumatology Unit.

**METHODS:** To apply current diagnostic criteria for PFAPA syndrome in a group of 359 adults with unexplained recurrent fevers monitored in our Unit between January 2007 and June 2011.

**RESULTS:** We have found 17 out of 359 patients fulfilling the diagnosis of PFAPA syndrome: these patients (10 males, 7 females) were Caucasian with a mean age of  $33.3 \pm 9.5$  years, had recurrent febrile episodes begun at a mean age of  $25.9 \pm 8.3$  years and a mean number of episodes of  $8.3 \pm 5.2$  per year with a mean duration of  $5.5 \pm 1.8$  days. In particular, 7/17 patients had the 3 cardinal signs, the other 10 had a combination of 2 signs. Corticosteroids were given in 14/17 patients;

tonsillectomy was performed in 9/17 patients: corticosteroid responsiveness and tonsillectomy efficacy were observed respectively in 11 and 2 patients.

CONCLUSIONS: Our case highlights the importance of considering PFAPA syndrome in adults presenting with unexplained recurrent fevers and symptoms commonly encountered in general medical practice.

Author information:

(1)Department of Nephrology, Ankara, Turkey. draysunaybal@yahoo.com

OBJECTIVE: The aim of this study was to evaluate the relationship of local intrarenal renin angiotensin system (RAS) with proteinuria in patients with renal AA amyloidosis.

METHODS: Thirty-two patients with renal AA amyloidosis (19 male, mean age:  $45 \pm 13$  years) and sixteen healthy controls (5 male, mean age:  $32 \pm 5$  years) were included in this study. Spot urine samples were obtained to measure urinary angiotensinogen (AGT) using human AGT-ELISA, urinary creatinine and protein levels. Logarithmic transformations of urinary AGT-creatinine ratio  $\log(\text{UAGT}/\text{Ucre})$  and urinary protein-to-creatinine ratio (UPCR) were done to obtain the normal distributions of these parameters.

RESULTS:  $\log(\text{UAGT}/\text{Ucre})$  was significantly higher in patients compared with the controls ( $1.88 \pm 0.92 \mu\text{g/g}$  vs.  $1.25 \pm 0.70 \mu\text{g/g}$ ;  $p = 0.023$ ). Importantly a significantly positive correlation was found between  $\log(\text{UAGT}/\text{Ucre})$  and  $\log\text{UPCR}$  in patients ( $r = 0.595$ ,  $p = 0.006$ ).

CONCLUSIONS: Urinary AGT levels are higher in renal AA amyloidosis patients than in controls. Also, there is a significant positive correlation between urinary AGT and proteinuria in renal AA amyloidosis.

Yonsei Med J. 2012 May;53(3):670.

Yonsei Med J. 2012 Jul 1;53(4):873.

Familial Mediterranean fever (FMF) is an auto-inflammatory disease characterized by periodic episodes of fever and recurrent polyserositis. It is caused by a dysfunction of pyrin (or marenostin) as a result of a mutation within the MEFV gene. It occurs mostly in individuals of Mediterranean origin; however, it has also been reported in non-Mediterranean populations. In this report, we describe the first case of FMF in a Korean child. An eight-year-old boy presented recurrent febrile attacks from an unknown cause, an acute scrotum and renal amyloidosis. He also showed splenomegaly, lymphadenopathy, pleural effusion, ascites and elevated acute phase reactants. After MEFV gene analysis, he was diagnosed as FMF combined with amyloidosis.

Clues to detect tumor necrosis factor receptor-associated periodic syndrome (TRAPS) among patients with idiopathic recurrent acute pericarditis: results of a multicentre study.

Cantarini L(1), Lucherini OM, Brucato A, Barone L, Cumetti D, Iacoponi F, Rigante D, Brambilla G, Penco S, Brizi MG, Patrosso MC, Valesini G, Frediani B, Galeazzi M, Cimaz R, Paolazzi G, Vitale A, Imazio M.

Author information:

(1)Interdepartmental Research Center of Systemic Autoimmune and Autoinflammatory Diseases, Rheumatology Unit, Policlinico Le Scotte, University of Siena, Italy.  
cantariniluca@hotmail.com

**BACKGROUND:** The potential clinical expression of tumor necrosis factor receptor-associated periodic syndrome (TRAPS), in the form of idiopathic recurrent acute pericarditis (IRAP) has not been explored in the medical literature. The aim of this study was to evaluate the incidence of TRAPS mutations in patients with recurrent pericarditis and identify possible clues to TRAPS diagnosis.

**METHODS:** Therefore, 131 consecutive Caucasian IRAP patients were investigated for mutations of the TRAPS gene and prospectively evaluated.

**RESULTS:** Out of 131 patients, 8 (6.1%) carried a mutation in the TNFRSF1A gene. Compared with those without genetic mutations, patients with TRAPS mutations had more frequently a positive family history for pericarditis and periodic fever syndromes ( $p < 0.001$ ), a higher mean number of recurrences after the first year ( $p < 0.001$ ), on colchicine treatment ( $p < 0.001$ ), and a higher need of immunosuppressive therapies ( $p < 0.001$ ).

**CONCLUSION:** TRAPS is a cause of recurrent pericarditis in 6% of unselected cases with recurrent pericarditis. A positive family history for pericarditis or periodic fever syndromes, a poor response to colchicine, recurrences after the first year from the index attack or on colchicine treatment, as well as the need of immunosuppressive agents are clues of the possible presence of TNFRSF1A gene mutations in patients with recurrent pericarditis.

[Serum amyloid a protein concentrations in patients with familial Mediterranean fever].

[Article in Russian]

Dzhndoian ZT.

AIM: the determination of serum amyloid A (SAA) protein concentrations in FMF patients: the colchicine-resistant patients and the patients responded to the different doses of colchicine, and estimation of the risk of the amyloidosis development in these patients. SAA concentration was measured in 58 FMF patients: 23 colchicine-resistant patients without amyloidosis and 35 patients responded to the different doses of colchicine also without amyloidosis as a group of comparison. Serum SAA concentration was measured by ELISA (Enzyme Linked-Immuno-Sorbent-Assay) method using "ANOGEN" kit (Canada). Serum SAA concentration was the same in both groups of the patients: colchicine-resistant patients and patients responded to the different doses of colchicine. The findings of our study indicate that the risk of the amyloidosis development is the same in colchicine-resistant patients and patients responded to the different doses of colchicine.

Plasma ghrelin levels in patients with familial Mediterranean fever.

Polat Z(1), Kilciler G, Ozel AM, Kara M, Kantarcioglu M, Uygun A, Bagci S.

Author information:

(1)Department of Gastroenterology, Gulhane Military Medical Academy, School of Medicine, Etlik, Ankara, Turkey.

BACKGROUND: Familial Mediterranean fever (FMF) is an auto-inflammatory disorder characterized by febrile attacks. Increased acute-phase reactants are characteristic during febrile attacks. Ghrelin is a natural G-protein that

decreases secretion of pro-inflammatory cytokines and acts as anti-inflammatory agent. The aim of this study was to investigate whether there is any change in ghrelin levels and whether increases in ghrelin levels can be used as a marker in these patients.

**SUBJECTS AND METHODS:** Thirty-seven male patients and 30 healthy men as a control group were included in the study. Blood samples were obtained for ghrelin measurements both before the attacks (pre-attack period; ghrelin 1 group) and during the attacks (ghrelin 2 group). Samples were kept at -80°C until the analysis was conducted and plasma ghrelin levels were measured using an immune-sorbent assay method.

**RESULTS:** Mean ghrelin levels measured during the attacks were significantly higher ( $11.01 \pm 4.78$  pg/ml) as compared to pre-attack levels ( $5.78 \pm 2.17$  pg/ml;  $p < 0.001$ ). Similarly, mean ghrelin levels measured in FMF patients during an attack were significantly different from that of the control group ( $6.57 \pm 4.13$  pg/ml;  $p < 0.001$ ).

**CONCLUSIONS:** In this study, high ghrelin levels were measured during attacks in FMF patients. This finding is in line with previous results regarding the fact that inflammatory response arising during an FMF attack is an acute inflammatory event. Our findings suggest that ghrelin levels measured during FMF attacks could be used as a biochemical indicator for the FMF attack in FMF patients and that it could be used for support of the diagnosis of the disease.

Sustained response and prevention of damage progression in patients with neonatal-onset multisystem inflammatory disease treated with anakinra: a cohort study to determine three- and five-year outcomes.

Sibley CH(1), Plass N, Snow J, Wiggs EA, Brewer CC, King KA, Zalewski C, Kim HJ, Bishop R, Hill S, Paul SM, Kicker P, Phillips Z, Dolan JG, Widemann B, Jayaprakash N, Pucino F, Stone DL, Chapelle D, Snyder C, Butman JA, Wesley R, Goldbach-Mansky R.

**OBJECTIVE:** Blocking interleukin-1 with anakinra in patients with the autoinflammatory syndrome neonatal-onset multisystem inflammatory disease (NOMID) reduces systemic and organ-specific inflammation. However, the impact of long-term treatment has not been established. This study was undertaken to evaluate the long-term effect of anakinra on clinical and laboratory outcomes and safety in patients with NOMID.

**METHODS:** We conducted a cohort study of 26 NOMID patients ages 0.80-42.17 years who were followed up at the NIH and treated with anakinra 1-5 mg/kg/day for at least 36 months. Disease activity was assessed using daily diaries, questionnaires, and C-reactive protein level. Central nervous system (CNS) inflammation, hearing, vision, and safety were evaluated.

**RESULTS:** Sustained improvements in diary scores, parent's/patient's and physician's global scores of disease activity, parent's/patient's pain scores, and inflammatory markers were observed (all  $P < 0.001$  at 36 and 60 months). At 36 and 60 months, CNS inflammation was suppressed, with decreased cerebrospinal fluid white blood cell counts ( $P = 0.0026$  and  $P = 0.0076$ , respectively), albumin levels, and opening pressures ( $P = 0.0012$  and  $P < 0.001$ , respectively). Most patients showed stable or improved hearing. Cochlear enhancement on magnetic resonance imaging correlated with continued hearing loss. Visual acuity and peripheral vision were stable. Low optic nerve size correlated with poor visual field. Bony lesions progressed. Adverse events other than viral infections were rare, and all patients continued to receive the medication.

**CONCLUSION:** These findings indicate that anakinra provides sustained efficacy in the treatment of NOMID for up to 5 years, with the requirement of dose escalation. Damage progression in the CNS, ear, and eye, but not bone, is preventable. Anakinra is well tolerated overall.

*Toxoplasma gondii* infection inhibits Th17-mediated spontaneous development of arthritis in interleukin-1 receptor antagonist-deficient mice.

Washino T(1), Moroda M, Iwakura Y, Aosai F.

Author information:

(1)Department of Infection and Host Defense, Chiba University Graduate School of Medicine, Chiba, Japan.

Interleukin 1 receptor antagonist (IL-1Ra)-deficient BALB/c mice develop spontaneous arthritis resembling human rheumatoid arthritis. We herein report that infection with *Toxoplasma gondii*, an intracellular protozoan, is capable of ameliorating the spontaneous development of arthritis in IL-1Ra-deficient mice. The onset of arthritis development was delayed and the severity score of

arthritis was significantly suppressed in *T. gondii*-infected mice. Expression of IL-12p40 mRNA from CD11c(+) cells of mesenteric lymph nodes (mLN) and spleen markedly increased at 1 week after peroral infection. While CD11c(+) cells also produced IL-10, IL-1 $\beta$ , and IL-6, CD4(+) T cells from *T. gondii*-infected mice expressed significantly high levels of T-bet and gamma interferon (IFN- $\gamma$ ) mRNA in both mLN and spleen. Levels of GATA-3/IL-4 mRNA or ROR $\gamma$ t/IL-17 mRNA decreased in the infected mice, indicating Th1 cell polarization and the reduction of Th2 and Th17 cell polarization. The severity of arthritis was related to Th1 cell polarization accompanied by Th17 cell reduction, demonstrating the protective role of the *T. gondii*-derived Th1 response against Th17 cell-mediated arthritis in IL-1Ra-deficient mice.

OTHER THEMES PUBLISHED IN THIS IMMUNOLOGY IN THE CLINIC REVIEW SERIES Allergy, Host Responses, Cancer, Type 1 diabetes and viruses, Metabolic diseases.SUMMARY: The disease-based discovery of the molecular basis for autoinflammatory diseases has led not only to a rapidly growing number of clinically and genetically identifiable disorders, but has unmantled key inflammatory pathways such as the potent role of the alarm cytokine interleukin (IL)-1 in human disease. Following its initial failures in the treatment of sepsis and the moderate success in the treatment of rheumatoid arthritis, IL-1 blocking therapies had a renaissance in the treatment of a number of autoinflammatory conditions, and IL-1 blocking

therapies have been Food and Drug Administration (FDA)-approved for the treatment of the autoinflammatory conditions: cryopyrin-associated periodic syndromes (CAPS). CAPS and deficiency of the IL-1 receptor antagonist (DIRA), both genetic conditions with molecular defects in the IL-1 pathway, have provided a pathogenic rationale to IL-1 blocking therapies, and the impressive clinical results confirmed the pivotal role of IL-1 in human disease. Furthermore, IL-1 blocking strategies have shown clinical benefit in a number of other genetically defined autoinflammatory conditions, and diseases with clinical similarities to the monogenic disorders and not yet identified genetic causes. The discovery that IL-1 is not only triggered by infectious danger signals but also by danger signals released from metabolically 'stressed' or even dying cells has extended the concept of autoinflammation to disorders such as gout, and those that were previously not considered inflammatory, such as type 2 diabetes, coronary artery disease, obesity and some degenerative diseases, and provided the conceptual framework to target IL-1 in these diseases. Despite the tremendous success of IL-1 blocking therapy, the use of these agents in a wider spectrum of autoinflammatory conditions has uncovered disease subsets that are not responsive to IL-1 blockade, including the recently discovered proteasome-associated autoinflammatory syndromes such as chronic atypical neutrophilic dermatitis with lipodystrophy and elevated temperatures (CANDLE), Japanese autoinflammatory syndrome with lipodystrophy (JASL), Nakajo-Nishimura syndrome (NNS) and joint contractures, muscle atrophy, panniculitis induced lipodystrophy (JMP), and urge the continued quest to characterize additional dysregulated innate immune pathways that cause autoinflammatory conditions.

Immunology in clinic review series; focus on autoinflammatory diseases: role of inflammasomes in autoinflammatory syndromes.

Ozkurede VU(1), Franchi L.

Author information:

(1)Department of Pathology and Comprehensive Cancer Center, University of Michigan Medical School, Ann Arbor, MI 48109, USA.

OTHER THEMES PUBLISHED IN THIS IMMUNOLOGY IN THE CLINIC REVIEW SERIES Allergy, Host Responses, Cancer, Type 1 diabetes and viruses, Metabolic diseases.SUMMARY: Autoinflammatory syndromes are disorders characterized by the hyperactivation of the innate immune system in the absence of microbial infection or autoantibody production. Some autoinflammatory syndromes are associated with recurrent episodes of fever and systemic inflammation that are caused by dysregulated activation of inflammasomes, molecular platforms responsible for the activation of caspase-1 and the production of interleukin (IL)-1 $\beta$ . In this review we will discuss the role of IL-1 $\beta$  and the inflammasomes in host defence and how mutations of two genes, NLRP3 and PYRIN, leads to the autoinflammatory syndromes, cryopyrin-associated periodic syndromes (CAPS) and familial Mediterranean fever (FMF). Both CAPS and FMF are characterized by increased inflammasome activity and overproduction of IL-1 $\beta$  which is ultimately responsible for disease manifestations. Importantly, understanding the molecular mechanisms of these syndromes has led to effective treatment for these rare diseases with biological drugs that target IL-1 $\beta$ -mediated signalling.

**SUMMARY:** Initiation of a successful immune response requires a working set of sensors that detect any noxious agent within the cellular microenvironment and molecular platforms that process this signal to trigger an appropriate effector response. Pattern recognition receptors can engage different signalling cascades that lead to proinflammatory gene expression. At the same time, transcription-independent events such as activation of proteases and/or phagocytosis are also initiated. The inflammasome pathway constitutes a signalling platform that leads to the activation of so-called inflammatory caspases, most notably caspase-1, which plays a pivotal role in the cleavage and thus maturation of proinflammatory cytokines, but also in the induction of pyroptosis, a special type of cell death. In this review we elaborate on the currently known inflammasome complexes with a special focus on the mechanism behind their activation. Understanding these mechanisms could provide important information regarding the potential signalling nodes that might be targeted for therapeutic intervention.

Clinical and genetic features of hereditary periodic fever syndromes in Hispanic patients: the Chilean experience.

Vergara C(1), Borzutzky A, Gutierrez MA, Iacobelli S, Talesnik E, Martinez ME, Stange L, Basualdo J, Maluje V, Jimenez R, Wiener R, Tinoco J, Jarpa E, Aróstegui JI, Yagüe J, Alvarez-Lobos M.

Author information:

(1)Department of Rheumatology and Clinical Immunology, Pontificia Universidad Católica de Chile, Santiago, Chile.

Hereditary periodic fever syndromes (HPFS) are rare genetic diseases characterized by recurrent episodes of inflammation. Little information is available concerning HPFS in Latin American Hispanic population. The purpose of this study was to determine the clinical and genetic features of HPFS in Chilean population. A multicenter retrospective study of Hispanic Chilean patients with genetically confirmed HPFS was performed. We included 13 patients, 8 with familial Mediterranean fever (FMF) and 5 with TNF receptor-associated periodic syndrome (TRAPS), evaluated at rheumatology or pediatric rheumatology clinics between January 2007 and December 2010. Median age of symptoms onset was 8 years (range 1-35) and 8 years (range 0.3-21) for FMF and TRAPS, respectively. Median duration of fever was 3 days (range 2.5-15) for FMF and 21 days (range 9.5-30) for TRAPS. Genotyping of the MEFV gene in FMF patients revealed a homozygous M694V missense mutation in one patient, and heterozygous missense mutations in seven patients: M694V (n = 3), E148Q, R717H, A744S, and A511V. Sequencing of the TNFRSF1A gene in TRAPS patients revealed heterozygous missense mutations in four patients: T50M, C30R, R92Q, and IVS3+30:G→A, and a two-base pair deletion (IVS2-17\_18del2bpCT) in one patient. Mutation in MEFV R717H and mutations in TNFRSF1A IVS2-17\_18del2bpCT and IVS3+30:G→A are novel and have not been described previously. This study reports the largest series of genetically confirmed HPFS

in Latin America, and adds evidence regarding the clinical and genetic characteristics of patients with FMF and TRAPS in Hispanic population. Mutations identified in MEFV and TNFRSF1A genes include defects reported in other ethnicities and novel mutations.

Systemic juvenile idiopathic arthritis (SJIA) is a chronic autoinflammatory condition. The association with macrophage activation syndrome, and the therapeutic efficacy of inhibiting monocyte-derived cytokines, has implicated these cells in SJIA pathogenesis. To characterize the activation state (classical/M1 vs. alternative/M2) of SJIA monocytes, we immunophenotyped monocytes using several approaches. Monocyte transcripts were analyzed by microarray and quantitative PCR. Surface proteins were measured at the single cell level using flow cytometry. Cytokine production was evaluated by intracellular staining and ELISA. CD14(++)CD16(-) and CD14(+)CD16(+) monocyte subsets are activated in SJIA. A mixed M1/M2 activation phenotype is apparent at the single cell level, especially during flare. Consistent with an M2 phenotype, SJIA monocytes produce IL-1 $\beta$  after LPS exposure, but do not secrete it. Despite the inflammatory nature of active SJIA, circulating monocytes demonstrate significant anti-inflammatory features. The persistence of some of these phenotypes during clinically inactive disease argues that this state reflects compensated inflammation.

Chronic infantile neurological cutaneous and articular syndrome (CINCA), also known as neonatal-onset multisystem inflammatory disease (NOMID), is a dominantly inherited systemic autoinflammatory disease and is caused by a heterozygous germline gain-of-function mutation in the NLRP3 gene. We recently found a high incidence of NLRP3 somatic mosaicism in apparently mutation-negative CINCA/NOMID patients using subcloning and subsequent capillary DNA sequencing. It is important to rapidly diagnose somatic NLRP3 mosaicism to ensure proper treatment.

