**OBJECTIVE:** Colchicine is an alkaloid that is used to alleviate acute gout and to prevent acute attacks of familial Mediterranean fever (FMF). However, it is not beneficial when given during the occurrence of an acute episode of FMF. It is believed that colchicine exerts its anti-inflammatory effect through direct interaction with microtubules. We aim to study the molecular basis of colchicine action by analysing the effect of this drug on global gene expression of HUVEC (human umbilical vein endothelial cell line) cells.

**METHODS:** HUVEC cells were exposed to various concentrations of colchicine and were harvested at different time points. Ribonucleic acid was extracted, amplified, reverse transcribed and hybridized to complementary deoxyribonucleic acid microarrays containing more than 40,000 probes to human expressed sequence tags. This approach enabled us to have a global look at the transcriptional response induced by colchicine treatment.

**RESULTS:** Colchicine changed the expression of many genes in HUVEC cells following exposure to a concentration of 100 ng/ml or higher. Following short exposure (30 or 120 min), colchicine affected genes known to be involved in the cell cycle and its regulation. However, change in expression of genes involved in neutrophil migration or other inflammatory processes were observed mainly after 12 to 24 h.

**CONCLUSIONS:** The anti-inflammatory effect of colchicine may be mediated not only through direct interaction with microtubules but also through changes at the transcriptional level. This latter effect apparently requires a higher concentration and a longer time to occur. This can explain the observation that colchicine does not have an immediate effect when given during an acute attack of FMF.

The relations between attacks and menstrual periods and pregnancies of familial Mediterranean fever patients.

Akar S(1), Soyturk M, Onen F, Tunca M.

Author information:

(1)Division of Rheumatology, Dokuz Eylul University School of Medicine, Inciralti, 35340 Izmir, Turkey.

Familial Mediterranean fever (FMF) is an autosomal recessive disease characterized by short lived, febrile serosal inflammatory attacks. Although majority of patients have random pattern of attacks, some reports described precipitating factors. There are also contradictory reports relating FMF attacks with menstruation and the natural course of their pregnancies. Seventy-two female patients with FMF with a mean age of  $34.9 \pm 12.4$  were interviewed. A standardized questionnaire was used inquiring any associations of FMF attacks of the patients with their menstruations and pregnancies. Thirty-eight patients (53%) reported that their attacks frequently coincided with their menstrual cycles and 17 patients noticed pleuritic chest pain in addition to their abdominal attacks. One patient experienced only febrile pleural attacks during her menstrual cycles. Unlike dysmenorrhoea, none of these patients' attacks responded to non-steroidal anti-inflammatory drugs. All of the patients could correctly differentiate their FMF attacks from dysmenorrhoea. Forty patients could give detailed information about the frequency and severity of their FMF attacks during 73 pregnancies: 25 patients (62.5%) experienced complete symptomatic remissions; the attacks were aggravated (7 patients), ameliorated (6 patients) or did not change (2 patients) in the rest of the pregnancies. Four patients continued to use colchicine during their pregnancies and delivered healthy babies. One patient gave birth to a child with Down's syndrome although she was not on colchicine therapy. Although FMF attacks and discomforts of menstrual cycles do overlap frequently, patients can easily differentiated them. Patients can be reasonably assured that the period of pregnancy will be comfortable but abstaining from colchicine should not be

recommended. Gynecologists must be aware of FMF in the differential diagnosis of dysmenorrhoea or endometriosis.

Regular abdominal pain and fever in each menstruation onset: an unusual menses-associated familial Mediterranean fever attacks and a favor result on colchicine treatment.

Düzgün N(1), Ateş A, Tuna S.

Author information:

(1)Department of Clinical Immunology and Rheumatology, Ankara University, School of Medicine, Ankara, Turkey. duzgun@medicine.ankara.edu.tr

We present a 38-year-old woman suffering from regular abdominal pain and fever only in each menstruation onset for 7 years. The clinical symptoms, along with inflammatory findings during painful attacks, the beneficial effect of colchicine and genetic mutation (M694 V and M680I) supported the diagnosis of familial Mediterranean fever (FMF). A literature review indicated that FMF attacks occurring only during menstruation are rarely seen. This clinical picture may be confused with gynecological disorders especially in the people of Mediterranean origin.

Loss of IL-4 secretion from human type 1a diabetic pancreatic draining lymph node NKT cells.

Kent SC(1), Chen Y, Clemmings SM, Viglietta V, Kenyon NS, Ricordi C, Hering B, Hafler DA.

Author information:

(1)Center for Neurologic Diseases, Brigham and Women's Hospital and Harvard Medical School, Boston, MA 02115, USA. skent@rics.bwh.harvard.edu

Altered frequency and function of peripheral invariant NKT (iNKT) cells have been implicated in the regulation of murine and human type 1a diabetes. To examine regulatory cells from the site of drainage of autoinflammatory tissue and autoantigenic T cell priming in diabetes, we directly cloned iNKT cells from human pancreatic draining lymph nodes (PLN). From 451 T cell clones from control and diabetic PLN, we derived 55 iNKT cells by two methods and analyzed function by cytokine secretion. iNKT cell clones isolated from control PLN secreted IL-4 and IFN-gamma upon TCR stimulation. For type 1a diabetic subjects, PLN iNKT cell clones from three samples secreted IFN-gamma and no IL-4. In a rare recent onset diabetic sample with islet-infiltrating CD4+ T cells, the phenotype of PLN iNKT cell clones was mixed. From normal and diabetic PLN, one-third of CD1d tetramer+-sorted T cell clones were reactive with CD1d transfectants or proliferated/secreted cytokine in response to alpha-galactosylceramide-pulsed PBMCs; tetramer-staining T cell clones from diabetic PLN did not secrete IL-4. This is the first report directly examining iNKT cells from lymph nodes draining the site of autoimmunological attack in humans; iNKT cells were altered in cytokine secretion as previously reported for circulating iNKT cells in human type 1a diabetes.

Familial Mediterranean fever responds well to infliximab: single case experience.

Ozgocmen S(1), Ozçakar L, Ardicoglu O, Kocakoc E, Kaya A, Kiris A.

Author information:

(1)Division of Rheumatology, Department of Physical Medicine and Rehabilitation, Faculty of Medicine, Firat University, Elazig, Turkey. sozgocmen@hotmail.com

The most common arthritic involvement in familial Mediterranean fever (FMF) is

acute recurrent monoarthritis; however, sometimes spondyloarthropathy-like findings or typical ankylosing spondylitis may also ensue. Reported here is our favorable experience with infliximab in an FMF patient who had been resistant to colchicine and disease-modifying antirheumatic drugs (sulfasalazine and methotrexate) treatments. A 72-week follow-up of the patient yielded complete remission of the febrile abdominal episodes, and spondylitis responded well. The patient's bilateral aseptic necrosis of the femoral head deteriorated and caused hip pain, discomfort, and disability. Overall, we believe that tumor necrosis factor (TNF) alpha has an important role in the disease pathogenesis and also that anti-TNF may represent a promising robust treatment alternative in FMF.

Possible effect of subclinical inflammation on daily life in familial Mediterranean fever.

Ozçakar ZB(1), Yalçinkaya F, Yüksel S, Acar B, Gökmen D, Ekim M.

Author information:

(1)Department of Pediatric Nephrology, Ankara University Medical School, Ankara, Turkey. zbozcakar@yahoo.com

This study was performed to investigate the attack-free complaints of patients with familial Mediterranean fever (FMF) and the impact of colchicine on these symptoms and on subclinical inflammation. A questionnaire that includes information about the disease course and symptoms during the attack-free period was administered to the parents of 50 FMF patients. For evaluation of the attack-free period, questions were asked about four items concerning daily activities of the children-weakness, lack of appetite, sleep problems, and decreased activity. The respondents rated the items and the total score was taken as the sum of all of the specific items. The laboratory values were noted from the patients' files. During the attack-free period, patients with mild disease had higher total scores, higher weakness, and decreased activity scores than patients with moderate disease. When we compared the daily activity scores before and after colchicine therapy, a statistically significant increase was observed

in the total scores and in all of the specific item scores. Also a significant decrease was seen in the erythrocyte sedimentation rate and white blood cell counts, and a significant increase was seen in the hemoglobin levels during the attack-free period after colchicine usage. Regression of inflammation together with improvement in daily activities were observed. FMF patients seem to have complaints during the attack-free period that may be related to subclinical inflammation. Moreover, colchicine besides preventing the FMF attacks and the dangerous complication of amyloidosis also seems to hinder the symptoms of the attack-free period in children with FMF.

OBJECTIVE: To investigate the molecular consequences of expressing mutated forms of tumor necrosis factor receptor I (TNFRI) as found in patients with

TNFR-associated periodic syndrome (TRAPS).

**METHODS:** We cloned and expressed full-length wild-type (WT) and T50K and P46L variants of TNFRI using a new tightly regulated doxycycline-dependent expression system. This system enabled the study of molecular interactions between these receptors at both physiologic and pathophysiologic levels of expression.

**RESULTS:** We used chemical crosslinking on the cell surface to show that WT and mutant forms of TNFRI, derived from TRAPS patients, interact in the absence of TNF ligand. Doxycycline-controlled up-regulation of one TNFRI allele, either WT or mutant, caused down-regulation of the other allele, indicating dynamic control of cell surface assembly. We also demonstrated that increased expression of mutant TNFRI (T50K) was associated with a parallel increase in NF-kappaB p65 (RelA) subunit activation, which did not occur with increased expression of WT TNFRI.

**CONCLUSION:** The T50K TRAPS-related variant is capable of sustaining inappropriate NF-kappaB activation, resulting in persistent auto-inflammation in target organs such as skin, synovial membrane, and the central nervous system. We conclude that some of the inflammatory processes seen in TRAPS do not involve direct interaction of TNF with its receptors, but that other proinflammatory mechanisms capable of up-regulating TNFRI expression may cause cellular activation through the NF-kappaB signaling pathway.

philippe.vinceneux@lmr.ap-hop-paris.fr

The progression of familial Mediterranean fever is marked by the recurrence, at varying intervals, of acute flares that regress spontaneously. Prognosis, which

depends on the occurrence of amyloidosis, has been transformed by colchicine treatment. Incidence of amyloidosis is higher in certain ethnic groups (Jews from North Africa, Turks) and depends on by the specific MEFV mutation. Amyloid is composed of clusters of protein strands identical to the AA protein of secondary amyloidosis and infiltrates the walls of all arterioles except those of the central nervous system. The earliest and most consistent localization is in the kidney, where it develops over several years and in 4 stages--preclinical (latency), proteinuric, nephrotic and uremic--before concluding in end-state renal failure. Before the advent of colchicine, dialysis and transplantation, only renal amyloidosis caused clinical manifestations and lethal complications; any amyloidosis at any other sites remained latent. Prolonged survival with hemodialysis and kidney transplantation now leaves time for manifestation of these other localizations, such as infiltration into the intestines causing malabsorption, or potentially lethal cardiac lesions. Treatment of familial Mediterranean fever is based on the continuous administration of colchicine, which at the average dose of 1 to 2 mg per day can prevent flares or at least reduce their frequency or intensity. Systematic use of colchicine also prevents the onset of amyloidosis, even in the rare cases where it cannot prevent flares. These data fully justify the systematic use of colchicine for continuous prophylactic treatment from diagnosis and even after kidney transplantation, to prevent recurrence of the grafted kidney or extension to other organs. The curative efficacy of colchicine on flares is debatable, although several studies report positive results against progression of early amyloidosis.

philippe.vinceneux@lmr.ap-hop-paris.fr

During the first attacks of familial Mediterranean fever, each of the disease symptoms can suggest a series of disorders. When the disease is older, the recurrence of symptoms may simulate some systemic diseases, but mainly suggests familial Mediterranean fever, one of a group of hereditary autoinflammatory diseases. Before the gene for familial Mediterranean fever was identified, various sets of criteria were used for diagnosis. The presence of MEFV mutations confirms the diagnosis, but the clinical criteria still determine who should undergo this genetic testing. The genotype-phenotype correlations add a prognostic dimension to the mutations identified. Genotyping can also lead to the diagnosis of the other autoinflammatory diseases, which constitute the basis of the differential diagnosis of familial Mediterranean fever. The hyperimmunoglobulinemia D syndrome (HIDS) is very similar to familial Mediterranean fever in its recessive transmission and abdominal and articular symptoms. It can be distinguished by the European origin of the patients, the presence of cervical lymph nodes and the increased IgD levels. Of the diseases with dominant transmission, the TNF receptor-associated periodic syndromes (TRAPS) are suggested by periorbital edema and migrating inflammatory cellulitis. Muckle and Wells syndrome is revealed by episodes of fever with urticaria and arthralgia, complicated by deafness and amyloidosis. Mutations in the same gene are responsible for two disorders, both appearing in childhood: familial cold urticaria syndrome (FCUS) and chronic infantile neurocutaneous articular syndrome (CINCA). The pathogenesis of familial Mediterranean fever is still unclear. Pyrin/marenostrin, the protein produced by the MEFV gene, appears to have a physiological antiinflammatory effect that inhibits proinflammatory cytokines. Mutation of the gene may eliminate this feedback mechanism and expose the patient to flares from any inflammatory stimulus, even minimal. Amyloid is produced by the serum amyloid A protein (SAA), and its occurrence is influenced by the type of MEFV mutation, but also the genotype of the gene producing SAA.

philippe.vinceneux@lmr.ap-hop-paris.fr

Familial Mediterranean fever is the best known of the recurrent hereditary autoinflammatory diseases. It predominantly affects subjects of Mediterranean origin, Sephardic Jews in particular. Its gene, MEFV, is located on chromosome 16 and has autosomal recessive transmission, with incomplete penetration. It codes for a protein called pyrin or marenostin, which is probably involved in the inflammatory process. In most cases, the first episodes appear before the age of 20 years and very rarely after the age of 40. Episodes usually last a few days, although they may extend over several weeks when localized in joints. Fever, occasionally pseudo-malaria, may accompany various symptoms, the most frequent of which are abdominal, articular, pleural or cutaneous. The abdomen is the classic site of this disease, and acute abdominal flares masquerade as abdominal emergencies. Musculoskeletal involvement is revealed by episodes of inflammation of the joints (more often mono- than oligoarthritis) and muscle pain. The flares are usually brief and totally reversible. Flares of thoracic pain corresponding to pleural inflammation and erysipelas-like skin eruptions have been observed. Acute symptoms disappear between flares, but hepatic splenomegaly, swollen lymph nodes or abnormal fundus of the eye may persist. Laboratory findings are typical of nonspecific inflammation, accompanied by moderate hyperleukocytosis during the flares.

Distinguishing in febrile children between harmless rashes and those, which require specific action, is a common problem in pediatric primary care. Major exanthematous diseases necessitating emergency hospitalization include invasive meningococcal disease and rarely gram-negative septicaemia caused by other pathogens, staphylococcal and streptococcal toxic shock syndrome, endocarditis, fever and rash in travellers returning from tropical countries and drug hypersensitivity syndrome. Therapeutic intervention is also necessary in patients with scarlet fever, rheumatic fever, varicella in postpuberal and immunocompromised individuals, in Kawasaki's disease, in Still's disease and in other non-infectious, inflammatory diseases (e.g., familial mediterranean fever). Finally, various specific measures need to be taken in reportable diseases, erythema infectiosum (parvovirus B19), primary HIV infection and in Henoch-Schölein purpura.

Familial Mediterranean fever is an autosomal recessive disorder characterized by transient attacks of fever and polyserositis with substantial risk of developing amyloidotic nephropathy over time. We report an Italian child with familial Mediterranean fever presenting with hematuria during attacks in whom kidney biopsy documented the presence of mesangial IgA deposits and the absence of amyloidosis. Kidney biopsy should be performed in patients showing microscopic or gross hematuria during attacks of familial Mediterranean fever in order to gain additional epidemiological data about specific features of renal involvement and to allow adequate treatment.

Chronic recurrent multifocal osteomyelitis (CRMO) is an autoinflammatory disorder that primarily affects bone but is often accompanied by inflammation of the skin and/or gastrointestinal tract. The etiology is unknown but evidence suggests a genetic component to disease susceptibility. Although most cases of CRMO are sporadic, there is an autosomal recessive syndromic form of the disease, called Majeed syndrome, which is due to homozygous mutations in LPIN2. In addition, there is a phenotypically similar mouse, called cmo (chronic multifocal osteomyelitis) in which the disease is inherited as an autosomal recessive disorder. The cmo locus has been mapped to murine chromosome 18. In this report, we describe phenotypic abnormalities in the cmo mouse that include bone, cartilage and skin inflammation. Utilizing a backcross breeding strategy, we refined the cmo locus to a 1.3 Mb region on murine chromosome 18. Within the refined region was the gene pstpip2, which shares significant sequence homology to the PSTPIP1. Mutations in PSTPIP1 have been shown to cause the autoinflammatory disorder PAPA syndrome (pyogenic arthritis, pyoderma gangrenosum and acne). Mutation analysis, utilizing direct sequencing, revealed a single base pair change c.293T --> C in the pstpip2 gene resulting in a highly conserved leucine at amino acid 98 being replaced by a proline (L98P). No other mutations were found in the coding sequence of the remaining genes in the refined interval, although a 50 kb gap remains unexplored. These data suggest that mutations in pstpip2 may be the genetic explanation for the autoinflammatory phenotype seen in the cmo mouse.

**BACKGROUND/AIMS:** Evaluation of the risk factors, and phenotype-genotype correlation of familial Mediterranean fever (FMF) gene (MEFV) and serum amyloid A1 (SAA1) gene polymorphisms in renal amyloidosis.

**METHODS:** We investigated MEFV and SAA1 genotypes (alpha, beta, and gamma isoforms) in 50 FMF patients and 50 healthy children. Tel-Hashomer criteria were used for the diagnosis and severity scoring of FMF.

**RESULTS:** The most common MEFV mutation and SAA1 genotype were M694V/M694V (n = 26/50) and SAA1 alpha/alpha (n = 26/50), respectively. Positive family history for amyloidosis was significantly higher ( $p < 0.001$ ) with more severe clinical course ( $p = 0.006$ ) in the amyloidosis group than the non-amyloid group. In M694V/M694V mutation, erysipelas-like skin erythema ( $p = 0.029$ ), arthritis ( $p = 0.004$ ), arthralgia ( $p < 0.001$ ) were significantly more frequent with higher severity scores ( $p = 0.008$ ) than the patients with other mutations. Comparison of the SAA1 alpha/alpha genotype with other genotypes revealed more frequent arthritis ( $p = 0.003$ ) in the SAA1 alpha/alpha genotype. In amyloidosis group patients having both M694V/M694V and SAA1 alpha/alpha genotypes were the largest subgroup (n = 14,  $p < 0.001$ ). Logistic regression analysis for amyloidosis corrected risk revealed a 1.2 times increase in M694V/M694V, a 2.4 times increase in SAA1 alpha/alpha genotypes and a 2.5 times increase when both are together.

**CONCLUSION:** Positive family history for amyloidosis and presence of SAA1 alpha/alpha genotype in M694V/M694V mutation may predispose to amyloidosis by

increasing the clinical severity. Therefore, in such children early colchicine treatment might be recommended even if they are asymptomatic.

**PURPOSE OF REVIEW:** The systemic autoinflammatory diseases are characterized by seemingly unprovoked inflammation, without major involvement of the adaptive immune system. This review focuses mainly on a subset of these illnesses, the hereditary recurrent fevers, which include familial Mediterranean fever, the tumor necrosis factor receptor-associated periodic syndrome, the hyperimmunoglobulinemia D with periodic fever syndrome, and cryopyrin-associated periodic syndromes. This review elucidates how recent advances have impacted diagnosis, pathogenesis, and treatment.

**RECENT FINDINGS:** More than 170 mutations have been identified in the four genes underlying the six hereditary recurrent fevers. Genetic testing has broadened the clinical and geographic boundaries of these illnesses, given rise to the concept of the cryopyrin-associated periodic syndromes as a disease spectrum, and permitted diagnosis of compound heterozygotes for mutations in two different hereditary recurrent fever genes. Genetics has also advanced our understanding of amyloidosis, a complication of the hereditary recurrent fevers, and suggested a possible role for common hereditary recurrent fever variants in other inflammatory conditions. Recent advances in molecular pathophysiology include the

elucidation of the N-terminal PYRIN domain in protein-protein interactions, the description of the NALP3 (cryopyrin) inflammasome as a macromolecular complex for interleukin-1 $\beta$  activation, and the identification of signaling defects other than defective receptor shedding in patients with tumor necrosis factor receptor-associated periodic syndrome. These molecular insights form the conceptual basis for targeted biologic therapies.

SUMMARY: Advances in molecular genetics extend our ability to recognize and treat patients with systemic autoinflammatory diseases and inform our understanding of the regulation of innate immunity in humans.

Curr Opin Rheumatol. 2005 Sep;17(5):566-7.

PURPOSE OF REVIEW: The purpose of this article is to review the foundational work and current developments on a group of rheumatic disorders associated with mutations in the caspase recruitment domain 15/nucleotide oligomerization domain 2 gene.

RECENT FINDINGS: To date, there are at least 10 arthritic conditions for which specific genetic mutations have been demonstrated. They include familial Mediterranean fever; tumor necrosis factor receptor associated periodic syndrome; hyper immunoglobulin D syndrome; neonatal onset multisystemic inflammatory disease; pyogenic arthritis pyoderma gangrenosum and acne; Muckle-Wells syndrome; familial cold autoinflammatory syndrome; immunodysregulation, polyendocrinopathy, enteropathy, X-linked syndrome; Crohn's disease; and familial and sporadic sarcoid granulomatous arthritis. This review focuses on recent progress in the

last two diseases and the caspase recruitment domain 15 genetic defects with which they are associated. Up to 50% of patients with familial granulomatous arthritis (Blau's syndrome), 90% of those with sporadic granulomatous arthritis (early-onset sarcoidosis), and 40% of individuals with Crohn's disease have documented mutations in the caspase recruitment domain 15 gene.

SUMMARY: Although histologically, Crohn's disease and familial and sporadic sarcoid granulomatous arthritis are distinct from rheumatoid arthritis because of the defining presence (albeit in not all cases) of non-caseating granulomata in the synovial and intestinal tissues, respectively, they still represent a promising model of both chronic synovitis and uveitis. In addition, once the actual mechanism is discovered by which defects of the caspase recruitment domain 15 gene product lead to chronic arthritis, it may uncover unsuspected biologic targets for therapeutics.

Effect of etanercept and anakinra on inflammatory attacks in the hyper-IgD syndrome: introducing a vaccination provocation model.

Bodar EJ(1), van der Hilst JC, Drenth JP, van der Meer JW, Simon A.

Author information:

(1)Division of General Internal Medicine, Department of Medicine, Radboud University Nijmegen Medical Centre, Nijmegen, Netherlands.

**BACKGROUND:** Hyper-IgD and periodic fever syndrome (HIDS) is an hereditary autoinflammatory syndrome, characterised by recurrent inflammatory attacks. Treatment of HIDS is difficult, although simvastatin is beneficial and etanercept might be effective. Studying the treatment of a rare periodic syndrome is complicated by the varying frequency and severity of symptoms and low prevalence. Our aim was to develop a system of clinical observations to evaluate effectiveness of treatment-on-demand.

**METHODS:** Seven fever episodes in three HIDS patients were monitored, with and without administration of etanercept or anakinra. We developed a clinical score, which includes 12 symptoms. In one patient, inflammatory attacks were provoked by vaccination.

**RESULTS AND CONCLUSIONS:** At the onset of an attack, all patients reported a clinical score between 20 and 25. The score was used to quantify severity and define the end of an attack. Reproducible monitoring of inflammatory episodes was difficult, even in this pilot study. The effect of early administration of etanercept was variable. In one patient, a fever episode could be readily provoked within 12 to 24 hours by vaccination. In this patient, the IL-1ra analogue anakinra was more successful in aborting the inflammatory attack than etanercept. We propose that this vaccination model will allow evaluation of

treatment-on-demand in a controlled setting.

Evaluation of disease severity in familial Mediterranean fever.

Mor A(1), Shinar Y, Zaks N, Langevitz P, Chetrit A, Shtrasburg S, Rabinovitz E, Livneh A.

Author information:

(1)Sheba Medical Center, Tel-Hashomer and Sackler School of Medicine, Tel-Aviv University, Tel-Aviv, Israel.

**OBJECTIVE:** To establish a new, objective, statistically based severity score for familial Mediterranean fever (FMF).

**METHODS:** One hundred consecutive FMF patients were evaluated independently by 2 FMF experts for severity of their disease and were assigned to 1 of 3 severity levels: mild, intermediate, or severe. Nine candidate criteria, reflecting objective suffering and disability, were analyzed to determine their weight for patient placement in the 3 predefined severity groups.

**RESULTS:** Candidate criteria best differentiating between the 3 patient categories were the frequency of attacks, the number of sites affected during an attack and during the course of the disease, and the duration of the attacks. These criteria were applied in a classification-tree model to establish a new FMF-severity score (F-SS). The first set of F-SS (F-SS-1) was highly sensitive and specific.

Integrating F-SS-1 with clinical parameters strongly associated with disease severity resulted in a simplified score, the second set of F-SS (F-SS-2).

**CONCLUSIONS:** New, useful, objective, and valid severity scores were established and found to distinguish between patients with mild, intermediate, and severe diseases with high sensitivity and specificity.

**RELEVANCE:** The F-SS established may be important for treatment decisions, prognosis evaluation, and comparative analysis of patient populations.

Familial cold autoinflammatory syndrome (FCAS) and the related autoinflammatory disorders, Muckle-Wells syndrome and neonatal onset multisystem inflammatory disease, are characterized by mutations in the CIAS1 gene that encodes cryopyrin, an adaptor protein involved in activation of IL-converting enzyme/caspase-1. Mutations in cryopyrin are hypothesized to result in abnormal secretion of caspase-1-dependent proinflammatory cytokines, IL-1beta and IL-18. In this study, we examined cytokine secretion in PBMCs from FCAS patients and found a marked hyperresponsiveness of both IL-1beta and IL-18 secretion to LPS stimulation, but no evidence of increased basal secretion of these cytokines, or alterations in basal or stimulated pro-IL-1beta levels. VX-765, an orally active IL-converting enzyme/caspase-1 inhibitor, blocked IL-1beta secretion with equal potency in LPS-stimulated cells from FCAS and control subjects. These results further link mutations in cryopyrin with abnormal caspase-1 activation, and support the clinical testing of caspase-1 inhibitors such as VX-765 in autoinflammatory disorders.