However, this approach requires large investments of time, cost, and labour that prevent routine genetic diagnosis of low-level somatic NLRP3 mosaicism. We developed a routine pipeline to detect even a low-level allele of NLRP3 with statistical significance using massively parallel DNA sequencing. To address the critical concern of discriminating a low-level allele from sequencing errors, we first constructed error rate maps of 14 polymerase chain reaction products covering the entire coding NLRP3 exons on a Roche 454 GS-FLX sequencer from 50 control samples without mosaicism. Based on these results, we formulated a statistical confidence value for each sequence variation in each strand to discriminate sequencing errors from real genetic variation even in a low-level allele, and thereby detected base substitutions at an allele frequency as low as 1% with 99.9% or higher confidence.

enussi@yahoo.com

The association between familial Mediterranean fever (FMF), early atherosclerosis, and electrocardiographic markers for arrhythmias remains controversial. There are conflicting results as to the occurrence of high QT dispersion in FMF. The aim of the present study was to further investigate repolarization dynamics and other repolarization-associated pro-arrhythmogenic markers in FMF patients. To explore repolarization in FMF, patients who responded well to colchicine and patients who had not responded to colchicine, yet were amyloidosis-free, were included. We aimed to evaluate whether increased

inflammatory burden, a characteristic of non-responsive patients, was specifically associated with abnormal repolarization. Included in the study were 53 FMF patients (27 colchicine non-responders) and 53 age- and sex-matched control subjects. Electrocardiograms were performed under strict standards. QT variability parameters were computed with custom-made computer software. No significant difference in any of the QT dynamic parameters was found in either FMF group compared with the healthy controls. Mean values of QT variability index, regardless of colchicine response, were similar to previously published results for healthy persons. In conclusion, patients with FMF who are continuously treated with colchicine and have not developed amyloidosis, regardless of their clinical response, have normal QT variability parameters, indicating normal repolarization dynamics and suggesting no increased risk of repolarization-associated cardiac arrhythmias.

Impact of IL-1 signalling on experimental uveitis and arthritis.

Planck SR(1), Woods A, Clowers JS, Nicklin MJ, Rosenbaum JT, Rosenzweig HL.

Author information:

(1)Casey Eye Institute, Oregon Health & Science University, Portland, OR 97239, USA.

**BACKGROUND:** Uveitis, or inflammatory eye disease, is a common extra-articular manifestation of many systemic autoinflammatory diseases involving the joints. Anakinra (recombinant interleukin (IL)-1 receptor antagonist (Ra)) is an effective therapy in several arthritic diseases; yet, few studies have investigated the extent to which IL-1 signalling or IL-1Ra influences the onset and/or severity of uveitis.

**OBJECTIVE:** To seek possible links between arthritis and uveitis pathogenesis related to IL-1 signalling.

**METHODS:** The eyes of IL-1Ra-deficient BALB/c mice were monitored histologically and by intravital videomicroscopy to determine if uveitis developed along with

the expected spontaneous arthritis in ankles and knees. Expression levels of IL-1R and its negative regulators (IL-1Ra, IL-1RII, IL-1RAcP and single Ig IL-1R-related molecule) in eye and joint tissues were compared. Differences in uveitis induced by intraocular injection of lipopolysaccharide (LPS) in mice lacking IL-1R or IL-1Ra were assessed.

RESULTS: Deficiency in IL-1Ra predisposes to spontaneous arthritis, which is exacerbated by previous systemic LPS exposure. The eye, however, does not develop inflammatory disease despite the progressive arthritis or LPS exposure.

Organ-specific expression patterns for IL-1Ra and negative regulators of IL-1 activity were observed that appear to predict predisposition to inflammation in each location in IL-1Ra knockout mice. The eye is extremely sensitive to locally administered LPS, and IL-1Ra deficiency markedly exacerbates the resulting uveitis.

CONCLUSION: This study demonstrates that IL-1Ra plays an important role in suppressing local responses in eyes injected with LPS and that there is discordance between murine eyes and joints in the extent to which IL-1Ra protects against spontaneous inflammation.

Familial Mediterranean fever (FMF) is an autosomal recessive hereditary disease characterized by recurrent attacks of fever, usually accompanied by sterile polyserositis. Although amyloidosis is the most common renal involvement, non-amyloid renal lesions, such as glomerulonephritis, have been described in patients with FMF. In this report, we present the first case of an FMF patient with heterozygous mutation of E148Q, mesangial proliferative glomerulonephritis, and no amyloidosis. While the association of mutation E148Q with renal involvement is still obscure, colchicine treatment is useful in mesangial proliferative glomerulonephritis with FMF.

We aimed to evaluate some of the vascular biomarkers in newly diagnosed, colchicine naive familial Mediterranean fever (FMF) patients. Our primary aim was to investigate the effect of regular colchicine treatment on these variables. Twenty-four (12 males [M] and 12 females [F],  $33.3 \pm 13.4$  years) newly diagnosed FMF patients were included in the study. These patients were started on colchicine treatment following the initial assessment and were studied again no earlier than 2 months. Five patients were lost to follow-up, and assessment of the on-treatment patients was performed on the remaining 19 patients (8 M and 11 F,  $33.6 \pm 11.8$  years). There were 19 healthy subjects (11 M and 8 F,  $32.2 \pm 7.2$  years) who served as a control group. Cellular adhesion molecules (CAMs; soluble intercellular adhesion molecule-1 [sICAM-1] and soluble CD146 [sCD146]), plasminogen activator inhibitor-1 (PAI-1), fetuin-A and hs-CRP were studied. Examinations were performed on attack-free periods. The levels of hs-CRP, fetuin-A, sICAM-1, and PAI-1 were significantly higher in newly diagnosed patients compared to those of controls ( $P < 0.05$ ). All studied parameters were significantly downregulated after regular colchicine therapy ( $P < 0.05$ ). Comparison of on-treatment data with controls showed that the levels of the vascular biomarkers, except sCD146, were similar between the groups ( $P > 0.05$ ). On-treatment sCD146 was found significantly lower than the controls ( $P < 0.05$ ). In regression analysis, none of the independent variables in the model significantly predicted the vascular biomarkers ( $P > 0.05$ ). Administration of therapeutic doses of colchicine markedly reduces vascular injury parameters and normalizes the values in FMF.

Familial and acquired hemophagocytic lymphohistiocytosis.

Janka GE(1).

Author information:

(1)Department of Hematology and Oncology, Children's University Hospital, Hamburg, Germany. janka@uke.uni-hamburg.de

Hemophagocytic lymphohistiocytosis (HLH) is a life-threatening syndrome in which an uncontrolled and ineffective immune response, triggered in most cases by infectious agents, leads to severe hyperinflammation. Familial forms of HLH (FHL), which are increasingly found also in adolescents and adults, are due to genetic defects leading to impaired function of natural killer cells and cytotoxic T cells. These mutations occur either in the perforin gene or in genes important for the exocytosis of cytotoxic granules. Cytotoxic granules contain perforin and granzymes, which induce apoptosis upon entering (infected) target cells. Additionally, perforin is important for the downregulation of the immune response. Acquired forms of HLH are encountered in association with (usually) viral infections, autoinflammatory/autoimmune diseases, malignant diseases, and acquired immune deficiency states (e.g., after organ transplantation). Treatment of HLH includes immune-suppressive and immune-modulatory agents, cytostatic drugs, and biological response modifiers. For patients with FHL, stem cell transplantation is indicated and can be curative.

Different clinical presentation of the hyperimmunoglobulin D syndrome (HIDS) (four cases from Turkey).

Tas DA(1), Dinkci S, Erken E.

Author information:

(1)Rheumatology-Immunology Department, Faculty Of Medicine, Cukurova University, Balcali Hastanesi, Sariçam, Adana, Turkey 01330. arslan\_didem@yahoo.com

Hyperimmunoglobulin D syndrome (HIDS) is one of the autoinflammatory syndromes which are characterized by febrile attacks. Duration and frequency of the febrile attacks, as well as typical organ involvements vary greatly. Recently, it is possible to reach more reliable data by the possibilities that are opened up by

molecular genetics in order to highlight the aetiopathogenesis of this group of diseases. Typical patients with HIDS have an onset of disease in the first year of life. Here, we report four Turkish HIDS cases; three of whom, the symptoms started at a later age. The diagnoses were made by relevant clinical symptoms along with MVK mutations detected by DNA sequencing method. As summarised in this article, HIDS could be presented with a broad spectrum of symptoms. Although most of the HIDS patients are reported from Europe and especially Dutch ancestry, case reports are presented from all over the world. For this reason, HIDS should be kept in mind for the differential diagnosis of periodic fever syndromes or before accepting an FMF patient as colchicine resistant. We suppose that the phenomenon of "later-onset HIDS" should shed light into unresolved clinical problems of patients with periodic fever. Especially in countries that FMF is more frequent such as Turkey, even though the symptoms start later than classic cases, HIDS should be kept in mind for differential diagnosis of periodic fever syndromes.

Femoral artery aneurysms (FAAs) are very rare, and their natural history is not well understood. In this study, we sought to analyze the pathogenesis of inflammatory FAAs in interleukin-1 receptor antagonist-deficient (IL-1Ra(-/-)) B6 mice. Systolic arterial pressures and plasma lipid levels of IL-1Ra(-/-) mice and wild-type (WT) mice did not differ significantly. However, IL-1Ra(-/-) mice spontaneously developed fusiform FAAs. Real-time PCR of 9-month-old IL-1Ra(-/-) mice revealed significantly increased mRNA levels of IL-1 $\beta$  (6.6-fold), tumor

necrosis factor- $\alpha$  (TNF- $\alpha$ ) (12.4-fold), and matrix metalloproteinase-9 (6.0-fold) compared with WT mice. Histological analysis revealed numerous inflammatory cells around the FAAs in IL-1Ra(-/-) mice, and elastin staining showed destruction of both the internal and external elastic lamina in IL-1Ra(-/-) mice. Afterward, macrophage function was studied. After lipopolysaccharide (1  $\mu$ g/mL) stimulation, IL-1Ra-deficient macrophages produced much higher levels of TNF- $\alpha$  than those from WT mice. Finally, we performed bone marrow cell transplantation. FAAs with many inflammatory cells in the adventitia were detected in several WT mice that received bone marrow cells from IL-1Ra(-/-) mice (44%), but not from WT mice (0%). Our study is the first to demonstrate that IL-1Ra deficiency in inflammatory cells disrupts immune system homeostasis and induces inflammatory FAAs in IL-1Ra(-/-) B6 mice. We believe that these mice will provide much information about the natural history and management of FAAs.

NOD2/CARD15 gene mutations in patients with familial Mediterranean fever.

Berkun Y(1), Karban A, Padeh S, Pras E, Shinar Y, Lidar M, Livneh A, Bujanover Y.

Author information:

(1)Department of Pediatrics and Pediatric Rheumatology, Hadassah Hebrew University Medical Center, Mount Scopus, Jerusalem, Israel. [berkun@post.tau.ac.il](mailto:berkun@post.tau.ac.il)

**OBJECTIVE:** Familial Mediterranean fever (FMF) and Crohn's disease are autoinflammatory disorders, associated with genes (MEFV and NOD2/CARD15, respectively) encoding for regulatory proteins, important in innate immunity, apoptosis, cytokine processing, and inflammation. Although mutations in the MEFV gene were shown to modify Crohn's disease, the role of NOD2/CARD15 gene mutations in the FMF disease phenotype was never studied before.

**PATIENTS AND METHODS:** The cohort consisted of 103 consecutive children with FMF,

followed in a single referral center. NOD2/CARD15 genotypes were analyzed in all patients and 299 ethnically matched unaffected controls. Demographic data, clinical characteristics, and disease course of FMF patients with and without NOD2/CARD15 mutation were compared.

**RESULTS:** A single NOD2/CARD15 mutation was detected in 10 (9.7%) FMF patients and 26 (8.7%) controls. No homozygous or compound heterozygous subjects were discovered in the 2 groups. FMF patients carrying a NOD2/CARD15 mutation had a higher rate of erysipelas-like erythema and acute scrotum attacks, a trend for a higher rate of colchicine resistance and a more severe disease as compared with patients without mutations.

**CONCLUSIONS:** NOD2/CARD15 mutations are not associated with an increased susceptibility to develop FMF. Nevertheless, the presence of these mutations in FMF patients appears to be associated with a trend to a more severe disease.

Erysipelas-like erythema as the presenting feature of familial Mediterranean fever.

Lidar M(1), Doron A, Barzilai A, Feld O, Zaks N, Livneh A, Langevitz P.

Author information:

(1)Rheumatology Unit and Medicine F, Heller Institute of Medical Research, Sheba Medical Center, Tel-Hashomer, affiliated with Sackler School of Medicine, Tel Aviv University, Tel Aviv, Israel. [merav.lidar@sheba.health.gov.il](mailto:merav.lidar@sheba.health.gov.il)

**BACKGROUND:** 'Erysipelas-like' erythema (ELE) is a well recognized, although uncommon, manifestation of familial Mediterranean fever (FMF), which is frequently mistaken for infectious erysipelas, especially when forming the initial disease presentation.

**AIM:** To clinically and genetically characterize ELE as the first manifestation of FMF.

**METHODS:** FMF patients with ELE as the first disease presentation (study group), were compared with FMF patients with ELE, appearing during the disease course (control group I), and to those FMF patients who never had ELE (control group II).

**RESULTS:** Patients of the study group were comparable to patients without ELE with respect to all demographic, clinical and genetic features studied, and yet differed from patients with ELE appearing later in the disease course in disease severity score ( $1.7 \pm 0.4$  vs.  $2.4 \pm 0.6$ ,  $P = 0.01$ ), length of diagnosis delay ( $7.2 \pm 6.4$  vs.  $2.3 \pm 3.3$  years,  $P=0.037$ ), age of FMF onset ( $24.8 \pm 19.9$  vs.  $5.6 \pm 5.7$  years of age,  $P=0.014$ ) and rate of homozygosity to the M694V mutation (14.3% vs. 68.7% respectively). ELE traits in the study and control groups were alike.

**CONCLUSIONS:** FMF with ELE as the first disease manifestation form an uncommon subgroup, clinically and genetically diverging from the rest of the FMF-ELE patients.

What do cytokine profiles tell us about subsets of juvenile idiopathic arthritis?

Cimaz R(1), Moretti D, Pagnini I, Marino A, Cantarini L, Simonini G.

Author information:

(1)AOU Meyer, Viale Pieraccini 24, 50139, Firenze, Italy. r.cimaz@meyer.it

Classification of juvenile idiopathic arthritis is an ongoing process and up to now has been predominantly based on clinical manifestations--mainly number of joints at onset of disease. In the meantime, basic studies have advanced our knowledge regarding the disease pathogenesis. Unfortunately, studies of cytokines and cytokine polymorphisms have not followed the predominantly clinical International League of Associations for Rheumatology classification in that no significant biological differences among the different disease categories have been demonstrated with robust associations. Only systemic-onset disease seems to

be quite different from other disease categories with regard to biologic mechanisms; indeed, it now seems closer to autoinflammatory than to classic autoimmune diseases. New players in the immunologic basis of juvenile idiopathic arthritis (eg, interleukin-17 and regulatory T cells) are also discussed in this review.

Systemic arthritis in children: a review of clinical presentation and treatment.

Gurion R(1), Lehman TJ, Moorthy LN.

Author information:

(1)Division of Pediatric Rheumatology, Rainbow Babies & Children's Hospital, University Hospitals Case Medical Center, 11100 Euclid Avenue, Cleveland, OH 44106, USA.

Systemic juvenile idiopathic arthritis (sJIA) constitutes a small part of juvenile idiopathic arthritis (JIA), yet has a disproportionally higher rate of mortality. Despite being grouped under JIA, it is considered to be a multifactorial autoinflammatory disease. The objective of this paper is to review the epidemiology, pathogenesis, genetics, clinical manifestations, complications, therapy, prognosis, and outcome of sJIA. The presentation and clinical manifestations of sJIA have not changed much in the past several decades, but the collective understanding of the pathogenesis and the development of new targeted therapies (particularly the biologic agents) have transformed and improved the disease outcome for children with sJIA.

Gulf War syndrome as a part of the autoimmune (autoinflammatory) syndrome induced by adjuvant (ASIA).

Israeli E(1).

Author information:

(1)The Zabłudowicz Center for Autoimmune Diseases, Chaim Sheba Medical Center, Tel-Hashomer, Israel. eitanister@gmail.com

Gulf War syndrome (GWS) is a multi-symptom condition comprising a variety of signs and symptoms described in the literature, which not been fully resolved. The various symptoms of the condition include muscle fatigue and tiredness, malaise, myalgia, impaired cognition, ataxia, diarrhoea, bladder dysfunction, sweating disturbances, headaches, fever, arthralgia, skin rashes, and gastrointestinal and sleep disturbances. In addition, excessive chemical sensitivity and odour intolerance is reported. The aetiology of the condition is unclear, but many reviews and epidemiological analyses suggest association with pyridostigmine bromide (PB), certain vaccination regimes, a variety of possible chemical exposures, including smoke from oil-well fires or depleted uranium from shells, as well as physical and psychological stress. Recently, Shoenfeld et al. suggested that four conditions--siliconosis, macrophagic myofaciitis (MMF), GWS and post-vaccination phenomena--that share clinical and pathogenic resemblances, may be incorporated into common syndrome called 'Autoimmune (Autoinflammatory) Syndrome induced by Adjuvants' (ASIA). Symptoms and signs of the four conditions described by Shoenfeld et al. show that at least eight out of ten main symptoms are in correlation in all four conditions. Namely, myalgia, arthralgias, chronic fatigue, neurological cognitive impairment, gastrointestinal symptoms, respiratory symptoms, skin manifestations and appearance of autoantibodies. Regardless of the aetiology of GWS, be it exposure to environmental factors or chemical drugs, vaccinations or the adjuvants in them, GWS fits well with the definition of ASIA and is included as part of 'Shoenfeld's syndrome'.

## The role of regulatory T cells in familial Mediterranean fever (FMF).

Rimar D(1), Rosner I, Slobodin G, Boulman N, Toubi E, Kessel A, Peri R, Rozenbaum M.

### Author information:

(1)Rheumatology Unit, Bnai Zion Medical Center, POB 4940, Haifa 31048, Israel.  
doronrimar@gmail.com

The role of regulatory T cells (T-regs) in familial Mediterranean fever (FMF) was never evaluated. Preliminary studies that we have conducted suggested a rise in the number of regulatory T cells after FMF attacks reaching a maximal level at 7 days. The aim of this study was to evaluate the percentage and activity of regulatory T cells in FMF. Six patients with refractory FMF and six healthy controls were evaluated. The percentage of T-reg cells and forkhead box protein 3 (Foxp3) expression was evaluated and compared between four states: FMF in remission, FMF at the first day of an attack, FMF 7 days after the start of the attack, and healthy controls. Four females and two males were included. All patients had FMF with high severity score,  $2.8 \pm 0.4$  (0-3). The mean age was  $31.6 \pm 6.2$ . The mean age at onset was  $9.3 \pm 9.3$ . The mean colchicine dose was  $2.6 \text{ mg} \pm 0.4$ . The expression of Foxp3 7 days after the attacks was significantly higher than in FMF at the first day of the attack, FMF in remission, and healthy controls  $10.08 \pm 2.36$  vs.  $7.005 \pm 0.3$  vs.  $5.3 \pm 1.06$  vs.  $4.44 \pm 1.8$ ;  $p < 0.05$  (Fig.1). The percentage of T-regs in peripheral blood was not statistically different between the four groups. The expression of Foxp3 by T-regs increases 7 days after attacks of FMF. Anti-inflammatory cytokines interleukin-10 and TGF- $\beta$  are known to activate T-regs and have been reported to increase in FMF attacks in line with the present findings. It is suggested that T-regs may have a role in terminating FMF attacks.

gyenokya@jhsph.edu

The etiology of recurrent attacks of serositis in familial Mediterranean fever (FMF) is not completely understood. Uncontrolled clinical case series have reported that factors associated with emotional, physiological, or physical stress precede and might trigger the attacks. This case-crossover study, conducted between July 2007 and May 2008, aimed to estimate the role of precipitating factors in attacks in a sample of Armenian FMF patients in Yerevan, Armenia, where 104 patients contributed 55 case and 189 control time periods. The authors used conditional logistic regression to compare frequency of exposure to stressful events, strenuous physical activity, menstrual periods, and high-fat food consumption prior to FMF attacks and on attack-free random days. Multiple stressful life events predicted FMF attacks 2 days following the event. After adjustment for treatment, an additional stressful event was associated with an estimated 70% increase in the odds of having an FMF attack on the second day (95% confidence interval: 1.04, 2.79). High levels of perceived stress were also associated with FMF attacks. Physical exertion and high-fat diet did not increase the likelihood of FMF attacks. The possibility of prevention of attacks in FMF needs to be tested through stress-reduction interventions.

Bridging the gap between the clinician and the patient with cryopyrin-associated periodic syndromes.

Cantarini L, Lucherini OM, Frediani B, Brizi MG, Bartolomei B, Cimaz R, Galeazzi M, Rigante D.

Cryopyrin-associated periodic syndromes are categorized as a spectrum of three

autoinflammatory diseases, namely familial cold auto-inflammatory syndrome, Muckle-Wells syndrome and chronic infantile neurological cutaneous articular syndrome. All are caused by mutations in the NLRP3 gene coding for cryopyrin and result in active interleukin-1 release: their rarity and shared clinical indicators involving skin, joints, central nervous system and eyes often mean that correct diagnosis is delayed. Onset occurs early in childhood, and life-long therapy with interleukin-1 blocking agents usually leads to tangible clinical remission and inflammatory marker normalization in a large number of patients, justifying the need to facilitate early diagnosis and thus avoid irreversible negative consequences for tissues and organs.

Th17 response and inflammatory autoimmune diseases.

Waite JC(1), Skokos D.

Author information:

(1)Department of Immunity and Inflammation, Regeneron Pharmaceuticals, Inc., 777 Old Saw Mill River Road, Tarrytown, NY 10591, USA.

The proinflammatory activity of T helper 17 (Th17) cells can be beneficial to the host during infection. However, uncontrolled or inappropriate Th17 activation has been linked to several autoimmune and autoinflammatory pathologies. Indeed, preclinical and clinical data show that Th17 cells are associated with several autoimmune diseases such as arthritis, multiple sclerosis, psoriasis, and lupus. Furthermore, targeting the interleukin-17 (IL-17) pathway has attenuated disease severity in preclinical models of autoimmune diseases. Interestingly, a recent report brings to light a potential role for Th17 cells in the autoinflammatory disorder adult-onset Still's disease (AOSD). Whether Th17 cells are the cause or are directly involved in AOSD remains to be shown. In this paper, we discuss the biology of Th17 cells, their role in autoimmune disease development, and in AOSD in particular, as well as the growing interest of the pharmaceutical industry in their use as therapeutic targets.

Evaluation of cochlear function using transient evoked otoacoustic emission in children with Familial Mediterranean Fever.

Uysal İÖ(1), Gürbüzler L, Kaya A, Koç S, Gültürk S, Cevit O, Müderris S.

Author information:

(1)Department of Otorhinolaryngology, Cumhuriyet University School of Medicine, Sivas, Turkey. dr.iuysal@hotmail.com

**OBJECTIVE:** The aim of this study was to investigate cochlear functions in children with Familial Mediterranean Fever (FMF).

**METHODS:** Fifty-six FMF patients (112 ears) and 30 healthy control subjects (60 ears) were included in the study. Transient evoked otoacoustic emission (TEOAE) was investigated. Numerical measurements of TEOAE, except the correlation percentage (%), included response amplitude (dB) and signal/noise (SN) ratio.

**RESULTS:** There was no statistically significant difference in age and sex in the two groups. Mean TEOAE correlation percentage, signal/noise ratio, TEOAE amplitudes in 1, 1.5, 2, 3 and 4 Hz frequency values were not different between the two groups ( $p>0.05$ ).

**CONCLUSIONS:** In this study using the TEOAE test, we found that FMF did not cause outer cell hair damage in children. In the literature, there is no study on outer cell hair damage in children or adults with FMF, so this is the first investigational study.

Regulatory T cells: mechanisms of differentiation and function.

Josefowicz SZ(1), Lu LF, Rudensky AY.

Author information:

(1)Howard Hughes Medical Institute and Immunology Program, Sloan Kettering Institute, New York, NY 10021, USA.

The immune system has evolved to mount an effective defense against pathogens and to minimize deleterious immune-mediated inflammation caused by commensal microorganisms, immune responses against self and environmental antigens, and metabolic inflammatory disorders. Regulatory T (Treg) cell-mediated suppression serves as a vital mechanism of negative regulation of immune-mediated inflammation and features prominently in autoimmune and autoinflammatory disorders, allergy, acute and chronic infections, cancer, and metabolic inflammation. The discovery that Foxp3 is the transcription factor that specifies the Treg cell lineage facilitated recent progress in understanding the biology of regulatory T cells. In this review, we discuss cellular and molecular mechanisms in the differentiation and function of these cells.

Dermatological research has been very active this year. Most of the numerous fields investigated involve the mechanisms of cutaneous regeneration and barrier function. A novel target of early ultraviolet-induced skin photodamage, the Syk kinase, has been recently identified. Synergistic relationship between telomere damage and cutaneous progerin production during cell senescence may also participate in the natural skin aging process. Interestingly, ultraviolet radiation induces an inhibitory effect on subcutaneous lipogenesis. Androgenetic alopecia or common baldness is not characterized by loss of hair follicle stem cells but by a defect in the conversion of hair follicle stem cells into active progenitor cells. It has been shown that the cornified envelope functions not only as a physicochemical barrier, but also as both a biochemical line of antioxidant defense and an immunological line of defense. Like human papillomaviruses, Merkel cell polyomavirus belongs to the skin microbiome and different studies have demonstrated the protective role of epidermal resident microflora through the activation of innate immunity. Production of antimicrobial peptides and the activation of inflammasome and plasmacytoid dendritic cells are involved in the modulation of the cutaneous barrier function. Results from different studies suggest that IL-22 and IL-36 may be common mediators of both innate and adaptive immune responses. All these pathways interact not only to maintain cutaneous homeostasis and integrity (wound healing) but also to regulate autoinflammatory and autoimmune dermatoses (psoriasis, lupus, rosacea, atopic dermatitis, etc...). In addition, molecular mechanisms that regulate T helper type 2 differentiation and the retention at the site of inflammation of Th2 cells have been identified. New promising therapeutic targets for different chronic dermatosis are thus suggested. Mechanobiology and mechanotransduction are also emerging fields that investigate mechanical interactions between living cells and their environment and the conversion of mechanical cues into biochemical signals. Electronic second skin is now a current concept through bio-integrated epidermal electronics platforms used for different monitoring and stimulations of body functions.

Evaluating MEFV mutation frequency in Turkish familial Mediterranean fever suspected patients and gender correlation: a retrospective study.

Doğan HO(1), Koca Y, Erden G, Karaaslan Y, Bozat H.

Author information:

(1)Department of Clinical Biochemistry, Ankara Numune Training and Research Hospital, 06100, Ankara, Turkey. halefokan@gmail.com

Familial Mediterranean fever (FMF) is the most frequent hereditary inflammatory disease. FMF causes different clinical manifestations in different ethnic groups and countries. In this study, we retrospectively reviewed the records of 1,152 FMF suspected patients (673 female and 479 male) from November 2006 to December 2010. A commercial kit assay for the identification of MEFV (Mediterranean fever) gene mutations based on PCR and reverse-hybridization was used to investigate 12 mutations of the MEFV gene. 52.17% of 1,152 FMF suspected patients had MEFV mutation and 45.25% of them were male. The rate of MEFV mutation among male and female patients were 56.78 and 48.88%, respectively. These results were statistically significant and might support the suggestion that FMF had much more penetrance in male patients ( $P = 0.009$ ). Not any significant difference was observed between the male and female patients in terms of heterozygote and homozygote mutation carriage rate ( $P = 0.071$ ). Also not any significant difference was observed between the male and female patients in terms of compound heterozygote mutation carriage rate ( $P = 0.058$ ).

New insights into the pathogenesis of Behçet's disease.

Pineton de Chambrun M(1), Wechsler B, Geri G, Cacoub P, Saadoun D.

Author information:

(1)Department of Internal Medicine and Laboratory I3 Immunology, Immunopathology, Immunotherapy, UMR CNRS 7211, INSERM U959, Groupe Hospitalier La Pitié-Salpêtrière, Université Pierre et Marie Curie, Paris 6, Paris, France

Behçet's disease (BD) is a recurrent systemic inflammatory disorder of unknown origin characterized by oral and genital mucous ulcer, uveitis, and skin lesions. Involvement of large vessels, central nervous system (CNS), gastrointestinal tract and thrombotic events are less frequent but can be life threatening. The aim of this review is to provide new insights into the pathogenesis of BD. Over the past year substantial advances have been done in the understanding of the genetic [1,2] and immunology [3] of BD. BD is at the crossroad between autoimmune and autoinflammatory syndromes. In common with autoimmune diseases BD shares class I MHC association. However, in contrast to autoimmune disorders, BD has clinical features that seem to be mostly autoinflammatory. The pathogenesis of BD is still unknown, but major determinants of the genetic and immune system abnormalities have been reported recently. Triggering infectious factors are supposed to participate in the outbreak of BD in genetically predisposed patients. Two recent large genome-wide association study (GWAS) conducted in Turkey and Japan reported association between single nucleotide polymorphism (SNP) of interleukin (IL)-10 and IL-23R/IL-12RB2 genes and BD. New insights into the perturbations of T cell homeostasis of BD recently emerged. We have recently demonstrated the promotion of Th17 responses and the suppression of regulatory T cells (Tregs) that were driven by interleukin (IL)-21 production and that correlates with BD activity. Inflammatory cells within BD inflammatory lesions included mostly neutrophils, Th1 and Th17 cells, and cytotoxic CD8+ and  $\gamma\delta$  T cells. Altogether, the recent progresses in the knowledge of BD pathogenesis pave the way for innovative therapy.

The multidrug resistance (MDR1) gene encodes a P-glycoprotein that plays a key role in drug bioavailability and response to drugs in different human populations. More than 50 SNPs have been described for the MDR1 gene. Familial Mediterranean fever (FMF) is considered an autosomal recessive hereditary disease, associated with a single gene named the Mediterranean fever gene (MEFV). However, about one-third of FMF patients have only one mutated allele, suggesting that this disease is expressed as an autosomal dominant trait with partial penetration or an additional gene might be responsible for the disease. We made genotype and haplotype analyses of the MDR1 gene in 142 FMF patients and 130 unrelated Turkish subjects; two MDR-1 genetic markers (C1236T and C3435T) were analyzed by PCR-RFLP analysis. FMF patients had a significantly higher frequency of the 3435 CT genotype compared with the control group (59.9% in FMF patients versus 44.6% in controls; odds ratio [OR] = 1.85; 95% confidence interval [CI] = 1.14-3.00). Based on haplotype analysis, the T-C shift was significantly more frequent in controls (14.4% versus 7.1% in FMF patients). This haplotype could be protective for FMF disease (OR = 0.45; 95%CI = 0.25-0.84). The frequency of CC-CT (1236-3435) binary genotype was significantly higher in FMF patients (14.79% versus 4.61% in controls; OR = 3.59; 95%CI = 1.40-9.20).

The etiology of cryopyrin-associated periodic syndrome (CAPS) is caused by germline gene mutations in NOD-like receptor family, pyrin domain containing 3 (NLRP3)/cold-induced autoinflammatory syndrome 1 (CIAS1). CAPS includes diseases with various severities. The aim of this study was to characterize patients according to the disease severity of CAPS. Five Japanese patients with four kinds of gene variations in NLRP3 were found and diagnosed as CAPS or juvenile idiopathic arthritis. Two mutations in NLRP3, Y563N and E688K, found in CAPS patients exhibit significant positive activities in the nuclear factor- $\kappa$ B reporter gene assay. Increased serum interleukin (IL)-18 levels were only observed in severe cases of CAPS. In mild cases of CAPS, the serum IL-18 levels were not increased, although lipopolysaccharide- or hypothermia-enhanced IL-1 $\beta$  and IL-18 production levels by their peripheral blood mononuclear cells were detectable. This series of case reports suggests that a combination of in vitro assays could be a useful tool for the diagnosis and characterization of the disease severity of CAPS.

Author information:

(1)Department of Internal Medicine, Atatürk Education and Research Hospital, Ankara, Turkey. sukanerten@yahoo.com

Familial Mediterranean fever (FMF) is an autosomal recessive, inherited autoinflammatory disease characterized by recurrent, self-limited attacks of fever and inflammation of serosal surfaces. There is an explosion of the data regarding inflammatory markers in FMF and clinical effects of chronic

inflammation on the disease presentation. Vitamin D (vit D) is the common denomination of a group of sterols with a crucial role in phospho-calcium metabolism. There are some data about the importance of vit D in the initiation and propagation of a range of autoimmune diseases. The aim of the present study was to determine whether vit D deficiency is present in patients with FMF compared with healthy individuals. The study group included 99 patients with diagnosis of FMF attended to our outpatient Rheumatology and Nephrology Clinics of Atatürk Education and Research Hospital. The control group comprised 51 age- and sex-matched healthy people selected from hospital staff. Serum baseline 25-hydroxy vit D levels were measured by HPLC method using an Agilent 1100 Liquid Chromatograph. We found significantly lower serum 25-hydroxy vit D levels among FMF patients compared with matched controls and a high prevalence of vit D deficiency. This study demonstrated that vit D deficiency is frequent in patients with FMF than the healthy controls. It is convenient to look for vit D deficiency and to correct vit D nutritional status in FMF patients.

Pro-resolution immunological networks: binding immunoglobulin protein and other resolution-associated molecular patterns.

Shields AM(1), Thompson SJ, Panayi GS, Corrigall VM.

Author information:

(1)Department of Academic Rheumatology, Centre for Molecular and Cellular Biology of Inflammation, 1st Floor New Hunts House, Guy's Campus, King's College London, London SE 1UL, UK.

Appropriate regulation and subsequent resolution of acute inflammatory events is critical to the prevention of autoinflammatory diseases. Indeed, the chronic inflammation observed in diseases such as RA is at least partially consequent on the failure of endogenous immunoregulation. Current RA therapies (e.g. anti-TNF- $\alpha$  inhibitors and MTX) inhibit components of the inflammatory disease process without directly promoting the resolution of inflammation. We propose that the

next generation of RA therapeutics will complement and augment endogenous immunoregulatory and pro-resolution immunological networks, thus promoting the definitive resolution of inflammation rather than temporary immunological control. Of particular interest with respect to this therapeutic approach is binding immunoglobulin protein [BiP; also known as glucose-regulated protein-78 (GRP78)], a member of the recently defined resolution-associated molecular pattern (RAMP) family of molecules. In this review, we consider the preclinical evidence from experiments in mouse and man that suggests BiP and other members of the RAMP family have the potential to herald a new generation of immunotherapeutics.

Evaluation of the current disease severity scores in paediatric FMF: is it necessary to develop a new one?

Kalkan G(1), Demirkaya E, Acikel CH, Polat A, Peru H, Karaoglu A, Sari E, Dursun I, Gok F, Ozen S; FMF Arthritis Vasculitis and Orphan Disease Research in Paediatric Rheumatology (FAVOR).

Author information:

(1)FMF Arthritis Vasculitis and Orphan Disease Research in Paediatric Rheumatology (FAVOR), Department of Paediatrics, Pediatric Nephrology and Rheumatology Unit, Gulhane Military Medical Faculty, School of Medicine, 06018 Etlik, Ankara, Turkey.

**OBJECTIVES:** Modified adult disease severity scoring systems are being used for childhood FMF. We aim to test the clinical consistency of two common severity scoring systems and to evaluate the correlation of scores with the type of FMF mutations in paediatric FMF patients since certain mutations are prone to severe disease.

**METHODS:** Two hundred and fifty-eight children with FMF were cross-sectionally studied. Assessment of the disease severity was performed by using the modified scoring systems of Mor et al. and Pras et al. Genetic analysis was performed

using PCR and restriction endonuclease digestion methods for the presence of 15 FMF gene mutations. FMF mutations were grouped into three based on well-known genotypic-phenotypic associations. Correlation between the mutation groups and the severity scoring systems was assessed. The consistency of the severity scoring systems was evaluated.

**RESULTS:** The results of two scoring systems were not statistically consistent with each other ( $\kappa = 0.171$ ). This inconsistency persisted even in a more homogeneous subgroup of patients with only homozygote mutations of M694V, M680I and M694I ( $\kappa = 0.125$ ). There was no correlation between the mutation groups and either of the scoring systems ( $P = 0.002$ ,  $r = 0.196$  for scoring systems of Mor et al.;  $P = 0.009$ ,  $r = 0.162$  for Pras et al.).

**CONCLUSIONS:** The inconsistency of the two scoring systems and lack of correlation between the scoring systems and mutation groups raises concerns about the reliability of these scoring systems in children. There is a need to develop a scoring system in children based on a prospective registry.

Estimating the allele frequency of autosomal recessive disorders through mutational records and consanguinity: the Homozygosity Index (HI).

Gialluisi A(1), Pippucci T, Anikster Y, Ozbek U, Medlej-Hashim M, Mégarbané A, Romeo G.

Author information:

(1)Unità Operativa di Genetica Medica, Dipartimento di Scienze Ginecologiche, Ostetriche e Pediatriche, Policlinico Sant'Orsola Malpighi, Università di Bologna, Bologna, Italy.

In principle mutational records make it possible to estimate frequencies of disease alleles ( $q$ ) for autosomal recessive disorders using a novel approach based on the calculation of the Homozygosity Index (HI), i.e., the proportion of homozygous patients, which is complementary to the proportion of compound heterozygous patients  $P(CH)$ . In other words, the rarer the disorder, the higher

will be the HI and the lower will be the P(CH). To test this hypothesis we used mutational records of individuals affected with Familial Mediterranean Fever (FMF) and Phenylketonuria (PKU), born to either consanguineous or apparently unrelated parents from six population samples of the Mediterranean region. Despite the unavailability of precise values of the inbreeding coefficient for the general population, which are needed in the case of apparently unrelated parents, our estimates of  $q$  are very similar to those of previous descriptive epidemiological studies. Finally, we inferred from simulation studies that the minimum sample size needed to use this approach is 25 patients either with unrelated or first cousin parents. These results show that the HI can be used to produce a ranking order of allele frequencies of autosomal recessive disorders, especially in populations with high rates of consanguineous marriages.

Author information:

(1)First Department of Internal Medicine, Democritus University of Thrace, Alexandroupolis, Greece.

Familial Mediterranean fever (FMF) is an autoinflammatory disease, characterized by MEFV gene mutations and self-limited recurrent episodes of fever and localized serositis. Complement system is a key regulator of the inflammatory process. The aim of this study was to investigate the genetic alterations and mRNA expression pattern of C5aR and C5L2 genes in neutrophils from attack-free FMF patients. No mutations were observed in the two receptors' genes, while the genetic alteration

observed in the C5aR1 gene was identified as N279 K polymorphic variant. Furthermore, lower mRNA expression of C5L2 gene was observed in neutrophils from FMF patients compared to control subjects. The binding capacity of rhC5a and the ability to produce reactive oxygen species was similar in neutrophils from healthy subjects and FMF patients and independent of the presence of N279 K polymorphism or mRNA expression of C5L2.

Mechanisms and pathophysiology of autoimmune disease.

Brooks WH(1).

Author information:

(1)Experimental HTS Core, SRB-3, H. Lee Moffitt Cancer Center & Research Institute, Tampa, FL 33612-9416, USA. wesley.brooks@moffitt.org

The first textbook on autoimmunity was published by Ian Mackay and McFarland Burnett in 1963. It was the first attempt to summarize existing knowledge on human autoimmunity. Since that time, there have been tens of thousands of experimental papers and numerous textbooks that focus on the diagnosis and treatment of human autoimmunity. There have been at least as many, if not more, directed at similar issues in animal models. Enormous strides have been made not only in diagnosis, but also in the pathophysiology and especially in treatment. We have gone from the era of simple HLA typing to deep sequencing and, more recently, epigenetic analysis. We have gone from the era of white blood cell differentials to detailed lymphoid phenotyping. We have gone from the era of simple antinuclear antibodies to detailed and sophisticated immunodiagnosis with recombinant autoantigens and disease-specific epitopes. We have gone from the era of using only corticosteroids to selective biologic agents. Diseases that were previously considered idiopathic are now very much understood as autoimmune. We are in the era of autoinflammatory reactions and the concept of both innate versus adaptive immunity in mediating immunopathology. In this edition of Clinical Reviews in Allergy and Immunology, we focus on key and cutting-edge issues in the pathophysiology of autoimmunity. The issues are very much oriented

and driven by hypothesis, i.e., a prediction of events expected to occur based on observations. It is not meant to be a complete summary of potential mechanisms of autoimmunity, but rather an attempt to accelerate discussion and better understanding. The primary goal is obviously to help our patients with autoimmune disease.

Bunyamin\_k@hotmail.com

Familial mediterranean fever (FMF) is an autosomal recessive disorder caused by mutations in the FMF gene (MEFV). The gene causing FMF, designated MEFV, encodes a protein called pyrin or marenostrin that is expressed mainly in myeloid bone marrow precursors, neutrophils, and monocytes. Since there are several etiological factors, FMF is the most common periodic fever syndrome. However, it is still unknown what triggers or ends these periodical attacks. As a pleiotropic hormone, vitamin D has immunomodulation effects. The aim of this study was to evaluate the vitamin D levels in FMF patients. The study group was comprised of 26 patients diagnosed with FMF (men/women: 12/14), and 34 healthy control (men/women: 17/17). Vitamin D levels in FMF patients and healthy controls were  $11.05 \pm 7.11$ ,  $17.15 \pm 6.49$ , respectively. FMF patients had significantly decreased vitamin D levels compared with healthy controls ( $P < 0.001$ ). In conclusion, it is thought that vitamin D deficiency in FMF patients may trigger the attacks. Further studies with larger patient populations need to hold to investigate the vitamin D deficiency in patients with FMF and that may assist to clarify the mechanism behind the colchicines resistant cases.