The risk associated with the serum amyloid A (SAA) 1 gene and developing AA-amyloidosis is still controversial. In familial Mediterranean fever or Caucasoid rheumatoid arthritis (RA), the SAA1.1 allele is a risk factor for the development of AA-amyloidosis. However, individuals with the SAA1.3 allele are susceptible to AA-amyloidosis in the Japanese RA population, but those with the SAA1.1 are not. Previous reports have indicated that the -13T/C single nucleotide polymorphism (SNP) at the 5'-flanking region of SAA1 appears to be a better marker of AA-amyloidosis than the exon-3 based haplotype, i.e., SAA1.1 or SAA1.3, in both Japanese and American Caucasian populations. So far, it is unknown why the -13T SNP increases the amyloidogenicity of the patients. In the present study, a luciferase reporter gene assay showed that the transcriptional activity of the SAA1 having the -13T-containing promoter was significantly higher than activities of those with -13C-containing promoters (Fisher's protected least significance difference test). We suggest that having the -13T SNP in the SAA1 promoter correlates with the amyloidogenicity in part as a result of this increased transcriptional activity.

[The autumn crocus: two millenniums of actuality].

[Article in French]

Fabre AJ.

Colchicum holds a singular place in the History of Medicine. Many names were given through the ages: "ephemera", "finger of Hermes", "pater noster", "tue-chiens". Modern phytonyms clearly refer to the land of Colchis, a mythical place close to Armenia. Several centuries were needed to understand that, despite

a frightening reputation, colchic was an elective treatment for the gout. In its long story, appears famous personages as Theophraste, Paulus Aeginata, Gilbertus Anglicus, the baron Storck and Benjamin Franklin. In modern times, colchicum has received besides gout, a wide array of new indications, among others: Behcet disease, collagen diseases and malignancies. A scarcely known chapter of genetics is the findings in 1889, by B. Pernice, an obscure physician from Palermo, of the major mitotic changes observed on gastric and intestinal mucosa of two dogs which had received large doses of colchicum. In spite of their scientific value, the works of Pernice remained largely ignored until 1949. Recent advances in colchicotherapy have shown fascinating new fields for research: thus in the familial Mediterranean fever, close to periodic disease, genetic disorder elective for subjects originated from all over Mediterranean and around Black Sea... the mythical country of Colchis. No other medicinal plant than colchic, except poppy, can give such records of perennial use in such a wide range of disorders.

Troponin for prediction of cardiovascular collapse in acute colchicine overdose.

van Heyningen C(1), Watson ID.

Author information:

(1)University Hospital Aintree, Liverpool L9 7AL, UK.

charles.vanheyningen@aht.nwest.nhs.uk

The use of colchicine, a treatment for acute gout and familial Mediterranean fever, is limited by its toxicity. A relatively low dose of colchicine may be fatal. After a colchicine overdose, monitoring should include 6-12 hourly serum troponin measurements. A rising troponin level predicts cardiovascular collapse and is an indication for more intensive management.

Mutations in cryopyrin and pyrin proteins are responsible for several autoinflammatory disorders in humans, suggesting that these proteins play important roles in regulating inflammation. Using a HEK293 cell-based reconstitution system that stably expresses ASC and procaspase-1 we demonstrated that neither cryopyrin nor pyrin or their corresponding disease-associated mutants could significantly activate NF-kappaB in this system. However, both cryopyrin and two disease-associated cryopyrin mutants induced ASC oligomerization and ASC-dependent caspase-1 activation, with the disease-associated mutants being more potent than the wild-type (WT) cryopyrin, because of increased self-oligomerization. Contrary to the proposed anti-inflammatory activity of WT pyrin, our results demonstrated that pyrin, like cryopyrin, can also assemble an inflammasome complex with ASC and procaspase-1 leading to ASC oligomerization, caspase-1 activation and interleukin-1beta processing. Thus, we propose that pyrin could function as a proinflammatory molecule.

rainer.straub@klinik.uni-regensburg.de

**CONTEXT:** TNF-receptor-associated periodic syndrome (TRAPS) is a hereditary fever syndrome that results from mutations in the TNF-receptor superfamily 1A gene (TNFRSF1A). It is characterized by periodic fever, arthralgia, abdominal pain, myalgia, headache, and skin lesions.

**OBJECTIVE:** Because adrenal and gonadal hormone cascades are modulated by TNF, this study aimed to investigate specific hormones and enzyme steps during an attack phase in a woman with TRAPS.

**DESIGN:** Morning blood samples were taken from a 38-yr-old woman before, during, and after the febrile episode in the late luteal, menstrual, and early follicular phase of the menstrual cycle, respectively.

**RESULTS:** Serum cortisol levels were markedly increased throughout the entire observation period and demonstrated a dip during the attack phase. In contrast, serum levels of dehydroepiandrosterone and 17-hydroxyprogesterone demonstrated a sharp rise during the febrile episode. Dehydroepiandrosterone in relation to androstenedione or cortisol was increased. Indicative of aromatase activation, estrone and 17beta-estradiol demonstrated a marked increase during the attack phase.

**CONCLUSION:** This study suggests that some important steroid hormone-conversion steps are activated (aromatase) and inhibited (second step of the P450c17 and the 3beta-hydroxysteroid dehydrogenase) during the inflammatory attack phase in a TRAPS patient. These changes of enzyme pathways are typical on the basis of increased TNF signaling.

**INTRODUCTION:** Recent studies have demonstrated that Colchicine (CO) prevents heterotopic ossification (HO) after total hip replacement in patients suffering from familial Mediterranean fever (FMF). Other investigators have proved that CO is an in vitro inhibitor of proliferation of osteoblasts and osteosarcoma cells, and is a non-selective mitosis inhibitor and selective inhibitor of mineralization.

**METHODS:** A double blind prospective study comprised four groups of adult rats. The left posterior tibia in each rat was fractured except in one of the control groups. The study groups were treated with CO 1 mg/kg/day 1 week before, or on the fracture day. The control groups did not receive CO treatment. Six weeks after fracture induction the groups were compared radiographically mechanically and histologically.

**RESULTS:** Prolonged CO treatment had a significant negative influence on fracture healing according to radiological, clinical, mechanical ( $p<0.02$ ), and pathological parameters ( $p<0.0001$ ).

**CONCLUSIONS:** We were able to demonstrate that prolonged CO treatment reduced bone healing.

The "self-inflammatory syndrome" gathers diseases all characterized by a recurrent inflammatory syndrome with fever, in the absence of infection or neoplasia. It is based on a genetic support characterized by mutations in genes implied in the inflammatory response and in the activation of the cytokine network. The diseases associated with this syndrome are familial Mediterranean fever (FMF), TRAPS (tumor necrosis factor receptor super family 1 A-associated periodic syndrome), familial cold urticaria, the Muckle-Wells syndrome, the hyper IgD syndrome and CINCA. The clinical symptoms of all these diseases include in the auto-inflammatory syndrome are quite similar: recurrent attacks, with fever, articular, abdominal, cutaneous symptoms, and an inflammatory syndrome.

The AGAPEPAEPAQPGVY proline-rich polypeptide (PRP) was isolated from neurosecretory granules of the bovine neurohypophysis; it is produced by N. supraopticus and N. paraventricularis. PRP possesses immune-modulating activity, preventing the death of Gram-negative bacteria-infected mice. Here we show that PRP does not affect human peripheral blood neutrophils and monocytes phagocytosis but dramatically enhances spontaneous or fMLP- and PMA-induced, and also phagocytosis-dependent, oxidative burst. We demonstrated the regulatory role of PRP on the oxidative burst induction of normal and relapsing inflammatory disease (Behcet's disease and familial Mediterranean fever) neutrophils and monocytes. Our results suggest a previously undescribed role for the hypothalamic peptide within primary activated neutrophils and monocytes, since we provide evidence

that PRP can differentially regulate both chemotaxis- and phagocytosis-dependent oxidative burst in normal and inflammatory disease effector cells.

Serum amyloid A serum concentrations and genotype do not explain low incidence of amyloidosis in Hyper-IgD syndrome.

van der Hilst JC(1), Drenth JP, Bodar EJ, Bijzet J, van der Meer JW, Simon A; International HIDS Study Group.

Author information:

(1)Department of General Internal Medicine, UMC St. Radboud, Nijmegen, The Netherlands. j.vanderhilst@aig.umcn.nl

**BACKGROUND:** Hyper-IgD and periodic fever syndrome (HIDS) is an autosomal recessively inherited disorder characterized by recurrent episodes of fever and inflammation. Unlike other chronic inflammatory conditions, amyloidosis is very rare in HIDS. For deposition of amyloid of the AA type, high concentrations of SAA are a prerequisite, together with certain SAA1 gene polymorphisms. The SAA1.1 genotype predisposes for amyloidosis, while SAA1.5 genotype exerts a protective effect.

**AIM OF THE STUDY:** To determine if SAA concentrations and SAA1 gene polymorphisms could explain the virtual absence of amyloidosis in HIDS patients.

**METHODS:** We measured SAA and CRP concentrations in serum of 20 HIDS patients during an attack and during the asymptomatic phase. Genotype of SAA1 gene was determined in 60 HIDS patients.

**RESULTS:** SAA serum concentrations during attacks were very high (median 205 mg/l; range 75-520 mg/l, normal <3.1 mg/l). During attack-free periods 45% of patients still had elevated SAA concentrations. The distribution of the genotype of SAA1 gene in HIDS was similar to healthy controls (SAA1.1 0.41 vs. 0.50 p=0.32).

**CONCLUSION:** Patients with HIDS have high SAA during attacks and show sub-clinical inflammation when asymptomatic. The low incidence of amyloidosis cannot be explained by a predominance of non amyloidogenic SAA related genotypes.

Malignant peritoneal mesothelioma.

Bani-Hani KE(1), Gharaibeh KA.

Author information:

(1)Department of Surgery, King Abdullah University Hospital, Faculty of Medicine, Jordan University of Science and Technology, Irbid, Jordan. banihani60@yahoo.com

Comment in

J Surg Oncol. 2006 Apr 1;93(5):434.

**BACKGROUND AND OBJECTIVES:** The incidence of malignant peritoneal mesothelioma (MPM) is rising. Our aim was to present our experience with this entity in order to increase the awareness about this disease to avoid misdiagnosis.

**METHODS:** Records of seven patients with histologically confirmed MPM were retrospectively reviewed. Demographic and clinicopathological findings were studied in detail.

**RESULTS:** There were two females and 5 males; mean age was 50.3 years (range 16-73). Asbestos exposure was recorded in two patients, familial Mediterranean fever in one and previous radiation in one. Main presentations were abdominal pain and distension. None of the patients was diagnosed preoperatively. The average delay in diagnosis was 10 months. Calretinin expression was identified in all tumors. Three patients were treated with cytoreductive surgery combined with systemic chemotherapy. Two patients who remain alive were young female patients who were diagnosed by laparoscopic incidental findings and were treated with cytoreductive surgery combined with hyperthermic intraoperative intraperitoneal chemotherapy (HIIC). Median survival was 19.7 months. The average survival time of the five patients who died of their diseases was 10.2 months.

**CONCLUSIONS:** An awareness of MPM is important to prevent misdiagnosis. Immunohistochemistry has an important role in confirming the diagnosis. MPM remains a difficult therapeutic challenge. Thorough cytoreductive surgery is the cornerstone of current treatment while HIIC is a promising strategy in suitable patients.

Urine leukotriene B4 in familial Mediterranean fever and other forms of right lower abdominal pain.

Bentancur AG(1), Naveh N, Lancri J, Selah BA, Shtrasburg S, Livneh A.

Author information:

(1)Emergency Medicine Department, Sheba Medical Center, Tel Hashomer, Israel.

**BACKGROUND:** Acute right lower abdominal pain may present a diagnostic dilemma.

Leukotrienes have been found to be elevated in familial Mediterranean fever

(FMF), a disease manifesting with recurrent episodes of "acute abdomen."

**OBJECTIVES:** To determine whether urine leukotriene B4 (LTB4) may differentiate between an FMF attack and some other forms of acute right lower abdominal pain.

**METHODS:** The LTB4 level was determined, using a commercial enzyme-linked immunosorbent assay (ELISA), in urine samples obtained from 36 patients with acute (< 24 hours) right lower abdominal pain presenting to the emergency department, and from 18 healthy volunteers.

**RESULTS:** Compared with the healthy control subjects, LTB4 was significantly higher in those who had FMF (12 patients,  $p < 0.03$ ). In other forms of acute right lower abdominal pain, including appendicitis (eight patients), urologic disorders (eight patients), and nonspecific abdominal pain (eight patients), intermediate levels of LTB4 were observed, not significantly different from those of either FMF patients or healthy control subjects.

**CONCLUSIONS:** In the samples tested, urine LTB4 levels were not instrumental in differentiating FMF from other acute right lower abdominal pain.

Homozygous mutations in LPIN2 are responsible for the syndrome of chronic recurrent multifocal osteomyelitis and congenital dyserythropoietic anaemia (Majeed syndrome).

Ferguson PJ(1), Chen S, Tayeh MK, Ochoa L, Leal SM, Pelet A, Munnich A, Lyonnet S, Majeed HA, El-Shanti H.

Author information:

(1)Department of Pediatrics, Division of Hematology/Oncology/Rheumatology, University of Iowa, Iowa City, IA, USA.

**BACKGROUND:** Majeed syndrome is an autosomal recessive, autoinflammatory disorder characterised by chronic recurrent multifocal osteomyelitis and congenital dyserythropoietic anaemia. The objectives of this study were to map, identify, and characterise the Majeed syndrome causal gene and to speculate on its function and role in skin and bone inflammation.

**METHODS:** Six individuals with Majeed syndrome from two unrelated families were identified for this study. Homozygosity mapping and parametric linkage analysis were employed for the localisation of the gene responsible for Majeed syndrome. Direct sequencing was utilised for the identification of mutations within the genes contained in the region of linkage. Expression studies and in silico characterisation of the identified causal gene and its protein were carried out.

**RESULTS:** The phenotype of Majeed syndrome includes inflammation of the bone and skin, recurrent fevers, and dyserythropoietic anaemia. The clinical picture of the six affected individuals is briefly reviewed. The gene was mapped to a 5.5 cM interval (1.8 Mb) on chromosome 18p. Examination of genes in this interval led to the identification of homozygous mutations in LPIN2 in affected individuals from the two families. LPIN2 was found to be expressed in almost all tissues. The function of LPIN2 and its role in inflammation remains unknown.

**CONCLUSIONS:** We conclude that homozygous mutations in LPIN2 result in Majeed syndrome. Understanding the aberrant immune response in this condition will shed light on the aetiology of other inflammatory disorders of multifactorial aetiology including isolated chronic recurrent multifocal osteomyelitis, Sweet syndrome, and psoriasis.

[Multisystemic amyloidosis. Clinical study of 39 patients in Lebanon].

[Article in French]

Saba M(1), Tohmé A, Abadjian G, Haddad F, Ghayad E.

Author information:

(1)Service de médecine interne, Hôtel-Dieu de France, Université Saint Joseph, Faculté de médecine, Beyrouth, Liban.

**OBJECTIVE:** Clinical analysis of multisystem amyloidosis in Lebanon, by histological type.

**METHOD:** Retrospective study of 39 cases of multisystem amyloidosis diagnosed histologically in a university hospital center between 1991 and 2002. It analyzed the following clinical data: age, gender, type of presentation, time from symptom onset to diagnosis, clinical features, concomitant diseases, family history of amyloidosis, biopsy sites, presence of urinary or serum monoclonal gammopathy, immunohistochemical type, prognosis and treatment.

**RESULTS:** Median age at diagnosis was 56+/-18 years. The overall ratio of men to woman was 1.4. AL amyloidosis (amyloid light chain) accounted for 54% (21/39) of the cases, AA (amyloid-associated) amyloidosis 36% (14/39), while 10% (4/39) were not typed. Among the 21 cases of AL amyloidosis, 12 were idiopathic (57%) and 9 (43%) were associated with multiple myeloma; among the 14 cases of AA amyloidosis, 7 were associated with familial Mediterranean fever and 5 with chronic disorders. Proteinuria was often the first symptom. The initial manifestations in AL amyloidosis patients with myeloma were more often related to amyloidosis than to myeloma. Renal involvement was seen in 95% (37/39) of all cases (95% of AL versus 93% of AA), proteinuria in 87% of cases and renal failure in 72%. Cardiac amyloidosis (57% of AL versus 7% of AA;  $p>0.05$ ), infiltration of the tongue (19% of AL versus 0% of AA;  $p>0.05$ ) and neurological manifestations (24% of AL versus 7% of AA;  $p>0.05$ ) were more frequent in AL amyloidosis. The 7 patients who died (18%) had AL amyloidosis (5 of them had myeloma). Heart failure was the most frequent cause of death related to amyloid.

**CONCLUSION:** Multisystem amyloidosis is frequent in Lebanon and familial Mediterranean fever is still frequently associated with the secondary type. Accurate diagnosis and classification are essential for the prognosis and

treatment of the disease. Poor prognosis was associated with the AL type, especially when accompanied by myeloma, and with cardiac amyloidosis.

Clinicopathological and epidemiological analysis of amyloidosis in Turkish patients.

Ensari C(1), Ensari A, Tümer N, Ertug E.

Author information:

(1)Atatürk Hospital Nephrology and Dialysis Unit, University of Ankara Medical School, Ankara, Turkey. aensari@ato.org.tr

**BACKGROUND:** The aim of the present study was to assess the correlation of immunohistochemical subtyping with clinical diagnosis in order to achieve useful epidemiological data regarding amyloidosis in Turkish patients.

**METHOD:** We carried out immunohistochemical studies on 128 biopsies from various sites of 111 patients with biopsy-proven amyloidosis and, based on the results, classified the patients. We assessed the correlation of immunohistochemical subtype with clinical diagnosis and gathered epidemiological data.

**RESULTS:** The sites most biopsied were kidney and rectum, followed by the testicle, liver, small intestine and bladder. Amyloid deposits showed positive staining with a single antibody in 120 biopsies. Pure amyloid A (AA) positivity was seen in 113 biopsies; six biopsies were positive for amyloid lambda (AL) and one for beta2-microglobulin (beta2MG). The clinical diagnoses of 81 patients (98 biopsies all AA positive) were suggestive of familial Mediterranean fever (FMF). Also AA positive were eight patients with tuberculosis, seven patients with rheumatoid arthritis, four patients with bronchiectasis and one patient with Crohn's disease. The biopsies from seven patients clinically suspected to have plasma cell dyscrasias were AL positive. One patient undergoing haemodialysis was beta2MG positive. Two patients without definite diagnoses showed double or triple positivity, which could not be interpreted and classified immunohistochemically.

**CONCLUSIONS:** This study demonstrates that the predominant association of AA amyloidosis is with FMF. It also suggests that the routine immunohistochemical

study of patients with amyloidosis who are of certain ethnic backgrounds suffices for classifying the subtype of amyloid fibril protein and the related disease.

Diagnosis delay in familial Mediterranean fever (FMF): social and gender gaps disclosed.

Lidar M(1), Tokov I, Chetrit A, Zaks N, Langevitz P, Livneh A.

Author information:

(1)Heller Institute of Medical Research, Sheba Medical Center, Tel-Hashomer, Israel.

**OBJECTIVE:** To characterize the factors contributing to a greater than 10 year delay in the diagnosis of familial Mediterranean fever (FMF).

**METHODS:** 50 patients, in whom diagnosis of FMF was delayed by more than 10 years, comprised the study population. The clinical, demographic and molecular genetic characteristics were compared to a control group of 50 FMF patients, in whom the diagnosis was made within a reasonable time period (less than 5 years from onset). Additional factors contributing to a delayed diagnosis in the study group, including physician-related factors, patient-related factors, disease-factors and other factors, were studied as well.

**RESULTS:** Overall, attack sites, duration and severity were comparable among study and control groups. No differences in ethnic origin or family history of FMF were noted between the groups. There were significantly more females ( $p = 0.009$ ), newly-arrived immigrants ( $p = 0.005$ ) and carriers of unidentified MEFV mutations ( $p = 0.04$ ) in the study group. Delayed diagnosis of FMF stemmed from misdiagnosis and physician negligence (70%), as well as from patient negligence (70%). The diagnosis was ultimately made mainly due to a change in disease pattern and other causes, such as diagnosis of FMF in a relative.

**CONCLUSION:** The study unveils unexpected causes behind a prolonged delay in the diagnosis of FMF such as social status (immigrant), female gender, physician negligence and lack of patient awareness. The possibility that the delay stems from a milder disease pattern was dismissed.

Familial Mediterranean fever and mesangial proliferative glomerulonephritis: report of a case and review of the literature.

Cagdas DN(1), Gucer S, Kale G, Duzova A, Ozen S.

Author information:

(1)Department of Pediatrics, Hacettepe University Faculty of Medicine, Ankara, Turkey.

In familial Mediterranean fever (FMF), a genetically inherited disease characterized by fever and serositis, renal involvement is mainly AA amyloidosis. We report a patient with FMF who developed mesangial proliferative glomerulonephritis; presumably in response to colchicine treatment, the activity of the disease decreased and renal function tests and urinary findings normalized. This report emphasizes the concurrent existence of mesangial proliferative glomerulonephritis with FMF in the absence of renal amyloidosis. Due to increased inflammatory response observed in FMF, immunologic glomerular injury, a common cause of glomerulonephritis, may occur more frequently in patients with FMF.

Severe disease in patients with rheumatoid arthritis carrying a mutation in the Mediterranean fever gene.

Rabinovich E(1), Livneh A, Langevitz P, Brezniak N, Shinar E, Pras M, Shinar Y.

Author information:

(1)Heller Institute of Medical Research, Sheba Medical Centre, Tel Hashomer 52621, Israel.

**BACKGROUND:** Pyrin is a newly recognised intracellular regulator of inflammation, and mutations in MEFV, the gene encoding pyrin, are the cause of familial Mediterranean fever.

**OBJECTIVE:** To determine if known mutations of MEFV are associated with rheumatoid arthritis (RA) morbidity or can modify RA severity.

**METHODS:** The frequency of the three most common MEFV mutations: M694V, V726A, and E148Q, was determined in 98 Israeli patients with RA (74 women, 24 men) and compared with that in 100 healthy subjects matched for origin. RA severity was determined using a new clinical score of 126 grades. The median severity score of mutation carrier and non-carrier groups was compared after confounding measures were eliminated by logistic regression.

**RESULTS:** 17/98 (17%) patients with RA (all women) were heterozygous for common MEFV mutations, predominantly E148Q (12 patients), and one patient was homozygous for the V726A mutation. The overall mutation rate was comparable between patients with RA and healthy subjects. Patients carrying a mutation had a higher median severity score than the non-carrier group (42 v 29,  $p = 0.0005$ ). The logistic regression model assigned a 15-fold odds ratio for severe RA in carriers, after adjusting for sex, presence of rheumatoid factor, age at onset, and disease duration ( $n = 97$ ,  $p = 0.01$ , 95% CI 1.74 to 128).

**CONCLUSION:** MEFV, and particularly the E148Q mutation, is an independent modifier of the clinical manifestations of RA. This is the second Th1-type autoimmune disease in which MEFV mutations have been shown to aggravate the clinical status.

Genetic screening of familial Mediterranean fever mutations in the Palestinian population.

Ayesh SK(1), Nassar SM, Al-Sharef WA, Abu-Libdeh BY, Darwish HM.

Author information:

(1)Molecular Genetics Laboratory, Makassed Islamic Charitable Hospital, Mount of Olives, PO Box 19482, Jerusalem 91194, Palestine. moleclab@alqudsnet.com

**OBJECTIVE:** To investigate the spectrum of mutations and genotypes in the pyrin gene in familial Mediterranean fever (FMF) patients.

**METHODS:** Blood samples of 511 suspected FMF patients, received from the Molecular Genetics Laboratory, Makassed Islamic Charitable Hospital, Mount Olives, Jerusalem during the period from June 1999 to August 2004, were investigated by genotyping 24 different MEFV mutations.

**RESULTS:** Our work revealed the presence of 14 different mutations from the identified 24 mutations in the gene which are assembled in 6 homozygous, 9 heterozygous and 16 compound heterozygous genotypes. The homozygous genotypes represent the predominant format among our patients representing approximately 38% of the revealed genotypes. Interestingly, in 94 (31.4%) of the tested subjects, only one mutation in the pyrin gene could be identified while the other mutant allele remains unidentified. Moreover, the genotype of 3 (1%) patients revealed the presence of triplet mutations in the pyrin gene.

**CONCLUSION:** The results of our study clearly suggest that the origin of FMF among the Palestinian population is mostly homozygous. The identification of a significant number of patients with one known mutation indicates potentially the presence of new mutations in the gene which will be investigated in the future.

The spectrum of familial Mediterranean fever gene mutations in Arabs: report of a large series.

Majeed HA(1), El-Khateeb M, El-Shanti H, Rabaiha ZA, Tayeh M, Najib D.

Author information:

(1)Department of Pediatrics, Faculty of Medicine, University of Jordan, Amman.  
habdelmajeed@yahoo.com

**OBJECTIVES:** To identify the frequency and distribution of familial Mediterranean fever (FMF) gene (MEFV) mutations in Arab patients.

**PATIENTS AND METHODS:** The study was performed in the pediatric FMF clinic of Jordan University Hospital over a period of 4 years. Patients were referred by their physicians for diagnosis, management, genetic study, and counseling. A diagnosis of FMF was made according to published criteria. Screening for 5 mutations, namely M694V, V726A, M694I, M680I, and E148Q, was performed by amplification refractory mutation system (ARMS) for the first 4 and by restriction endonuclease testing for E148Q.