2843. Int J Pediatr Otorhinolaryngol. 2012 Feb;76(2):244-7. doi: 10.1016/j.ijporl.2011.11.013. Epub 2011 Dec 15.

Cochlear involvement in Familial Mediterranean Fever: a new feature of an old disease.

Koybasi S(1), Atasoy Hİ, Bicer YO, Tug E.

Author information:

(1)Abant İzzet Baysal University, Medical Faculty, Department of Otolaryngology, Turkey. serapkoybasi@yahoo.com

**OBJECTIVES:** In this study we first aimed to assess the cochlear functions in children with Familial Mediterranean Fever. The second aim was to investigate the correlation between the hearing levels and some clinical features of Familial Mediterranean Fever including the duration of the disease, age at onset, genetic analysis and colchicine use.

**METHODS:** Thirty-four children with Familial Mediterranean Fever and 27 age matched children were included in the study. Following otologic examination, all children underwent audiometric evaluation, including Pure Tone Average measurements and Distortion Product Otoacoustic Emission testing. Audiological results of the two groups were compared and correlation between the audiological status and clinical parameters of the disease like the duration of disease, age at onset, mutations and colchicine treatment were studied.

**RESULTS:** Pure tone audiometry hearing levels were within normal levels in both groups. Hearing thresholds of Familial Mediterranean Fever patients were found to be increased at frequencies 8000, 10,000, 12,500 and 16,000 ( $p<0.05$ ). In otoacoustic emission evaluation, distortion products and signal-noise ratio of FMF children were lower in the tested frequencies, from 1400 Hz to 4000 Hz ( $p<0.05$ ). Interaction of the disease duration and age of disease onset was found to predict hearing levels, distortion products and signal-noise ratios of children with Familial Mediterranean Fever (F value=2.034;  $p=0.033$ ).

**CONCLUSIONS:** To our knowledge this is the first study demonstrating cochlear involvement in children with Familial Mediterranean Fever which showed increased hearing thresholds at higher frequencies in audiometry together with decreased

distortion products and signal-noise ratios demonstrated by distortion product otoacoustic emission testing. Similar studies must be carried out on adult patients to see if a clinical hearing impairment develops. The possible mechanisms that cause cochlear involvement and the effect of colchicine treatment on cochlear functions must be enlightened.

Systemic amyloidosis comprises a group of diseases that develop as a consequence of an abnormal accumulation of different proteins in several organs, altering their function. Secondary amyloidosis develops after the accumulation of serum amyloid A protein (an acute phase reactant), mainly in the course of chronic inflammatory conditions such as rheumatologic diseases, familial Mediterranean fever, or tuberculosis. Inflammatory bowel disease (IBD) may also cause secondary amyloidosis. However, little is known about the true prevalence, risk factors, and clinical outcomes of amyloidosis among IBD patients. A few studies suggest that amyloidosis is more prevalent in Crohn's disease than in ulcerative colitis, mainly occurring in patients with an extensive, long-lasting, and penetrating disease pattern. In this article we review the available data on secondary amyloidosis and IBD, focusing on prevalence, risk factors, clinical presentation and therapeutic measures.

**OBJECTIVE:** To describe the genotypes, phenotypes, immunophenotypes, and treatments of PAPA syndrome (pyogenic sterile arthritis, pyoderma gangrenosum, and acne), a rare autoinflammatory disease, in 5 patients.

**METHODS:** Clinical information was gathered from medical records and through interviews with 5 patients from 4 kindreds. PSTPIP1 (CD2BP1) exon 10 and exon 11 sequencing was performed in each patient. Neutrophil granule content and cytokine levels were determined in plasma and stimulated peripheral blood mononuclear cells (PBMCs) from patients and controls.

**RESULTS:** We identified 2 previously described PAPA syndrome-associated PSTPIP1 mutations, A230T and E250Q, and a novel change, E250K. Disease penetrance was incomplete, with variable expressivity. The cutaneous manifestations included pathergy, cystic acne, and pyoderma gangrenosum. Interleukin-1 $\beta$  (IL-1 $\beta$ ) and circulating neutrophil granule enzyme levels were markedly elevated in patients compared to those in controls. PBMC stimulation studies demonstrated impaired production of IL-10 and enhanced production of granulocyte-macrophage colony-stimulating factor. Good resolution of pyoderma gangrenosum was achieved in 3 patients with tumor necrosis factor  $\alpha$  (TNF $\alpha$ ) blockade treatment.

**CONCLUSION:** This analysis of 5 patients demonstrates that mutations in PSTPIP1 are incompletely penetrant and variably expressed in the PAPA syndrome.

Neutrophil granule proteins are markedly elevated ex vivo and in the plasma, and elevated levels might be compatible with a diagnosis of PAPA syndrome. TNF $\alpha$

blockade appears to be effective in treating the cutaneous manifestations of PAPA syndrome.

A retrospective review of autoinflammatory diseases in Saudi children at a rheumatology clinic.

Alenazi A(1), Al Sonbul A, Al Jumaah S, Al Mehaidib A, Al-Mayouf SM.

Author information:

(1)Department of Pediatrics, Section of Rheumatology, King Faisal Specialist Hospital and Research Center, Riyadh, Saudi Arabia.

**BACKGROUND AND OBJECTIVE:** Published data from Saudi Arabia regarding autoinflammatory diseases are scarce. In this study, we describe the clinical and laboratory features of autoinflammatory diseases in Saudi children.

**DESIGN AND SETTING:** Restrospective, hospital-based study conducted from January 2010 until June 2010.

**PATIENTS AND METHODS:** Patients with autoinflammatory disease treated at the Pediatric Rheumatology Clinic at King Faisal Specialist Hospital and Research Center, Riyadh, over the past 10 years were included. Autoinflammatory diseases included the following: familial Mediterranean fever (FMF); chronic recurrent multifocal osteomyelitis (CRMO); early-onset sarcoidosis (EOS); periodic fever, aphthous stomatitis, pharyngitis and cervical adenitis syndrome (PFAPA); chronic infantile neurologic cutaneous and articular syndrome (CINCA); and Muckle-Wells syndrome (MWS). Demographic characteristics, diagnosis, age at onset, disease duration, follow-up duration, clinical and laboratory variables, and outcome data were compiled. Gathered laboratory data were part of patients' usual medical care.

**RESULTS:** Thirty-four patients (females, 53%) with autoinflammatory diseases were included (mean age, 151 months). Mean disease duration was 118 months; mean age

at onset was 32 months; consanguinity was present in 40%. Patients were diagnosed as follows: FMF, 50%; CRMO, 23.5%; CINCA, 8.8%; EOS, 8.8%; MWS, 6%; and PFAPA, 2.9%. The referral diagnosis was inaccurate in all patients except for FMF patients. Gene study was informative in 9 of 14 FMF patients who had molecular analyses. None of our cohort had amyloidosis. All CRMO patients had a favorable response to treatment except 1 patient, who had refractory, progressive disease. All patients with EOS had multiorgan involvement, including uveitis. All CINCA patients had a favorable response to anakinra.

**CONCLUSION:** Our report shows that autoinflammatory diseases other than FMF may be overlooked. Increased awareness among pediatricians about these conditions will help to provide better health care to patients in the form of early diagnosis and management.

kuemmerle.deschner@uni-tuebingen.de

**INTRODUCTION:** Muckle-Wells syndrome (MWS) is an inherited autoinflammatory disease characterized by fever, rash, arthralgia, conjunctivitis, sensorineural deafness and potentially life-threatening amyloidosis. The NLRP3/CIAS1 E311K mutation caused a heterogeneous phenotype of MWS in a large family. This study analyzes the clinical spectrum, patterns of inflammatory parameters and reports on response to treatment.

**METHODS:** A total of 42 patients and family members were screened for the presence of the NLRP3 mutation. Clinical symptoms were reviewed in all family members.

Classical (erythrocyte sedimentation rate (ESR, C-reactive protein (CRP)) and novel MWS inflammatory markers (serum amyloid A (SAA), cytokines, cytokine receptor levels) were determined. Patients were treated with the IL-1 inhibitors Anakinra or Canakinumab.

RESULTS: All 13 clinically affected patients were heterozygous carriers of the amino acid substitution p.Glu311Lys/E311K encoded by exon 3 of the NLRP3 gene, but none of the healthy family members. Disease manifestations varied widely. Except for one child, all carriers suffered from hearing loss and severe fatigue. TNF- $\alpha$ , IL-6, TNF-RI, and TNF-RII levels as well as SAA were elevated in three, two, one, six and ten patients, respectively. Both clinical and laboratory parameters responded quickly and sustainedly to treatment with Anakinra or Canakinumab.

CONCLUSION: The NLRP3 E311K mutation is associated with a heterogeneous clinical spectrum, which may expand the view on MWS presentation. The leading symptom was hearing loss. Pericarditis, a rare but severe clinical feature of MWS, was diagnosed in three patients. One patient had a severe course, which led to renal failure secondary to amyloidosis. IL-1 inhibition leads to rapid and sustained improvement of symptoms.

Increased oxidative stress in patients with familial Mediterranean fever during attack period.

Ediz L(1), Ozkol H, Tekeoglu I, Tuluçe Y, Gulcu E, Koyuncu I.

Author information:

(1)Yuzuncu Yil University, Medical Faculty, Physical Medicine-Rehabilitation and Rheumatology Department, Van, Turkey. leventediz@gmail.com

OBJECTIVES: We aimed to investigate the status of oxidant and antioxidants during attack period (AP) and attack free periods (AFP) in Familial Mediterranean fever (FMF) patients.

METHODS: Measured the levels of malondialdehyde (MDA), protein carbonyl (PC),

glutathione (GSH) and antioxidant vitamins (A,C and E) as well as the activities of catalase (CAT) and glutathione peroxidase (GSH-Px) in serum and whole blood of FMF patients in FMF-AP and FMF-AFP.

RESULTS: Levels of MDA and PC were found significantly higher ( $p < 0.05$ ) both in serum and whole blood of FMF-AP group compared with other groups. The CAT and GSH-Px activities in FMF-AP group were found markedly lower ( $p < 0.05$ ) comparing to HC group. However, there were no statistically significant differences between the groups in terms of antioxidant vitamin levels.

CONCLUSIONS: Our study demonstrated increased oxidative stress in patients with FMF during AP. Investigations are needed to establish the effect of antioxidant supplementation on FMF attack frequency and severity. We also suggest that these increased MDA and PC levels and decreased antioxidants may be used as supportive markers to differentiate AP from AFP. These conclusions need to be validated in further multicenter studies with high number of FMF patients.

**OBJECTIVE:** Monogenic autoinflammatory diseases are disorders of Mendelian inheritance that are characterized by mutations in genes that regulate innate immunity and whose typical features are systemic inflammation without high-titer autoantibodies or antigen-specific T cells. Skin and bone inflammation in the newborn period have been described in 3 of these autoinflammatory disorders: neonatal-onset multisystem inflammatory disease, Majeed syndrome, and deficiency of interleukin-1 (IL-1) receptor antagonist (DIRA) syndrome. This study was undertaken to present the characteristics of the DIRA syndrome in 2 cases from Brazil, and describe a novel mutation in IL1RN.

**METHODS:** Two unrelated Brazilian patients were evaluated for the clinical signs and symptoms of these 3 disorders, and peripheral blood samples were assessed for mutations in NLRP3, LPIN2, and IL1RN by DNA resequencing analysis. A mutation in IL1RN that encodes a mutant protein was identified, and the expression and function of this mutant protein were compared to those of the wild-type protein.

**RESULTS:** Both patients presented with pustular dermatitis resembling generalized pustular psoriasis, recurrent multifocal aseptic osteomyelitis, and elevation in the levels of acute-phase reactants, all of which are features most consistent with the DIRA syndrome. Chronic lung disease was observed in 1 of the patients, and jugular venous thrombosis was observed in the other patient. Both patients showed a partial response to corticosteroid therapy, and 1 patient experienced an initial improvement of dermatitis with the use of acitretin. Both patients were homozygous for a novel 15-bp (in-frame) deletion on the IL1RN gene. The mutated protein expressed in vitro had no affinity with the IL-1 receptor, and stimulation of the patients' cells with recombinant human IL-1 $\alpha$  or IL-1 $\beta$  led to oversecretion of proinflammatory cytokines, similar to the findings obtained in previously reported patients.

**CONCLUSION:** The presence of the same homozygous novel mutation in IL1RN in 2 unrelated Brazilian patients suggests that this genetic variant may be a founder mutation that has been introduced in the Brazilian population.

Cephalometric evaluation of children with familial Mediterranean fever.

Gungor AY(1), Arica V, Gungor O, Tutanc M.

Author information:

(1)Department of Orthodontics, Faculty of Dentistry, University of Akdeniz, Antalya, Turkey.

**OBJECTIVE:** To test the null hypothesis that no differences exist in craniofacial morphology between patients with familial Mediterranean fever (FMF) and the healthy population.

**MATERIALS AND METHODS:** Standardized lateral cephalograms of 32 FMF patients (mean age,  $11.50 \pm 2.72$  years) and 32 healthy controls (mean age,  $11.86 \pm 2.19$  years) were obtained. Cranial and dentofacial parameters were measured using a cephalometric analysis program (Nemoceph Imaging Cephalometric and Tracing Software S.L., Spain). All statistical analyses were conducted using SPSS version 17.0.0 (SPSS Inc., Chicago, Ill). Descriptive statistics were calculated for all measurements, and the independent t-test was used to evaluate intergroup differences.

**RESULTS:** The ANB angle was significantly greater in the FMF group ( $P < .05$ ). Differences in SNA and SNB angles were insignificant. Anterior ( $P < .001$ ) and posterior ( $P < .05$ ) face heights were significantly shorter in the FMF group. Mandibular body length ( $P < .001$ ) and condylion to gnathion ( $P < .05$ ) measurements were significantly shorter in the FMF group. The upper lip was more protrusive in the FMF group ( $P < .05$ ). U1-NA (mm;  $P < .001$ ) and L1-NB (mm;  $P < .05$ ) measurements were significantly shorter in the FMF group.

**CONCLUSION:** The hypothesis is rejected. Significant differences exist between the craniofacial morphology of patients with FMF and the healthy population.

Interplay between innate and adaptive immunity in the development of non-infectious uveitis.

Willermann F(1), Rosenbaum JT, Bodaghi B, Rosenzweig HL, Childers S, Behrend T, Wildner G, Dick AD.

Author information:

(1)Department of Ophthalmology, CHU St-Pierre and Brugmann, Université Libre de Bruxelles, Belgium. fwillerm@ulb.ac.be

In vertebrates, the innate and adaptive immune systems have evolved seamlessly to protect the host by rapidly responding to danger signals, eliminating pathogens and creating immunological memory as well as immunological tolerance to self. The innate immune system harnesses receptors that recognize conserved pathogen patterns and alongside the more specific recognition systems and memory of adaptive immunity, their interplay is evidenced by respective roles during generation and regulation of immune responses. The hallmark of adaptive immunity which requires engagement of innate immunity is an ability to discriminate between self and non-self (and eventually between pathogen and symbiont) as well as peripheral control mechanisms maintaining immunological health and appropriate responses. Loss of control mechanisms and/or regulation of either the adaptive or the innate immune system lead to autoimmunity and autoinflammation respectively. Although autoimmune pathways have been largely studied to date in the context of development of non-infectious intraocular inflammation, the recruitment and activation of innate immunity is required for full expression of the varied phenotypes of non-infectious uveitis. Since autoimmunity and autoinflammation implicate different molecular pathways, even though some convergence occurs, increasing our understanding of their respective roles in the development of uveitis will highlight treatment targets and influence our understanding of immune mechanisms operative in other retinal diseases. Herein, we extrapolate from the basic mechanisms of activation and control of innate and adaptive immunity to how autoinflammatory and autoimmune pathways contribute to disease development in non-infectious uveitis patients.

The NLRP3 inflammasome is active but not essential in endotoxin-induced uveitis.

Rosenzweig HL(1), Woods A, Clowers JS, Planck SR, Rosenbaum JT.

Author information:

(1)Casey Eye Institute, Oregon Health & Science University, Portland, OR, USA.  
rosenzwh@ohsu.edu

**OBJECTIVE:** The inflammasome complex involving caspase-1 and nucleotide-binding domain, leucine-rich repeat containing protein (NLRP)3, also known as NALP3 or cryopyrin is important for host responses to microbial pathogens and several autoinflammatory diseases. We investigated the extent to which NLRP3 and caspase-1 control ocular interleukin (IL)-1 $\beta$  production and severity of uveitis (intraocular inflammatory disease) in an established, acute inflammatory uveitis model, endotoxin-induced uveitis (EIU).

**METHODS:** Expression of NLRP3, its adaptor molecule ASC, also known as PYCARD (PYD and CARD domain containing), and caspase-1 were examined by immunoblotting. IL-1 $\beta$  production was measured by enzyme-linked immunosorbent assay (ELISA). Using knockout mice, roles for caspase-1 and NLRP3 were examined in uveitis induced by intraocular injection of *Escherichia coli* lipopolysaccharide (LPS).

**RESULTS:** NLRP3, ASC, and caspase-1 proteins are constitutively expressed in eye tissue. During EIU, IL-1 $\beta$  protein production increases; this requires the presence of both caspase-1 and NLRP3. However, severity of EIU is not altered by deficiency in either caspase-1 or NLRP3, as assessed by both intravital microscopy and histology.

**CONCLUSIONS:** These data identify the importance of the NLRP3 inflammasome for IL-1 $\beta$  production in the eye, yet indicate that its participation in EIU is nonessential.

QT dispersion is not increased in familial Mediterranean fever.

Topal F(1), Tanindi A, Kurtoglu HG, Akbulut S, Kucukazman M, Topal FE.

Author information:

(1)Department of Gastroenterology, Cankiri State Hospital, Cankiri, Turkey.

Familial Mediterranean fever (FMF) is an autoimmune disease inherited as an autosomal recessive trait and is characterized by recurrent attacks of fever and sterile polyserositis. This study examined electrocardiographic ventricular repolarization parameters (QT interval and QT dispersion) in 38 FMF patients and 35 healthy controls. The QT interval was measured manually from the onset of QRS to the end of the T wave (return to the TP baseline). QT dispersion was defined as the difference between the maximum and minimum QT values, and corrected QT was calculated according to the Bazett formula. There were no significant differences between FMF patients and healthy control subjects in any parameter of ventricular repolarization; hence QT dispersion was not affected by FMF. Electrocardiographic assessment of QT interval and QT dispersion are, therefore, of little value for the evaluation of cardiac impairment and risk of arrhythmia in FMF patients.

2855. Thromb Haemost. 2012 Jan;107(1):88-98. doi: 10.1160/TH11-08-0556. Epub 2011 Nov 24.

Platelet soluble CD40L and matrix metalloproteinase 9 activity are proinflammatory mediators in Behçet disease patients.

Fernández Bello I(1), Álvarez MT, López-Longo FJ, Arias-Salgado EG, Martín M, Jiménez-Yuste V, Rodríguez de la Rúa A, Butta NV.

Author information:

(1)Hematology Unit, Hospital Universitario La Paz-IdiPaz, Madrid, Spain.

Platelets are the major source of plasma-soluble CD40L (sCD40L), an important inflammatory mediator. This study explored the impact of platelet-derived sCD40L on Behçet disease (BD), an autoinflammatory vasculitis. We also searched for influences by platelet matrix metalloproteinases (MMP) -2 and MMP-9, implicated in several inflammatory diseases, on CD40L shedding from platelet membrane. Platelet activation were studied by flow cytometry and aggregometry, surface expression of CD40L and platelet-leukocyte aggregates by flow cytometry, sCD40L by ELISA, cellular CD40L and CD40 levels by Western blot and MMPs activity by gelatin zymography. The effect of sCD40L on MMP9 expression was studied in cultured MEG-01 cells. Plasma and platelet-released sCD40L levels were higher in BD patients. No differences in platelet activation and in platelet-leukocyte aggregates formation were observed between BD patients and controls. Plasma and platelet MMP-9 levels were increased in BD patients, whereas there was no difference in platelet MMP-2 activity. Since a correlation between plasma sCD40L and platelet MMP-9 activity was observed, we studied the influence of sCD40L on MMP-9 levels in the megakaryoblastic cell line MEG-01. Treatment of MEG-01 cells with recombinant sCD40L increased MMP-9 but did not change MMP-2 levels. In conclusion, sCD40L release from platelets was mediated by MMP-9, and MMP-9 expression was in turn upregulated by sCD40L in the MEG-01 cell line. We conclude that platelets and megakaryocytes might participate in a positive feedback loop occurring between sCD40L and MMP-9 which would contribute to the proinflammatory state observed in BD.

Tumour necrosis factor receptor trafficking dysfunction opens the TRAPS door to pro-inflammatory cytokine secretion.

Turner MD(1), Chaudhry A, Nadjai B.

Author information:

(1)Centre for Diabetes, The Blizard Institute, Barts and The London School of

Medicine and Dentistry, Queen Mary University of London, Whitechapel, London E1 2AT, UK. M.D.Turner@qmul.ac.uk

Cytokines are secreted from macrophages and other cells of the immune system in response to pathogens. Additionally, in autoinflammatory diseases cytokine secretion occurs in the absence of pathogenic stimuli. In the case of TRAPS [TNFR (tumour necrosis factor receptor)-associated periodic syndrome], inflammatory episodes result from mutations in the TNFRSF1A gene that encodes TNFR1. This work remains controversial, however, with at least three distinct separate mechanisms of receptor dysfunction having been proposed. Central to these hypotheses are the NF- $\kappa$ B (nuclear factor  $\kappa$ B) and MAPK (mitogen-activated protein kinase) families of transcriptional activators that are able to up-regulate expression of a number of genes, including pro-inflammatory cytokines. The present review examines each proposed mechanism of TNFR1 dysfunction, and addresses how these processes might ultimately impact upon cytokine secretion and disease pathophysiology.

dru\_canpolat@yahoo.com

**BACKGROUND:** Familial Mediterranean fever (FMF) is characterized by sporadic, acute attacks of fever and serositis. Cardiovascular involvement is one of the leading cause of morbidity and mortality among FMF patients. Herein, we aimed to evaluate cardiac autonomic functions in FMF patients without overt cardiac symptoms.

**METHODS:** We enrolled 38 patients (20 female; mean age  $34.4 \pm 10.2$  years) with FMF and 34 healthy subjects (18 female; mean age  $33.2 \pm 9.3$  years). All participants underwent 24-hour Holter recording. Heart rate recovery (HRR) indices were calculated by subtracting first, second, and third minute heart rates from maximal heart rate. All patients underwent heart rate variability (HRV), heart rate turbulence (HRT) and QT dispersion analysis. The mean FMF duration was  $9.8 \pm 4.2$  years.

**RESULTS:** Both groups were similar with regard to baseline characteristics. Mean HRR1 ( $p=0.001$ ), HRR2 ( $p=0.003$ ) and HRR3 ( $p<0.001$ ) were significantly lower in FMF group. SDNN (standard deviation of all NN intervals), SDANN (SD of the 5 min mean RR intervals), RMSSD (root square of successive differences in RR interval), and PNN50 (proportion of differences in successive NN intervals  $>50$  ms) and high-frequency (HF) components were significantly decreased, but low frequency (LF) and LF/HF were significantly higher in FMF patients. HRT onset and slope were significantly less negative in FMF patients. Also, QTd was significantly higher in FMF patients ( $p<0.001$ ).

**CONCLUSION:** Patients with FMF showed delayed recovery of heart rate and abnormal HRV and HRT parameters with respect to normal subjects. Cardiac autonomic functions might be involved in FMF patients even in patients without cardiac symptoms.

Susac syndrome: an organ-specific autoimmune endotheliopathy syndrome associated with anti-endothelial cell antibodies.

Magro CM(1), Poe JC, Lubow M, Susac JO.

Author information:

(1)Department of Pathology and Laboratory Medicine, Weill Medical College of Cornell University, New York, NY 10065, USA.

Susac syndrome (SS) is the triad of encephalopathy, branch retinal artery

occlusions (BRAOs), and hearing loss. Migraines may herald and accompany encephalopathy. Little is known about pathogenesis. Based on light microscopic findings in brain biopsy material analogous to anti-endothelial cell antibody (AECA)-mediated microvascular injury, we postulated that SS microangiopathy was attributable to AECAs. We examined serum samples from 11 patients with SS for AECAs; 9 were positive by indirect immunofluorescence and Western blot studies. A highly distinctive band on Western blots corresponding to a 50-kDa protein was observed in 8 positive SS samples; the other positive case exhibited specific reactivity with a protein band at 40 kDa. Of the 2 negative cases, 1 had been inactive since 1988; the other was an abortive variant characterized solely by BRAOs. There was enhanced surface binding of SS serum using live endothelial cell substrates compared with samples from healthy subjects. Additional serum samples from apparently healthy patients, 2 with atypical migraines, and patients with other forms of autoinflammatory disease did not show the distinctive band of immunoreactivity. SS is a distinct autoimmune endotheliopathy syndrome associated with AECAs; the antibody target seems specific in many cases and may be a disease biomarker. The exact role of AECAs in disease propagation remains unanswered.

Leprosy initially misdiagnosed as sarcoidosis, adult-onset still disease, or autoinflammatory disease.

Simeoni S(1), Puccetti A, Tinazzi E, Codella OM, Sorletto M, Patuzzo G, Colato C, Tessari G, Lunardi C.

Author information:

(1)Department of Medicine, University of Verona, Verona, Italy.

Leprosy is a chronic granulomatous disease caused by *Mycobacterium leprae*. We describe the case of a 20-year-old man from India living in Italy since 2003, who presented with erythematous papules and nodules distributed on his arms, legs, and face in 2006. He also had episodes of high fever, polyarthrititis, and episcleritis. Sarcoidosis was suspected on the basis of elevated angiotensin-converting enzyme and bronchoalveolar lavage fluid, and the patient

was treated with corticosteroids for about a year. A flare of the disease occurred each time corticosteroid was tapered or suspended. An autoinflammatory disease was then suspected and treated with immunosuppressant. Only the third deep skin biopsy revealed the presence of *M. leprae*. The lack of clinical suspicion and the unfamiliarity with the histology of leprosy delayed diagnosis and treatment. Leprosy should be considered in the differential diagnoses of patients presenting with rheumatic and cutaneous manifestations especially when they come from countries where the disease is endemic.

Familial Mediterranean fever and related periodic fever syndromes/autoinflammatory diseases.

Savic S(1), Dickie LJ, Battellino M, McDermott MF.

Author information:

(1)Department of Clinical Immunology, NIHR-Leeds Musculoskeletal Biomedical Research Unit (NIHR-LMBRU), Leeds Institute of Molecular Medicine, St. James's University Hospital, Leeds, UK.

**PURPOSE OF REVIEW:** The spectrum of periodic fever syndromes (PFS)/autoinflammation diseases is continuously expanding. This review provides an overview of the primary research and an update on the main clinical developments in these disorders published in the past 12-18 months.

**RECENT FINDINGS:** IL-1 $\beta$  is pivotal to the pathogenesis of most of the PFS. In familial Mediterranean fever (FMF) MEFV mutations lead to gain of pyrin function, resulting in inappropriate IL-1 $\beta$  release that is dependent on ASC but not the NLRP3 inflammasome. Anti-IL-1 therapy is effective in tumour necrosis factor receptor-associated periodic syndrome (TRAPS), whilst both spontaneous and pathogen-associated molecular patterns (PAMPs) induced IL-1 $\beta$  release have been demonstrated in NLRP12-associated periodic syndrome (NAPS12). Somatic NLRP3/CIAS1 mosaicism is a significant cause of cryopyrin-associated periodic syndromes (CAPS). Close connections have also been established between metabolic and inflammatory pathways. In TRAPS increased reactive oxygen species (ROS) of

mitochondrial origin leads to production of pro-inflammatory cytokines, whilst NLRP3 inflammasome activation in type 2 diabetes (T2D) is induced by oligomers of islet amyloid polypeptides (IAPP).

SUMMARY: Caspase 1 activation and IL-1 $\beta$  release is central to the pathogenesis of many autoinflammatory syndromes. This is supported by the effectiveness of anti-IL-1 biologics in treatment of these disorders.

Rheumatol Int. 2014 Aug;34(8):1185-6.

To evaluate the Mean Platelet Volume (MPV) levels in children diagnosed with familial Mediterranean fever (FMF), during attack and attack-free periods. The records of a total of 117 children with FMF, diagnosed using the Tel-Hashomer criteria, have been scanned. The study consisted of 53 patients during an attack (group 1), 64 patients in attack-free period (group 2), and 57 healthy controls (group 3). Erythrocyte sedimentation rate, C-reactive protein, white blood cell count, platelet count, and MPV levels were retrospectively recorded. The MPV and platelet values in FMF patients during attack (group 1) and FMF patients during attack-free periods (group 2) have been found to be significantly higher than those of the health control group (group 3). Positive correlation has been found between the MPV and platelet values in Group 1 and the disease's severity score ( $r = 0.224$ , and  $r = 0.268$ , respectively). Positive correlation ( $r = 0.528$ , and  $r$

= 0.485, respectively) has been also identified between MPV and blood platelet count in patients in Group 1 and 2. No correlation was found between the Colchicine treatment period and MPV ( $r = -0.005$ ). The MPV values in the complete group of FMF diagnosed children have been found to be much higher compared to those in healthy children. As a consequence, we consider the MPV value as a useful marker that demonstrates the risk of early stage atherosclerosis in children with FMF.

Abnormal heart rate variability in AA amyloidosis of familial Mediterranean fever.

Nussinovitch U(1), Volovitz B, Nussinovitch M, Lidar M, Feld O, Nussinovitch N, Livneh A.

Author information:

(1)Israel Naval Medical Institute, IDF Medical Corps, Haifa, Israel.

**BACKGROUND:** A scarcity of data exists relating to the effect of amyloidosis of Familial Mediterranean fever (FMF) on the autonomic nervous system. Our aim was to further investigate the presence of dysautonomia in FMF-AA amyloidosis, using a comparative case series design.

**MATERIAL AND METHODS:** The study group consisted of 40 patients with FMF: 20 without co-morbidities or amyloidosis and 20 in various stages of renal amyloidosis. Time domain and power spectral analyses of heart rate dynamics were performed according to accepted procedures. Findings were compared with 20 healthy control subjects.

**RESULTS:** No statistically significant differences were found in any of the studied heart rate variability (HRV) parameters between patients with uncomplicated FMF and controls. In contrast, patients with progressive amyloidosis (post renal transplantation or on dialysis) had significantly lower HRV parameters compared to control subjects (i.e. mean low frequency power spectral components  $104.30 \text{ ms}^2$  vs.  $172.09 \text{ ms}^2$ ,  $p < 0.05$ , mean standard deviation of all normal RR intervals  $32.27 \text{ ms}$  vs.  $51.51 \text{ ms}$ ,  $p < 0.05$ , mean HRV triangular

index 9.08 vs. 15.82,  $p < 0.05$ ). The adjusted odds ratio was 14.5 (95%CI 1.21-165.03,  $p = 0.04$ ) for HRV triangular index lower than 12.2 in the progressive amyloidosis group, 41.24 (95%CI 1.81-938.68,  $p = 0.02$ ) for low frequency power spectral components values lower than 142.35 ms<sup>2</sup>, and 12.67 (95%CI 1.04-153.96,  $p = 0.04$ ) for standard deviation of all normal RR intervals values lower than 40.15 ms.

CONCLUSION: Amyloidosis of FMF, particularly at a progressive stage, is associated with HRV abnormalities suggestive of the presence of autonomic nervous system dysfunction.

Social interaction with a rhythmic rat enhances the circadian pattern of the motor activity and temperature of LL-induced arrhythmic rats.

Cambras T(1), Castejón L, Díez-Noguera A.

Author information:

(1)Departament de Fisiologia, Facultat de Farmàcia, Universitat de Barcelona, Barcelona, Catalunya, Spain. cambras@ub.edu

Although light is the main factor that influences circadian rhythms, social interaction may also have a role on their regulation. Here, the influence of social interaction on rat circadian behavior was investigated, addressing the question of whether cohabitation would induce the appearance of a circadian rhythm in arrhythmic rats due to constant light. To this end, circadian rhythms of motor activity and body temperature of male and female LL-induced arrhythmic rats were studied before, during and after a 20-day period in which rats stayed in the same cage with a rat of the same sex but with stronger rhythm. Results showed that the manifestation of the circadian motor activity rhythm of LL-induced arrhythmic rats increased after cohabitation. In the case of the expression of the body temperature rhythm, there was a progressive daily increase in the power content of a daily 24 hour pattern throughout the cohabitation days, which remained when animals were again isolated. Thus, the presence of a rhythmic

rat increases the strength of the circadian behavior of rats showing a weak circadian rhythm.

Nucleotide-binding oligomerization domain-like receptors and inflammasomes in the pathogenesis of non-microbial inflammation and diseases.

Mason DR(1), Beck PL, Muruve DA.

Author information:

(1)Department of Medicine, Immunology Research Group and the Institute of Infection, Immunity and Inflammation, University of Calgary, Calgary, Alta., Canada.

The nucleotide-binding oligomerization domain (NOD)-like receptor (NLR) or nucleotide-binding domain leucine-rich repeat-containing family of genes plays an important role in the development of innate immune responses. Some family members are known to form multiprotein complexes known as inflammasomes that regulate the processing and secretion of proinflammatory mediators, such as interleukin-1 $\beta$  and interleukin-18. Activity of the inflammasome is triggered not only by microbial infection, but also by a wide range of both exogenous and endogenous noninfectious stimuli. Consequently, the dysregulation of inflammasome activity is associated with numerous proinflammatory, non-microbial human diseases. The discovery of NLRP3 gene mutations in autoinflammatory diseases such as Muckle-Wells syndrome has led to the association of NLRs in the pathogenesis of many non-microbial diseases that include arthritis, neurodegenerative disorders, metabolic disorders (obesity and diabetes), cardiovascular disease (atherosclerosis, myocardial infarction), inflammatory bowel disease, kidney disease and hypersensitivity dermatitis. A number of NLRs are also associated with human disease in the absence of inflammasome activity, suggesting additional roles for NLRs in the regulation of inflammation and disease. This review serves to provide a summary of NLR-associated diseases and, where possible, the

mechanisms behind the associations.

QT dispersion and cardiac involvement in children with Familial Mediterranean fever.

Koca B(1), Kasapçopur O, Bakari S, Sönmez E, Oztunç F, Eroğlu AG, Saltik L, Calay O.

Author information:

(1)Department of Pediatric Cardiology, Cerrahpasa Medical Faculty, İstanbul University, Istanbul, Turkey. bkoca78@yahoo.com

Familial Mediterranean fever is a hereditary disease characterised by recurrent and self-terminated attacks of fever and polyserositis. An earlier study found that adult patients of Familial Mediterranean fever had an abnormally longer QT dispersion and corrected QT dispersion, markers for ventricular arrhythmogenicity. QT dispersion is a simple non-invasive arrhythmogenic marker that can be used to assess homogeneity of cardiac repolarisation; however, it has not been studied in children with Familial Mediterranean fever before. The aim of this study was to assess QT dispersion and corrected QT dispersion, and their relationship with systolic and diastolic function of the left ventricle in a group of children with Familial Mediterranean fever. We performed electrocardiography and Doppler echocardiography on patients and controls. Maximum QT, minimum QT, QT dispersion, corrected QT, maximum corrected QT, minimum corrected QT, and corrected QT dispersion intervals were measured from standard 12-lead electrocardiography. No statistically significant differences were found between the groups in QT dispersion, corrected QT dispersion, and systolic-diastolic function of the left ventricle parameters. During the 12 months of follow-up, no ventricular arrhythmias were documented in either group.

Role of tumour necrosis factor (TNF)- $\alpha$  and TNFRSF1A R92Q mutation in the pathogenesis of TNF receptor-associated periodic syndrome and multiple sclerosis.

Caminero A(1), Comabella M, Montalban X.

Author information:

(1)Centre d'Esclerosi Múltiple de Catalunya, CEM-Cat, Unitat de Neuroimmunologia Clínica, Hospital Universitari Vall d'Hebron, Barcelona, Spain.  
caminero.nrl@gmail.com

It has long been known that tumour necrosis factor (TNF)/TNFRSF1A signalling is involved in the pathophysiology of multiple sclerosis (MS). Different genetic and clinical findings over the last few years have generated renewed interest in this relationship. This paper provides an update on these recent findings. Genome-wide association studies have identified the R92Q mutation in the TNFRSF1A gene as a genetic risk factor for MS (odds ratio 1.6). This allele, which is also common in the general population and in other inflammatory conditions, therefore only implies a modest risk for MS and provides yet another piece of the puzzle that defines the multiple genetic risk factors for this disease. TNFRSF1A mutations have been associated with an autoinflammatory disease known as TNF receptor-associated periodic syndrome (TRAPS). Clinical observations have identified a group of MS patients carrying the R92Q mutation who have additional TRAPS symptoms. Hypothetically, the co-existence of MS and TRAPS or a co-morbidity relationship between the two could be mediated by this mutation. The TNFRSF1A R92Q mutation behaves as a genetic risk factor for MS and other inflammatory diseases, including TRAPS. Nevertheless, this mutation does not appear to be a severity marker of the disease, neither modifying the clinical progression of MS nor its therapeutic response. An alteration in TNF/TNFRSF1A signalling may increase proinflammatory signals; the final clinical phenotype may possibly be determined by other genetic or environmental modifying factors that have not yet been identified.

Author information:

(1)Department of Pediatrics, SB Tepecik Teaching Hospital, Tepecik, Izmir, Turkey.

The aim of this study was to determine the relationship between clinical findings and the most common mutated alleles of MEFV gene in a childhood population and to determine the sensitivity of the 12-mutation-strip assay test in familial Mediterranean fever (FMF). Records of 452 FMF children living in western Anatolia, Turkey, ( $12.3 \pm 4.7$  years mean) were retrospectively reviewed. Of the 408 patients who met the Tel-Hashomer criteria, 364 were classified into two main groups (two-mutant/one-mutant allele) either of which had three subgroups. The two-mutant allele frequency was 51% and one-mutant allele 38%; 1% had complex-mutant alleles and 10% no mutant-alleles. The mean severity score was  $8.3 \pm 2.5$ . Most common clinical features were fever (81.9%), abdominal pain (86.3%) and myalgia (58.8%), and the least common ones: diarrhea (1.7%), protracted febrile myalgia (1.2%) and acute orchitis (1.5%). We detected 33 different genotypes of the MEFV gene: the most common mutant allele was M694V followed by symptomatic allele mutation of E148Q. Although not significantly associated with clinical findings, P369S mutation was not rare (7.5%). Phenotype-genotype correlation revealed that patients with two-allele mutations had more severe clinical presentation and high constipation rate (22.5%); 32.6% of patients with M694V/M694V had splenomegaly. Acute orchitis and protracted febrile myalgia as rare clinical findings were more common in M694V homozygotes.

Comparisons of clinical findings among patients with one-mutation allele were made for the first time, but no significant association was found. Positive predictive value of strip assay screening for 12 mutations was recorded as 89%. We suggest that whole sequence analysis for supportive diagnosis of FMF should be performed for selected patients only.

The value of procalcitonin measurements in children with familial Mediterranean fever.

Yüksel S(1), Ekim M, Ozçakar ZB, Yalçınkaya F, Acar B, Oztuna D, Akar N.

Author information:

(1)Department of Pediatric Nephrology, Pamukkale University School of Medicine, Denizli, Turkey. selcukyüksel.nephrology@gmail.com

It is well known that the serum procalcitonin (PCT) levels increase in severe bacterial infections. However, there is little information about the levels of PCT in diverse diseases except mainly the infectious diseases. The aim of this study was to investigate the progress of serum levels of PCT together with traditional acute phase reactants in children with familial Mediterranean fever (FMF) during the attack and attack-free periods and to test whether PCT could help to diagnose the attack in FMF patients. The study group comprised 21 FMF patients (mean age  $10 \pm 4.6$  years) and 19 healthy controls (mean age  $10.6 \pm 4.2$  years). Serum levels of PCT and traditional acute phase reactants were measured during the attack and attack-free periods. Blood samples were obtained within the first 6-24 h of the attack period, 7 days later, and at least 2 months after the attack. Traditional acute phase reactants (hs-CRP, ESR, and fibrinogen) during the attack period were significantly higher than the attack-free levels and controls. PCT levels of the FMF patients during the attack period were also significantly higher than the attack-free and control group levels (median values, 0.044 ng/ml vs. 0.028 ng/ml and 0.031 ng/ml,  $P = 0.04$ , respectively). Although this difference was statistically significant ( $P = 0.04$ ), median PCT

values of the attack, attack-free period, and healthy subjects were lower than 0.05 ng/ml. As a result, these findings suggested that PCT levels were not conspicuously affected from inflammation and could not be used as a descriptive marker for attack in FMF patients.

Is there a real adrenal axis dysfunction in patients with amyloidosis associated with familial Mediterranean fever?

Yılmaz G(1), Masatlioglu S, Yetkin DO, Demirtunç R, Boysan SN, Kaplan S, Ince N.

Author information:

(1)Haydarpaşa Numune Training and Research Hospital, Istanbul, Turkey.