**RESULTS:** Of the 407 unrelated patients investigated, 239 (59%) had 1 or 2 mutations and 168 (41%) had none of the studied mutations detected. Of those with mutations, 92 were homozygous, 53 were compound heterozygotes, 3 had complex alleles, and 91 patients had only 1 identifiable mutation. Of the mutations, M694V, V726A, M694I, M680I, and E148Q accounted for 38, 26, 14, 10 and 13%, respectively. Twelve of our patients developed the protracted febrile myalgia syndrome (PFMS) of whom 5 (42%) were homozygous for M694V. Only 2 developed chronic renal failure, both of whom were homozygous for M694V and were not on colchicine prophylaxis. However, 43 patients had a family history of chronic renal failure, and 15 (35%) were homozygous for M694V.

**CONCLUSIONS:** Our data indicate that the 5 MEFV mutations are well distributed in Arabs. They also show that M694V is the most common mutation in Arab patients with FMF and seems to have an association with the development of amyloidosis and the PFMS. The high frequency of V726A, and the unique high frequency of M694I in Arabs compared with 3 other ethnic groups, are confirmed.

Interaction of pyrin with 14.3.3 in an isoform-specific and phosphorylation-dependent manner regulates its translocation to the nucleus.

Jéru I(1), Papin S, L'hoste S, Duquesnoy P, Cazeneuve C, Camonis J, Amselem S.

Author information:

(1)INSERM U.654, Hôpital Henri-Mondor, Créteil, France.

**OBJECTIVE:** Pyrin, the familial Mediterranean fever gene product, exists in several isoforms of unknown functions. The recombinant full-length isoform (pyrin.fl) is cytoplasmic, whereas an alternatively spliced isoform lacking exon 2 (pyrin.DeltaEx2) concentrates in the nucleus. Native pyrin, mainly consisting of pyrin.fl, is also cytoplasmic in monocytes but is predominantly nuclear in other cell types. To understand pyrin-dependent biologic pathways and to decipher the mechanisms accounting for such different patterns of subcellular compartmentalization, binding partners and posttranslational modifications of pyrin were assessed.

**METHODS:** A yeast 2-hybrid screen was performed with pyrin.fl as the bait. The interaction identified between pyrin.fl and 14.3.3 proteins was confirmed by immunoprecipitation of (35)S-radiolabeled protein complexes; similar experiments were performed with pyrin.DeltaEx2, pyrin.fl after alkaline phosphatase treatment, and pyrin.fl mutants in which several exon 2-encoded serine residues were replaced by nonphosphorylatable alanines. The subcellular localization of the different wild-type and mutated pyrin proteins was assessed by immunofluorescence.

**RESULTS:** Two members of the 14.3.3 protein family were identified as pyrin partners. Whereas pyrin.fl interacted with 14.3.3tau and 14.3.3epsilon, these interactions did not occur with pyrin.DeltaEx2. Pyrin.fl was phosphorylated, and this modification mediated 14.3.3 binding. Serines 208, 209, and 242, within exon 2, acted as critical residues in the interaction between pyrin.fl and 14.3.3. When an S208-S209-S242A pyrin.fl triple mutant or wild-type pyrin.fl in the presence of an inhibitor of 14.3.3-ligand interactions was used, promotion of nuclear translocation of pyrin was observed.

**CONCLUSION:** These results disclose the role played by 14.3.3 in the regulation of the subcellular compartmentalization of pyrin in a phosphorylation- and isoform-dependent manner. They also reconcile the observations made in vitro with those made in vivo, while providing a direct link between 14.3.3-dependent pathways and pyrin.

Periodic fever in children with hyperimmunoglobulinemia D and mevalonate kinase mutations.

Grose C(1).

Author information:

(1)Childrens Hospital of Iowa, University of Iowa Iowa City, IA, USA.

Hyperimmunoglobulinemia D syndrome (HIDS) is one cause of periodic fevers in children. HIDS is associated with mutations in the mevalonate kinases gene on chromosome 12. Most cases of HIDS have been reported from the Netherlands and surrounding European countries. It is likely that HIDS is underdiagnosed in the United States.

Distinguishing among prolonged, recurrent, and periodic fever syndromes: approach of a pediatric infectious diseases subspecialist.

Long SS(1).

Author information:

(1)Department of Pediatrics, Drexel University College of Medicine, Philadelphia, PA 19134, USA. sarah.long@drexelmed.edu

Most children with prolonged, recurrent, or periodic fever are healthy and have self-limited, common illnesses, and the primary care practitioner usually can reassure families and continue to reassess the patient as circumstances dictate.

For a child with true fever of unknown origin, a pediatric infectious diseases subspecialist should be consulted. This article discusses three objectives for the clinician: (1) to categorize patterns of fever illnesses and prioritize differential diagnoses; (2) to diagnose and manage the most frequently encountered prolonged fever syndrome, deconditioning; and (3) to expand knowledge and approach to diagnosing periodic fever syndromes. The approach described in this article represents the honed, 30-year experience of a pediatric infectious diseases subspecialist.

Dramatic improvement of pyoderma gangrenosum with infliximab in a patient with PAPA syndrome.

Stichweh DS(1), Punaro M, Pascual V.

Author information:

(1)UT Southwestern Medical Center at Dallas and Texas Scottish Rite Hospital for Children, Dallas, Texas, USA.

Infliximab, a chimeric antitumor necrosis factor alpha monoclonal antibody (anti-TNF alpha), has been recently shown to have a beneficial effect on pyoderma gangrenosum associated with inflammatory bowel disease. Patients with the syndromic triad of pyogenic sterile arthritis, pyoderma gangrenosum, and acne, an autoinflammatory process caused by mutations in the CD2 binding protein-1 (CD2BP1) gene, can have severe pyoderma gangrenosum. We describe a 14-year-old patient with this syndrome who was unresponsive to multiple therapies. A dramatic improvement in his pyoderma gangrenosum was observed after one infusion of infliximab, and a second infusion led to its resolution. Our observation extends the therapeutic use of infliximab to this component of PAPA syndrome.

MEFV gene is a probable susceptibility gene for Behçet's disease.

Imirzalioglu N(1), Dursun A, Tastan B, Soysal Y, Yakicier MC.

Author information:

(1)Department of Medical Genetics, Military Medical Academy, Ankara, Turkey.

**OBJECTIVE:** Behçet's disease (BD) is a rare, chronic, multisystem inflammatory disorder. The prevalence of BD is higher in the Middle Eastern and Mediterranean populations. Another chronic inflammatory disease, familial Mediterranean fever (FMF), is also known to be highly prevalent in these populations. The prevalence of BD is higher in the FMF patient population than in populations known to be rich in BD. Both BD and FMF have some pathophysiological features in common and they result from inappropriate activation of neutrophils. Clinical manifestations of both diseases can mimic each other and the coexistence of both diseases in the same patient has been reported. Given that BD and FMF have similar pathophysiological, epidemiological, and clinical features, we hypothesized that the gene responsible for FMF, MEFV, may also play a role in the pathogenesis of BD.

**METHODS:** Forty-two BD patients who had no symptoms and family history for FMF and 66 healthy controls were screened for common MEFV gene mutations (E148Q, M680I, M694V, and V726A).

**RESULTS:** Fifteen patients (36%) displayed MEFV mutations (nine M694V, five E148Q, and one M680I) and mutation rates were significantly elevated compared to 66 (11%) healthy controls ( $p = 0.0034$ ).

**CONCLUSION:** The occurrence of frequent MEFV mutations in BD patients suggests

that the MEFV gene is involved in the pathogenesis of Behçet's disease.

Treatment of hidradenitis suppurativa with infliximab in a patient with Crohn's disease.

Rosi YL(1), Lowe L, Kang S.

Author information:

(1)Department of Dermatology, University of Michigan, Ann Arbor, MI 48109, USA.

**BACKGROUND:** Hidradenitis suppurativa is a chronic, inflammatory, scarring disease characterized by recurrent flares. Recently, a group of 'autoinflammatory disorders' has been described. These disorders are characterized by recurrent inflammatory episodes not mediated by autoantibodies or antigen-specific T-cells. Some of these autoinflammatory disorders have been successfully treated with anti-tumor necrosis factor antibodies.

**OBSERVATIONS:** We describe a patient with hidradenitis suppurativa and a history of inactive Crohn's disease who was treated with infliximab, with subsequent improvement in her skin disease.

**CONCLUSIONS:** This case suggests that infliximab may be effective in the treatment of hidradenitis suppurativa in association with Crohn's disease. We also suggest that hidradenitis suppurativa may be closely linked with this new group of autoinflammatory disorders.

The clinical potential of chemokine receptor antagonists.

Ribeiro S(1), Horuk R.

Author information:

(1)Department of Molecular Pharmacology, Berlex Biosciences, 2600 Hilltop Drive, Richmond, CA 94804, USA.

Chemokines belong to a family of chemotactic cytokines that direct the migration of immune cells towards sites of inflammation. They mediate their biological effects by binding to cell surface receptors, which belong to the G protein-coupled receptor superfamily. Since chemokines and their receptors have been implicated in the pathophysiology of a number of autoinflammatory diseases, chemokine receptor antagonists could prove to be useful therapeutics to target these diseases. Here, we review the role of chemokines in autoimmunity, concentrating mainly on the chemokine receptors CCR1 and CCR5, and discuss the potential utility of antagonists that target these 2 receptors as they progress through the clinic.

Author information:

(1)Department of Pediatrics, Dokuz Eylül University Medical Faculty, Inciralti,

Izmir, Turkey.

Familial Mediterranean fever (FMF) is a multisystem disease characterized by recurrent polyserositis episodes seen in certain ethnic groups. In recent years the clinical picture of FMF has been expanded and severe myalgia is a frequently recognized component of the syndrome. Protracted febrile myalgia syndrome (PFMS), characterized by severe paralyzing myalgia, high fever, abdominal pain, diarrhea, arthritis/arthralgia, and transient vasculitic rashes mimicking Henoch-Schonlein purpura, was first described in patients with FMF in 1994. We describe an 11-year-old Turkish girl with a second attack of PFMS before being diagnosed as having FMF, emphasizing the importance of myalgia for the diagnosis of FMF even in the absence of other symptoms.

Nature. 2005 May 12;435(7039):151-2.

Nature. 2005 Nov 24;438(7067):E5; discussion E5-6.

In autoimmune type 1 diabetes, pathogenic T lymphocytes are associated with the specific destruction of insulin-producing beta-islet cells. Identification of the autoantigens involved in triggering this process is a central question. Here we examined T cells from pancreatic draining lymph nodes, the site of islet-cell-specific self-antigen presentation. We cloned single T cells in a non-biased manner from pancreatic draining lymph nodes of subjects with type 1

diabetes and from non-diabetic controls. A high degree of T-cell clonal expansion was observed in pancreatic lymph nodes from long-term diabetic patients but not from control subjects. The oligoclonally expanded T cells from diabetic subjects with DR4, a susceptibility allele for type 1 diabetes, recognized the insulin A 1-15 epitope restricted by DR4. These results identify insulin-reactive, clonally expanded T cells from the site of autoinflammatory drainage in long-term type 1 diabetics, indicating that insulin may indeed be the target antigen causing autoimmune diabetes.

Co-existence of *Helicobacter pylori* infection in patients with Familial Mediterranean Fever (FMF) and the effect of *Helicobacter pylori* on the frequency and severity of FMF attacks.

Demirtürk L(1), Ozel AM, Cekem K, Yazgan Y, Gultepe M.

Author information:

(1)Department of Gastroenterology, Gülhane Military Medical Academy Haydarpaşa Training Hospital, 81327 Istanbul, Turkey.

**BACKGROUND:** The inflammatory reactions both in Familial Mediterranean Fever and in *Helicobacter pylori* infection have similarities. Whether there is interactions in case of co-existence of both diseases has not been evaluated. **AIM.:** To evaluate, if there is a significant relation between *H. pylori* infection and Familial Mediterranean Fever; if *H. pylori* has an effect on the frequency and severity of Familial Mediterranean Fever attacks; and if eradication treatment has any affects.

**METHODS:** Thirty-two Familial Mediterranean Fever patients were tested for *H. pylori* infection. Acute phase responses were evaluated and attack frequency and severity were determined in both *H. pylori*-positive and *H. pylori*-negative groups. Same determinations were done after the eradication treatment in *H. pylori*-positive patients. Levels of acute phase determinants as well as frequency and severity of attacks were compared in *H. pylori*-positive and -negative groups.

**RESULTS:** C-reactive protein, erythrocyte sedimentation rate, white blood count

and fibrinogen levels were significantly ( $p<0.01$ ) higher during the attacks than before the attacks in all patients. However, there was no difference between the groups. *H. pylori*-positive patients have a higher frequency and a longer duration of attacks when compared to *H. pylori*-negative patients before treatment ( $p<0.05$ ). The frequency was also significantly lower and duration was shorter in patients whose infections were eradicated ( $p<0.05$ ).

CONCLUSION: *H. pylori* infection was not significantly frequent in our group of Familial Mediterranean Fever patients. *H. pylori* can decrease both the frequency and the duration of the attacks. Studies that will evaluate the relationship of *H. pylori* and MEFV gene along with the roles of yet unknown cytokines, which can presumably play a role in the pathogenesis of both diseases, are needed to reach better conclusions.

Encapsulating peritonitis and familial Mediterranean fever.

Dabak R(1), Uygur-Bayramiçli O, Aydın DK, Dolapçioğlu C, Gemici C, Erginel T, Turan C, Karadayi N.

Author information:

(1)Department of Family Medicine, Kartal State Hospital, 36660 Istanbul, Turkey.

AIM: To investigate the relationship between encapsulating peritonitis and familial Mediterranean fever (FMF).

METHODS: The patient had a history of type 2 diabetes and laparoscopic cholecystectomy was performed one year ago for cholelithiasis. Eleven months after the operation she developed massive ascites. Biochemical evaluation revealed hyperglycemia, mild Fe deficiency anemia, hypoalbuminemia and a CA-125 level of 2 700 IU. Ascitic evaluation showed characteristics of exudation with a cell count of 580/mm<sup>3</sup>. Abdominal CT showed omental thickening and massive ascites. At exploratory laparotomy there was generalized thickening of the peritoneum and a laparoscopic clip encapsulated by fibrous tissue was found adherent to the uterus. Biopsies were negative for malignancy and a prophylactic total abdominal hysterectomy and bilateral salpingoophorectomy were performed.

RESULTS: The histopathological evaluation was compatible with chronic nonspecific findings and mild mesothelial proliferation and chronic inflammation at the uterine serosa and liver biopsy showed inactive cirrhosis.

CONCLUSION: The patient was evaluated as sclerosing encapsulating peritonitis induced by the laparoscopic clip acting as a foreign body. Due to the fact that the patient had FMF the immune response was probably exaggerated.

Meningitis associated with familial Mediterranean fever.

Karachaliou I(1), Karachalios G, Charalabopoulos A, Charalabopoulos K.

Author information:

(1)Second Department of Medicine, Red Cross Hospital, Athens, Greece.

Neurologic involvement in patients with familial Mediterranean fever is relatively uncommon, and rarely described in the literature. Although headache occurs frequently, meningitis and convulsions are rare. We describe the case of a 30-year-old man with attacks of meningitis. After colchicine therapy, no further recurrence of fever and meningitis were observed. These findings suggest that meningitis should be considered as an unusual manifestation of familial Mediterranean fever.

Comment in

J Rheumatol. 2005 Nov;32(11):2278; author reply 2278.

**OBJECTIVE:** To clinically and genetically characterize patients with familial Mediterranean fever (FMF) in whom arthritis constitutes the only manifestation, and to establish the most important features distinguishing FMF arthritis in such a setting from other forms of mono/oligo arthritides.

**METHODS:** The study population comprised 14 patients with episodes of arthritis as the only manifestation of FMF who nevertheless fulfilled the diagnostic criteria for FMF. The control group consisted of 28 patients with episodic mono/oligo arthritis of different disease entities (palindromic, reactive, inflammatory bowel disease, Reiter's, seronegative spondyloarthropathy, chronic juvenile, Behcet's, and gouty arthritis) who presented to the rheumatology clinic during the study period. Patients in both groups underwent clinical evaluation and donated blood for FMF gene analysis.

**RESULTS:** The study and control groups shared similar age and sex distribution and experienced the monoarthritic attacks at similar sites, usually the knee and ankle joint. The 2 groups differed significantly in features of arthritis (which were febrile and of short duration in FMF), family history of FMF, mutation analysis, and response to colchicine. These differences allowed the defining of a rule, which readily distinguishes FMF arthritis from other forms of episodic mono/oligo arthritis.

**CONCLUSION:** The clinical, ethnic, and genetic features of recurrent monoarthritis of FMF are specific and may separate FMF from other entities with mono/oligo arthritis.

Tumor necrosis factor (TNF) receptor-associated periodic syndrome (TRAPS) is an autosomal dominant inherited condition of periodic fever and pain. TRAPS is caused by mutations of the TNFRSF1A gene localized at 12p13. The gene encodes extracellular region of the p55 TNF-alpha receptor, resulting in impaired cleavage and down-regulation of the membrane expressed form of the receptor, a diminished shedding of potentially antagonistic soluble form of the receptor and, as a consequence, an unbalanced TNF-alpha action. Most affected patients are from northern Europe. Fever, sterile peritonitis, pleural pain, arthralgia, myalgia, skin rash, and/or conjunctivitis occur during the syndrome episodes; some patients also develop systemic amyloidosis, with some differences among patients. An acute-phase response occurs during the episodes. We describe a case of a 23-year-old Moldavian woman, living in Italy presenting recurrent fever episodes with abdominal pain and skin rash. A biopsy showed small vessel vasculitis. The genetic analysis showed a TNFRSF1A gene (R92Q) mutation. In this paper we report also a literature review on this rare disease.

It has been generally accepted that the clinical onset of familial Mediterranean fever (FMF) begins before 20 years of age in most patients. In this study, we aimed to investigate the demographic and clinical characteristics of our FMF patients with an age of onset  $\geq 20$ . Records of 401 patients (female/male: 204/197) that followed up between 1990 and 1999 were reviewed according to a pre-defined protocol. All patients fulfilled the diagnostic criteria of Livneh et al. The demographic and clinical features of adult-onset FMF patients were compared to those of patients with a disease onset before 20 years of age. There were 57 patients (14%) who experienced symptoms of FMF at  $\geq 20$  years of age; 34 of them (8.5%) reported their first attack between 20 and 29 years of age; 18 of them (4.5%) between 30 and 39 years of age and five patients (1.25%) had their first attack after 40 years of age. Arthritis (42 vs. 65%,  $p = 0.001$ ) and erysipelas-like erythema (7 vs. 17%,  $p = 0.047$ ) were significantly less frequent in patients with adult-onset FMF compared to patients with disease onset before 20 years of age. Arthritis and erysipelas-like erythema were less frequent in adult-onset patients compared to those with an earlier disease onset. Adult-onset FMF may be a form of disease with distinct clinical, demographic and molecular characteristics. Prospective clinical studies and investigation of genotypic features are needed to identify the characteristics of this phenotypic variant.

Tumour necrosis factor receptor-associated periodic syndrome (TRAPS), a rare autosomal dominant disorder, is characterised by recurrent attacks of fever, myalgias, and abdominal pain. However, manifestations in the central nervous system are hardly known. We describe a family in which one of three affected members developed central nervous system symptoms. First diagnosed as multiple sclerosis (MS), the demyelination seems to be a feature of TRAPS rather than MS. The syndrome is discussed as a rare differential diagnosis of MS.

Familial Mediterranean fever is a hereditary syndrome characterised by recurrent episodes of fever and serositis, resulting in pain in the abdomen, chest, joints and muscles. It is primarily diagnosed in people of Jewish, Arabic, Turkish or Armenian ancestry and is caused by mutations in the gene encoding for pyrin. Abdominal FMF attacks resemble the clinical presentation of 'acute abdomen', with severe abdominal pain and rigidity, but in FMF symptoms always resolve spontaneously. It is important to distinguish these regular pain episodes from small bowel obstruction due to adhesions to prevent life-threatening bowel strangulation. In most cases, colchicine will prevent new painful attacks. This seminar also discusses other causes of abdominal pain in FMF patients.

Auto-inflammatory syndromes are a group of hereditary diseases characterised by intermittent bouts of clinical inflammation with focal organ involvement mainly: abdomen, musculoskeletal system and skin. The most frequent is familial Mediterranean fever, which affects patients of Mediterranean descent all over the world. Three other types have been recently clinically as well as genetically characterised. A thorough diagnosis is warranted, as clinical and therapeutic management is specific for each of these diseases, as underlied by a specific

inflammatory pathway. This new group of diseases has already opened new avenues in our understanding of the inflammatory response.

Human autoinflammatory diseases (except for the periodic fever, adenopathy, pharyngitis, aphthae syndrom) are a heterogeneous group of genetically determined diseases characterized by seemingly unprovoked inflammation, in the absence of autoimmune or infective causes. Tremendous advances in the understanding of these disorders have been seen in the last decade. This article discusses hereditary autoinflammatory syndromes that are associated with recurrent fevers.

Comment in

Arthritis Rheum. 2005 Sep;52(9):2952; author reply 2952-3.

**OBJECTIVE:** Tumor necrosis factor receptor-associated periodic syndrome (TRAPS) is an autoinflammatory syndrome associated with mutations in the gene that encodes tumor necrosis factor receptor superfamily 1A (TNFRSF1A). The purpose of this study was to describe a novel TNFRSF1A mutation (C43S) in a patient with TRAPS and to examine the effects of this TNFRSF1A mutation on tumor necrosis factor alpha (TNFalpha)-induced signaling in a patient-derived primary dermal fibroblast line.

**METHODS:** TNFRSF1A shedding from neutrophils was measured by flow cytometry and enzyme-linked immunosorbent assay (ELISA). Primary dermal fibroblast lines were established from the patient with the C43S TRAPS mutation and from healthy volunteers. Activation of NF-kappaB and activator protein 1 (AP-1) was evaluated by electrophoretic mobility shift assays. Cytokine production was measured by ELISA. Cell viability was measured by alamar blue assay. Apoptosis was measured by caspase 3 assay in the fibroblasts and by annexin V assay in peripheral blood mononuclear cells.

**RESULTS:** Activation-induced shedding of the TNFRSF1A from neutrophils was not altered by the C43S TRAPS mutation. TNFalpha-induced activation of NF-kappaB and AP-1 was decreased in the primary dermal fibroblasts with the C43S TNFRSF1A mutation. Nevertheless, the C43S TRAPS fibroblasts were capable of producing interleukin-6 (IL-6) and IL-8 in response to TNFalpha. However, TNFalpha-induced cell death and apoptosis were significantly decreased in the samples from the patient with the C43S TRAPS mutation.

**CONCLUSION:** The C43S TNFRSF1A mutation results in decreased TNFalpha-induced nuclear signaling and apoptosis. Our data suggest a new hypothesis, in that the C43S TRAPS mutation may cause the inflammatory phenotype by increasing resistance to TNFalpha-induced apoptosis.

A new CARD15 mutation in Blau syndrome.

van Duist MM(1), Albrecht M, Podswiadek M, Giachino D, Lengauer T, Punzi L, De Marchi M.

Author information:

(1)Department of Clinical and Biological Sciences, Division of Medical Genetics, University of Torino, Orbassano, Italy.

The caspase recruitment domain gene CARD15/NOD2, encoding a cellular receptor involved in an NF-kappaB-mediated pathway of innate immunity, was first identified as a major susceptibility gene for Crohn's disease (CD), and more recently, as responsible for Blau syndrome (BS), a rare autosomal-dominant trait characterized by arthritis, uveitis, skin rash and granulomatous inflammation. While CARD15 variants associated with CD are located within or near the C-terminal leucine-rich repeat domain and cause decreased NF-kappaB activation, BS mutations affect the central nucleotide-binding NACHT domain and result in increased NF-kappaB activation. In an Italian family with BS, we detected a novel mutation E383K, whose pathogenicity is strongly supported by cosegregation with the disease in the family and absence in controls, and by the evolutionary conservation and structural role of the affected glutamate close to the Walker B motif of the nucleotide-binding site in the NACHT domain. Interestingly, substitutions at corresponding positions in another NACHT family member cause similar autoinflammatory phenotypes.

Comment in

Intern Med. 2005 Mar;44(3):177-8.

Familial Mediterranean fever (FMF) is an inherited inflammatory disease occurring mainly in Mediterranean and Middle Eastern populations. FMF is caused by mutations in the MEFV gene that encodes pyrin/marenostrin. Here, we report a Japanese female FMF patient with heterozygosity for the compound pyrin E148Q/M694I showing recurrent fever, serositis or delay in skin wound healing. Her father and elder sister were heterozygous for pyrin variant M694I alone and sometimes suffered from mild fever or delay in wound healing, but her mother was heterozygous for pyrin variant E148Q alone and had no symptoms. This suggested that the inheritance of FMF occurred not only in an autosomal recessive manner but also in an autosomal dominant manner in this Japanese family, and the severity of the disease differed among the family members in relation to the mutation. In the treatment of FMF, colchicine, reserpine or prazosin hydrochloride have been reported to prevent the attacks, but, in our patient such drugs were ineffective or caused side effects, and only the anti-allergic drug azelastine was of benefit in relieving the attacks.

Henoch-Schönlein purpura in a child with hyperimmunoglobulinemia D and periodic fever syndrome.

Wickiser JE(1), Saulsbury FT.

Author information:

(1)Department of Pediatrics, University of Virginia Health System, Charlottesville, Virginia 22908, USA.

This report describes a 3-year-old girl with a long history of periodic fever who presented with Henoch-Schönlein purpura. She was diagnosed with hyperimmunoglobulinemia D and periodic fever syndrome by means of mutation analysis of the mevalonate kinase gene. The serum IgA concentration was markedly elevated, but the serum IgD concentration was normal. This report emphasizes that Henoch-Schönlein purpura may be an important clinical feature of hyperimmunoglobulinemia D and periodic fever syndrome. In addition, this syndrome should be considered in patients with Henoch-Schönlein purpura in whom there is a history of recurrent fevers, even when the serum IgD concentration is normal.

A case of recurrent pancreatitis due to hyperlipidemia misdiagnosed as familial Mediterranean fever.

Birlik M, Demir T, Zeybel M, Akar S, Onen F, Comlekci A, Tunca M, Akkoc N.