Systemic amyloidosis with AA-type amyloid deposition is the major complication of FMF, leading to end stage renal disease. There is no clear data on the prevalence of adrenal involvement in patients with FMF amyloidosis. The aim of this study is to determine the adrenal axis function in patients FMF with amyloidosis. Twenty patients with FMF with amyloidosis (F/M: 10/10, mean age;  $38 \pm 11$  SD years), twenty without amyloidosis (F/M: 14/6, mean age  $32 \pm 10$  years), and healthy controls (F/M: 12/8, mean age:  $30 \pm 7.6$  SD years) were recruited. A dose of 250 mg tetracosactide (Synacthen) was then administered intravenously and further blood samples collected 30 and 60 min later. Blood samples were separated and collected at 4°C, and serum cortisol levels were measured. A normal cortisol response to Synacthen was defined as a post-stimulation peak cortisol value of  $>18$  mg/d either at 30 or 60 min. sample. The mean disease duration was  $8.8 \pm 6$  SD years, (range, 2-21) in FMF patients without amyloidosis compared to  $16 \pm 9.5$  years (range, 0-30) in FMF with amyloidosis ( $P = 0.001$ ). The cortisol concentrations increased significantly at 30 and 60 min compared to baseline after injection of synacthen in all groups. There were no statistically significant differences found among three groups, for basal, 30 and 60 min for cortisol levels ( $P = 0.154$ ). FMF patients with amyloidosis do not exhibit overt adrenal insufficiency even though their basal cortisol levels were mildly lower.

Update on the pathogenesis and treatment of systemic idiopathic arthritis.

Sikora KA(1), Grom AA.

Author information:

(1)William S. Rowe Division of Rheumatology, Cincinnati Children's Hospital Medical Center, Cincinnati, Ohio, USA.

**PURPOSE OF REVIEW:** Systemic juvenile idiopathic arthritis (SJIA) is an inflammatory condition characterized by fever, lymphadenopathy, rash, arthritis, and serositis. Although the ultimate cause of this disorder remains elusive, recent work defining cytokine effector mechanisms has led to a new treatment paradigm for this condition. In this review, we describe the recent immunological reclassification of SJIA as an autoinflammatory disorder as well as detailing the dramatic changes in its treatment.

**RECENT FINDINGS:** SJIA is an autoinflammatory disorder in which defects of innate immune system pathways lead to significant inflammation. Recent studies of the pathophysiology, as well as successful treatment trials, have established interleukin-1 $\beta$  (IL-1 $\beta$ ) and IL-6 as key cytokines in the pathogenesis of this condition. As a result, their inhibition has become the centerpiece of the current SJIA treatment paradigm.

**SUMMARY:** There has been a major shift away from the traditional treatments of SJIA towards therapeutics that inhibit IL-1 $\beta$  and IL-6. In fact, the IL-1 blocker anakinra is now regarded as standard of care for SJIA patients with systemic symptoms, while the IL-6 inhibitor tocilizumab shows great potential. Future research holds promise for the development of more efficient cytokine inhibition as well as a more comprehensive knowledge of the innate cytokine networks in this disease.

[Behçet's disease from the aspect of autoinflammatory disease].

[Article in Japanese]

Ishigatsubo Y(1), Samukawa S.

Author information:

(1)Department of Internal Medicine and Clinical Immunology, Yokohama City University.

Behçet's disease is a systemic inflammatory disease presented with recurrent oral aphtha, cutaneous manifestations, uveitis, and genital ulcer. The etiology of Behçet's disease is still unknown, but both genetic background and environmental factors are thought to be important in the pathogenesis of Behçet's disease. Behçet's disease has long been regarded as a Th1 type autoimmune disease, because of the association with HLA-B51 and hyperreactivity against streptococcal antigen. However, it was recently found that Behçet's disease and autoinflammatory diseases share several clinical features. Furthermore, increased activity of neutrophils and elevated levels of interleukin-1 $\beta$  are observed in both Behçet's disease and autoinflammatory diseases. The relationship between Behçet's disease and autoinflammatory diseases, especially Familial Mediterranean fever, is speculated, because both diseases are prevalent in the Mediterranean basin and treated with colchicine. Genetic researches on Behçet's disease and FMF suggest that the MEFV gene mutated in Familial Mediterranean fever is a probable susceptibility gene for Behçet's disease. Although many observations suggest that Behçet's disease might be autoinflammatory, there is evidence implying autoimmune pathogenesis of Behçet's disease. For example, some symptoms of Behçet's disease is treated with T cell suppressing agents. Recent data suggest that a novel subset of T cells, Th17, plays a crucial role in pathogenesis of Behçet's disease, and genome-wide association researches verified it. IL-17, which is the secreted from of Th17 activates neutrophils. Hence, IL-17 might cause the symptoms resembling autoinflammatory diseases. Recently, Anti-IL-1 treatment proved to be effective and other susceptibility genes are being investigated. These new findings will shed light on the long-sought pathogenesis of Behçet's disease.

[Periodic fever, aphthous stomatitis, pharyngitis and adenitis syndrome].

[Article in Japanese]

Kusuhara K(1).

Author information:

(1)Department of Pediatrics, University of Occupational and Environmental Health.

Periodic fever, aphthous stomatitis, pharyngitis and adenitis (PFAPA) syndrome is a non-hereditary autoinflammatory disease, characterized by relatively regular recurrence of febrile episodes of 3-6 days duration, accompanied by aphthous stomatitis, pharyngitis/tonsillitis, and/or cervical adenitis. It is considered to be the most common periodic fever syndrome in Japan. Although no responsible gene is identified, some genetic factors may confer the predisposition toward this disorder. Important differential diagnosis includes hereditary periodic syndromes and cyclic neutropenia. Although its etiology is still to be elucidated, a recent study suggested an environmentally triggered activation of complement and IL-1 $\beta$ /IL-18 during PFAPA syndrome flares, with induction of Th1-chemokines and subsequent retention of activated T cells in peripheral tissues. This study also demonstrated the possibility that IP-10/CXCL10 might serve as a potential biomarker to differentiate PFAPA syndrome from other periodic fever syndromes. Therapeutic strategy for PFAPA syndrome has not been well established. Recent advances in the understating of etiology and pathophysiology might lead to re-evaluation of recent therapeutic options and/or development of new treatment.

[Nakajo-Nishimura syndrome].

[Article in Japanese]

Kanazawa N(1), Arima K, Ida H, Yoshiura K, Furukawa F.

Author information:

(1)Department of Dermatology, Wakayama Medical University.

Nakajo-Nishimura syndrome (NNS) (MIM256040, ORPHA2615) is a distinct inherited inflammatory and wasting disease, which usually begins in early infancy with a pernio-like rash. The patients develop periodic high fever and nodular erythema-like eruptions, and gradually progress lipomuscular atrophy in the upper body, mainly the face and the upper extremities, to show the characteristic long clubbed fingers with joint contractures. So far about 30 cases have been reported from Kansai, especially Wakayama and Osaka, Tohoku and Kanto areas. In addition to 10 cases in Kansai area, which have been confirmed to be alive by national surveillance, an infant case has newly been discovered in Wakayama and more cases will be added. Although cause of the disease has long been undefined, a homozygous mutation of the PSMB8 gene, which encodes the  $\beta 5i$  subunit of immunoproteasome, has been identified by homozygosity mapping. By analyses of the patients-derived cells and tissues, it has been suggested that accumulation of ubiquitinated and oxidated proteins due to deficiency of proteasome activities cause hyperactivation of p38 MAPK and overproduction of IL-6. Similar diseases with PSMB8 mutations have recently been reported from Europe and the U.S.A., and therefore, it is becoming clear that proteasome deficiency syndromes are globally distributed as a new category of the autoinflammatory diseases.

[Hyperimmunoglobulinemia D and periodic fever syndrome].

[Article in Japanese]

Sakai H(1), Heike T.

Author information:

(1)Department of Pediatrics, Shizuoka municipal hospital.

Hyperimmunoglobulinemia D and periodic fever syndrome (HIDS) is inherited autoinflammatory syndrome caused by deficiency of the mevalonate kinase (MK), which is involved in metabolism of cholesterol. The disease is characterized as periodic fever from early infancy accompanied by elevated serum C-reactive protein. Since clinical symptoms such as abdominal symptom, skin rash, and arthritis are common to other autoinflammatory disease, the diagnosis of HIDS during clinical work is difficult for the physicians without suspicion of HIDS for infants suffering from fever of unknown origin. Moreover, serum IgD levels are not high during infancy conflicting to the name of the disease, which is often misunderstood in the clinicians. Thus, the diagnosis of HIDS in Japan is bothering, depending on the lack of correct recognition of the disease and on the lack of commercially available examination for the disease. It is important for clinicians, especially pediatricians to update current knowledge about HIDS and to learn the appropriate way to the definitive diagnosis of HIDS, because HIDS patients exist also in Japan and the specific therapies for HIDS would be developed in the near future.

[CAPS: cryopyrin-associated periodic syndrome].

[Article in Japanese]

Saito MK(1).

Author information:

(1)Center for iPS cell research and application, Kyoto university, Japan.

Cryopyrin-associated periodic syndrome (CAPS) is an autoinflammatory syndrome caused by heterozygous mutations of NLRP3 gene. CAPS consists of three

phenotypically similar but distinct syndromes: familial cold autoinflammatory syndrome (FCAS), Muckle-Wells syndrome and CINCA syndrome. Among them, FCAS shows the mildest phenotype while CINCA is the severest. Common symptoms include sporadic or cold-induced nonpruritic urticarial rash and fever. Severe cases suffers from deafness, meningitis, articular contracture and secondary amyloidosis. Gain-of-function mutations of NLRP3 causes excessive production of a potent proinflammatory cytokine IL-1 $\beta$ , thereby evokes autoinflammatory symptoms of CAPS. Recent advances of anti-IL-1 therapy dramatically improved the prognosis of CAPS. Currently three anti-IL-1 medicines are available, and all of them significantly improved clinical symptoms of CAPS patients. Although long-term observation is still needed, the molecular-targeted therapy has opened up a new opportunity for managing CAPS.

[Progress in classification and treatment for TNF receptor-associated periodic syndrome].

[Article in Japanese]

Tsukamoto H(1), Ueda N, Horiuchi T.

Author information:

(1)Department of Medicine and Biosystemic Science, Kyushu University Graduate School of Medical Sciences.

TNF receptor-associated periodic syndrome (TRAPS) is an autosomal dominant autoinflammatory disorder characterized by recurrent febrile attacks. TRAPS is associated with mutation in the gene encoding TNF Receptor I (TNFRI) and seven mutations have been reported in Japan. Molecular modeling experiments indicate that the mutant TNFRI accumulates intracellularly in the endoplasmic reticulum due to misfolding and activates MAP kinase (MAPK) through induction of mitochondrial reactive oxygen species production. MAPK activation is further enhanced by the stimulation through toll-like receptor, resulting in the enhanced proinflammatory cytokine production. Febrile attacks last 21 days on average and

occur every one to several months. Myalgia, erythematous macular rash, abdominal pain, conjunctivitis, periorbital edema, chest pain and arthralgia are commonly seen during the attacks. Glucocorticoid is effective in decreasing the severity and duration of the febrile attacks. Soluble TNF receptor etanercept, IL-1 receptor antagonist Anakinra(TM) and IL-6 receptor antagonist tocilizumab are effective in some patients. Japanese study group of TRAPS conducted national survey to make new diagnostic criteria in 2010.

[Clinical aspects of Familial Mediterranean fever].

[Article in Japanese]

Migita K(1), Agematsu K.

Author information:

(1)Clinical Research Center, NHO Nagasaki Medical Center.

Familial Mediterranean fever (FMF) is a hereditary autoinflammatory disease characterized by recurrent and short duration (1-3 days) of fever, and serositis. Based on the nationwide survey of FMF in Japan, the estimated number of Japanese FMF patients is about three hundred. High grade fever was observed in 95.5%, chest pain in 35.8% abdominal pain in 62.7% and arthritis in 31.3% among Japanese FMF patients. AA amyloidosis was confirmed in 5 patients (3.7%). Colchicine was effective in 91.8% of Japanese FMF patients. A significant number of FMF patients exist in Japan, and early diagnosis and treatments should be required to prevent AA amyloidosis.

["The inflammasomes"].

[Article in Japanese]

Masumoto J(1).

Author information:

(1)Department of Molecular Pathology, Shinshu University Graduate School of Medicine.

Inflammation is a host adaptational response to cell injury caused by various exogenous and endogenous stimuli. IL-1 $\beta$ , which is an important proinflammatory cytokine secreted at the site of cellular injury, plays an important role in inflammation. Inflammasome is an intracellular multi-protein complex that mediates caspase-1-dependent processing of IL-1 $\beta$ . In this review, inflammasome function and its dysregulation are discussed in relation to autoinflammatory diseases.

[Pattern recognition receptors].

[Article in Japanese]

Hayashi T(1), Nakamura T, Takaoka A.

Author information:

(1)Research Center of Infection-Associated Cancer, Hokkaido University, Sapporo, Japan.

Immunity is based on self/nonself discrimination. In vertebrates, two major systems, innate and adaptive immune systems, constitute host defense against invading microbes. Adaptive immunity is characterized by specific immune responses through B- or T-cell antigen receptors that are generated by somatic recombination, whereas nonspecific responses to microbes had been accentuated in

innate immunity. However, the discovery of pattern recognition receptors (PRRs) that are encoded in the germ-line, including Toll-like receptors, RIG-I-like receptors, NOD-like receptors and AIM2-like receptors, advanced our understanding of a mechanism for innate immune recognition. These types of PRR recognize pathogen- or damage-associated molecular patterns (PAMPs or DAMPs) during infection or tissue damage, and commonly evoke the downstream gene induction programme, such as expression of type I interferons, inflammatory cytokines and chemokines. Dysregulation of PRR-triggered signal activation leads to pathologic inflammatory responses. In this regard, it has been shown that many of "autoinflammatory diseases", recently defined clinical entity, have putatively causative mutations in the genes that encode PRRs or their signaling mediators. In this review article, we describe recent overview of PRRs as innate sensors and update knowledge of "autoinflammatory diseases" particularly by focusing on their association with innate signaling.

Erratum in

Clin Exp Rheumatol. 2012 Jan-Feb;30(1):146.

Familial Mediterranean fever (FMF) is a hereditary disorder characterised by recurrent attacks of fever with peritonitis or pleuritis, arthritis, myalgia or erysipelas-like skin lesions. The continuous inflammation in FMF is associated with increased serum amyloid A (SAA) protein which may lead to secondary amyloidosis and deposition of this insoluble protein in the kidney, gut, spleen, liver, heart etc. Therefore, treatment of patients with FMF is beneficial not only for the prevention of the acute attacks but also for improving their

prognosis. In the present review we summarise the medical literature concerning FMF treatment, including new therapeutic agents and management of colchicine-resistant patients. Three electronic databases (MEDLINE, EMBASE, and the Cochrane Library) were searched from 1 January 1960 to 28 February 2010 for any therapeutic approach to FMF, with MeSH headings and text words (Familial Mediterranean Fever, FMF treatment, colchicine, infliximab, anakinra, SSRI). In conclusion, colchicine remains the mainstay therapeutic option in FMF. It is effective in various manifestations of the disease such as fever, peritonitis and pleuritis. It prevents the development of amyloidosis. It is safe in humans regarding fertility, and can be used during pregnancy and nursing. Dose adjustment should be made in patients with renal or hepatic failure. It is less effective in arthritis or myalgia, requiring additional treatment with NSAIDs and steroids. In the few cases where FMF is resistant to colchicine other measures, including corticosteroids, non-biological and biological DMARDs, interferon alpha and SSRIs should be employed.

The frequency of familial Mediterranean fever in an emergency unit.

Masatlioglu S(1), Dulundu E, Gogus F, Hatemi G, Ozdogan H.

Author information:

(1)Department of Internal Medicine, Haydarpasa Haydarpasa Numune Research and Education Hospital, Istanbul, Turkey. sevalmasatlioglu@yahoo.com

Approximately 90% of patients with familial Mediterranean fever (FMF) complain of recurrent attacks of fever and abdominal pain of various severities. Prior to the diagnosis of FMF, the majority of patients are admitted to emergency units with a suspicion of acute abdomen pain and at least half of them undergo unnecessary abdominal interventions. The purpose of this study is to determine the frequency of FMF among the patients who are admitted to emergency units for acute abdominal pain. One hundred consecutive patients who were admitted to an emergency unit in Istanbul, Turkey, with acute abdominal pain were screened for FMF. When the definite cases were considered, a frequency of 2% was encountered which was

significantly high compared to the frequency of FMF in Turkey. Physicians working in emergency units should include FMF in their differential diagnosis list when evaluating a patient with acute abdominal pain, especially in countries where the disease is prevalent.

Familial Mediterranean fever in small children in Turkey.

Yalcinkaya F(1), Ozcakar ZB, Tanyildiz M, Elhan AH.

Author information:

(1)Ankara University School of Medicine, Department of Pediatric Nephrology, Ankara, Turkey. yalcinkaya@tr.net

**OBJECTIVES:** Familial Mediterranean fever (FMF) is an autosomal recessive disease, characterised by recurrent, self limited attacks of fever with serositis. The aim of our study was to describe the demographic, clinical and genetic features of FMF patients who had early disease onset and to compare them with late onset patients. Our second aim was to investigate the factors associated with delay in diagnosis.

**METHODS:** The study group consisted of recently diagnosed FMF patients who came to routine follow-up visits between January and July 2009. Patients were divided into two groups according to age of disease onset (Group I:  $\leq 3$  years of age; Group II:  $>3$  years of age). In the second part, patients were analysed according to the duration of delay in diagnosis.

**RESULTS:** There were 83 patients in group I and 73 patients in Group II. Median delay in diagnosis was 4 years in Group I and 2 years in Group II ( $p<0.001$ ). The presence of M694V mutation was more frequent in Group I (81%) as compared to Group II (65%), ( $p=0.034$ ). Mean attack Hb was lower ( $p<0.01$ ) and mean attack leukocyte count was higher ( $p=0.017$ ) in Group I. Final colchicine dosages were higher in Group I as compared to Group II. There was a statistically significant negative correlation between the age at disease onset and period of delay in diagnosis ( $p<0.001$ ).

**CONCLUSIONS:** This study suggests that FMF patients with early disease onset have

more severe disease. Moreover, the smaller the age of disease onset, the more likely their diagnoses are delayed.

MEFV, TNFRSF1A and CARD15 mutation analysis in Behçet's disease.

Baruch Y(1), Dagan E, Rosner I, Fiorilli M, Gershoni-Baruch R, Rozenbaum M.

Author information:

(1)Department of Clinical Medicine, University of La Sapienza, Rome, Italy.  
yoavi100@gmail.com

**OBJECTIVES:** Given the pathological similarities between Behçet's disease (BD), Familial Mediterranean fever (FMF), TNF receptor-associated periodic syndrome (TRAPS) and Crohn's disease (CD) we evaluated the frequency of mutations and polymorphisms in MEFV, TNFRSF1A and CARD15 in Israeli BD patients of either Jewish or Arab descent.

**METHODS:** Fifty-four BD patients (11 Jews and 43 Arabs), evaluated with respect to the entire spectrum of BD disease manifestations, were granted a systemic severity score for BD. An association between BD manifestations and MEFV, TNFRSF1A and CARD15 variants was analysed.

**RESULTS:** Twelve patients (20.7%) displayed a single MEFV mutation and four patients (7.4%) had two mutated FMF alleles. Two patients (3.8%) carried a CARD15 variation and none carried a TNFRSF1A polymorphism. The frequency and distribution of mutated alleles between patients and controls was comparable ( $p=0.27$ ). No statistically significant differences between carriers and non-carriers with respect to disease manifestations and severity score were calculated. Arab patients were diagnosed earlier than Jewish patients ( $25.8\pm 11.6$  and  $37.2\pm 10.7$ , respectively,  $p=0.06$ ).

**CONCLUSIONS:** The overall MEFV high carrier frequency in our cohort of BD patients seems to be attributed to their Mediterranean extraction rather than related to BD. The propensity of Arab patients (79.6%) in a cohort of BD patients from northern Israel is highlighted in face of their proportion (20%) in the general population lending further support to arguments that favour a genetic component

for BD.

(1)Department of Paediatric Rheumatology, Children's Hospital, University Duisburg-Essen, Hufelandstr. 55, 45147 Essen, Germany. elke.lainka@uni-due.de

Autoinflammatory diseases (AIDs) are characterized by recurrent, self-limiting systemic inflammation. Disorders include hereditary recurrent fever (HRF) syndromes such as hyperimmunoglobulinemia D and periodic fever syndrome (HIDS). To determine the incidence of HIDS and report clinical and genetic characteristics together with the underlying MVK genotypes in German children, a prospective active surveillance was conducted in Germany during a period of 3 years. Monthly inquiries were sent to 370 children's hospitals by the German Paediatric Surveillance Unit (Clinic-ESPED, n1) and to two laboratories

(Laboratory-ESPED, n2) performing genetic analyses. Inclusion criteria were a MVK mutation-positive patient  $\leq 16$  years of age with more than three self-limiting episodes of fever  $>38.5^{\circ}\text{C}$  associated with increased inflammation markers. Clinical, epidemiological, and genetic data were assessed via questionnaires. Eight out of 16 patients were identified in Clinic-ESPED (n1) and 15 of 16 in Laboratory-ESPED (n2). Clinical and laboratory surveys overlapped in 7 of 16 cases. Incidence of HIDS was estimated to be 0.39 (95% CI: 0.22, 0.64) per 10(6) person-years. HIDS symptoms generally started in infancy with recurrent fever episodes lasting 3-12 (median, 4.5) days and recurring every 1-12 weeks. Fever was accompanied by abdominal pain, vomiting, diarrhea, cervical lymphadenopathy, and sometimes by headache, skin and joint symptoms. The patients carried 11 different MVK mutations mostly in compound heterozygosity (75%, 12 out of 16). The most frequent mutation was p.Val377Ile (81%, 13 out of 16). In Germany, the incidence of HIDS is very low with 0.39 per 10(6) person-years.

Homozygous M694V as a risk factor for amyloidosis in Turkish FMF patients.

Akpolat T(1), Özkaya O, Özen S.

Author information:

(1)Department of Nephrology, Ondokuz Mayıs University School of Medicine, Samsun, Turkey. tekinakpolat@yahoo.com

Secondary amyloidosis is the most severe complication of familial Mediterranean fever (FMF). Since the M694V mutation was associated with clinical severity, it was expected to be associated with amyloidosis as well. However, a number of contradicting reports have been published, especially pertinent to Turkish patients nearly 10 years ago. The aim of this study was to analyze recent data regarding the association between M694V mutation and amyloidosis among FMF patients in Turkey. We conducted a comprehensive review of the literature regarding the role of M694V mutation in the development of amyloidosis secondary to FMF. Twenty-seven papers from 20 centers including 3505 Turkish subjects were

reviewed. Four-hundred patients had amyloidosis and homozygous M694V was detected in 189 (47%) of the 400 amyloidotic patients which was significantly higher than that in the FMF patients not developing amyloidosis ( $p < 0.0001$ ). In the presented analysis we were able to reach a patient number of 400 which is much higher than all those published hitherto. Our findings confirmed that homozygous M694V is associated with amyloidosis in the Turkish population as well similar to Armenia, Israel, and Arabian countries. The necessity to treat asymptomatic or mildly symptomatic FMF patients with this genotype, even in countries where amyloidosis is rare, should be considered carefully.

[PFAPA syndrome: study of 10 cases].

[Article in Spanish]

Antón-Martín P(1), Ortiz Movilla R, Álvarez García A, Guillén Martín S, Ruiz Jiménez M, Ramos Amador JT.

Author information:

(1)Unidad de Infectología Pediátrica, Departamento de Pediatría, Hospital Universitario de Getafe, Madrid, España. pilarantonmartin@hotmail.com

**BACKGROUND AND OBJECTIVES:** «PFAPA syndrome» is an autoinflammatory entity consisting of periodic fever, aphthous stomatitis, pharyngitis and cervical adenitis. Its etiology is unknown although a dysregulation in the control of the autoinflammatory response seems to play a role. Although a genetic origin is suspected, no specific mutation has been determined yet. Corticosteroids are the mainstay of the treatment during the acute attacks. However, in long-term follow-up the role of tonsillectomy is controversial.

**PATIENTS AND METHODS:** A retrospective study of the pediatric cases diagnosed with the PFAPA syndrome was performed in our center during the last 4 years.

**RESULTS:** Ten patients were diagnosed with the syndrome who received corticosteroids as the only treatment with improvement and favourable prognosis.

**CONCLUSION:** PFAPA syndrome is the most common periodic fever disorder described in childhood whose genetic background has not been yet clarified. Our contribution with 10 patients further supports the common existence of this entity and the need to keep it in mind when having recurrent fevers.

Mutation screening of the IL-1 receptor antagonist gene in chronic non-bacterial osteomyelitis of childhood and adolescence.

Beck C(1), Girschick HJ, Morbach H, Schwarz T, Yimam T, Frenkel J, van Gijn ME.

Author information:

(1)University of Wurzburg, Germany. beck\_c@kinderklinik.uni-wuerzburg.de

**OBJECTIVES:** Chronic non-bacterial osteomyelitis CNO is an inflammatory disorder of the musculoskeletal system with unknown etiology. In addition to bone inflammation, patients may present with inflammatory involvement of other tissues including, e.g., skin. Recently, a novel syndrome due to deficiency of interleukin-1 receptor antagonist (IL1RN), DIRA has been identified. Clinically the syndrome is characterized by neonatal onset of pustular dermatosis, periostitis and chronic sterile multifocal osteomyelitis, strongly resembling CNO. Homozygous mutations of IL1RN have been identified and resulted in a truncated protein that is not secreted, hence leaving the action of interleukin-1 unopposed.

**METHODS:** Because of similar clinical, radiological and histological features of CNO and DIRA, we hypothesized that both disorders might share a common autoinflammatory process. Thus, we searched for the presence of mutations in the interleukin-1 receptor antagonist gene in 60 patients diagnosed with CNO.

**RESULTS:** In one patient with chronic multifocal osteomyelitis a heterozygous missense variant: c.281G>T (p.Cys94Phe) was detected. In the other patients only

frequent polymorphisms were found.

CONCLUSIONS: Our findings were not able to confirm mutations in IL1RN being an important contributing factor to the pathogenesis of CNO.

The fresco of autoinflammatory diseases from the pediatric perspective.

Rigante D(1).

Author information:

(1)Department of Pediatric Sciences, Università Cattolica Sacro Cuore, Rome, Italy. drigante@gmail.com

Autoinflammatory diseases are genetic or acquired clinical entities globally caused by the aberrant release of the proinflammatory cytokine interleukin-1 and mostly characterized by recurrent spontaneous inflammatory events which do not produce antigen-specific T cells or autoantibodies. Within the past decade, the list of autoinflammatory diseases has included cryopyrin-associated periodic syndromes, familial Mediterranean fever, mevalonate kinase deficiency, tumor necrosis factor receptor-associated periodic syndrome, hereditary pyogenic disorders, pediatric granulomatous autoinflammatory diseases, idiopathic febrile syndromes, complement dysregulation syndromes and Behçet's disease. Most of these conditions interact with the inflammasomes, intracellular molecular complexes coordinating the phylogenetically ancient response of the innate immune system. The pathogenetic mechanisms of these diseases have shown the evidence of disrupted interleukin-1 signaling for most of them and allowed to locate interleukin-1 as an attractive therapeutic target. The whole fresco of autoinflammatory diseases in pediatrics will be discussed in this review with the aim of establishing both diagnostic clues and treatments for each condition.

# Spectrum of mutations and carrier frequency of familial Mediterranean fever gene in the Algerian population.

Ait-Idir D(1), Khilan A, Djerdjouri B, El-Shanti H.

## Author information:

(1)Faculte des Sciences Biologiques, Universite des Sciences et de laTechnologie Houari Boumediene, Alger.

**OBJECTIVES:** FMF is characterized by recurrent self-limiting episodes of fever and painful polyserositis. We aimed to study the spectrum and distribution of MEFV mutations in an Algerian patient cohort using a comprehensive mutation detection method. Using the same methodology, we also studied the carrier rate in an unaffected ethnically matched control cohort.

**METHODS:** We recruited 71 unrelated subjects clinically diagnosed with FMF from various clinics in the central region of Algeria. Two hundred and thirty control subjects were recruited as well. Mutation detection in MEFV was performed by re-sequencing the promoter region, the entire coding sequence and all exon-intron boundaries.

**RESULTS:** We detected eight different mutations located in exons 10 (p.M694I, p.M694V, p.A744S, p.M680I, p.I692Del), 9 (p.I591T), 3 (p.P369S/p.R408Q) and 2 (p.E148Q). Out of the 71 patients, 31 carried at least one mutation. While the 71 patients are expected to have 142 mutant chromosomes, only 50 were identified. p.M694I (17.6%) is the most common mutation, followed by p.M694V (5%), p.E148Q (4.2%), p.A744S (3.5%) and p.M680I (3%). One novel variant was identified in the promoter region in the heterozygous state in three patients and in two controls. The carrier rate of the identifiable mutations is estimated to be 1 : 5.

**CONCLUSION:** This study describes the MEFV mutational spectrum and distribution in the Algerian population. It shows that p.M694I is the most common MEFV mutation in Algerians. It also shows that, similar to other Arabic populations, <50% of mutant chromosomes are identified, even when employing comprehensive strategies.

The relative contribution of environmental and genetic factors to phenotypic variation in familial Mediterranean fever (FMF).

Ben-Zvi I(1), Brandt B, Berkun Y, Lidar M, Livneh A.

Author information:

(1)Department of Internal Medicine F and the national FMF center, Sheba Medical Center, Ramat-Gan, 52621 Israel. Ilan.Benzvi@sheba.health.gov.il

**INTRODUCTION:** Familial Mediterranean fever (FMF) is an autosomal recessive disease, caused by mutations in the FMF gene MEFV (MEditerranean FeVer). It has a large phenotypic diversity even in patients with similar genotypes. Despite evidence that environmental factors (EFs) and genetic factors, including MEFV mutations (such as M694V, E148Q) and background modifier genes (MGs), affect the clinical manifestations of FMF, the relative contribution of each remains unknown.

**METHODS:** To investigate the relative contribution of environmental and genetic factors to the phenotype of FMF, we compared the intra-pair clinical concordance of 10 mono and 7 dizygotic twins with FMF. The part played by EFs was determined by the phenotypic discordance of the monozygous twins, and the MGs effect was determined by deducing the environmental effect, computed for MZ twins, from the phenotypic discordance of the dizygous twins.

**RESULTS:** The mean $\pm$ SD of intra-pair concordance was higher in the MZ than in DZ twin group (88.1 $\pm$ 13.2 vs. 70.7 $\pm$ 14.1 respectively, P value<0.05). Based on the concordance in clinical manifestations in MZ and DZ twins, the environmental effect on the phenotype of FMF is estimated as 11.9% $\pm$ 6.6% and the MGs effect as 17.4% $\pm$ 15.5% in average.

**CONCLUSIONS:** In FMF the phenotype is affected by MEFV mutations, MGs and EFs in an estimated ratio of about 6:1.5:1 respectively.

Neutrophil proteinase 3 induces diabetes in a mouse model of glucose tolerance.

Bae S(1), Choi J, Hong J, Jhun H, Hong K, Kang T, Song K, Jeong S, Yum H, Kim S.

Author information:

(1)Laboratory of Cytokine Immunology, Institute of Biomedical Science and Technology, College of Medicine, Konkuk University, Seoul, Republic of Korea.

Type 1 diabetes is considered to be an autoimmune disease in which T cells attack pancreatic islet cells. Impaired glucose tolerance with type 2 diabetes has been classified as an obesity-associated metabolic syndrome. However, recent studies have revealed that type 2 diabetes is an autoinflammatory disease due to an imbalance of inflammatory cytokine production and related molecular components that cause inflammation. Insulin-like growth factor (IGF) and the insulin-like growth factor-binding protein-3 (IGFBP3) system are known to be involved in the development of experimental diabetic nephropathy, and urinary IGFBP3 protease activity has been observed in patients with type 2 diabetes. A serine protease was found to be responsible for the proteolytic activity in diabetic urine; however, the identity of the precise enzyme remains unknown. We investigated neutrophil proteinase 3 (PR3) to see whether it has specific enzymatic activity associated with insulin-like growth factor-1 and IGFBP3. In our study, both molecules were sufficiently degraded, which leads us to believe that PR3 may induce insulin resistance in the mouse model utilized. In addition, we found that PR3 in the urine of diabetic patients similarly affects insulin resistance. Moreover, PR3-immunized mice had an increase in glucose clearance due to inhibition of PR3 activity. As such, PR3 can be considered as an inflammatory enzyme directly linking inflammation to type 2 diabetes through downregulation of insulin-like growth factor-1/IGFBP3.

Efficacy of etanercept in the tumor necrosis factor receptor-associated periodic syndrome: a prospective, open-label, dose-escalation study.

Bulua AC(1), Mogul DB, Aksentijevich I, Singh H, He DY, Muenz LR, Ward MM, Yarboro CH, Kastner DL, Siegel RM, Hull KM.

Author information:

(1)National Institute of Arthritis and Musculoskeletal and Skin Diseases, NIH, Bethesda, MD 20892, USA.

**OBJECTIVE:** To investigate the efficacy of etanercept in improving the symptoms and underlying inflammation in patients with tumor necrosis factor receptor-associated periodic syndrome (TRAPS).

**METHODS:** Fifteen patients with TRAPS were enrolled in a prospective, open-label, dose-escalation study. Patients recorded attacks, symptom severity, and use of ancillary medications in a daily diary. Blood samples were collected during each period and measured for levels of acute-phase reactants. Between 7 years and 9 years after the conclusion of the initial study, patients completed a followup survey and were evaluated to determine the long-term outcome of etanercept treatment.

**RESULTS:** Etanercept treatment significantly attenuated the total symptom score and reduced the frequency of symptoms. Etanercept also reduced levels of acute-phase reactants, particularly during asymptomatic periods. During a 10-year followup period, patients continued to receive etanercept for a median of 3.3 years, with a number of patients switching to anti-interleukin-1 $\beta$  receptor therapy or not receiving biologic agents, most frequently citing injection site reactions and lack of efficacy as reasons for discontinuation. However, patients continuing to receive etanercept had reduced symptoms at followup.

**CONCLUSION:** Etanercept reduces symptoms and serum levels of inflammatory markers of TRAPS in a dose-dependent manner, but does not completely normalize symptoms or acute-phase reactant levels. Although long-term adherence to etanercept is poor, continuing to receive etanercept may provide continued symptomatic benefit.

The anti-inflammatory drug colchicine lacks efficacy in hidradenitis suppurativa.

van der Zee HH(1), Prens EP.

Author information:

(1)Department of Dermatology, Erasmus MC, University Medical Center, Rotterdam, The Netherlands. h.vanderzee@erasmusmc.nl

**BACKGROUND:** Hidradenitis suppurativa (HS) is a chronic, inflammatory skin disease. Since current treatments are unsatisfactory for many patients, there is a high need for effective drugs for this debilitating disease. Recent pathogenic insights suggest inflammasome activation and IL-1 $\beta$  production are important in HS. Colchicine is efficacious in the IL-1 $\beta$ - and inflammasome-mediated diseases gout, familial Mediterranean fever and Behçet's disease, and therefore a potentially effective drug in HS.

**OBJECTIVE:** To investigate the efficacy of colchicine in HS.

**METHODS:** In an open prospective pilot study, 8 HS patients were treated with the accepted gout maintenance regimen of 0.5 mg colchicine b.i.d. orally up to 4 months. Efficacy was assessed by a physician global assessment.

**RESULTS:** Colchicine treatment did not result in a clinically relevant improvement of disease severity. Three patients experienced nausea and diarrhea as known side effects.

**CONCLUSION:** Colchicine in the used dose regimen does not ameliorate HS severity.

'Silent' carriage of two familial Mediterranean fever gene mutations in large families with only a single identified patient.

Camus D(1), Shinar Y, Aamar S, Langevitz P, Ben-Zvi I, Livneh A, Lidar M.

Author information:

(1)Heller Institute of Medical Research and Medicine F, Sheba Medical Center, Tel-Hashomer, affiliated with the Sackler School of Medicine, Tel Aviv University, Tel Aviv, Israel.

The presence of two mutations in the familial Mediterranean fever gene, without overt familial Mediterranean fever (FMF), designated as phenotype III, predisposes to developing 'silent' AA amyloidosis, recognized as phenotype II, due to the absence of medical supervision and colchicine prophylaxis. We sought to determine the prevalence of phenotype III in large families with only one subject affected with FMF, in order to assess the population at risk for transformation to phenotype II. A total of seven large families were recruited for the study. Siblings were screened for MEFV mutations and underwent a clinical interview to assess for unrecognized FMF manifestations. Phenotype III, most commonly associated with a V726A/E148Q genotype, was detected in 10% of siblings of index cases from informative families, corresponding to a 10-fold increase in comparison to the expected rate in the general population ( $p < 0.01$ ). Unnoticed 'FMF-like' manifestations were detected among two siblings in the five families in which the index case was heterozygous, but in none of the siblings of the homozygous index cases. The enrichment for phenotype III and detection of occult FMF in large families, in which only a single member is afflicted with FMF, mandates routine clinical evaluation and genetic screening of siblings.

cantariniluca@hotmail.com

Most autoinflammatory disorders typically come out in the pediatric population, although a limited number of patients may experience disease onset during adulthood. To date, a late disease onset has been described only in familial Mediterranean fever, caused by mutations in the MEFV gene, and in tumor necrosis factor receptor-associated periodic syndrome, caused by mutations in the TNFRSF1A gene. The relative rarity and lack of information on adult-onset autoinflammatory diseases make it likely that mutations will be found in an even smaller percentage of cases. With the aim of improving the genetic diagnosis in adults with suspected autoinflammatory disorders, we recently identified a set of variables related to the probability of detecting gene mutations in MEFV and TNFRSF1A and, in addition, we have also proposed a diagnostic score for identifying those patients at high risk of carrying mutations in these genes. In the present study we evaluated the preliminary score sensitivity and specificity on a wider number of patients in order to validate the goodness of fit of the model. Two hundred and nineteen consecutive patients with a clinical history of periodic fever attacks were screened for mutations in MEFV and TNFRSF1A genes; detailed information about family/personal history and clinical manifestations were also collected. For the validation of the score we considered data both from the 110 patients used to build the preliminary diagnostic score and from the additional 219 patients enrolled in the present study, for a total number of 329 patients. Early age at disease onset, positive family history for recurrent fever episodes, thoracic pain, abdominal pain and skin rash, which are the variables that had previously been shown to be significantly associated with a positive genetic test result (12), were used for validation. On univariate analysis the associations with a positive genetic test were: age at onset (odds ratio [OR] 0.43,  $p=0.003$ ), positive family history for recurrent fever episodes (OR 5.81,  $p<0.001$ ), thoracic pain (OR 3.17,  $p<0.001$ ), abdominal pain (OR 3.80,  $p<0.001$ ) and skin rash (OR 1.58,  $p=0.103$ ). The diagnostic score was calculated using the linear combination of the estimated coefficients of the logistic multivariate model (cut-off equals to 0.24) revealing good sensitivity (0.778) and good specificity (0.718). In conclusion, our score may serve in the diagnostic evaluation of adult patients presenting with recurrent fever episodes suspected of having an autoinflammatory disorder, helping identify the few subjects among them who may be carriers of mutations in MEFV and TNFRSF1A genes.

Clinical and biochemical landmarks in systemic autoinflammatory diseases.

Cantarini L(1), Rigante D, Brizi MG, Lucherini OM, Sebastiani GD, Vitale A, Gianneramo V, Galeazzi M.

Author information:

(1)Interdepartmental Research Center of Systemic Autoimmune and Autoinflammatory Diseases, Unit of Rheumatology, Policlinico Le Scotte, University of Siena, Siena, Italy. cantariniluca@hotmail.com

Systemic autoinflammatory diseases are a group of inherited disorders of the innate immune system characterized by seemingly unprovoked inflammation recurring at variable intervals and involving skin, serosal membranes, joints, and gastrointestinal apparatus, with reactive amyloidosis as a possible severe long-term complication. Recent advances in genetics and molecular biology have improved our understanding of the pathogenesis of these diseases, including familial Mediterranean fever, mevalonate kinase deficiency syndrome, tumor necrosis factor receptor-associated periodic syndrome, cryopyrin-associated periodic syndromes, and hereditary pyogenic and granulomatous disorders: the vast majority of these conditions are related to the activation of the interleukin-1 pathway, which results in (or from?) a common unifying pathogenetic mechanism. Their diagnostic identification derives from the combination of clinical data, evaluation of acute phase reactants, clinical efficacy in response to specific drugs, and recognition of specific mutations in the relevant genes, although genetic tests may be unconstructive in some cases. This review will discuss clinical and laboratory clues useful for a diagnostic approach to systemic autoinflammatory diseases.

Regulation of IL-2 gene expression by Siva and FOXP3 in human T cells.

Hench VK(1), Su L.

Author information:

(1)Lineberger Comprehensive Cancer Center, School of Medicine, The University of North Carolina at Chapel Hill, USA.