Familial Mediterranean fever (FMF) is prevalent among Arabic, Turkish, Armenian, and Jewish people and it must always be considered in the differential diagnosis of patients from these ethnic groups presenting with recurrent abdominal pain with fever. In cases of fever and recurrent abdominal pain, acute pancreatitis is an important clinical condition, which should be considered in the differential diagnosis. Serum amylase concentration in acute pancreatitis is usually more than three times the upper limit of normal. However, in recurrent pancreatitis

secondary to hypertriglyceridemia, serum amylase levels, for reasons that are not well understood, may be normal or mildly elevated. Recurrent pancreatitis secondary to hypertriglyceridemia may thus pose a problem in the differential diagnosis and may lead to an erroneous diagnosis of FMF. Measurement of serum triglyceride along with amylase levels should be required for a suspected diagnosis. Computerized examination of the abdomen may need to be undertaken to exclude acute pancreatitis in the presence of hypertriglyceridemia since serum amylase levels may be normal or slightly elevated.

Tendonitis in variant hyperimmunoglobulinaemia D and periodic fever syndrome--a rare disease with a new symptom.

Armbrust S(1), Drenth JP, Schröder C, Domning E, Poeschl E, Wiersbitzky SK.

Author information:

(1)University Children's Hospital, Soldmannstrasse 15, 17487, Greifswald, Germany. sven.armbrust@web.de

Hyperimmunoglobulinaemia D syndrome (HIDS) is defined as recurrent fever, generalised lymphadenitis, abdominal pain, arthritis and raised polyclonal serum IgD >100 IU/ml. The cause is a mutation in the mevalonate kinase gene. Other periodic fever syndromes are known. We report a new patient and describe orbital tendonitis as a hitherto unreported symptom. CONCLUSION: Without any underlying cause, the tendonitis must be seen as new symptom of variant hyperimmunoglobulinaemia D syndrome. We speculate that the inflammation of the Tenon spatium is similar to the process of inflammation of the connective tissue in the joint in hyperimmunoglobulinaemia D syndrome where deposits of C3 and IgM are present. Variant hyperimmunoglobulinaemia D syndrome can be present in one family.

Spontaneous renal laceration as the presenting feature of polyarteritis nodosa in a patient with familial Mediterranean fever after hepatitis A infection.

Candan F(1), Ayan S, Tas F, Gökce G, Elagoz S.

Author information:

(1)Department of Internal Medicine, School of Medicine of Cumhuriyet University, Sivas, Turkey, 58140. fcandan@cumhuriyet.edu.tr

We report a life-threatening spontaneous renal laceration with no history of bleeding diathesis or any trauma in a patient with FMF after acute hepatitis A virus (HAV) infection. Right nephrectomy was inevitable and histological investigation of the removed right kidney revealed a polyarteritis nodosa (PAN). This case underlines the possibility that simultaneous PAN and immunosuppressive treatment besides colchicine should be considered for patients with FMF. Also, patients with FMF who are not immune may be vaccinated for HAV which could be a predisposing mechanism for vasculitic hemorrhage.

Molecular studies have shown that CD1 proteins present self and foreign lipid Ags to T cells, but the possible roles of CD1 in human autoimmune diseases in vivo are not known, especially for the group 1 CD1 isoforms (CD1a, CD1b, and CD1c). To investigate the hypothesis that CD1-restricted T cells might be activated and home to target tissues involved in Hashimoto's thyroiditis and Graves' disease, we performed ex vivo analysis of lymphocytes from peripheral blood and autoimmune lesions of thyroid tissue. Immunofluorescence analysis identified two types of CD1-expressing APCs in inflamed thyroid tissues. CD1a, CD1b, and CD1c were expressed on CD83+ dendritic cells, and CD1c was expressed on an abundant population of CD20+ IgD+ CD23- CD38- B cells that selectively localized to the mantle zone of lymphoid follicles within the thyroid gland. CD1c-restricted, glycolipid-specific T cells could not be detected in the peripheral blood, but were present in polyclonal lymphocyte populations isolated from affected thyroid glands. In addition, polyclonal thyroid-derived lymphocytes and short-term T cell lines were found to recognize and lyse targets in a CD1a- or CD1c-dependent manner. The targeting of CD1-restricted T cells and large numbers of CD1-expressing APCs to the thyroid gland during the early stages of autoimmune thyroiditis suggests a possible effector function of CD1-restricted T cells in tissue destruction and point to a new model of organ-specific autoimmune disease involving lipid Ag presentation.

Familial Mediterranean Fever (FMF), also known as paroxysmal polyserositis, is an autosomal recessive disease affecting mainly Mediterranean populations (Jews, Armenians, Arabs, Turks). It is characterised by recurrent crises of fever and serosal inflammation, leading to abdominal, thoracic or articular pain.

Erysipela-like erythema affecting mainly feet and legs and effort-induced myalgia are less frequently encountered symptoms. The major complication of FMF is the development of renal amyloidosis. Standard laboratory tests of FMF patients are non-informative, except for the high sedimentation rate and white blood cell count, but during and immediately after crises, diminished albumin concentrations and elevated fibrinogen, C-reactive protein, beta2 and alpha2 M globulins, haptoglobin and lipoprotein concentrations are noted. Studies have measured immunoglobulin (Ig) levels in the sera of FMF patients and found elevated levels of IgA, IgM, IgG, and IgD in 23%, 13%, 17% and 13%, respectively. FMF crises are characterised by a massive influx of polymorphonuclear leukocytes into the inflamed regions. Moreover, the peritoneal fluid of FMF patients contains abnormally low levels of the inhibitor of complement fragment C5a and interleukin 8. Failure to suppress inflammatory response to C5a may explain the typical inflammatory FMF crises. The MEFV (for MEiterranean FeVer) gene responsible for the disease has been identified on 16p13.3. It is composed of 10 exons and spans approximately 14 Kb of genomic DNA. More than 35 mutations have so far been identified. The most frequent are M694V, M694I, M680I, V726A and E148Q. The M694V mutation is the most frequent mutation in the various ethnic groups considered,

although its frequency varies from group to group. The V726A mutation is observed mainly among Ashkenazi and Iraqi Jews, Druzes and Armenians, and the M680I among Armenians and Turks. M694I and A744S seem specific to Arab populations, and R761H is frequently found in Lebanese FMF patients. The M694V mutation is often correlated with severe phenotypes, mainly in the homozygous state. It has been specifically correlated with arthritis, pleuritis and especially amyloidosis. Patients with other mutations in the 694 and 680 codons can also have severe phenotypes. The V726A mutation, although identified in FMF patients with a relatively mild phenotype, has also been detected in patients with renal amyloidosis. E148Q is often associated with a mild phenotype, and whether it is even a polymorphism has been questioned. The MEFV gene codes for a protein that was respectively called pyrin and marenostrin by the French and international consortia that simultaneously identified the gene. Its function is still not determined, but it was recently colocalised with microtubules and actin filaments in the cytoplasm. It contains a death domain called PYD (Pyrin Domain), usually associated with proteins involved in apoptosis. Some genes have been tested to assess their possible modifying effects on clinical features of FMF. The alpha/alpha genotype of the serum amyloid A or SAA1 gene is associated with an increased risk of amyloidosis in FMF patients, especially in patients homozygous for M694V, whereas the MICA (Major Histocompatibility Complex, MHC class-I-chain-related type A) gene seems to have an effect on disease course but not its clinical manifestations. The most effective treatment for FMF patients is colchicine, which should be taken regularly on a life-long basis. It decreases the frequency and severity of crises and prevents renal amyloidosis.

Until recently, the diagnosis of familial Mediterranean fever (FMF) was, based on clinical manifestations, ethnicity, family history and response to colchicines. The aim of this study is to evaluate the use of polymerase chain reaction (PCR) for diagnosis of FMF and to detect the prevalence of the most common MEFV gene (FMF gene) mutations, M694V and V726A in FMF Egyptian patients. From January 2002 to December 2002, twenty patients with FMF as well as 10 healthy subjects with no symptoms suggestive of FMF were enrolled in this study. All patients were subjected to PCR for MEEV gene mutations detection. Fifteen patients (75%) have age of onset of FMF less than 20 years. Five patients (25%) had past history of appendicectomy or laparotomy. The clinical features of patients during attacks were fever (100%), abdominal pain (95%), arthritis (55%), pleurisy (40%) and no skin rash or pericarditis. The M694V mutation was detected in 20 patients (100%) and V726A mutation in 17 patients (85%). No false positive or false negative results were obtained by using the three sets of primers for each sample, indicating a sensitivity and specificity of 100% of this assay.

Comment in

Arch Dermatol. 2005 Feb;141(2):242-7.

Neonatal-onset multisystem inflammatory disorder (NOMID) is a rare congenital disorder characterized by a neonatal-onset urticarial rash, arthropathy, recurrent fevers, and central nervous system disease. We report 3 cases in which patients presented with neonatal-onset urticarial eruption and other organ

involvement of varying severity. Genetic testing of 2 of these patients revealed previously unreported genetic mutations in exon 3 of the CIAS1 gene, a recently discovered member of the pyrin gene family. The third patient did not demonstrate a CIAS1 mutation. These cases illustrate the genetic basis of NOMID, an autoinflammatory disorder, and highlight the emerging role of the pyrin gene family in the regulation of nuclear factor kappaB signaling and other pathways involved in inflammation and apoptosis.

Author information:

(1)Department of Internal Medicine, Catholic University, Largo F. Vito 1, 00168

Rome, Italy.

Familial Mediterranean Fever (FMF), an autosomal recessive disorder, is characterised by recurrent attacks of fever and serositis, lasting 24-72 hours. Since 1972 colchicine has become the drug of choice for prophylaxis against FMF attacks and amyloidosis FMF-associated. Colchicine, an alkaloid neutral, is absorbed in the jejunum and ileum. It is metabolised by liver and only small amounts are recovered unchanged in the urine. Really plasma half-life is prolonged in patients with liver or renal failure. Colchicine is able to prevent activation of neutrophils, binding beta-tubulin and making beta-tubulin-colchicine complexes; this way inhibits assembly of microtubules and mitotic spindle formation; moreover its mode of action includes modulation of chemokines, prostanoids production, inhibition of neutrophil and endothelial cell adhesion molecules. The minimal daily dose in adults is 1.0 mg/die, but in children there is not a definite dose. Since in vitro high dosages of colchicine stop mitosis, this drug might interfere with male and female fertility and with children growth, but, according to current guidelines and because of rare side effects of the drug, FMF patients are recommended to take colchicine. Since colchicine treatment is often complicated by frequent gastrointestinal side effects, by our experience, in order to improve colchicine tolerance we recommend: lactose-free diet and treatment of intestinal bacterial overgrowth and/or Hp-infection, assessed by breath tests. Since our data showed that 10-15% of FMF patients seem are non-responders or intolerant to colchicine, today we are working in the design of colchicine analogues which may have lesser toxicities and a larger therapeutic window.

tamsar@sci.am

Familial Mediterranean Fever (FMF, MIM 249100), or Periodic disease, is a recessively transmitted and ethnically restricted condition prevalent in population from the Mediterranean decent. FMF notoriously has been hard to diagnose until mutations in the MEFV gene have been identified and as a tremendous help are used for the diagnosis of difficult cases. Since FMF can be controlled by medication, it is extremely desirable to have a firm diagnosis. The aim of this study was to establish the frequency of the most common mutations and genotypes in Armenian population. Molecular analysis of MEFV gene mutations in 3000 Armenian patients has demonstrated direct correlation between the clinical severity and the molecular diagnostic criteria of the disease, including the development of renal amyloidosis with MEFV genotypes. MEFV genotyping performed in the framework of a genetic counseling may reveal and identify affected individuals in presymptomatic phase, providing the possibility of a precocious start of the therapy.

MEFV mutation carriers and diseases other than familial Mediterranean fever: proved and non-proved associations; putative biological advantage.

Cattan D(1).

Author information:

(1)Praticien Hospitalier, Faculté de Médecine de Créteil, Centre Hospitalier, F 94195 Villeneuve-Saint-Georges, France. danielcattan@yahoo.fr

Vasculitis is definitely associated with familial Mediterranean fever. This familial Mediterranean fever-associated vasculitis takes one of three forms: polyarteritis nodosa, with or without microscopic polyangiitis, and Henoch-Schonlein purpura. Behcet disease and inflammatory bowel diseases may also be associated with familial Mediterranean fever, though this is yet to be formally proven. The selective biological advantage, if any, for carriers of simple heterozygotic mutations in the gene responsible for familial Mediterranean fever, MEFV, is not known. Indirect arguments are given for a better defense

against certain groups of bacterial pathogens and amongst intra-cellular bacteria, *Mycobacterium tuberculosis*.

konstant@mb.sci.am

According to modern images and results of our observations the oxidative stress (OS) is a non-specific though certain component of pathogenesis at numerous diseased states of organism having in the basis the thoroughness of pathogenic disturbances of phospholipids (PL) metabolism and processes of their free radical oxidation (FRO), which takes place in the membrane formations of as the whole cell, as well as the mitochondrial and microsomal fractions (MCF and MSF) of the white rat brain, liver mitochondria, lung shadows, at the same time erythrocyte and lymphocyte shadows at brain acute edema, ischemia, reperfusion and desympathization, infarction of myocardium, tuberculosis of lungs, diabetes, Familial Mediterranean Fever (FMF), intoxications under halothane anaesthesia (HA) and with micotoxin zearalenon. The regularities observed promote to understand from the point of view of modern approaches the molecular mechanisms of initiation, development and generalization of factors for OS formation under pathologic conditions. It is more obvious at zearalenon intoxication with intensification of lipids FRO processes and failures in PL-PL ratio phenomena. The lymphocytes membranes of the white rats spleen subjected OS induced by zearalenon intoxication permit us conclude that the general immune status of the organism decreases. It is generally peculiar to the states under conditions of generalized intoxication. The observed increase of phospholipase A(2) activity induces the release of high concentrations of lysophosphatidylcholines (LPC) and

non-etherified fatty acids (NEFA) of polyenic range with prevail of arachidonic acid as a pathogenic factor, namely, at modelling brain acute edema by tetraethylolovo to white rats. Formation of the above mentioned disturbances to some extent depends on hydrophobic properties of toxins, particularly, zearalenon. The latter gives certain tropism to dopamine-beta-monooxygenase (DBM), and ability to stimulate functional activity of the enzyme. Striking haemolytic properties of phospholipase A(2) induced by existence of LPC and NEFA high concentrations, and products of their peroxidation, promote elimination of separate protein fractions of erythrocyte membranes (EM) responsible for OS formation and decrease of erythrocytes resistance to peroxide hemolysis. Increase of DBM activity under the effect of relatively moderate doses of zearalenon (1-15 microg/ml) is accompanied with extra intensification of catecholamine synthesizing function of the organism with lethal result. Data of publications represented testify exceptional efficiency of sodium thiosulfate (STS) as a powerful synergist for endogenous factors of antioxidant effect, particularly alpha-tocopherol (alpha-T), which is the main component for the system of cell antiradical defence. Detoxicating effect of STS can be demonstrated indeed on the example of zearalenon intoxication during the first two hours with the reduction of metabolism disturbances of PL and products of its peroxidation. Comparative evaluation of molecular mechanisms of STS normalizing effect as a supplier for hydrogen and sulphur ions, as well as an effective synergist for alpha-T on the level of various formations of the live cell in compare with the effects of alpha-T and ubiquinone, allowed to make a special accent on the role of STS in interaction with energy-dependent enzymatic systems of cell antiradical defence, as well as accumulation and transformation of energy on the level of mitochondrial membranes. The results obtained by us confirm a number of clinical experimental observations, which demonstrate treatment and prophylactic role of STS at different pathologic states of the organism. STS protectory role at toxic injuries of the organism is higher at its preliminary introduction to the organism before modelling of the studied diseased states, especially at zearalenon and halothane (H) intoxication (in the last case before HA). These data serve a sound affirmation for protectory function of STS, detailed revelation of molecular properties of pathogenesis of the studied intoxication to which a part of our clinical and experimental studies at present is devoted.

Behçet's disease as an autoinflammatory disorder.

Gül A(1).

Author information:

(1)Division of Rheumatology, Department of Internal Medicine, Istanbul Faculty of Medicine, Istanbul University, Turkey. agul@istanbul.edu.tr

Autoinflammatory diseases are a group of heritable disorders that are characterized by seemingly unprovoked episodes of inflammation at certain locations and relative lack of high-titer autoantibodies or antigen-specific T cells. Behçet's disease is an inflammatory disorder of unknown aetiology, and many of its characteristic recurrent manifestations overlap with those of autoinflammatory diseases. Behçet's disease has a complex genetic aetiology, and it is more prevalent in certain geographic regions and/or in particular ethnic groups. Enhanced inflammatory response and over-expression of proinflammatory cytokines are the prominent features of Behçet's disease, and they are compatible with the findings in other autoinflammatory disorders. There are also evidences of antigen-driven immune response in Behçet's disease, but it possibly develops on the background of enhanced innate immune reactivity. Delineation of the similarities of Behçet's disease to other hereditary autoinflammatory diseases may help to clarify its pathogenesis and also to identify the missing links in the shared inflammatory pathways.

Molecular and genetic characteristics of hereditary autoinflammatory diseases.

Tunca M(1), Ozdogan H.

Author information:

(1)Dokuz Eylül University School of Medicine, Department of Internal Medicine, 35340 Izmir, Turkey. mehmet.tunca@deu.edu.tr

Autoinflammatory diseases are defined as recurrent "unprovoked" inflammatory events which do not produce high-titer autoantibodies or antigen-specific T cells. There are currently eight hereditary forms of these diseases: Familial Mediterranean fever (FMF), hyperimmunoglobulinemia D with periodic fever syndrome (HIDS), tumor necrosis factor receptor-associated periodic syndrome (TRAPS), Muckle-Wells syndrome (MWS), familial cold autoinflammatory syndrome (FCAS), chronic infantile neurologic cutaneous articular (CINCA) syndrome or neonatal-onset multisystem inflammatory disease (NOMID), pyogenic sterile arthritis, pyoderma gangrenosum, acne (PAPA) and Blau syndrome. Apart from FMF (which has a prevalence of about 0.1 percent among non-Ashkenazi Jews, Armenians, Turks and Arabs), they are very rare disorders. FMF and HIDS are autosomal recessive diseases, all the other members of the family are autosomal and dominantly transmitted. Their common clinical features are recurrent and usually short attacks of synovitis and various skin eruptions; abdominal pain and fever are also frequently observed. The genes of all of these diseases have been discovered and, with the exception of HIDS, it was found that the proteins they encode share certain domains taking part in innate immunity and apoptosis. Thus it was evident that hereditary autoinflammatory diseases may help us understand better a number of important and prevalent pathologic events. We have reviewed the recent and rapidly accumulating knowledge on the molecular aspects of these disorders.

Familial Mediterranean fever in the post-genomic era: how an ancient disease is providing new insights into inflammatory pathways.

Schaner PE(1), Gumucio DL.

Author information:

(1)University of Michigan, Department of Cell and Developmental Biology, Ann Arbor, MI 48109-0616, USA.

Familial Mediterranean fever (FMF, MIM24900), described as a clinical entity only

slightly over a half-century ago, has ancient roots among populations surrounding the Mediterranean basin. It is the most prevalent of the hereditary periodic fever syndromes, a group of disorders characterized by episodic attacks of fever and inflammation. Seven years ago, it was discovered that FMF is caused by mutations in MEFV, a gene that encodes a protein variously called pyrin or marenostin. As exciting as that discovery was, physicians and patients alike were disappointed that the protein sequence of pyrin/marenostin did not immediately suggest clues as to the molecular etiology of FMF. Though we are still far from a complete understanding of the function of pyrin/marenostin at the cellular level, continued study of this intriguing protein is revealing new molecular details about inflammatory processes; the emerging information is relevant not only to FMF, but to innate immunity in general. Data from several laboratories demonstrate that pyrin/marenostin is intimately connected to three important cellular pathways: apoptosis, cytoskeletal signaling and cytokine secretion. These connections occur, at least in part, through the direct interaction of the pyrin/marenostin protein with two cytosolic protein adaptors: ASC (also called PyCARD or Tms1) and PSTPIP (also called CD2BP1). Here, we review the more recent literature regarding the molecular and cellular biology of pyrin/marenostin and pinpoint open questions for future study.

Amyloidosis and auto-inflammatory syndromes.

Grateau G(1), Jéru I, Rouaghe S, Cazeneuve C, Ravet N, Duquesnoy P, Cuisset L, Dodé C, Delpech M, Amselem S.

Author information:

(1)Service de médecine interne, L'Hôtel-Dieu, Assistance publique-hôpitaux de Paris, Paris, France. gilles.grateau@tnn.ap-hop-paris.fr

Amyloidosis remains currently a severe potential complication of many chronic inflammatory disorders. It is not exactly known why some patients develop a progressive amyloidosis, whereas others do not although latent deposits may be present. A permanent acute phase response, ideally evaluated with serial

measurement of serum protein SAA, the precursor of the AA protein deposited in tissues, seems to be a prerequisite to the development of inflammatory (AA) amyloidosis. Genetic factors have however been recently emphasized. Among persistent or emerging causes of AA amyloidosis, hereditary periodic fever syndromes also known as auto-inflammatory syndromes are a group of diseases characterised by intermittent bouts of clinical inflammation with focal organ involvement mainly: abdomen, musculoskeletal system and skin. The most frequent is familial Mediterranean fever which affects patients of Mediterranean descent all over the world. Three other types have been recently clinically as well as genetically characterised. A thorough diagnosis is warranted, as clinical and therapeutic management is specific for each of these diseases.

Familial Mediterranean fever and E148Q pyrin gene mutation in Greece.

Konstantopoulos K(1), Kanta A, Lilakos K, Papanikolaou G, Meletis I.

Author information:

(1)First Department of Medicine, Athens University Medical School, Athens, Greece. kkonstan@med.uoa.gr

Familial Mediterranean fever (FMF) is an inherited disease characterized by recurrent inflammatory polyserositis. Although FMF is classically expected only in Middle East populations, it is becoming evident that the disease affects more groups than initially thought. The disease is associated with a number of mutations of the MEFV gene, which codes for a protein named pyrin. The role of E148Q pyrin gene mutation in the development of FMF remains inconclusive. Some authors believe it causes the disease, whereas others favor the concept of a noncausative role. To understand better the role of this mutation, gathering data from different populations may be of value. We studied 60 Greek cases fulfilling the criteria for FMF diagnosis, 30 cases being a definite FMF diagnosis and 30 a probable diagnosis. Twenty-one of the patients, carried mutation E148Q. One was a homozygote (E148Q/E148Q), and 20 carried mutation E148Q in combination with other mutations (compound heterozygotes). In 6 of the 60 cases studied, no mutations

were found. Compared with the results for healthy controls, E148Q mutation is significantly frequent. Because different populations may exhibit different patterns of pyrin mutations, association of the E148Q mutation with FMF should be considered in connection with origin data.

Sacroiliitis in familial Mediterranean fever and seronegative spondyloarthropathy: importance of differential diagnosis.

Balaban B(1), Yasar E, Ozgul A, Dincer K, Kalyon TA.

Author information:

(1)Department of Physical Medicine and Rehabilitation, Gulhane Military Medical Academy, 06018, Etlik-Ankara, Turkey. bbalaban@gata.edu.tr

Familial Mediterranean fever (FMF) is a multisystemic autosomal recessive disease, occasionally accompanied by sacroiliitis. Transient and non-erosive arthritis of the large joints is the most frequent articular involvement. Amyloidosis is also the most significant complication of FMF, leading to end stage renal disease. Here we present three cases of FMF with sacroiliitis and review the literature for spinal arthritic involvement of FMF. All cases were referred to our clinic with a diagnosis of seronegative spondyloarthropathy and with low back pain sourced by sacroiliitis. They also had homozygous M694V gene mutations and negative HLA B27 antigens. Molecular analysis of the gene mutation is recommended during the evaluation of uncertain cases in order to clarify diagnostic discrimination. We suggest that FMF with sacroiliitis, which is rare in rheumatological practice, should be considered in the differential diagnosis of seronegative spondyloarthropathy or other rheumatologic diseases causing spinal involvement.

Familial Mediterranean fever mimicking septic arthritis.

Uthman I(1), El-Sayyad J, El-hajj I, Bizri AR.

Author information:

(1)Department of Internal Medicine, Faculty of Medicine, American University of Beirut Medical Center, PO Box: 113-6044, Beirut, Lebanon. iuthman@aub.edu.lb

We report the case of a young Lebanese female who presented with recurrent episodes of left knee and calf swelling and a synovial fluid leucocyte count suggestive of septic arthritis, however bacteriologic cultures were negative. Familial Mediterranean fever (FMF) was suspected in view of a positive family history and genetic analysis for the mutations in the pyrin/marenostrin (MEFV) gene revealing a homozygote mutation at methionine-694-valine. The arthritis was controlled with prophylactic colchicine therapy. FMF should be considered in the differential diagnosis of acute monoarticular arthritis with elevated synovial fluid white blood cells counts in regions with high incidence of FMF.

Evaluation of joints using Tc 99m-MDP bone scintigraphy in patients with familial Mediterranean fever: should bone scans be used for diagnosis and follow-up?

Yildiz M(1), Tunc SE, Sahin M, Okudan B, Aydin O, Suslu H, Ozbek M.

Author information:

(1)Department of Nuclear Medicine, Faculty of Medicine, Suleyman Demirel University, Istiklal Mah. Güven Cad. 38/8, Isparta, Turkey.  
mustiyildiz01@superonline.com

Familial Mediterranean fever (FMF) is an autosomal recessively-inherited disorder typically manifested by recurrent attacks of fever and polyserositis. The articular disease occurs in 50-70% of patients. Bone scintigraphy is more sensitive in the diagnosis of arthritis than clinical examination or conventional radiological imaging, allowing earlier diagnosis through the visualization of disease in multiple sites. To assess joint involvements in FMF patients with or without joint symptoms, bone scintigraphy was performed in 36 patients with FMF and in 25 controls. There was arthritis in 72% of patients. Of these, 65% knee, 42% ankle, 50% sacroiliac, 8% elbow, 8% wrist, 4% sternoclavicular and 4% hip involvements were found. The sacroiliac joints with sacroiliac index higher than 1.34 were diagnosed as sacroiliitis, which was higher than 2 SD of normal. FMF is frequently associated with joint disease such as knee and ankle arthritis and sacroiliitis. This high incidence of sacroiliitis in our study has not been previously reported. This difference could be explained by the different methodology used for the screening of the joints. Thus, we recommend that bone scintigraphy can be used in patients with FMF to determine the presence of

arthritis, especially in sacroiliac joints, even asymptomatic.