**BACKGROUND:** Severe autoinflammatory diseases are associated with mutations in the Foxp3 locus in both mice and humans. Foxp3 is required for the development, function, and maintenance of regulatory T cells (Tregs), a subset of CD4 cells that suppress T cell activation and inflammatory processes. Siva is a pro-apoptotic gene that is expressed across a range of tissues, including CD4 T cells. Siva interacts with three tumor necrosis factor receptor (TNFR) family members that are constitutively expressed on Treg cells: CD27, GITR, and OX40.

**RESULTS:** Here we report a biophysical interaction between FOXP3 and Siva. We mapped the interaction domains to Siva's C-terminus and to a central region of FOXP3. We showed that Siva repressed IL-2 induction by suppressing IL-2 promoter activity during T cell activation. Siva-1's repressive effect on IL-2 gene expression appears to be mediated by inhibition of NFkappaB, whereas FOXP3 repressed both NFkappaB and NFAT activity.

**CONCLUSIONS:** In summary, our data suggest that both FOXP3 and Siva function as negative regulators of IL-2 gene expression in Treg cells, via suppression of NFAT by FOXP3 and of NFkappaB by both FOXP3 and Siva. Our work contributes evidence for Siva's role as a T cell signalling mediator in addition to its known pro-apoptotic function. Though further investigations are needed, evidence for the biophysical interaction between FOXP3 and Siva invites the possibility that Siva may be important for proper Treg cell function.

(3)Division of Nephrology and Hypertension, Department of Internal Medicine, Mayo Clinic, Rochester, MN, USA ; Division of Hematology, Department of Internal Medicine, Mayo Clinic, Rochester, MN, USA.

We report a case of relapsing mesangial and endocapillary proliferative glomerulonephritis (GN) associated with a periodic fever syndrome. The patient presented 11 times in >4 years with acute febrile episode followed in 1-3 days by hematuria, thrombocytopenia and other symptoms of acute GN with variable severity of acute kidney injury. In three episodes, the patient required renal replacement therapy for 7, 10 and 2 treatments, respectively. Shortly after the acute symptoms of the febrile episode had resolved each time, the kidney function would recover and the serum creatinine would return to baseline. Two kidney biopsies obtained during separate episodes showed acute tubular injury along with morphological changes resembling post-infectious GN but with no clinical evidence to support an infectious etiology. Multiple treatment regimens were unable to control the disease. Symptoms were alleviated by rituximab but did not completely remit. Stable remission of the periodic fever and GN was finally achieved after anakinra therapy was initiated 18 months ago. Since then, the patient had several episodes of documented infection without high fever and nephritic kidney manifestations. His kidney function remained stable with normal serum creatinine.

Familial mediterranean fever in an Iranian patient with behcet disease.

Mobini M(1).

Author information:

(1)Department of Internal Medicine, Imam Khomeini Hospital, Mazandaran University of Medical Sciences, Sari, Iran.

**BACKGROUND:** Familial Mediterranean fever (FMF) is the most prevalent disorder among the hereditary autoinflammatory syndromes. This disorder is characterized by fever and some painful attacks such as abdominal, chest or joint pain and potentially development of AA amyloidosis. Several vasculitis are more common in FMF than general population. There are some reports about association of FMF with Behcet Disease (BD).

**CASE PRESENTATION:** In this study, we describe a 27 year old patient with BD who suffered from attacks of fever, arthralgia, abdominal pain and genetic study confirmed the diagnosis of FMF.

**CONCLUSION:** FMF should be considered in a patient with Behcet disease who is suffering from attacks of fever, arthralgia and abdominal pain.

Mutations in proteasome subunit  $\beta$  type 8 cause chronic atypical neutrophilic dermatosis with lipodystrophy and elevated temperature with evidence of genetic and phenotypic heterogeneity.

Liu Y(1), Ramot Y, Torrello A, Paller AS, Si N, Babay S, Kim PW, Sheikh A, Lee CC, Chen Y, Vera A, Zhang X, Goldbach-Mansky R, Zlotogorski A.

Author information:

(1)National Institute of Arthritis and Musculoskeletal and Skin Diseases, NIH, Bethesda, MD 20892, USA.

**OBJECTIVE:** Chronic atypical neutrophilic dermatosis with lipodystrophy and elevated temperature (CANDLE syndrome) is an autoinflammatory syndrome recently described in children. We undertook this study to investigate the clinical

phenotype, genetic cause, and immune dysregulation in 9 CANDLE syndrome patients.

**METHODS:** Genomic DNA from all patients was screened for mutations in PSMB8 (proteasome subunit  $\beta$  type 8). Cytokine levels were measured in sera from 3 patients. Skin biopsy samples were evaluated by immunohistochemistry, and blood microarray profile and STAT-1 phosphorylation were assessed in 4 patients and 3 patients, respectively.

**RESULTS:** One patient was homozygous for a novel nonsense mutation in PSMB8 (c.405C>A), suggesting a protein truncation; 4 patients were homozygous and 2 were heterozygous for a previously reported missense mutation (c.224C>T); and 1 patient showed no mutation. None of these sequence changes was observed in chromosomes from 750 healthy controls. Of the 4 patients with the same mutation, only 2 shared the same haplotype, indicating a mutational hot spot. PSMB8 mutation-positive and -negative patients expressed high levels of interferon- $\gamma$  (IFN $\gamma$ )-inducible protein 10. Levels of monocyte chemotactic protein 1, interleukin-6 (IL-6), and IL-1 receptor antagonist were moderately elevated. Microarray profiles and monocyte STAT-1 activation suggested a unique IFN signaling signature, unlike in other autoinflammatory disorders.

**CONCLUSION:** CANDLE syndrome is caused by mutations in PSMB8, a gene recently reported to cause "JMP" syndrome (joint contractures, muscle atrophy, microcytic anemia, and panniculitis-induced childhood-onset lipodystrophy) in adults. We extend the clinical and pathogenic description of this novel autoinflammatory syndrome, thereby expanding the clinical and genetic disease spectrum of PSMB8-associated disorders. IFN may be a key mediator of the inflammatory response and may present a therapeutic target.

Acute phase response and oxidative stress status in familial Mediterranean fever (FMF).

Guzel S(1), Andican G, Seven A, Aslan M, Bolayirli M, Guzel EC, Hamuryudan V.

Author information:

(1)Department of Biochemistry, Medical Faculty, Namik Kemal University, Tekirdag, Turkey. savasguzel@yahoo.com

We aimed to determine acute phase response (APR) and oxidative stress in patients with familial Mediterranean fever (FMF) and compare these characteristics with those in healthy controls; 20 patients with FMF and 15 healthy controls were enrolled in the study. The erythrocyte sedimentation rate (ESR), and C-reactive protein (CRP), fibrinogen, and leukocyte levels were determined as markers of APR. Thiobarbituric acid reactive substances (TBARS), conjugated diene, and lipid hydroperoxide levels were measured as markers of lipid peroxidation. Carbonyl group and thiol (T-SH) levels were analyzed to determine the oxidative damage to proteins, and 8-hydroxy-2-deoxyguanosine (8-OHdG) was measured to reflect DNA oxidation. The erythrocyte glutathione (GSH) level, and glutathione peroxidase (GSH-Px), CuZn superoxide dismutase (CuZn SOD), and catalase activities were measured as markers of antioxidant status. Conjugated diene ( $p < 0.001$ ) and carbonyl group ( $p < 0.05$ ) levels were significantly higher and GSH-Px activity ( $p < 0.01$ ) was significantly lower in FMF patients compared with controls. FMF patients in the attack period ( $n = 8$ ) had significantly higher CRP, ESR, fibrinogen, and leukocyte levels ( $p < 0.001$ ) than patients in the attack-free period ( $n = 12$ ). The T-SH level ( $p < 0.05$ ) was significantly higher and CuZn SOD activity was significantly lower ( $p < 0.05$ ) in FMF patients in the attack period. The findings revealed upregulated APR during the attack period in FMF patients and enhanced oxidative stress in the FMF patients as compared to controls.

Author information:

(1)Department of Medicine, University of Oklahoma Health Sciences Center, Oklahoma City, OK 73104, USA. aikaterini-thanou@ouhsc.edu

Comment in

J Clin Rheumatol. 2013 Oct;19(7):420.

Adult-onset Still's disease (AOSD), an autoinflammatory syndrome of unknown etiology, typically manifests with spiking fevers, polyarthritis, and characteristic evanescent rash. We describe a young woman with AOSD complicated by calf fasciitis that serendipitously responded to clarithromycin administered for another indication. Remarkable improvement followed rechallenges with clarithromycin for subsequent AOSD flares. In addition to their antibacterial actions, macrolides demonstrate immunomodulatory effects, including suppression of proinflammatory cytokine production and neutrophil action. Previous clinical trials provide promising preliminary evidence of a therapeutic effect of macrolides in chronic inflammatory diseases. Although AOSD pathogenesis remains unclear, a role for dysregulation of innate immunity is supported by recent literature. Based on this possible innate immune mechanism, we suspect that macrolides may have induced a therapeutic response in this patient with AOSD. A clinical trial is warranted to establish or refute their therapeutic efficacy.

Effects of anti-tumor necrosis factor agents for familial mediterranean fever patients with chronic arthritis and/or sacroiliitis who were resistant to colchicine treatment.

Bilgen SA(1), Kilic L, Akdogan A, Kiraz S, Kalyoncu U, Karadag O, Ertenli I, Dogan I, Calguneri M.

Author information:

(1)From the Division of Rheumatology, Department of Internal Medicine, Hacettepe University, Ankara, Turkey.

BACKGROUND: Effectiveness of anti-tumor necrosis factor (anti-TNF) agents in colchicine-resistant familial Mediterranean fever (FMF) patients has attracted attention in recent years.

**OBJECTIVE:** We analyzed the effect of anti-TNF agents on clinical findings of colchicine-resistant FMF patients with chronic arthritis and/or sacroiliitis.

**METHODS:** Data from 10 FMF patients (5 male and 5 female patients: mean age, 30.1 [SD, 8.5] years) with chronic arthritis and/or sacroiliitis who were on anti-TNF agents are reviewed. Frequency of FMF attacks before and after treatment with anti-TNF agents was recorded from hospital files. The effects of the anti-TNF treatment were determined by using the number of tender and/or swollen joints, serum acute phase reactant levels, and Bath Ankylosing Spondylitis Disease Activity Index scores. Change in urine protein loss was also evaluated in patients with amyloidosis. In 6 patients, FMF attacks had been considered to be unresponsive to colchicine, and 4 patients were partial responders before treatment with anti-TNF agents.

**RESULTS:** Mean attack frequency of the patients in the 3 months' period before anti-TNF agent treatment was 3.8 (SD, 3.1). After anti-TNF treatment, in 3 patients, FMF attack frequency decreased, and in the remaining 7 patients, no attack occurred. Serum acute phase reactant levels were decreased significantly at 3 and 6 months after anti-TNF treatment ( $P < 0.05$  for all). After anti-TNF treatment Bath Ankylosing Spondylitis Disease Activity Index scores were also decreased significantly (6.2 [SD], 1.7 vs. 2.1 [SD], 1.7;  $P = 0.012$ ). In all 3 patients with amyloidosis, urine protein loss decreased without any increase in serum creatinine levels.

**CONCLUSION:** Anti-TNF treatment can have beneficial effects for controlling FMF attacks in FMF patients with chronic arthritis and/or sacroiliitis.

Tumor necrosis factor receptor associated periodic fever syndrome with photographic evidence of various skin disease and unusual phenotypes: case report and literature review.

Yao Q(1), Englund KA, Hayden SP, Tomecki KJ.

Author information:

(1)Department of Rheumatic and Immunologic Diseases, Cleveland Clinic, Cleveland,

**OBJECTIVES:** To report a case of tumor necrosis factor receptor associated periodic fever syndrome (TRAPS) with unusual clinical phenotypes and a systematic review.

**METHODS:** The relevant English literature of TRAPS was searched using the keywords TRAPS, autoinflammatory disease, and gene mutation. Original and review articles were reviewed and the clinical scenarios were exemplified with a case report.

**RESULTS:** A 58-year-old Jewish woman with Eastern European Ashkenazic background presented with photographic evidence of various skin disease, including previously unreported vesicles and alopecia, as well as other systemic manifestations. The complaints of urinary foreign bodies prompted a discovery of ureteral strictures with atypia perhaps from autoinflammation. A R92Q gene mutation of TNFRSFA1 was detected. The clinical manifestations of this disease are protean and its pathogenesis is complex, involving the interaction of wild-type and mutated gene products, innate immune system, and proinflammatory cytokines. Glucocorticoid and anticytokine therapy is generally efficacious but some cases remain refractory to the current treatment.

**CONCLUSIONS:** TRAPS is a systemic autoinflammatory disease with variable clinical phenotypes associated with gene mutations. Recognition of the unusual phenotypes may enhance early accurate diagnosis.

Cytoplasmic inflammasomes are formed through activation of pattern recognition receptors (PRR) of the innate immune system. Endogenous and exogenous danger signals, e.g. DNA- and RNA-fragments, urate- and cholesterol crystals, silica and asbestos,  $\beta$ -amyloid, UV-light and skin irritants, may induce NOD-like receptor protein (NLRP)3 inflammasomes. These inflammasomes govern the induction of proinflammatory cytokines such as IL-1 $\beta$ , IL-18 and IL-33. PRR and inflammasome dysfunctions may underly immunoinflammatory diseases such as gout and other arthritides, type 1 diabetes and arteriosclerosis.

T and B lymphocytes of the acquired immune system are functionally superimposed on the evolutionary old innate immune system. The latter recognizes conserved microbial structures through pattern recognition receptors (PRR) which are coactivated by "danger" signals through cytoplasmic PRR termed NOD-like receptors (NLR). These signals include nuclear fragments released by stressed or dying cells. NLR-signalling activates the enzyme caspase-1, which is required for release of pro-inflammatory cytokines such as interleukin (IL)-1 $\beta$ , IL-18 and IL-33. Dysfunction of innate immunity is central to autoinflammation and may contribute to autoimmunity.

**BACKGROUND:** Familial Mediterranean fever (FMF) is an autosomal recessive autoinflammatory disorder, for which systemic AA amyloidosis is the major complication revealed most of the time by renal abnormalities. Current treatment is daily colchicine that prevents both recurrent inflammatory attacks and amyloidosis deposition in most patients. However, some patients still develop amyloidosis and renal failure. Functional studies suggest that interleukin (IL)-1 is implicated in the inflammatory reaction in FMF and therefore, IL-1 inhibitors could be a new approach to treat FMF. The aim of this series study was to evaluate anakinra in patients with FMF complicated with amyloidosis and renal failure.

**METHODS:** We studied a series of adult patients with FMF complicated with amyloidosis and treated with anakinra in one reference centre were reviewed. A search for published patients with FMF associated amyloidosis treated with anakinra was performed by screening PubMed.

**RESULTS:** We report four cases of patients with FMF-associated amyloidosis treated with anakinra and discuss the clinical pertinence of its use in these particular clinical settings.

**CONCLUSIONS:** Anakinra has a strong effect on both inflammatory attacks and general status in patients with FMF-associated amyloidosis. It may contribute to changing the prognosis of these patients. Long-term studies are needed to appreciate the effect of anakinra or other IL-1 inhibitors on the natural history of amyloidosis in these patients.

Autoinflammatory diseases are often associated with various kinds of febrile episodes such as fever of unknown origin, periodic fever and recurrent fever. Therefore, in the differential diagnosis of fever of unknown cause, autoinflammatory diseases should be considered after exclusion of infections, malignancy and autoimmune diseases. As autoinflammatory diseases now include TRAPS (TNF receptor-associated periodic syndrome), CAPS (cryopyrin -associated periodic syndromes), FMF(familial Mediterranean fever), MAPS (mevalonate kinase-associated periodic fever syndrome, hyper-IgD syndrome) and many others, and show symptoms and signs of wide variations, we need to make an accurate diagnosis of them to prevent possible complications such as amyloidosis.

**INTRODUCTION:** Autoinflammatory diseases are characterized by seemingly unprovoked episodes of inflammation, without high titers of autoantibodies or antigen-specific T cells, and derive from genetic variants of the innate immune system. This study characterized a cohort of patients with similar phenotypes and nucleotide oligomerization domain 2 (NOD2) gene mutations.

**METHODS:** Diagnostically challenging patients with the following clinical and genetic characteristics were prospectively studied between January 2009 and April 2011: periodic fever, dermatitis, polyarthritis, serositis, negative serum autoantibodies and additional positive NOD2 IVS8+158 gene mutation. Genetic testing for gene mutations of NOD2, tumor necrosis factor receptor-associated periodic fever syndrome (TRAPS) and familial Mediterranean fever (FMF) was performed.

**RESULTS:** All seven patients with the disease were Caucasians, with four being male. The mean age at disease onset was 40.7 years and disease duration was 3.2 years. These patients characteristically presented with periodic fever, dermatitis and inflammatory polyarthritis. There were gastrointestinal symptoms in three patients, granulomas of the skin and gut in two, and recurrent chest pain in two, with one having pleuritis and pericarditis. Three patients had sicca-like symptoms. Five patients had increased acute phase reactants. All seven patients had negative tests for autoantibodies but carried the NOD2 gene mutation IVS8+158 with four having concurrent R702W mutation.

**CONCLUSIONS:** Our cohort may represent a new disease category of autoinflammatory disease with characteristic clinical phenotypes and genotypes. It may somewhat resemble pediatric Blau's syndrome.

Lyn kinase deficient mice represent a well established genetic model of autoimmune/autoinflammatory disease that resembles systemic lupus erythematosus. We report that IL-10 plays a crucial immunosuppressive role in this model, modulating the inflammatory component of the disease caused by myeloid and T-cell activation. Double-mutant lyn(-/-)IL-10(-/-) mice manifested severe splenomegaly and lymphadenopathy, dramatically increased proinflammatory cytokine production, and severe tissue inflammation. Single-mutant lyn(-/-)mice showed expansion of IL-10-producing B cells. Interestingly, WT B cells adoptively transferred into lyn(-/-) mice showed increased differentiation into IL-10-producing B cells that assumed a similar phenotype to endogenous lyn(-/-) IL-10-producing B cells, suggesting that the inflammatory environment present in lyn(-/-) mice induces IL-10-producing B-cell differentiation. B cells, but not T or myeloid cells, were the critical source of IL-10 able to reduce inflammation and autoimmunity in double mutant lyn(-/-)IL-10(-/-) mice. IL-10 secretion by B cells was also crucial to sustain transcription factor Forkhead Box P3 (Foxp3) expression in regulatory T cells during disease development. These data reveal a dominant immunosuppressive function of B-cell-derived IL-10 in the Lyn-deficient model of autoimmunity, extending our current understanding of the role of IL-10 and IL-10-producing B cells in systemic lupus erythematosus.

**OBJECTIVES:** To assess the sensitivity of the phagocyte-specific molecules myeloid-related protein (MRP) 8 and MRP14 (calprotectin) for monitoring disease activity during anti-interleukin (IL)-1 therapies in patients with cryopyrin-associated periodic syndromes (CAPS), including familial cold autoinflammatory syndrome (FCAS), Muckle-Wells syndrome (MWS) and chronic infantile neurological, cutaneous and articular (CINCA) syndrome.

**METHODS:** A total of 39 patients with CAPS, including 5 FCAS, 16 MWS and 18 CINCA syndrome, received anti-IL-1 therapy. All patients with CINCA and 12 with MWS were treated with IL-1Ra (anakinra), 14 patients with MWS with a monoclonal anti-IL-1 $\beta$  antibody (canakinumab) and patients with FCAS received IL-1 Trap (rilonacept). During serial clinical visits serum amyloid A, C-reactive protein, erythrocyte sedimentation rate and MRP8/14 serum levels were analysed.

**RESULTS:** Untreated patients with CAPS had significantly elevated MRP8/14 values. In response to treatment there was a significant reduction of MRP8/14 levels in CINCA (2,830 (range 690 - 8,480) ng/ml to 670 ng/ml,  $p < 0.001$ ) and MWS patients (anakinra-treated: 4,390 (1790 - 9780) ng/ml to 1,315 ng/ml ( $p = 0.003$ ); canakinumab-treated: 3,000 (500 - 13060) ng/ml to 630 ng/ml ( $p=0.001$ )). However, in many patients with CAPS, MRP8/14 levels were still elevated compared with healthy individuals, reflecting residual disease activity. However, canakinumab-treated patients with CAPS showed normalised MRP8/14 levels, suggesting control of phagocyte activation.

**CONCLUSIONS:** Monitoring of cellular systems involved in inflammatory cascades of the innate immunity was successfully applied to the IL-1-driven CAPS diseases.

This is the first study illustrating different states of subclinical disease activity in all types of CAPS depending on the type of anti-IL-1 therapy. MRP8/14 is a sensitive biomarker for monitoring disease activity, status of inflammation and response to IL-1 blockade in patients with CAPS.