Author information:

(1)Department of Gastroenterology, Türkiye Yüksek İhtisas Hospital, Ankara, Turkey. gskoklu@yahoo.com

AIMS: To evaluate the levels of endogenous interferon-gamma (IFN-gamma) in patients with familial Mediterranean fever (FMF).

METHODS: Plasma levels of IFN-gamma were assayed in 29 FMF patients in attack-free period (mean age: 32, min-max: 17-48; male/female: 10/19), 18 FMF patients with acute FMF attack (mean age: 32, min-max: 19-50; male/female: 8/10), and 19 healthy controls (mean age: 31.94 +/- 1.50, min-max: 23-42; male/female: 11/8). IFN-gamma levels were also compared among colchicine treated and untreated groups.

RESULTS: Median plasma IFN-gamma levels were significantly higher in patients both with and without FMF attack than the control group ( $P < 0.05$ ). Moreover, plasma IFN-gamma levels were higher in patients with acute FMF attack compared to patients in attack-free periods ( $P < 0.05$ ). Plasma levels of IFN-gamma were

comparable in colchicine treated and untreated groups.

CONCLUSION: Our results suggest that IFN-gamma may contribute to the inflammatory cascade of FMF.

Hyperimmunoglobulinemia D syndrome in an Arab child.

Hammoudeh M.

Hyperimmunoglobulinemia D syndrome (HIDS) is newly recognized and resembles familial Mediterranean fever (FMF). It is inherited as an autosomal recessive trait. Mutation of the gene coding for mevalonate kinase is responsible for the disease. The gene is located at chromosome 12q24. The patients initially described were of Dutch ancestry. Other cases from Turkey and Armenia were reported. The case we present is the first from Arab countries to be registered in the International HIDS Registry and to our knowledge the first to be reported.

Prevalence and significance of mutations in the familial Mediterranean fever gene in patients with Crohn's disease.

Karban A(1), Dagan E, Eliakim R, Herman A, Nesher S, Weiss B, Berkowitz D, Shamir R, Gershoni-Baruch R.

Author information:

(1)Department of Gastroenterology, Rambam Medical Center, Haifa, Israel.

The concurrence of Crohn's disease (CD) and familial Mediterranean fever was repeatedly reported. In this study we determined the distribution and

contribution of MEFV gene mutations to CD susceptibility and clinical heterogeneity. An Israeli cohort of 209 CD patients (120 men and 89 women) was investigated for mutations in the MEFV gene. A detailed chart review, interview and physical examination were used to determine sociodemographic and clinical characteristics. MEFV and NOD2/CARD15 genotypes were analyzed in all patients and a genotype-phenotype correlation analysis was undertaken. The results of this study do not implicate MEFV mutations as major modifiers in CD. However, the E148Q MEFV variant was associated with susceptibility to perianal disease. More specifically, 19% (9/47) of CD patients with perianal disease carried the E148Q mutation compared to 6.7% (11/162) of CD patients without perianal involvement (OR 3.26, 95% CI 1.2-8.8, P=0.02). Although, for all mutations taken together, the prevalence of MEFV gene mutations among CD patients and controls was similar, the hypothesis that E148Q mutation modulates the phenotypic expression of CD is corroborated by the results of this study and needs to be further evaluated.

Different ELR (+) angiogenic CXC chemokine profiles in synovial fluid of patients with Behçet's disease, familial Mediterranean fever, rheumatoid arthritis, and osteoarthritis.

Erdem H(1), Pay S, Serdar M, Simşek I, Dinç A, Muşabak U, Pekel A, Turan M.

Author information:

(1)Department of Rheumatology, Gülhane Military School of Medicine, Etlik, Ankara 06018, Turkey. herdem67@gata.edu.tr

The aim of the present study was to determine synovial levels of ELR (+) CXC chemokines, known to attract mainly neutrophils to inflamed tissues by binding the neutrophil chemokine receptors CXCR1 and CXCR2 and promoting neovascularization in patients with various inflammatory disorders. The study group consisted of 14 patients with Behçet's disease and nine with familial Mediterranean fever. Fourteen patients with rheumatoid arthritis and 16 with osteoarthritis served as controls. Synovial chemokine levels were measured by two-step sandwich enzyme-linked immunosorbent assay, and significant differences

were found in the various chemokines studied. In addition to its angiogenic properties, increased synovial levels of interleukin-8 by attraction of more neutrophils to synovial fluids might also be responsible for the acute synovitis in patients with Behçet's disease. However, the absence of chronic changes with the eventual development of pannus and erosions might result from relatively lower expression of interleukin-8 and the transient, short-lived nature of the arthritis observed in these patients.

The familial Mediterranean fever (MEVF) gene as a modifier of Crohn's disease.

Fidder H(1), Chowers Y, Ackerman Z, Pollak RD, Crusius JB, Livneh A, Bar-Meir S, Avidan B, Shinar Y.

Author information:

(1)Department of Gastroenterology and The Heller Institute of Medical Research, Chaim Sheba Medical Center, Tel Hashomer, Israel.

**OBJECTIVES:** Crohn's disease (CD) has been reported to be more frequent among non-Ashkenazi Jewish patients suffering from familial Mediterranean fever (FMF). Interestingly, functional similarities between the CD susceptibility gene (NOD2/CARD15) and the FMF gene (MEFV) have been described: both belong to the death domain containing protein family, important in the regulation of apoptosis, cytokine processing and inflammation.

**AIMS:** To investigate the prevalence of MEFV mutations in Jewish non-Ashkenazi CD patients and its putative effect on CD presentation.

**METHODS:** Germline DNA of 105 Israeli CD patients of non-Ashkenazi and mixed Ashkenazi-non-Ashkenazi ethnic background was analyzed for three most common MEFV mutations: M694V, V726A, and E148Q. Five patients (4.7%) with a clinical diagnosis of FMF were included. Data obtained from each patient included: age of onset, disease location, and behavior, the presence of extraintestinal manifestations of CD and therapeutic regimens.

**RESULTS:** The overall prevalence of mutation carriers among non-FMF-CD patients was 13% (13/100). A stricturing disease pattern was observed in 56% (10/18) of

all carriers, FMF-CD, and non-FMF-CD patients, and in 25% (22/87) of noncarriers (OR: 3.7, 95% CI: 1.3-10.5,  $p=0.015$ ). The prevalence of fistulas was comparable in both groups. Extraintestinal manifestations were significantly more frequent among carriers than noncarriers (65% vs 32%, OR 3.9, 95% CI = 1.3-11.5,  $p=0.015$ ). No differences were observed in disease location and disease severity.

CONCLUSIONS: MEFV mutations are not associated with CD susceptibility, yet the presence of these mutations appears to be associated with a stricturing disease pattern and extraintestinal disease manifestations of CD.

Author information:

(1)Department of Infectious Diseases and Immunology, Children's Hospital, University of Munich, Germany. [florian.hoffmann@med.uni-muenchen.de](mailto:florian.hoffmann@med.uni-muenchen.de)

The hyperimmunoglobulinemia D and periodic fever syndrome (HIDS) is an autosomal recessively inherited autoinflammatory disease caused by mutations in the mevalonate kinase (MVK) gene on chromosome 12q24, which lead to a depressed enzymatic activity of mevalonate kinase (MK). TNF-receptor associated periodic syndrome (TRAPS), on the other hand, is the most frequent autosomal dominantly inherited periodic fever syndrome due to mutations in exons 2-4 and 6 of the TNFRSF1A gene on chromosome 12p13.2. We describe a girl with heterozygosity for the common MVK V377I mutation and for a novel T(1132) --> C transition, leading to the exchange of serine (TCC) by proline (CCC) at amino-acid position 378. Interestingly, our patient presented only with mild clinical features typical of HIDS and slightly increased immunoglobulin D levels, but a distinctly diminished MK activity. The girl was also heterozygous for the TNFRSF1A R92Q low-penetrance mutation, which may have significant proinflammatory effects. However, at the time of presentation, the patient had no TRAPS-associated symptoms.

Familial Mediterranean fever (FMF) is an autosomal recessive disease that is prevalent among eastern Mediterranean populations, mainly non-Ashkenazi Jews, Armenians, Turks, and Arabs. Since a large proportion of all the FMF patients in the world live in Turkey, the Turkish FMF Study Group (FMF-TR) was founded to develop a patient registry database and analyze demographic, clinical, and genetic features. The cohort was composed of 2838 patients (mean age, 23.0 +/- 13.33 yr; range, 2-87 yr), with a male:female ratio of 1.2:1. There was a mean period of 6.9 +/- 7.65 years from disease onset to diagnosis; the period was about 2 years shorter for each decade since 1981. Ninety-four percent of patients were living in the central-western parts of the country; however, their familial origins (70% from the central-eastern and Black Sea regions) reflected not only the ongoing east to west migration, but also the historical roots of FMF in Turkey. Patients' clinical features included peritonitis (93.7%), fever (92.5%), arthritis (47.4%), pleuritis (31.2%), myalgia (39.6%), and erysipelas-like erythema (20.9%). Arthritis, arthralgia, myalgia, and erysipelas-like erythema were significantly more frequent ( $p < 0.001$ ) among patients with disease onset before the age of 18 years. Genetic analysis of 1090 patients revealed that M694V was the most frequent mutation (51.4%), followed by M680I (14.4%) and V726A (8.6%). Patients with the M694V/M694V genotype were found to have an earlier age of onset and higher frequencies of arthritis and arthralgia compared with the other groups (both  $p < 0.001$ ). In contrast to other reported studies, there was

no correlation between amyloidosis and M694V homozygosity in this cohort. However, amyloidosis was still remarkably frequent in our patients (12.9%), and it was prevalent (27.8%) even among the 18 patients with a disease onset after age 40 years. Twenty-two patients (0.8%) had nonamyloid glomerular diseases. The high prevalence of vasculitides (0.9% for polyarteritis nodosa and 2.7% for Henoch-Schonlein purpura) and high frequency of pericarditis (1.4%) were striking findings in the cohort. Phenotype II cases (those patients with amyloidosis as the presenting or only manifestation of disease) were rare (0.3% or less). There was a high rate of a past diagnosis of acute rheumatic fever, which suggested a possible misdiagnosis in children with FMF presenting with recurrent arthritis. To our knowledge, this is the largest series of patients with FMF reported from 1 country. We describe the features of the disease in the Turkish population and show that amyloidosis is still a substantial problem.

Tumor necrosis factor receptor associated periodic syndrome (TRAPS) is an autosomic-dominant periodic syndrome associated with mutations in the extracellular domain of the 55 kDa TNF receptor. Clinically, episodes of severe myalgia, arthralgia/arthritis, sterile peritonitis, scrotal inflammation, serositis, migratory rash, conjunctivitis, and recurrent fever are characteristic. We describe a 9-year-old African American boy with the P46L mutation of the TNF receptor who presented with 2 previously unrecognized manifestations: sacroiliitis and myocardiopathy, both showing a reversible course.

Narrative review: diseases that masquerade as infectious cellulitis.

Falagas ME(1), Vergidis PI.

Author information:

(1)Alfa HealthCare, Athens, Greece. matthew.falagas@tufts.edu

Comment in

Ann Intern Med. 2005 Jun 7;142(11):949.

Ann Intern Med. 2005 Oct 18;143(8):614.

For cellulitis that does not respond to conventional antimicrobial treatment, clinicians should consider, among other explanations, several noninfectious disorders that might masquerade as infectious cellulitis. Diseases that commonly masquerade as this condition include thrombophlebitis, contact dermatitis, insect stings, drug reactions, eosinophilic cellulitis (the Wells syndrome), gouty arthritis, carcinoma erysipelatoides, familial Mediterranean fever, and foreign-body reactions. Diseases that uncommonly masquerade as infectious cellulitis include urticaria, lymphedema, lupus erythematosus, sarcoidosis, lymphoma, leukemia, Paget disease, and panniculitis. Clinicians should do an initial diagnostic work-up directed by the findings from a detailed history and complete physical examination. In many cases, skin biopsy is the only tool that helps identify the correct diagnosis. Special tests may also be needed.

Familial mediterranean fever (FMF) is an hereditary disease transmitted in an autosomal recessive way and characterized by recurrent and brief episodes of fever and pain secondary to serositis. The pain is usually located in abdomen simulating an acute abdomen, and in thorax in the form of pleuritic pain. The most severe complication of the FMF is the development of amyloidosis being the main cause of death. This illness affects an specific ethnic group of the mediterranean area, but the prevalence in our area is low. We present the case of

a 30 years old man with recurrent thoracic and abdominal pain, whose final diagnostic was FMF. Insisting on the difficulty that it was recognize this proper illness.

**BACKGROUND/AIMS:** Familial Mediterranean fever (FMF) is an autosomal recessive disease characterised by recurrent fever attacks and polyserositis which may lead to the development of AA amyloidosis and end-stage renal disease (ESRD). In this study, we aimed to evaluate the efficacy of continuous ambulatory peritoneal dialysis (CAPD) in FMF-amyloidosis patients with ESRD.

**METHODS:** Forty age- and sex-matched patients undergoing CAPD at our centre between 1996 and 2002 were included in the study. Of these, 10 had FMF-amyloidosis, 10 had diabetes mellitus (DM), 10 had chronic glomerulonephritis (CGN) and 10 had chronic interstitial nephritis (CIN). Efficiency of CAPD, development of complications, presence of other diseases and survival were compared.

**RESULTS:** With the onset of ESRD, the frequency of FMF peritonitis attacks decreased, with less attacks occurring during CAPD in FMF-amyloidosis patients ( $p < 0.05$ ). There was no significant difference between the FMF-amyloidosis group and other groups in terms of efficiency of CAPD, peritoneal function, complications and survival. DM patients had a shorter survival period compared with CGN and CIN patients ( $p < 0.05$ ), but there was no survival difference between FMF-amyloidosis patients and other groups ( $p > 0.05$ ).

**CONCLUSIONS:** We conclude that CAPD is an effective and safe renal replacement

therapy for FMF-amyloidosis patients with ESRD.

Although recurrence of amyloid A deposition in the allograft can be seen in patients with secondary amyloidosis due to familial Mediterranean fever (FMF), renal transplantation remains to be a choice of treatment for end-stage renal disease. The aim of this study was to determine short- and long-term results of renal transplantation in patients with FMF amyloidosis. We compared the outcomes of 17 patients with FMF amyloidosis among 431 (3.9%) transplants with 209 control patients. We observed 93% and 94% graft and patient survivals at 1 year, and 89% and 90% at 5 years. Also, the mean serum creatinine levels at 1 and 5 years posttransplant were similar. Recurrence of amyloidosis was documented in two allograft recipients presenting with nephrotic range proteinuria (12%), one of whom lost the allograft due to recurrence. Eleven patients had FMF gene analysis. The results of MEFV mutation analyses were: M694V/M694V homozygote in six patients, M694V/EQ148 in one patient, M694V/V726A in one patient, 680M-I/E148Q in one patient. FMF gene analysis was negative in two patients. Recurrence was noticed in one patient with M694V/M694V, while the other did not have an FMF gene analysis. Colchicine was reduced in nine patients due to side effects. In conclusion, the long-term outcomes of transplantation in patients with amyloidosis secondary to FMF is similar to that in the general transplant population and maintenance colchicine, even at low dose, appears to effectively

prevent recurrence of amyloidosis in the allograft.

Oxidative stress status in familial Mediterranean fever with or without proteinuria.

Gurbuz M(1), Yamanel L, Bulucu F, Inal V, Aydin A.

Author information:

(1)Internal Medicine Department, Gulhane School of Medicine, Etlik/Ankara TR-06018, Turkey.

Although several studies have indicated oxidative system abnormalities in patients with familial Mediterranean fever, it is still obscure whether proteinuria seen in this disease has an effect on the oxidative system. In the present study, oxidative system changes were investigated in familial Mediterranean fever with or without proteinuria. Plasma malondialdehyde levels in proteinuric and nonproteinuric patients were higher than those of the controls and they were also significantly higher in the patients with proteinuria compared to patients without proteinuria. The patients had significantly lower plasma glutathione peroxidase activities than the controls. Glutathione peroxidase activities did not show statistically significant differences between the patients with and those without proteinuria. A significant difference was not established for erythrocyte superoxide dismutase activities. These data suggest that there is an increase in lipid peroxidation in familial Mediterranean fever. Decreased plasma glutathione peroxidase activities seem to be responsible for increased plasma malondialdehyde levels in both patient groups. However, the fact that higher plasma malondialdehyde levels in proteinuric patients were observed compared to nonproteinuric patients in the presence of the unchanged plasma glutathione peroxidase activities in these groups suggests that the nephrotic state may have a contribution to this situation.

Clinical and genetic heterogeneity among Spanish patients with recurrent autoinflammatory syndromes associated with the CIAS1/PYPAF1/NALP3 gene.

Aróstegui JI(1), Aldea A, Modesto C, Rua MJ, Argüelles F, González-Enseñat MA, Ramos E, Rius J, Plaza S, Vives J, Yagüe J.

Author information:

(1)Hospital Clínic, Barcelona, Spain. 30864jag@comb.es

**OBJECTIVE:** To investigate the involvement of the CIAS1/PYPAF1/NALP3 gene in 7 unrelated Spanish families with recurrent autoinflammatory diseases characterized by early onset, recurrent fever, and a chronic urticarial rash, in whom a clinical diagnosis of cryopyrin-associated periodic syndromes (CAPS) is suspected.

**METHODS:** Clinical symptoms, results of laboratory analyses, and data on previous treatments in members of the 7 families were recorded on a questionnaire specific for hereditary autoinflammatory diseases. All coding regions and intronic flanking boundaries of the CIAS1/PYPAF1/NALP3 gene were amplified by polymerase chain reaction and sequenced.

**RESULTS:** Five different missense mutations, including 2 de novo and 1 previously unreported mutation (R488K), were identified in exon 3 of the CIAS1/PYPAF1/NALP3 gene in 5 of the 7 affected families. Expanded genetic analysis among the healthy individuals identified incomplete penetrance in 2 families. No mutations were found in 2 of the 3 patients with chronic infantile neurologic, cutaneous, articular (CINCA) syndrome/neonatal-onset multisystem inflammatory disease (NOMID).

**CONCLUSION:** The clinical data suggested a diagnosis of familial cold-induced autoinflammatory syndrome in 3 families, CINCA/NOMID syndrome in 3 others, and a possible Muckle-Wells syndrome, whereas mutational analysis showed different CIAS1/PYPAF1/NALP3 missense mutations in 5 families. These data are consistent with a common molecular basis of these diseases and highlights the phenotypic heterogeneity among CIAS1/PYPAF1/NALP3 gene-associated syndromes. The previously unreported mutation and the incomplete penetrance found in 2 families expand the genetic basis underlying these autoinflammatory syndromes. These findings should alert clinicians to the possible genetic basis of these conditions, even in the

absence of a family history, in their attempts to establish an accurate diagnosis and the optimal therapeutic approach.

An adolescent boy had had recurrent episodes of fever, abdominal pain, and arthralgias since the age of 7 years. Progressive renal failure due to renal amyloidosis developed, leading to renal transplant at the age of 14.5 years. Five years later, he developed AA amyloidosis in the transplant as well as the thyroid gland. His father had had similar symptoms including systemic amyloidosis since the age of 6 years. DNA sequence analysis revealed a heterozygous mutation in the TNFRSF1A (TNF $\alpha$ -receptor 1) gene (T50M) in both father and son causing tumor necrosis factor receptor-associated periodic syndrome (TRAPS). Previous phenotype/genotype analyses have proposed that this mutation is usually not associated with the occurrence of amyloidosis. This difference in the clinical course in different families may indicate a strong influence of modifier genes. Treatment with a TNFRSF1B fusion protein TNF antagonist (etanercept) favorably influenced the disease course.

alimsherif@yahoo.com

**BACKGROUND:** Neuromyopathy was reported to be a problem among live donor familial Mediterranean fever (FMF) amyloid kidney transplant recipients. We aimed to address this issue on a long-term basis.

**METHODS:** 14 FMF amyloid live donor kidney transplant recipients with a mean post-transplant follow-up period of 82.43 +/- 50.1 months in comparison to a control group of 19 non-amyloid renal transplant patients were subjected to thorough neurological examination, laboratory and electrophysiologic studies.

**RESULTS:** Both groups were comparable with regard to mean serum creatinine levels cyclosporine doses ( $p > 0.05$ ), however trough cyclosporine levels were significantly lower in the amyloidotics than the controls ( $p = 0.04$ ). Serum creatine phosphokinase was comparable in both groups ( $p = 0.59$ ). The amyloid patients showed significantly increased polyphasic motor unit potentials and abnormal interference patterns in the biceps brachii muscle ( $p = 0.03$ ) and the abductor polices brevis muscle ( $p = 0.05$ ). Multivariate analysis showed a significant level for biceps myopathy in amyloidotics ( $p = 0.001$ ). Both groups attained no difference with regard to median nerve conduction velocity.

**CONCLUSION:** Electrophysiologically evidenced neuromyopathy is more liable to occur in long-term live donor FMF amyloidotic kidney transplant recipients than in the other non-amyloidotic kidney transplant recipients even with no clinical manifestations or high creatine phosphokinase levels.

Etanercept plus colchicine treatment in a child with tumour necrosis factor receptor-associated periodic syndrome abolishes auto-inflammatory episodes without normalising the subclinical acute phase response.

Aróstegui JI(1), Solís P, Aldea A, Cantero T, Rius J, Bahílllo P, Plaza S, Vives J, Gómez S, Yagüe J.

Author information:

(1)Servicio de Immunologia, Hospital Clínic, Villarroel 170, 08036 Barcelona, Spain. 30864jag@comb.es

We investigated the cause of hereditary periodic fever syndrome in a Spanish child with recurrent long episodes of fever, migratory skin rash, myalgia, arthralgia, conjunctivitis and abdominal pain. Infectious and autoimmune causes were ruled out. No familial history was reported. Analysis of the tumour necrosis factor receptor superfamily 1A (TNFRSF1A) gene identified a missense mutation (G36E) on exon 3. The absence of this variant in the patient's parents and in controls identified it as a de novo disease-associated mutation. Clinical symptoms disappeared with administration of etanercept; however, levels of acute-phase reactants remained increased and could not be stabilised by the addition of colchicine. We believe that this patient gained some symptomatic relief with etanercept therapy, although not enough to completely avoid the risk of amyloidosis. Thus it is debatable whether etanercept alone or combined with other drugs, is the treatment of choice for patients with tumour necrosis factor receptor-associated periodic syndrome. CONCLUSION: Since there is variability in treatment responses among different patients with tumour necrosis factor receptor-associated periodic syndrome, we suggest that a systematic evaluation of acute-phase reactants, especially SAA-1, could be useful in maintaining or modifying a given therapeutic approach in these patients.

A very rare consequence of steroid therapy: ileal perforation in a patient with familial mediterranean fever.

Sakallioğlu AE(1), Arda IS, Sevmiş S, Baskin E, Bilezikçi B, Hiçsönmez A.

Author information:

(1)Department of Pediatric Surgery, Baskent University Faculty of Medicine, Ankara, Turkey.

Intestinal perforation rarely occurs in children with familial Mediterranean fever (FMF). When this does happen, it is the result of untreated intestinal obstruction caused by compression from peritoneal adhesions. Intestinal perforation is a well-known complication of steroid therapy in all ages. The duodenum is affected most frequently, but perforation may also occur in other parts of the small intestine and, very rarely, the colon. Intestinal wall changes that occur in chronic FMF may promote the harmful effects of steroids. Here we present an unexpected complication, ileal perforation, in an 8-year-old boy who was taking prednisolone for FMF-related arthritis.

Although some information is available regarding immune activation in familial Mediterranean fever (FMF), little is known about either peripheral blood T cell activation marker expression or the T cell proliferative response to phytohaemagglutinin (PHA). In the present study, we aimed to investigate the percentages of peripheral blood lymphocyte subsets, T cell expression of cellular activation markers (CD25, CD69, HLA-DR), the T cell response to PHA and serum levels of soluble interleukin-2 receptor (sIL-2R) and interleukin (IL)-10 in patients with FMF. Forty patients with FMF were enrolled into the study. Control

groups were sex- and age-matched and consisted of 20 healthy blood donors and 15 patients with inactive Behcet's disease. The patients with FMF in an attack period had higher levels of sIL-2R than those in an attack-free period, and also in comparison with both control groups. The levels of sIL-2R were also found to be higher in patients with FMF in an attack-free period than those in both control groups. The mean levels of IL-10 were found to be lower in patients with FMF in an attack-free period than those in an attack period and were also lower than those in the healthy controls. In an acute attack period, the absolute counts of CD3+HLA-DR+, CD4+CD69+, CD8+CD25+ and CD8+CD69+ T cells in peripheral blood samples were also higher than those in both control groups. Both the percentages and absolute counts of CD4+CD69+ T cells in peripheral blood samples of patients with FMF in an attack-free period were slightly but significantly higher than those in the healthy controls. In conclusion, our study indicates that the T cell system is abnormally activated in patients with FMF in both the attack and attack-free period and that decreased IL-10 levels may create a tendency to perpetuate subclinical immune activation in the attack-free period.

Prevention of cold-associated acute inflammation in familial cold autoinflammatory syndrome by interleukin-1 receptor antagonist.

Hoffman HM(1), Rosengren S, Boyle DL, Cho JY, Nayar J, Mueller JL, Anderson JP, Wanderer AA, Firestein GS.

Author information:

(1)Division of Rheumatology, Allergy, and Immunology, University of California at San Diego School of Medicine, La Jolla, CA 92093-0635, USA. hahoffman@ucsd.edu

**BACKGROUND:** Familial cold autoinflammatory syndrome (FCAS) is an autosomal dominant disorder characterised by recurrent episodes of rash, arthralgia, and fever after cold exposure. The genetic basis of this disease has been elucidated. Cryopyrin, the protein that is altered in FCAS, is one of the adaptor proteins that activate caspase 1, resulting in release of interleukin 1.

**METHODS:** An experimental cold challenge protocol was developed to study the acute inflammatory mechanisms occurring after a general cold exposure in FCAS patients and to investigate the effects of pretreatment with an antagonist of interleukin 1 receptor (IL-1Ra). ELISA, real-time PCR, and immunohistochemistry were used to measure cytokine responses.

**FINDINGS:** After cold challenge, untreated patients with FCAS developed rash, fever, and arthralgias within 1-4 h. Significant increases in serum concentrations of interleukin 6 and white-blood-cell counts were seen 4-8 h after cold challenge. Serum concentrations of interleukin 1 and cytokine mRNA in peripheral-blood leucocytes were not raised, but amounts of interleukin 1 protein and mRNA were high in affected skin. IL-1Ra administered before cold challenge blocked symptoms and increases in white-blood-cell counts and serum interleukin 6.

**INTERPRETATION:** The ability of IL-1Ra to prevent the clinical features and haematological and biochemical changes in patients with FCAS indicates a central role for interleukin 1beta in this disorder. Involvement of cryopyrin in activation of caspase 1 and NF-kappaB signalling suggests that it might have a role in many chronic inflammatory diseases.

**RELEVANCE TO PRACTICE:** These findings support a new therapy for a disorder with no previously known acceptable treatment. They also offer insights into the role of interleukin 1beta in more common inflammatory diseases.

Autosomal recessive autoinflammatory disorder caused by mutations of the mevalonate kinase gene (MVK), leading to mild, incomplete MK enzyme deficiency (MKD), has been known so far as Hyper-IgD and periodic fever syndrome (HIDS) and regarded as mostly occurring in Northern Europe. Here we report the results of the molecular characterization of the first Italian series of patients affected with autoinflammatory disorders and periodic fever. A total of 13 different mutations, scattered throughout the MVK coding region, were identified in either homozygous or compound heterozygous state in 15 patients. The mutation leading to the V377I amino-acid change, already described also in other series, resulted the most common with a frequency of 50% of all MKD alleles. Among the other mutations, eight had never been described before, including an interstitial deletion of 19 nucleotides in exon 2. In addition to these nucleotide changes, private and polymorphic MVK variants have been detected in the patients under analysis and checked also in a set of control individuals. Clinical features are reported for each of the 15 MKD patients, and life-threatening infections and systemic amyloidosis presented as unexpected MKD-related complications. Our study demonstrates that MKD is a common cause of recurrent fever also in the Italian population, where it is associated with both a wide spectrum of previously unreported MVK mutations and peculiar phenotypic features.

Identification of bacterial muramyl dipeptide as activator of the NALP3/cryopyrin inflammasome.

Martinon F(1), Agostini L, Meylan E, Tschopp J.

Author information:

(1)Department of Biochemistry, University of Lausanne, Chemin des Boveresses 155, CH-1066 Epalinges, Switzerland.

Activation of caspase-1 and subsequent processing and secretion of the pro-inflammatory cytokine IL-1 $\beta$  is triggered upon assembly of the inflammasome complex. It is generally believed that bacterial lipopolysaccharides (LPS) are activators of the inflammasome through stimulation of Toll-like receptor 4

(TLR4). Like TLRs, NALP3/Cryopyrin, which is a key component of the inflammasome, contains Leucine-Rich-Repeats (LRRs). LRRs are frequently used to sense bacterial components, thus raising the possibility that bacteria directly activate the inflammasome. Here, we show that bacterial peptidoglycans (PGN), but surprisingly not LPS, induce NALP3-mediated activation of caspase-1 and maturation of proIL-1 $\beta$ . Activation is independent of TLRs because the PGN degradation product muramyl dipeptide (MDP), which is not sensed by TLRs, is the minimal-activating structure. Macrophages from a patient with Muckle-Wells syndrome, an autoinflammatory disease associated with mutations in the NALP3/Cryopyrin gene, show increased IL-1 $\beta$  secretion in the presence of MDP. The activation of the NALP3-inflammasome by MDP may be the basis of the potent adjuvant activity of MDP.

Lipopolysaccharide-induced expression of multiple alternatively spliced MEFV transcripts in human synovial fibroblasts: a prominent splice isoform lacks the C-terminal domain that is highly mutated in familial Mediterranean fever.

Diaz A(1), Hu C, Kastner DL, Schaner P, Reginato AM, Richards N, Gumucio DL.

Author information:

(1)Department of Cell and Developmental Biology, University of Michigan Medical School, 1301 Catherine Street, Ann Arbor, MI 48109, USA.

**OBJECTIVE:** To investigate the expression of the familial Mediterranean fever (FMF) gene (MEFV) in human synovial fibroblasts.

**METHODS:** MEFV messenger RNA in synovial fibroblasts, chondrocytes, and peripheral blood leukocytes (PBLs) was analyzed by semiquantitative and real-time polymerase chain reaction and ribonuclease protection assay. The subcellular localization of pyrin, the MEFV product, was determined in transfected synovial fibroblasts and HeLa cells with plasmids encoding pyrin isoforms. Native pyrin was detected with an antipyrin antibody.

**RESULTS:** MEFV was expressed in synovial fibroblasts, but not in chondrocytes. Four alternatively spliced transcripts were identified: an extension of exon 8

(exon 8ext) resulting in a frameshift that predicts a truncated protein lacking exons 9 and 10, the addition of an exon (exon 4a) predicting a truncated protein at exon 5, the in-frame substitution of exon 2a for exon 2, and the previously described removal of exon 2 (exon 2Delta). Exon 8ext transcripts represented 27% of the total message population in synovial fibroblasts. All other alternatively spliced transcripts were rare. Consensus and alternatively spliced transcripts were induced by lipopolysaccharide in synovial fibroblasts and PBLs. In transfected cells, the proteins encoded by all highly expressed splice forms were cytoplasmic. In contrast, native pyrin was predominantly nuclear in synovial fibroblasts, neutrophils, and dendritic cells, but was cytoplasmic in monocytes. CONCLUSION: Several MEFV transcripts are expressed and inducible in synovial fibroblasts. A prominent isoform lacks the C-terminal domain that contains the majority of mutations found in patients with FMF. While recombinant forms of all major pyrin isoforms are cytoplasmic, native pyrin is nuclear in several cell types. Thus, mechanisms in addition to splicing patterns must control pyrin's subcellular distribution.

Other than familial mediterranean fever: Four hereditary diseases presenting in the form of intermittent inflammatory flares are now recognized and have been characterised clinically and genetically. At the head of this group is Familial Mediterranean Fever (FMF), which affects thousands of patients originating from the Mediterranean area. However the familial Mediterranean Fever is no longer the only recurrent hereditary inflammatory disease. Three other entities have now

been clearly defined: intermittent fever secondary to mutations in the type 1A Tumour Necrosis Factor receptor (TNF), of dominant autosomic genetic transmission, the hyperimmunoglobulinemia D syndrome and an entity regrouping the Muckle Wells syndrome, familial cold-induced urticaria, and the Chronic Infantile Neurological Cutaneous and Articular (CINCA) syndrome. IN PRACTICE: Because they require specific management and treatment, precise diagnosis of these entities is crucial.

Severe outcome of juvenile idiopathic arthritis (JIA) associated with familial Mediterranean fever (FMF).

Rozenbaum M(1), Rosner I.

Author information:

(1)Department of Rheumatology, Bnai Zion Medical Center, Haifa, Israel.  
mrozenb@netvision.net.il

Juvenile Idiopathic Arthritis (JIA) and Familial Mediterranean Fever (FMF) may involve the same population of children and be confused at times. In a cohort of 350 consecutive FMF patients followed by us, 98 had onset before 10 years of age and, of those, JIA was present in 3. All three had the M694 V mutation of the MEFV gene and were of North African ancestry. The prognosis of these 3 was extremely poor: one developed bilateral knee osteonecrosis with total joint replacement, repeated ileal obstruction with small bowel resection, renal failure and sterility due to amyloidosis and osteoporotic fractures and died at 42 years of age; a second developed deforming erosive arthropathy and underwent bilateral total hip replacement; the third developed severe erosive polyarthritis and also underwent bilateral hip replacements. Aggressive treatment is indicated when JIA and FMF coexist.

Protracted febrile myalgia (PFM) includes severe myalgia of the upper and lower extremities accompanied by fever lasting up to 6 weeks, an elevated erythrocyte sedimentation rate and leucocytosis. We report a 13-year-old girl with PFM, and discuss the magnetic resonance imaging findings of the involved calf muscles. To our knowledge these are the only images of the pathology in the literature.

Urine leukotriene B4 in familial Mediterranean fever.

Bentancur AG(1), Naveh N, Lancri J, Selah BA, Livneh A.

Author information:

(1)Emergency Medicine Department, Sheba Medical Center, Tel Hashomer, Israel.

**OBJECTIVE:** To determine urinary leukotriene B4 (LTB4) levels and their role in FMF:

**METHODS:** Urinary LTB4 levels were studied using a commercial ELISA kit in 12 FMF patients during abdominal attacks, and 20 FMF patients during remission.

**RESULTS:** Urinary LTB4 levels in FMF patients during attacks were comparable to those during remission, but higher than normal levels ( $p = 0.03$ ).

**CONCLUSIONS:** These findings suggest a persistent activation of the leukotriene pathway in FMF. Whether elevated LTB4 levels are the cause or the effect of inflammation is yet to be determined.

The efficacy of continuous interferon alpha administration as an adjunctive agent to colchicine-resistant familial Mediterranean fever patients.

Calguneri M(1), Apras S, Ozbalkan Z, Ozturk MA, Ertenli I, Kiraz S.

Author information:

(1)Section of Rheumatology, Department of Internal Medicine, Hacettepe University Faculty of Medicine, Ankara, Turkey.

**OBJECTIVE:** About 10-20% of familial Mediterranean fever (FMF) patients are resistant to regular colchicine treatment and have painful recurrent attacks due to polyserositis. In clinical practice there is no alternative drug for such patients. In a previous pilot study on a small number of colchicine-resistant patients, interferon-alpha (IFN-alpha) was administered when painful attacks were about to occur.

**METHODS:** In this study we gave IFN-alpha continuously to 8 colchicine-resistant FMF patients in a schedule while the colchicine therapy had been continued. All those patients were complicated with vasculitis or arthritis or together during the FMF course. Those complications were treated with the other immunosuppressive drugs. While they were under intense immunosuppressive therapy, the abdominal and the other serosal attacks remained to continue.

**RESULTS:** After the administration of IFN-alpha therapy only one out of eight patients had abdominal painful attacks in twice, and one patient had arthritis in knees and ankles, the others responded well. Observed side effects were generally mild and acceptable.

**CONCLUSION:** Continuous IFN administration in addition to the regular colchicine treatment may be useful for the colchicine-resistant attacks in FMF patients.

PMID: 15515783 [Indexed for MEDLINE]

The effect of interferon alpha administration on acute attacks of familial Mediterranean fever: A double-blind, placebo-controlled trial.

Tunca M(1), Akar S, Soytürk M, Kirkali G, Resmi H, Akhunlar H, Gönen O, Gallimore JR, Hawkins PN, Tankurt E.

Author information:

(1)Dokuz Eylül University School of Medicine, Department of Internal Medicine, Izmir, Turkey. tunca@superonline.com

**BACKGROUND:** About a quarter of familial Mediterranean fever (FMF) patients are partially or totally resistant to colchicine. A previous observation reported that acute attacks may be shortened by administration of interferon alpha (IFN).

**OBJECTIVE:** We designed a double-blind, placebo-controlled trial to test our initial observations of a beneficial response with IFN in FMF attacks.

**METHODS:** We treated 34 acute abdominal attacks with IFN 5 million IU or placebo sc in the early phase of the attack. Leucocytes, thrombocytes, the erythrocyte sedimentation rate, fibrinogen, C-reactive protein (CRP), serum amyloid A protein (SAA), haptoglobin, transferrin, IL-1beta and TNF-alpha were measured at hours 0, 6, 12, 24 and 48.

**RESULTS:** The median time to recovery in those treated with IFN and placebo was not significantly different, while the leucocytosis and high levels of fibrinogen were significantly more prolonged in placebo-treated patients. CRP and SAA were extremely elevated and peaked at 24h, remaining less marked in the IFN-treated patients but the difference was not statistically significant. Observations regarding the other parameters were unremarkable.

**CONCLUSIONS:** Although there were some clues indicating a depressed inflammatory response with IFN, we could not demonstrate a definitive effect of this agent in this double-blind trial. The drug may suppress the acute inflammation of FMF only if administered at the earliest phase. CRP and SAA may be more sensitive indicators of an attack than ESR or fibrinogen.

Levels of interleukin-6 (IL-6) and its soluble receptor (sIL-6R) in familial Mediterranean fever (FMF) patients and their first degree relatives.

Oktem S(1), Yavuzsen TU, Sengül B, Akhunlar H, Akar S, Tunca M.

Author information:

(1)Ege University School of Medicine, Department of Rheumatology, Bornova 35100, Izmir, Turkey. seldaoktem@yahoo.com

**OBJECTIVE:** Familial Mediterranean Fever (FMF) is a hereditary disease characterized by recurrent inflammatory attacks. A subclinical inflammation may persist in periods between the attacks and heterozygotes may have higher than normal levels of acute phase proteins. We investigated the levels of interleukin-6 (IL-6) and its soluble receptor (sIL-6R) in FMF patients and their obligatory carrier relatives.

**METHODS:** Serum levels of IL-6 and sIL-6R were measured during acute attacks (n = 18) and in attack-free FMF patients (n = 26), obligatory carriers of FMF (n = 17) and normal controls (n = 11).

**RESULTS:** The median levels of IL-6 were significantly higher (45.71 pg/ mL, p = 0.001) during acute attacks of FMF only, and were normal (0.01 pg/ mL) in the other groups studied. There was no statistically significant difference in the median sIL-6R values between any of the groups (p = 0.22).

**CONCLUSION:** IL-6 was extremely elevated during FMF attacks but could not detect hypothetical "subclinical" inflammation during attack-free intervals or in the heterozygote relatives of patients. Serum levels of sIL-6R were comparable in all four groups.

Increased frequency of familial Mediterranean fever in Central Anatolia, Turkey.

Onen F(1), Sumer H, Turkay S, Akyurek O, Tunca M, Ozdogan H.

Author information:

(1)Dokuz Eylul University School of Medicine, Department of Internal Medicine, Division of Immunology and Rheumatology, 35340 Izmir, Turkey.  
fatos.onen@deu.edu.tr

**OBJECTIVE:** It has been observed that familial Mediterranean fever is more prevalent among people coming from central Anatolia in Turkey. To test this observation the frequency of FMF was investigated by a field survey in Sivas, a

city located in central of Turkey.

**METHODS:** The survey was conducted in a cohort of 4809 persons selected by systematic sampling from 2 districts of Sivas, with a total population of 83,274. Face to face interviewing was done with registered households using a standard questionnaire developed to screen FMF. A second interview was conducted by a rheumatologist and an internist of those individuals who were regarded to have possible FMF.

**RESULTS:** The suspicion of FMF emerged in the cases of 46 individuals during the survey and 36 were interviewed for a second time. FMF was diagnosed in 10 cases. Only one had a previous diagnosis of FMF. The overall frequency of FMF among a cohort of 3,948 inhabitants of Sivas was 1/395 (0.25%).

**CONCLUSION:** This study indicates that the prevalence of FMF in Sivas may be higher than that in general Turkish population, which has been reported to be 0.1%.

The prevalence of familial Mediterranean fever in the Turkish province of Denizli: a field study with a zero patient design.

Cobankara V(1), Fidan G, Türk T, Zencir M, Colakoglu M, Ozen S.

Author information:

(1)Department of Rheumatology, Pamukkale University, Faculty of Medicine, Denizli, Turkey. vcobankara@hotmail.com

**OBJECTIVE:** This study had two aims: (1) to investigate the prevalence of familial Mediterranean fever (FMF) and Behçet's disease (BD) in school students in Denizli, a province in western Turkey; and (2) to determine whether the previously suggested "zero patient design" was reliable for use in a prevalence survey.

**METHODS:** The field survey was performed in two stages. In the first stage 7,389 students (3,847 females and 3,542 males) were asked to fill out a questionnaire in the classroom. In the questionnaire, filtering questions for FMF (the presence of recurrent attacks of fever accompanying abdominal pain, joint pain/swelling,

and/or chest pain) and BD (presence of aphthous stomatitis) were asked. The second stage consisted of two parts. In the first, 3225 questionnaires were completed by 1778 female and 1447 male students calculated according to the zero patient design, who were selected randomly from among 7389 students for evaluation. Students with any suspicion of FMF and Behçet's disease were called to the hospital for detailed investigation. In the second step the remaining students were evaluated.

RESULTS: Out of 3225 children questioned in the first step, 156 claimed recurrent abdominal pain and/or chest pain, and/or joint pain/swelling with accompanying fever, which might suggest the presence of FMF. However, this diagnosis was excluded after further clinical evaluation. In the second step 152 students were called for detailed investigation: 2 patients, one 10 years and the other 12 years old, were diagnosed as having FMF. None were diagnosed to have Behçet's disease.

CONCLUSION: The prevalence of FMF in Turkey in general is about 0.093%. The prevalence rate found in this survey was lower (0.027%) which may be due to the historic background of the region. This is the first study that has shown that the "zero patient design" can be used in an epidemiological survey.

The outcome of pregnancy in the wives of men with familial mediterranean fever treated with colchicine.

Ben-Chetrit E(1), Berkun Y, Ben-Chetrit E, Ben-Chetrit A.

Author information:

(1)Department of Medicine, Hadassah University Hospital, POB 12000, Jerusalem, Israel. eldad@hadassah.org.il

**OBJECTIVE:** To evaluate the outcome of pregnancies of normal women married to men with familial Mediterranean fever (FMF), some of whom took colchicine during the conception with their wives.

**PATIENTS AND METHODS:** We followed the outcome of pregnancies and deliveries of 60 wives of FMF patients; 53 of the husbands were taking colchicine during that time. As a control group we screened the outcome of pregnancy and delivery from 230 healthy women married to healthy men.

**RESULTS:** The 60 FMF patients- wives had 222 pregnancies, of which 206 ended in term delivery with 209 live births. Sixteen pregnancies ended in spontaneous abortions (7%). Three of the newborns in the study group were born with congenital malformations. In the control group, of 788 pregnancies, 127 ended in abortions (16%). Six of the newborns were born with congenital malformations. The rate of the late abortions (second trimester) in both groups was comparable.

**CONCLUSIONS:** The results of our study indicates that neither FMF nor colchicine increases the rate of abortions or congenital malformations. Therefore we believe that there is no need to discontinue colchicine treatment in men with FMF before the conception with their wives.

In silico prediction of the deleterious effect of a mutation: proceed with caution in clinical genetics.

Tchernitchko D(1), Goossens M, Wajcman H.

Author information:

(1)Service de Biochimie et de Génétique Moléculaire and INSERM U468, Hôpital Henri-Mondor, 94010 Créteil, France.

When a sequence variation is found in a candidate gene for a disease, it is important to establish whether this change is neutral or responsible for the observed disorders in a patient. To answer this question, in the absence of further experimental investigations, several simulation programs have been proposed to predict whether a nonsynonymous single-nucleotide polymorphism is likely to have or not have a deleterious effect on the phenotype. In this work, we tested two such programs, PolyPhen and SIFT, using two kinds of targets. The first ones concerned the products of the hemoglobin and glucose-6-phosphate dehydrogenase genes, which are abundantly documented. The second concerned two systems for which much less information is available: (a) the TNFRSF1A gene, implicated in tumor necrosis factor receptor-associated periodic syndrome, and (b) the MEFV gene, which is believed to be involved in familial Mediterranean fever. Our data suggest that, from a practical point of view, these programs should not be used to decide, in the absence of other tests or arguments, whether the sequence variation found in a patient is or is not responsible for the disease. The consequence of an erroneous prediction may be disastrous in the perspective of genetic counseling.

Acute colchicine intoxication during clarithromycin administration.

Rollot F(1), Pajot O, Chauvelot-Moachon L, Nazal EM, Kélaïdi C, Blanche P.

Author information:

(1)Internal Medicine, Cochin Hospital, Paris, France.

**OBJECTIVE:** To report a case of colchicine intoxication occurring with institution of clarithromycin.

**CASE SUMMARY:** A 76-year-old man with familial Mediterranean fever (FMF) had received colchicine 1.5 mg daily for 6 years. The patient underwent 7 days of clarithromycin, amoxicillin, and omeprazole treatment for *Helicobacter pylori*-associated gastritis. Fever, abdominal pain, and diarrhea occurred 3 days after treatment initiation. On day 8, dehydration, pancytopenia, metabolic acidosis, and increased lipase level necessitated hospitalization. Alopecia was observed 2 weeks later. The patient recovered fully after the colchicine dosage was reduced to 0.5 mg/day and rehydration was performed. The previous dosage was then reinstituted without adverse reaction. An objective causality assessment revealed that the adverse event was probable.

**DISCUSSION:** Continuous colchicine administration is used in treatment of microcrystalline arthritis, Behcet's disease, and FMF. Colchicine is primarily eliminated through biliary excretion. Renal elimination and cytochrome P450 metabolism play a less significant role. Colchicine is also a substrate of P-glycoprotein, a transporter involved in cellular efflux and elimination of numerous drugs. Three cases of intoxication have been reported when colchicine was combined with erythromycin, josamycin, or clarithromycin. Macrolides are

inhibitors of P-glycoprotein and cytochrome P450-dependent enzymes and may decrease colchicine's biliary excretion through P-glycoprotein inhibition.

CONCLUSIONS: Coadministration of colchicine and macrolides may impair colchicine elimination, resulting in excess drug exposure and toxicity. To this end, colchicine should be used with extreme caution in patients receiving P-glycoprotein inhibitors, particularly if they are elderly and/or renally compromised.

A possible favorable effect of colchicine in IgA nephropathy in a carrier of a MEFV mutation.

Koukoui L(1), Blau A, Kopolovic J, Pras M, Livneh A.

Author information:

(1)Department of Medicine F, Sackler Faculty of Medicine, Tel Aviv University, Tel Aviv, Israel.

IgA nephropathy is the most common primary glomerulopathy. Currently, no satisfactory treatment is available and as a result, a significant proportion of affected patients progress to end-stage renal disease. We present a patient with IgA nephropathy in whom continuous colchicine treatment induced remission, which has lasted for 22 years. The patient was a carrier of a mutation in the FMF gene (MEFV). This case raises hopes for a better prognosis in at least one subgroup of IgA nephropathy, consisting of patients who happen to be heterozygous carriers of MEFV mutations.

Autoinflammatory diseases: the hereditary periodic fever syndromes.

Fietta P(1).

Author information:

(1)Osteo-Articular Department, Hospital of Parma, Parma, Italy.

farnese15@libero.it

Human autoinflammatory diseases (HAIDs) are a heterogeneous group of genetically determined affections characterized by seemingly unprovoked inflammation, in the absence of autoimmune or infective causes. The hereditary periodic fever syndromes (HPFSs) are a HAID subset consisting of three main nosologic entities: familial Mediterranean fever (FMF), hyperimmunoglobulinemia D and periodic fever syndrome (HIDS), and tumor necrosis factor receptor superfamily 1A-associated periodic syndrome (TRAPS). FMF and HIDS are autosomal recessive diseases, while TRAPS is dominantly inherited. Although each HPFS presents genetic and phenotypic peculiarities, globally these affections share an intermittent expression, in form of acute attacks of fever variably associated with serosal, synovial and/or cutaneous inflammation, usually self-limiting. Amyloidosis is the most severe, life-threatening complication of FMF and TRAPS, whereas it has not been till now reported in HIDS. The HPFS molecular bases have been recently identified. In this paper, the most recent information on HPFSs is reviewed and summarized.

[Hyper-IgD syndrome and other hereditary periodic fever syndromes].

[Article in Italian]

Scolozzi R(1), Boccafogli A, Vicentini L.

Author information:

(1)Centro di ricerca e servizi per lo studio delle malattie allergiche, Azienda Ospedaliera Universitaria di Ferrara, Ferrara. slr@unife.it.

Hereditary periodic fever syndromes are a group of systemic disorders characterized by recurrent attacks of systemic inflammation (autoinflammation) without infectious or autoimmune cause. The hyper-IgD syndrome (HIDS) is a rare autosomal recessive inflammatory disorder characterized by recurrent fever, increased serum IgD (normal value < 100 U/ml) and generalized inflammation (lymphadenopathy, arthralgias/arthritis, abdominal complaints, skin rash, and headache). The attacks persist during the entire life although frequency and severity tend to diminish with age. HIDS is caused by specific mutations in the gene encoding mevalonate kinase, resulting in depressed enzymatic activity. At present the therapy for the syndrome is only supportive. Other than HIDS, other hereditary systemic inflammatory disorders have been described: the Familial Mediterranean Fever, the tumour necrosis factor receptor associated periodic syndrome (TRAPS), a disease related to the mutations of one of the TNF receptors, the Familial Cold Urticaria and the Muckle-Wells syndrome. The differential diagnosis with other causes of periodic fever is crucial for assessing

appropriate management and treatment.

E148Q is a disease-causing MEFV mutation: a phenotypic evaluation in patients with familial Mediterranean fever.

Topaloglu R(1), Ozaltin F, Yilmaz E, Ozen S, Balci B, Besbas N, Bakkaloglu A.

Author information:

(1)Hacettepe University Faculty of Medicine, Department of Paediatric Nephrology

and Rheumatology, 06100 Ankara, Turkey. rtopalog@.hacettepe.edu.tr

**BACKGROUND:** Familial Mediterranean fever (FMF) is one of the periodic fever syndromes. It is common among Turks, Jews, Arabs, and Armenians. Several mutations in the MEFV gene, including E148Q, have been identified as causing this disease. It has been suggested that the E148Q mutation is the mildest mutation and some reports have questioned its disease association.

**OBJECTIVE:** To evaluate the phenotypic features of the patients with E148Q mutation.

**SUBJECTS:** 26 patients homozygous for E148Q, 10 compound heterozygous for E148Q, and eight complex cases were assessed.

**RESULTS:** Although four of the 26 patients with E148Q/E148Q were asymptomatic at the time of evaluation, abdominal pain was seen in 77% of the patients, fever in 66%, arthralgia in 50%, arthritis in 15.4%, and vomiting in 23.8%. Compound heterozygotes and complex cases had a higher frequency of abdominal pain, fever, arthralgia, arthritis, myalgia, and chest pain than subjects who were homozygous for E148Q, but none of these symptoms reached statistical significance. None of our patients had amyloidosis but two with E148Q/E148Q had a family history of amyloidosis and one had rapidly progressive glomerulonephritis secondary to vasculitis, which progressed to chronic renal failure.

**CONCLUSIONS:** Patients homozygous for E148Q have a heterogeneous clinical presentation. Most are symptomatic and colchicine treatment is required in these patients.

Systemic reactive (AA) amyloidosis, leading to renal failure, is a severe complication of most hereditary periodic fever syndromes. The risk of developing this life-threatening condition varies widely among these disorders, being higher for patients affected by familial Mediterranean fever and tumor necrosis factor receptor-associated periodic syndrome. In spite of an acute-phase response during attacks, amyloidosis has never, to date, been described in patients affected with the hyperimmunoglobulinemia D with periodic fever syndrome (HIDS). This is the first report to describe the occurrence of renal AA amyloidosis causing severe nephrotic syndrome in a young Italian man affected with HIDS. The diagnosis of HIDS was established according to clinical, laboratory, and genetic criteria as required by the international Nijmegen HIDS registry. In this patient, 2 mutations in the mevalonate kinase gene were identified, one of which, the leucine-to-arginine substitution at codon 265, is novel.

Patients with recurrent or relapsing arthritis are frequently seen in rheumatological practice. Besides crystal arthritis, the most frequent cause of recurrent arthritis, there are several diseases that may present clinically as intermittent mono- or polyarthritis. Palindromic rheumatism is the paradigm of this type of condition, but other diseases such as systemic autoinflammatory disorders (periodic fever syndromes), Whipple's disease, arthritis associated with hyperlipidemia, intermittent hydrarthrosis and other diseases should be taken into account in the differential diagnosis of patients with recurrent arthritis. In this chapter, we discuss recent developments in these diseases with special emphasis on palindromic rheumatism, a common condition whose close

relationship with rheumatoid arthritis remains intriguing.

Once-daily use of colchicine in children with familial Mediterranean fever.

Koşan C(1), Ozkan B.

Author information:

(1)Department of Pediatric Nephrology, Faculty of Medicine, Atatürk University, Erzurum-Turkey.

Patients with familial Mediterranean fever routinely take daily multiple doses of colchicine to prevent acute attacks and to reduce the risk of amyloidosis. However, although there is no research in this regard in the literature, some clinicians believe that the use of colchicine in children as daily single dose may cause toxic side effects. The efficiency and the side effects of the administration of daily single dose versus daily multiple doses of colchicine were evaluated in the treatment of patients with familial Mediterranean fever. Thirty-nine patients being observed at Atatürk University Medical Faculty Pediatrics outpatient clinic with the diagnosis of familial Mediterranean fever were randomly divided into 2 groups. Group I consisted of 20 patients who continued taking colchicine in 2 or 3 divided doses daily as they did before the study. Group II comprised 19 patients who were given the total daily colchicine dose at 1 time. Patients were re-examined at 30-day intervals and both groups maintained this regimen for an average duration of 8 months. There was no difference between these 2 groups with respect to frequency of side effects, number of attacks, and acute phase response. Therefore, the daily colchicine dose can be given to children once daily.

The feeling of fatigue--fatigue severity by unidimensional versus composite questionnaires.

Naschitz JE(1), Rozenbaum M, Shaviv N, Fields MC, Enis S, Babich JP, Manor H, Yeshurun D, Sabo E, Rosner I.

Author information:

(1)Department of internal medicine, Haifa, Isreal.

Naschitz@techunix.techion.ac.il

The authors' purpose in this study was to compare the perception of fatigue severity as measured by different fatigue questionnaires. The authors evaluated 3 groups of patients in a cross-sectional study: chronic fatigue syndrome (CFS, n = 20), non-CFS fatigue (n = 20), and familial Mediterranean fever (FMF n = 25). In

addition, the authors tracked 7 patients with CFS longitudinally for severity of fatigue. The severity of fatigue-related symptoms was assessed with 2 questionnaires: the unidimensional Chalder's Fatigue Severity Scale (CH) and the composite Fatigue Impact Scale (FI) which has 3 subscales--cognitive, physical, and social--and a total score. In the cross-sectional study, correlations between CH and FI cognitive scores were  $r = .78$  ( $p < .0001$ ), CH versus FI physical scores  $r = .603$  ( $p < .0001$ ), CH versus FI social scores  $r = .66$  ( $p < .0001$ ), and CH versus FI total scores  $r = .74$  ( $p < .0001$ ). In the longitudinal survey of CFS patients, the authors compared 30 questionnaires revealing correlations of CH versus FI cognitive scores  $r = .64$  ( $p = .0004$ ), CH versus FI physical  $r = .68$  ( $p = .0001$ ), CH versus FI social  $r = .87$  ( $p < .0001$ ), and CH versus FI total  $r = .90$  ( $p < .0001$ ). Fatigue severity as assessed by the unidimensional CH scale and the composite FI scale is comparable. The simple CH scale may be adequate for the assessment of the feeling of fatigue, in general, and for monitoring the severity of fatigue in CFS, in particular.

Periodic fever syndromes (PFSs) comprise a subset of the hereditary autoinflammatory disorders that are defined by recurrent self-resolving attacks of systemic inflammatory reactions in the absence of infection or autoimmunity. Recent advances have led to the discovery that members of a new family of genes, the PYRIN family, account for several hereditary PFSs. Here we discuss new insights into the function of PYRIN proteins and the molecular basis of PFSs.

Renal involvement with amyloidosis is common but causes patient survival to be poor, rarely reaching 5 years. In this study, we retrospectively reviewed clinical and biological characteristics as well as treatments and outcomes of patients with renal amyloidosis followed for more than 5 years. Between 1975 and 2003, 485 patients were diagnosed with renal amyloidosis including only 12 patients who were followed more than 5 years. The six men and six women of mean age 42.4 years (range 18 to 66 years) displayed renal signs of lower limb edema in all cases; hypertension in four cases, proteinuria on urinalysis in all cases with microscopic hematuria in five cases. Biological tests showed nephrotic syndrome in 11 patients, normal renal function in nine patients, and renal failure in three patients whose mean creatinine was 481.6 micromol/L (range 294 to 726). The amyloidosis was AA type in 11 cases and non-AA in one case. An etiologic survey revealed spondylarthropathy in one patient, pulmonary tuberculosis in two patients, chronic bronchitis in three patients, hepatic hydatid cyst in one patient, Mediterranean familial fever in two patients, Crohn's disease in one patient, Hodgkin's lymphoma in one patient, and multiple myeloma in one patient. Specific treatment was initiated with colchicine in seven patients. At a 110-month mean follow-up (range 53 to 153 months), remission of nephrotic syndrome was observed in four cases, progression to chronic renal failure in two patients, and to end-stage renal failure in five cases (range 53 to 196 months), with stabilization of renal function in seven patients. In conclusion, primary amyloid disease should be optimally suppressed in patients with renal involvement. The role of this treatment in remission of renal amyloidosis is not well established. This efficacy of the treatment has been demonstrated in some patients with improved survival.

[Nuclei and nucleolar organizing regions in chromosomes of lymphocytes on different stages of periodic disease].

[Article in Russian]

Karalova EM, Abroian LO, Akopian LO, Karagezian KG, Magakian IuA.

By scanning cytomorphometry a cytological study was first performed on the behavior of nuclei and nucleolar organizing regions (NOR) in chromosomes of peripheral blood lymphocytes of healthy men and of patients with periodic disease (familial Mediterranean fever, FMF) on different stages of development, including its complication with amyloidosis. The volume and total surface of nuclei, the sum total volume and sum total surface of NOR, the mean number of NOR for one nucleus and distribution of nuclei according to NOR number were measured. It is shown that the parameters of nuclei and NOR for patients with FMF on all stages clearly and trustworthy differ from those for healthy men. They are sufficiently informative, can be successfully used in clinical practice and even serve as an early diagnostic test for amyloidosis complication.

The efficacy of interferon-alpha in a patient with resistant familial Mediterranean fever complicated by polyarteritis nodosa.

Calguneri M(1), Apras S, Ozbalkan Z, Ozturk MA.

Author information:

(1)Hacettepe University Faculty of Medicine, Internal Medicine Department, Section of Rheumatology, Ankara, Turkey.

Familial Mediterranean fever (FMF) is a recurrent self-limiting polyserositis. Polyarteritis nodosa (PAN) complicating FMF is very rare. Here, we present a 17-year-old male patient with FMF who subsequently developed PAN 2 weeks after hepatitis A infection. This case was also complicated with perirenal haematoma,

and right nephrectomy was performed. The clinical condition of the patient was improved after therapy with intravenous and oral corticosteroid and intravenous cyclophosphamide. However, the FMF attacks and vasculitic skin lesions again occurred while he was using colchicine plus immunosuppressive agents a few months later. Interferon-alpha therapy was administered and the attacks were resolved within 3 months. He has not experienced any other symptom during the follow-up period of 28 months.

**OBJECTIVE:** To investigate the effect of mutations in tumor necrosis factor receptor superfamily 1A (TNFRSF1A) on the ability of the receptors to be cleaved from the cell surface upon stimulation. The mutations we studied are associated with clinically distinct forms of TNF receptor-associated periodic syndrome (TRAPS). We also investigated different cell types within the same form of TRAPS.

**METHODS:** The shedding of TNFRSF1A in response to stimulation with phorbol myristate acetate was assessed in leukocytes and dermal fibroblasts from patients with C33Y TRAPS, and in HEK 293 cell lines stably transfected with constructs containing wild-type TNFRSF1A and/or TNFRSF1A mutants identified in TRAPS patients.

**RESULTS:** The shedding of TNFRSF1A differed between cell types within the same form of TRAPS. In particular, dermal fibroblasts, but not leukocytes, from C33Y TRAPS patients demonstrated reduced shedding of TNFRSF1A. Shedding of both wild-type and mutant TNFRSF1A from the transfected HEK 293 cells showed minor

differences, but was in all cases induced to a substantial extent.

CONCLUSION: Differences in TNFRSF1A shedding are not purely a function of the TNFRSF1A structure, but are also influenced by other features of genetic makeup and/or cellular differentiation. It is unlikely that a defect in TNFRSF1A shedding per se can fully explain the clinical features that are common to TRAPS patients with different TNFRSF1A mutations.

Aberrations of CVR (cardiovascular reactivity), an expression of autonomic function, lack specificity for a particular disorder. Recently, a CVR pattern particular to chronic fatigue syndrome has been observed. In the present study, we aimed to develop methodologies for assessing disease-specific CVR patterns. As a prototype, a population of 50 consecutive patients with FMF (familial Mediterranean fever) was studied and compared with control populations. A 10 min supine/30 min head-up tilt test with recording of the heart rate and blood pressure or the pulse transit time was performed. Five studies were conducted applying different methods. In each study, statistical analysis identified independent predictors of CVR in FMF. Based on regression coefficients of these predictors, a linear DS (discriminant score) was computed for every subject. Each study established an equation to assess CVR, calculate DS for FMF and determine the sensitivity and specificity of the DS cut-off. In each of the five studies, abnormal CVR was observed in FMF patients. The best accuracy (88% sensitivity and 90.1% specificity for FMF) was obtained by a method based on beat-to-beat heart

rate and pulse transit time recordings. Data was processed by fractal and recurrence quantitative analysis with recordings in FMF patients compared with a mixed control population. Identification of disease-specific CVR patterns was possible with the methodologies described in the present study. In FMF, disease-specific CVR may be explained by the interplay between neuroendocrine loops specific to FMF with cardiovascular homeostatic mechanisms. Recognition of disease-specific CVR patterns may advance the understanding of homeostatic mechanisms and have implications in clinical practice.

Familial Mediterranean fever (FMF) is an autosomal recessive disease due to mutations in pyrin, which normally inhibits pro-interleukin-1beta (IL-1beta) cytokine processing to the active form. A novel role for pyrin has been proposed by Shoham et al., who studied patients with an autosomal dominant disease called pyogenic arthritis, pyoderma gangrenosum, and acne (PAPA) syndrome. They demonstrated an interaction between pyrin and proline serine threonine phosphatase-interacting protein 1 (PSTPIP1), the protein involved in PAPA, and thus revealed a biochemical pathway common to both FMF and PAPA.

Effect of inflammatory attacks in the classical type hyper-IgD syndrome on immunoglobulin D, cholesterol and parameters of the acute phase response.

Simon A(1), Bijzet J, Voorbij HA, Mantovani A, van der Meer JW, Drenth JP.

Author information:

(1)Department of General Internal Medicine, University Medical Centre St Radboud, 541 PO Box 9101, 6500 HB Nijmegen, the Netherlands. a.simon@aig.umvn.nl

**BACKGROUND:** Classical type hyper-immunoglobulin D (IgD) syndrome (HIDS) is an hereditary auto-inflammatory disorder, characterized by recurrent episodes of fever, lymphadenopathy, abdominal distress and a high serum concentration of IgD. It is caused by mevalonate kinase deficiency.

**OBJECTIVE:** To further characterize the acute phase response during fever attacks in HIDS in order to improve diagnosis.

**SUBJECTS:** Twenty-two mevalonate kinase-deficient HIDS patients.

**METHODS:** Blood samples were drawn during and in between febrile attacks, and concentrations of C-reactive protein (CRP), ferritin, procalcitonin, pentraxin 3, IgD and cholesterol in several lipoprotein fractions were determined.

**RESULTS:** The marked acute phase response at the time of a fever attack in classical type HIDS is reflected by a rise in CRP accompanied by a moderate but statistically significant rise in procalcitonin and pentraxin 3. In only two of 22 patients, procalcitonin concentration rose above 2 ng mL<sup>-1</sup> during fever attack, compatible with the noninfectious nature of these attacks. Ferritin does not reach the high concentrations found in adult-onset Still's disease. Despite the defect in mevalonate kinase, a component of cholesterol metabolism, serum cholesterol did not change during attacks. IgD concentration is elevated regardless of disease activity, although there is appreciable variation during life. Its role in HIDS remains unclear.

**CONCLUSION:** The combination of high CRP concentration plus procalcitonin concentration <2 ng mL<sup>-1</sup> in a symptomatic HIDS patient might indicate a febrile attack without (bacterial) infection; this observation warrants further investigation for its usefulness as a marker in clinical practice.

[Recurrent bouts of fever accompanied by abdominal pain and emesis].

[Article in German]

Blassneck K(1), Nusko G, Benninger J, Hahn EG, Harsch IA.

Author information:

(1)Innere Medizin, Klinik Bad Windsheim. [blassneck@gmx.de](mailto:blassneck@gmx.de)

A 34 year-old Turkish patient was admitted to hospital several times with the same symptoms of abdominal pain, fever up to 39.2 degrees C and vomiting. The diagnosis always was an acute attack of chronic pancreatitis. The inflammation scores in the blood were high and he had a moderate increase in pancreatic enzymes. He always got well in a few days on a strict diet and regime of analgesics. Taking these symptoms and his ethnic affiliation into consideration, differential diagnosis should include familial Mediterranean fever (FMF). Therapy with colchicine should be initiated even if genetic testing does not reveal the mutation characteristics for FMF. Immediate and consistent therapy helps to avoid amyloid nephropathy as the most dangerous complication of this disease.

**OBJECTIVE:** To describe the effect of Etanercept treatment in systemic AA amyloidosis in tumour necrosis factor receptor-associated periodic syndrome (TRAPS).

**METHODS:** Etanercept therapy was given to a 27 year old woman, with systemic amyloidosis and nephrotic syndrome, and to her 51 year old father, also affected by TRAPS, who had previously undergone renal transplant for amyloidosis. Serum SAA levels, plasma cytokines, glomerular filtration rate and serum amyloid P scanning were monitored.

**RESULTS:** Etanercept treatment resulted in initial clinical resolution of nephrotic syndrome in the 27 year old female. Both subjects demonstrated improvements in GFR and initial reduction or stabilisation of amyloid deposits on SAP scanning.

**CONCLUSION:** Etanercept may reverse or slow the progression of systemic AA amyloidosis in subjects with C33Y TNFRSF1A mutation. Treatment may however need to be continuous and life-long to prevent progression to end stage disease.

ian.todd@nottingham.ac.uk

Tumour necrosis factor (TNF)-receptor-associated periodic syndrome (TRAPS) is a hereditary autoinflammatory disorder involving autosomal-dominant missense mutations in TNF receptor superfamily 1A (TNFRSF1A) ectodomains. To elucidate the molecular effects of TRAPS-related mutations, we transfected HEK-293 cells to produce lines stably expressing high levels of either wild-type (WT) or single mutant recombinant forms of TNFRSF1A. Mutants with single amino acid substitutions in the first cysteine-rich domain (CRD1) were produced both as full-length receptor proteins and as truncated forms lacking the cytoplasmic signalling domain (deltasig). High-level expression of either WT or mutant full-length TNFRSF1A spontaneously induced apoptosis and interleukin-8 production, indicating that the mutations in CRD1 did not abrogate signalling. Consistent with this, WT and mutant full-length TNFRSF1A formed cytoplasmic aggregates that co-localized with ubiquitin and chaperones, and with the signal transducer TRADD, but not with the inhibitor, silencer of death domain (SODD). Furthermore, as expected, WT and mutant deltasig forms of TNFRSF1A did not induce apoptosis or interleukin-8 production. However, whereas the WT full-length TNFRSF1A was expressed both in the cytoplasm and on the cell surface, the mutant receptors showed strong cytoplasmic expression but reduced cell-surface expression. The WT and mutant deltasig forms of TNFRSF1A were all expressed at the cell surface, but a proportion of the mutant receptors were also retained in the cytoplasm and co-localized with BiP. Furthermore, the mutant forms of surface-expressed deltasig TNFRSF1A were defective in binding TNF-alpha. We conclude that TRAPS-related CRD1 mutants of TNFRSF1A possess signalling properties associated with the cytoplasmic death domain, but other behavioural features of the mutant receptors are abnormal, including intracellular

trafficking and TNF binding.

Mutations in the human CIAS1 (hCIAS1) gene have been identified in a continuum of inflammatory disorders including familial cold autoinflammatory syndrome (FCAS), Muckle-Wells syndrome (MWS), and neonatal onset multisystem inflammatory disease (NOMID). CIAS1 codes for the protein Cryopyrin, which appears to play a role in innate immune function by regulating the production of proinflammatory cytokines. Human and mouse Cryopyrin are highly conserved and consist of three functional domains including a pyrin domain, an NACHT domain, and a leucine-rich repeat (LRR) domain that are characteristics of the NALP family of proteins. The pyrin and NACHT domains of Cryopyrin and other NALP proteins are highly conserved among primate and nonprimate mammals, suggesting purifying selection throughout mammalian evolution. Cryopyrin expression is also very similar in human and mouse with mouse CIAS1 mRNA expression found primarily in peripheral blood leukocytes consistent with the postulated inflammatory function. We also detected significant expression in mouse eye and skin tissue, which is consistent with symptoms observed in human Cryopyrin-associated diseases.

The Infevers database (<http://fmf.igh.cnrs.fr/infevers/>) was established in 2002 to provide investigators with access to a central source of information about all sequence variants associated with periodic fevers: Familial Mediterranean fever (FMF), TNF Receptor Associated Periodic Syndrome (TRAPS), Hyper IgD Syndrome (HIDS), Familial Cold Autoinflammatory Syndrome/Muckle-Wells Syndrome/Chronic Infantile Neurological Cutaneous and Articular Syndrome (FCAS/MWS/CINCA). The prototype of this group of disorders is FMF, a recessive disease characterized by recurrent bouts of unexplained inflammation. FMF is the pivotal member of an expanding family of autoinflammatory disorders, a new term coined to describe illnesses resulting from a defect of the innate immune response. Therefore, we decided to extend the Infevers database to genes connected with autoinflammatory diseases. We present here the biological content of the Infevers database, including the introduction of two new entries: Crohn/Blau and Pyogenic sterile arthritis, pyoderma gangrenosum and acne (PAPA syndrome). Infevers has a range of query capabilities, allowing for simple or complex interrogation of the database. Currently, the database contains 291 sequence variants in related genes (MEFV,

TNFRSF1A, MVK, CARD15, PSTPIP1, and CIAS1), consisting of published data and personal communications, which has revealed or refined the preferential mutational sites for each gene. This database will continue to evolve in its content and to improve in its presentation.

Continuity of cytokine activation in patients with familial Mediterranean fever.

Bagci S(1), Toy B, Tuzun A, Ates Y, Aslan M, Inal A, Gulsen M, Karaeren N, Dagalp K.

Author information:

(1)Department of Gastroenterology, Gulhane School of Medicine, Etlik-Ankara, Turkey. [saitbagci@yahoo.com](mailto:saitbagci@yahoo.com)

Familial Mediterranean fever (FMF) is a recessively inherited inflammatory disorder, characterized by recurrent attacks of fever and polyserositis. It has been considered that miscellaneous cytokines take part in the pathogenesis of the disease. The aim of this study was to investigate serum levels of soluble interleukin-2 receptor (sIL-2R), interleukin-6 (IL-6), and interleukin-10 (IL-10) in patients with FMF. The study included 42 patients with FMF (3 females, 39 males, mean age: 24.43 years) and 20 healthy volunteers as the control group (18 males, 2 females, mean age: 23.2 years). The patients were chosen according to Eliakim criteria. After recording their history and performing an examination, leukocyte counts, erythrocyte sedimentation rates (ESR), C-reactive protein (CRP), fibrinogen, sIL-2R, IL-6, and IL-10 levels were measured before and during attacks. A significant increase was found in leukocyte (  $p<0.001$ ), ESR (  $p<0.001$ ), CRP (  $p<0.001$ ), and fibrinogen (  $p<0.001$ ) levels of the patient group in the attack period compared to those in the quiescent state. sIL-2R (  $p=0.019$ ) and IL-6 (  $p<0.001$ ) levels showed significant increases during attacks compared to the levels before an attack. There was no significant difference between IL-10 levels. The levels of the three cytokines were significantly high both before and

during the attacks compared to the control group. As a result, the elevation of sIL-2R and IL-6 levels both before and during the attacks compared to control group suggests the existence of continuous cytokine activation in the patients. No significant increase in the IL-10 levels in spite of the significant rise of sIL-2R and IL-6 during attacks supports the notion of inflammation and also reveals that compensation by anti-inflammatory IL-10 does not seem to occur.

A comparison of clinical findings of familial Mediterranean fever patients with and without amyloidosis.

Cefle A(1), Kamali S, Sayarlioglu M, Inanc M, Ocal L, Aral O, Konice M, Gul A.

Author information:

(1)Department of Rheumatology, Division of Internal Medicine, Istanbul University Faculty of Medicine, Istanbul, Turkey. kcefle@hotmail.com

**OBJECTIVE:** This study investigates the clinical and demographic characteristics of familial Mediterranean fever (FMF) patients with and without amyloidosis.

**PATIENTS AND METHODS:** The clinical data of 503 patients with FMF (females:males 250:253) were reviewed. Fifty of these patients had amyloidosis (f:m 23:27).

**RESULTS:** The ages of attack onset in patients with and without amyloidosis were 7.8+/-6.2 and 11.1+/-8.5, respectively ( $P<0.05$ ). The time between disease onset and diagnosis was longer in patients with amyloidosis than those without (187.6+/-99.4 months and 132.5+/-110.2 months, respectively,  $P<0.001$ ). More patients in the amyloidosis group had positive family histories of FMF (68% vs 54%,  $P<0.05$ ). The frequencies of chest pain (78% vs 51%,  $P<0.001$ ), arthritis (80% vs 60%,  $P<0.01$ ), and erysipelas-like erythema (44% vs 16%,  $P<0.001$ ) were higher in the amyloidosis group.

**CONCLUSION:** In the amyloidosis group, FMF-related manifestations of chest pain, arthritis, and erysipelas-like erythema are more frequent. Our results also support that long periods between disease onset and diagnosis are associated with a high risk of developing amyloidosis.

Tumor necrosis factor receptor-associated periodic syndrome (TRAPS): definition, semiology, prognosis, pathogenesis, treatment, and place relative to other periodic joint diseases.

Masson C(1), Simon V, Hoppé E, Insalaco P, Cissé I, Audran M.

Author information:

(1)Rheumatology Department, Angers Teaching Hospital, 49033 Angers cedex 1, France. ChMasson@chu-angers.fr

Tumor necrosis factor receptor-associated periodic syndrome (TRAPS) is an autosomal dominant inherited condition of periodic fever and pain. Most patients are of northern European descent. The attacks manifest as fever and pain in the joints, abdomen, muscles, skin, or eyes, with variations across patients. An acute-phase response occurs during the attacks. Patients with TRAPS are at risk for AA amyloidosis, the most common targets being the kidneys and liver. Soluble TNFRSF1A is usually low between the attacks and may be normal during the attacks, when TNF levels are high. TNFRSF1A is found in abnormally high numbers on leukocyte cell membranes. TRAPS is the first condition for which naturally occurring mutations in a TNF receptor were found; the mutations affect the soluble TNFRSF1A gene in the 12p13 region. In some patients, the pathogenesis involves defective TNFRSF1A shedding from cell membranes in response to a given stimulus. Thus, TRAPS is a model for a novel pathogenic concept characterized by failure to shed a cytokine receptor. This review compares TRAPS to other inherited periodic febrile conditions, namely, familial Mediterranean fever, Muckle-Wells syndrome, cold urticaria, and hyper-IgD syndrome. The place of TRAPS relative to other intermittent systemic joint diseases is discussed. Colchicine neither relieves nor prevents the attacks, whereas oral glucocorticoid therapy is effective when used in dosages greater than 20 mg/day. The pathogenic hypothesis involving defective TNFRSF1A shedding suggests that medications targeting TNF may be effective in TRAPS.

**OBJECTIVE:** To identify potential mutations in the tumour necrosis factor receptor superfamily 1A gene (TNFRSF1A) in a Japanese female patient with recurrent fever complicated by systemic lupus erythematosus (SLE), and in her family members.

**METHODS:** DNA sequencing of exons 1-10 of the TNFRSF1A gene was performed to determine mutations that might be associated with the tumour necrosis factor receptor-associated periodic syndrome (TRAPS). Moreover, the TNFRSF1A gene was examined in Japanese patients with autoimmune diseases, including SLE, rheumatoid arthritis (RA), mixed connective tissue disease (MCTD) and Behçet's disease, and in healthy Japanese controls. Enzyme-amplified sensitivity immunoassay (EASIA) analysis was used to assess serum levels of TNF, the 55-kDa TNF receptor (TNFRSF1A) and the 75-kDa TNF receptor (TNFRSF1B). Membrane TNFRSF1A expression was analysed on the surface of peripheral blood mononuclear cells by flow cytometry.

**RESULTS:** A novel mutation, a heterozygous C to T transition in exon 3 which substitutes an isoleucine for a threonine at position 61 (T61I) was detected in the TNFRSF1A gene derived from the genomic DNA of a Japanese female TRAPS patient. Two nieces and one nephew, all with a similar clinical phenotype, also possessed the same TNFRSF1A mutation. We further demonstrated the same mutation in five of 60 SLE patients (8.3%) and in five of 120 healthy individuals (4.2%), with no significant differences. Although high titres of serum TNF and soluble TNFRSF1B protein were observed in this patient, low titres of soluble TNFRSF1A

protein were detected. However, a defect in TNFRSF1A shedding in vitro was not observed in monocytes derived from this patient.

CONCLUSION: This is the first report of a TRAPS patient associated with SLE with a novel TNFRSF1A mutation (T61I).

Is there any relationship between *Chlamydomydia pneumoniae* infection and juvenile idiopathic arthritis?

Altun S(1), Kasapcopur O, Aslan M, Karaarslan S, Koksall V, Saribas S, Ergin S, Arisoy N, Kocazeybek B.

Author information:

The role of *Chlamydomydia pneumoniae* in the development and exacerbation of juvenile idiopathic arthritis (JIA) was investigated. Blood samples were taken from 60 JIA patients during an active disease period and for 4 weeks after. Synovial fluid samples were obtained from 20 of the 60 patients. In addition, 22 patients with familial Mediterranean fever (FMF) during the active period and 35 healthy children were included in the study as control groups. Synovial fluid samples were also obtained from three children with FMF. IgG, IgM and IgA levels against *C. pneumoniae* in serum samples were studied by immunofluorescence and IgG antibody and PCR studies were performed for *C. pneumoniae* DNA in synovial fluid samples. Twenty-nine (48.3 %) patients with JIA, 18 (81.8 %) patients with FMF and 22 (62.8 %) healthy children were found to be pre-infected with *C. pneumoniae*. Pre-infection with *C. pneumoniae* among FMF patients was found to be significantly higher than among those with JIA. We did not find a significant difference between JIA patients and healthy children. Chronic *C. pneumoniae* infection was observed only in six JIA patients, one FMF patient and two healthy children. Synovial fluid antibodies were found at higher than 1/512-fold dilution in one JIA patient and four times higher than normal serum in three JIA patients. *C. pneumoniae* DNA was not detected in any synovial fluid sample from FMF or JIA

patients by PCR. In conclusion, *C. pneumoniae* infection does not have a triggering or a progressive effect on the clinical situation in JIA aetiopathogenesis, as a result of a multifactorial aetiology. New, extensive and serial studies (especially PCR studies of synovial tissue) are needed in order to confirm the indirect results.

[Familial Mediterranean fever].

[Article in French]

Leclercq P(1), Hermesse A, Malaise MG.

Author information:

(1)ULg.

Familial Mediterranean Fever (FMF) is an hereditary disease that especially affects people living around the Mediterranean sea. It is characterized by recurring fever and abdominal pain, eventually associated with localised pleuritis, synovitis or skin inflammation. The most serious complication is amyloidosis, which can lead to terminal renal failure. The attacks and complications can be avoided by life long administration of colchicine. Two independent French and American teams discovered the gene responsible for the disease in 1997. It encodes for a protein named pyrin/marenostrin involved in the homeostasis the inflammatory mechanisms. The main mutations have been identified and are henceforth accessible for molecular screening.

Periodic fever syndromes--a clinical overview.

Aringer M(1).

Author information:

(1)Division of Rheumatology, Department of Internal Medicine III, Medical University of Vienna, Vienna, Austria. martin.aringer@akh-wien.ac.at

Most hereditary periodic fever syndromes known today have their onset in the first year of life. Only two, namely Familial Mediterranean Fever (FMF) and TNF-Receptor Associated Periodic Syndrome (TRAPS) occur later, with most patients having become symptomatic by their twentieth birthday. Therefore this review will concentrate on FMF and TRAPS, the latter being a very rare disease, while the former has become somewhat more common in mid-Europe as a result of migration.

Activity of eosinophils and immunoglobulin E concentration in the peritoneal fluid of women with endometriosis.

Eidukaite A(1), Tamosiunas V.

Author information:

(1)Department of Molecular Immunology, Institute of Immunology, Vilnius, Lithuania. elza@takas.lt

Autoinflammatory phenomena, including autoantibody production and atopy, have been regarded as associated with endometriosis. The present study investigates the activity of eosinophils and the distribution of immunoglobulin E concentrations in the peritoneal fluid of women with early endometriosis. The study group consisted of 30 patients with laparoscopically diagnosed early endometriosis. The healthy control group consisted of 18 females with no evident changes in the abdominal cavity and no endometrial foci. Concentrations of immunoglobulin E in serum and peritoneal blood were determined by enzyme

immunoassay. The activity of eosinophils was estimated according to the expression of the early activation molecule CD69 by the flow cytometry method. The concentrations of immunoglobulin E in the peripheral blood and peritoneal fluid were similar in both groups. However, the count of CD69+ eosinophils was higher in the peritoneal fluid of women with endometriosis. The results indicate that activated eosinophils accumulate in the peritoneal fluid in early endometriosis and can play a significant role in the pathogenesis of the disease.

Dominant mutations in the CIAS1 gene cause a spectrum of autoinflammatory diseases such as familial cold autoinflammatory syndrome, FCAS, which is characterized by episodes of urticaria, arthralgia, fever and conjunctivitis after generalized exposure to cold. We here describe patients of two German families with the 592G-->A, V198M mutation, which has been described to induce FCAS before. However, in our patients the clinical phenotype was very different from this disease. They never had urticaria, cold induced fever or conjunctivitis; instead the following symptoms occurred: Very regular periodic fever, irregular severe febrile episodes, relatively mild arthralgia, dry cough, cardiomyopathy, nephropathy and euthyroid thyroiditis all being reversible. We conclude that the clinical phenotype associated with mutations in the CIAS1 gene is much broader than assumed before.

Author information:

(1)Rheumaklinik Bad Bramstedt, Poliklinik für Rheumatologie, Universitätsklinikum Schleswig-Holstein, Campus Lübeck. lamprecht@rheuma-zentrum.de

Familial Mediterranean fever (FMF), hyperimmunoglobulinemia D periodic fever syndrome (HIDS), and tumor necrosis factor receptor-associated periodic syndrome (TRAPS) are hereditary periodic fever syndromes. FMF is caused by mutations in the Mediterranean fever gene, HIDS by mutations in the mevalonat-kinase gene, and TRAPS by mutations in the TNF-receptor superfamily 1A gene. Impaired function of the encoded proteins, i.e. pyrin in FMF, mevalonat-kinase in HIDS, and the p55 TNF-receptor in TRAPS, induces a dysregulated cytokine balance. Clinical manifestations are relapsing fever, serositis, arthralgia, myalgia, and miscellaneous forms of rash. The diagnosis is made through molecular genetic analysis of mutations of the MEFV-gene (FMF), MVK-gene (HIDS), or TNFRSF1A-gene

(TRAPS). Colchicine is the therapy of choice in FMF. HIDS is treated symptomatically. Impaired TNF-alpha regulation in TRAPS can be treated with etanercept.

Author information:

(1)Office of the Clinical Director, National Institute of Arthritis and Musculoskeletal and Skin Diseases, National Institutes of Health, Department of Health and Human Services, Bethesda, USA.

Interleukin-6 (IL-6) is a pleiotropic cytokine with a wide range of biological activities that plays an important role in immune regulation and inflammation. Among other actions, it induces terminal differentiation of B lymphocytes into antibody-forming cells and the differentiation of T cells into effector cells. IL-6 also has multiple potent proinflammatory effects. An association between IL-6 and lupus was demonstrated in murine models of SLE and blocking IL-6 improved lupus in all models tested. Data from several studies suggest that IL-6 plays a critical role in the B cell hyperactivity and immunopathology of human SLE, and may have a direct role in mediating tissue damage. Based on these data, we propose that blocking the effect of IL-6 in humans may improve lupus by interacting with the autoinflammatory process both systemically and locally.

The genetic background of tumour necrosis factor receptor-associated periodic

syndrome and other systemic autoinflammatory disorders.

Stjernberg-Salmela S(1), Ranki A, Karenko L, Pettersson T.

Author information:

(1)Department of Dermatology, Helsinki University Central Hospital, Helsinki, Finland.

Systemic autoinflammatory disorders are hereditary diseases with symptoms of acute inflammation and a rise in serum acute phase proteins as a consequence, but with no signs of autoimmunity. By the end of the 1990s, four types of hereditary periodic fever had been described in the medical literature: familial Mediterranean fever, hyperimmunoglobulinemia D with periodic fever syndrome (HIDS), tumour necrosis factor receptor-associated periodic fever syndrome (TRAPS) and Muckle-Wells syndrome. Since then, the number of diseases classified as systemic autoinflammatory disorders has increased to eight. In patients of Nordic descent, cases of HIDS and TRAPS have been reported. We provide an overview of the genetic background and main clinical aspects of the different autoinflammatory disorders, with an emphasis on TRAPS.

**OBJECTIVE:** To describe biochemical findings and the spectrum of mevalonate kinase (MVK) gene mutations as well as an associated TNFRSF1A low-penetrance variant in a series of patients with clinical features of the hyperimmunoglobulinemia D with periodic fever syndrome (HIDS).

**METHODS:** The MVK gene was sequenced in 8 children and 1 adult (including 2 siblings) fulfilling the clinical criteria for HIDS. In addition, sequencing of exons 2, 3, 4, and 6 of the TNFRSF1A gene was performed in patients with only one or no MVK mutation. Mevalonate kinase (MK) enzyme activity in leukocytes and renal excretion of mevalonic acid were also measured.

**RESULTS:** Mutations in the coding region of the MVK gene were detected in 6 patients, and the most common mutation was V377I. Among these patients were 2 novel mutations, both of which were located in exon 6. These novel mutations resulted in the substitution of tryptophan (TGG) by a stop codon (TGA) at amino acid position 188 (W188X) and in the exchange of valine (GTG) for alanine (GCG) at amino acid position 203 (V203A). In 1 patient, a combination of one MVK (V377I) mutation and one TNFRSF1A (R92Q) mutation was present. The patient's clinical phenotype resembled a mixture of variant-type HIDS and tumor necrosis factor receptor-associated periodic syndrome (TRAPS). Her IgD values varied between normal and slightly increased, and the MK activity was in the low-normal range, while urinary mevalonate concentrations were always normal.

**CONCLUSION:** The genotype findings indicate that a relatively small number of genes may be involved in the clinical manifestation of HIDS, with low-penetrance TNFRSF1A variants possibly influencing the HIDS phenotype or MVK mutations contributing to TRAPS.

Familial Mediterranean fever (MFF) is an autosomic recessive, inherited inflammatory disease principally seen in persons from the Mediterranean area. Clinical findings include fever, abdominal pain, and pleuritis. The most severe complication of MFF is renal amyloidosis, manifested as nephrotic syndrome, which evolves into chronic renal failure. In this study, we described clinical findings, evolution, and response to treatment in 52 patients diagnosed with MFF living in Mexico City in whom the most important clinical features were fever and abdominal pain. Differing from previous reported series of patients from the Mediterranean area, patient developed renal amyloidosis during the 20-year follow-up, which suggests that an environmental factor might have a significant influence in development of renal amyloidosis.

Influence of Serum Amyloid A (SAA1) and SAA2 gene polymorphisms on renal amyloidosis, and on SAA/C-reactive protein values in patients with familial mediterranean fever in the Turkish population.

Bakkaloglu A(1), Duzova A, Ozen S, Balci B, Besbas N, Topaloglu R, Ozaltin F, Yilmaz E.

Author information:

(1)Department of Pediatrics, Hacettepe University Faculty of Medicine, Ankara, Turkey. aysin@hacettepe.edu.tr

**OBJECTIVE:** To evaluate the effect of serum amyloid A (SAA) 1 and SAA2 gene polymorphisms on SAA levels and renal amyloidosis in Turkish patients with familial Mediterranean fever (FMF).

**METHODS:** SAA1 and SAA2 gene polymorphisms and SAA levels were determined in 74 patients with FMF (39 female, 35 male; median age 11.5 yrs, range 1.0-23.0). All patients were on colchicine therapy. SAA1 and SAA2 gene polymorphisms were

analyzed using polymerase chain reaction restriction fragment length polymorphism (PCR-RFLP). SAA and C-reactive protein (CRP) values were measured and SAA/CRP values were calculated.

**RESULTS:** The median SAA level was 75 ng/ml (range 10.2-1500). SAA1 gene polymorphisms were: a/a genotype in 23 patients (31.1%), a/beta genotype in 30 patients (40.5%), a/g genotype in one patient (1.4 %), beta/beta genotype in 14 patients (18.9%), beta/g genotype in 5 patients (6.8 %), and g/g genotype in one patient (1.4%). Of the 23 patients who had a/a genotype for the SAA1 polymorphism, 7 patients had developed renal amyloidosis (30.4%) compared to only one patient without this genotype (1/51; 2.0%);  $p < 0.001$ . SAA2 had no effect on renal amyloidosis. SAA1 and SAA2 genotypes had no significant effect on SAA levels. SAA/CRP values were significantly lower in patients with the SAA1a/a genotype, compared to other SAA1 genotypes: 0.16 (0.025-1.96) versus 0.23 (0.012-28.20),  $p < 0.05$ .

**CONCLUSION:** SAA1a/a genotype is one genetic factor that confers a significant risk for amyloidosis in the Turkish FMF population. Neither the SAA1 nor SAA2 genotypes had a significant effect on SAA level.

E148Q/M694I mutation in 3 Japanese patients with familial Mediterranean fever.

Kotone-Miyahara Y(1), Takaori-Kondo A, Fukunaga K, Goto M, Hayashino Y, Miki M, Takayama H, Sasada M, Uchiyama T.

Author information:

(1)Department of Hematology and Oncology, Graduate School of Medicine, Kyoto University, 54 Shogoin-Kawaracho, Sakyo-ku, Kyoto 606-8507, Japan.

We describe 3 unrelated Japanese patients with familial Mediterranean fever (FMF) due to a compound heterozygous E148Q/M694I mutation in the MEFV gene. The first patient is a 38-year-old man who also has chronic myelogenous leukemia (CML). Because genomic DNA analysis of the patient's nail revealed the E148Q/M694I mutation, we concluded that the individual mutations were obtained congenitally. Interferon alpha therapy was effective against not only the CML but also the FMF.

The second patient is a 42-year-old man with consanguineous parents and a 14-year history of recurrent lower abdominal and back pain associated with fever. He successfully responded to colchicine treatment. The third patient is a 23-year-old woman who has a family history of FMF and since the age of 11 years has had recurrent chest and abdominal pain with fever. The onset of FMF was at an early age in this case, in contrast with the late onset of the disease in the first 2 cases. This patient's mother also has a heterozygous M694I mutation and experienced the same symptoms until 30 years of age. Our data suggest that it should be recognized that there are more FMF patients in Japan than previously expected and that the frequency of the E148Q/M694I mutation may be significant in Japanese FMF patients.

The aim of this study was to evaluate bone mineral content (BMC), serum and urinary bone turnover parameters in patients with familial Mediterranean fever (FMF), an autosomal recessive disease characterized by recurrent episodes of inflammation of serous membranes. Demographic characteristics and MEFV mutations were defined in 48 children diagnosed with FMF (23 F, 25 M; median age 7.0 years (3.0-10.0)). We evaluated the blood counts, acute-phase proteins and serum and urinary bone turnover parameters during attack-free periods. The BMC and BA (bone area) of vertebrae L1-L4 were measured by DEXA. Thirty-eight age-, sex- and ethnicity-matched healthy children constituted the control group. Mean L1-L4 BMC in Group I (patients with two mutations) and II (patients with no or single mutations) were 15.49 $\pm$ 5.99 g and 15.68 $\pm$ 4.89 g, respectively, both significantly lower than the mean L1-L4 BMC of control patients, which was

19.59+/-6.7 g ( $p<0.05$ ). Mean L1-L4 BMD in Group I, Group II and the control group were 0.466+/-0.066 g/cm<sup>2</sup>, 0.487+/-0.085 g/cm<sup>2</sup> and 0.513+/-0.079 g/cm<sup>2</sup>, respectively. Mean z-scores in Group I, Group II and the control group were -1.87+/-0.74, -1.55+/-0.92 and -1.39+/-0.84, respectively. Mean L1-L4 BMD and z-score of Group I were lower than in the control group ( $p<0.05$ ). ESR and SAA (serum amyloid A) levels were higher in Group I patients: 28.3+/-14.5 mm/h and 350+/-62 mg/l in Group I; and 20.5+/-11.7 mm/h and 190+/-68 mg/l in Group II, respectively. In conclusion, FMF patients had lower BMC, BMD and z-scores than a control group. We suggest that decreased BMD, BMC and z-score in FMF patients may be secondary to subclinical inflammation.

Inflammatory caspases: linking an intracellular innate immune system to autoinflammatory diseases.

Martinon F(1), Tschopp J.

Author information:

(1)Department of Biochemistry, University of Lausanne, Chemin des Boveresses 155, CH-1066 Epalinges, Switzerland.

Caspases not only play an essential role during apoptotic cell death, but a subfamily of them-the inflammatory caspases-are associated with immune responses to microbial pathogens. Activation of inflammatory caspases, such as caspase-1 and caspase-5, occurs upon assembly of an intracellular complex, designated the inflammasome. This results in the cleavage and activation of the proinflammatory cytokines IL-1 $\beta$  and IL-18. Mutations in one of the scaffold proteins of the inflammasome, NALP3/Cryopyrin, are associated with autoinflammatory disorders underscoring the importance of regulating inflammatory caspase activation.

Familial Mediterranean fever (FMF) is an autosomal recessive disease characterized by recurrent self-limiting attacks of joint, chest and abdominal associated with fever. We present an unusual case of FMF with prolonged arthritis and amyloidosis. Familial Mediterranean fever should be considered in the differential diagnosis of prolonged hip pain, even in the absence of symptoms or signs of FMF.

Recent technological advances, such as DNA chip devices that allow automated, high-throughput genotyping, promise to considerably improve the detection capability of single-nucleotide polymorphisms (SNPs) in clinically relevant genes. We used the NanoChip(R) Molecular Biology Workstation (Nanogen, [www.nanogen.com](http://www.nanogen.com)) and recently introduced microelectronic array technology to develop a detection method for the more frequent mutations involved in familial Mediterranean fever (FMF), an autosomal recessive disease that affects several ethnic groups in the Mediterranean population, whose early diagnosis is crucial if severe complications are to be prevented. We adapted the previously described Nanogen procedures to FMF mutation analysis, introducing modifications that notably improve the technique. First, as the original procedure makes use of costly dye-tagged reporter sequences, we devised a universal reporter strategy, which was first evaluated and validated on the robust, previously established factor V Leiden and factor II (prothrombin) NanoChip diagnostic assays. FMF (MEFV), factor V (F5), and factor II (F2) genotypes identified using this improved system were totally concordant with results of other genotyping methods (denaturing gradient gel electrophoresis [DGGE], SSCP, and RFLP analysis).

Second, we showed that the target sequences loaded on the NanoChip cartridges can be rehybridized several times in a highly reproducible manner, allowing sequential analysis of mutations. Thus, we devised a strategy that allows us to monitor the possible interference of additional mutations or SNPs at probe or stabilizer sequences. Finally, a comparative cost per sample analysis demonstrates that the accurate and reproducible FMF mutation detection assay we developed can be readily implemented in the clinical laboratory setting at reasonable expense.

Author information:

(1)Unité de Génétique Médicale, Faculté de Médecine, Université Saint-Joseph, Beirut, Lebanon.

Familial Mediterranean fever (FMF) is an autosomal recessive inflammatory disorder predominantly affecting people living in or originating from areas around the Mediterranean Sea. It is caused by a number of mutations within the MEFV gene, which differently affect the severity of the disease phenotype. Because patients usually present with rather nonspecific clinical symptoms, MEFV genotyping can confirm and refine FMF diagnosis and improve treatment of affected individuals. We have performed a method comparison study on 100 Lebanese FMF patients to evaluate the potential of a rapid reverse-hybridization teststrip-based assay (FMF StripAssay) to serve as a first-line screening test for our population. When results obtained by reverse-hybridization and DNA sequencing of exons 2, 3, 5, and 10 were compared, the FMF StripAssay identified 144/149 mutations, and correctly typed all 12 different MEFV mutations covered. We conclude that reverse-hybridization provides a very rapid, accurate and

easy-to-perform screening method, and, in combination with more comprehensive diagnostic methods, represents an efficient strategy for FMF genotyping.

Amyloidosis remains a severe potential complication of many chronic inflammatory disorders, foremost of rheumatoid arthritis. It is not exactly known why some patients develop a progressive amyloidosis while others do not, although latent deposits may be present. It is likely that more potent anti-inflammatory drugs recently used in rheumatoid arthritis have led to a decrease of amyloid-associated (AA) amyloidosis. However, overt amyloidosis remains a severe complication of some chronic inflammatory disorders and it has a poor prognosis. Hereditary fevers are a group of diseases characterized by intermittent bouts of clinical inflammation with focal organ involvement, mainly abdomen, musculoskeletal system and skin. The most frequent is familial Mediterranean fever which affects patients of Mediterranean descent all over the world. Three other types have been recently characterized clinically as well as genetically. A

thorough diagnosis is warranted, as clinical and therapeutic management is specific for each of these diseases.

Association of FMF-related (MEFV) point mutations with secondary and FMF amyloidosis.

Atagunduz MP(1), Tuglular S, Kantarci G, Akoglu E, Direskeneli H.

Author information:

(1)Department of Rheumatology, Marmara University School of Medicine, Istanbul, Turkey.

**BACKGROUND:** Familial Mediterranean fever (FMF) is the major cause of AA amyloidosis in Turkey. M694V mutation in MEFV gene was suggested to be associated with severe clinical features and amyloidosis of FMF.

**METHODS:** In this study, the frequencies of three FMF-related MEFV mutations (M694V, M680I and V726A) were investigated in FMF patients with (AA-FMF, n = 37) and without amyloidosis (non-AA-FMF, n = 35), in patients with secondary amyloidosis related to non-FMF inflammatory conditions (S-AA, n = 19) and in a non-inflammatory control group (n = 185) by molecular genetic studies using polymerase chain reaction with the ARMS (amplification refractory mutation system) method.

**RESULTS:** Both AA and non-AA-FMF patients had significantly higher MEFV mutations compared to non-inflammatory controls (81 and 62.7% respectively vs. 4.2%,  $p = 0.0001$ ). AA-FMF patients carried significantly more MEFV mutations than non-AA-FMF patients ( $p = 0.01$ ). M694V was the most common mutation in both FMF groups (63.5 vs. 51.4%), however allele frequency ( $p = 0.17$ ) and the number of homozygous patients for this mutation did not differ between the groups ( $p = 0.77$ ). Although lower compared to FMF patients, S-AA patients also had a significantly higher incidence of MEFV mutations than non-inflammatory controls (21 vs. 4.2%) ( $p = 0.0002$ ). M694V was the only MEFV mutation in this group.

**CONCLUSION:** MEFV mutations are found to be increased both in FMF and non-FMF associated secondary amyloidosis in our study; however, no clear association

between M694V and amyloidosis is observed, except in the non-FMF group. Our results suggest that MEVF mutations may also serve as a severity marker for other inflammatory conditions.

Simvastatin treatment for inflammatory attacks of the hyperimmunoglobulinemia D and periodic fever syndrome.

Simon A(1), Drewe E, van der Meer JW, Powell RJ, Kelley RI, Stalenhoef AF, Drenth JP.

Author information:

(1)Department of General Internal Medicine, University Medical Center St Radboud, Nijmegen, The Netherlands.

Hyperimmunoglobulinemia D (hyper-IgD) and periodic fever syndrome, a hereditary autoinflammatory syndrome, is characterized by lifelong recurrent episodes of fever and inflammation. No effective treatment is known. It is caused by a defect of mevalonate kinase, an enzyme that follows 3'-hydroxy-3'-methylglutaryl-coenzyme A (HMG-CoA) reductase in the isoprenoid pathway. We wanted to test the hypothesis that inhibition of HMG-CoA reductase would ameliorate the inflammatory attacks. Six patients with hyper-IgD syndrome and proven mevalonate kinase deficiency were followed up for 2 treatment periods with either simvastatin, 80 mg/d, or placebo for 24 weeks, separated by a 4-week washout period in a double-blind fashion. Simvastatin resulted in a drop in urinary mevalonic acid concentration in all patients and decreased the number of febrile days in 5 of 6 patients. No side effects were observed. These data offer preliminary evidence for the hypothesis that simvastatin may improve inflammatory attacks in the hyper-IgD syndrome. This highlights the anti-inflammatory properties of HMG-CoA reductase inhibition.

We investigated the hypothesis that low-penetrance mutations in genes (TNFRSF1A, MEFV and NALP3/CIAS1) associated with hereditary periodic fever syndromes (HPFs) might be risk factors for AA amyloidosis among patients with chronic inflammatory disorders, including rheumatoid arthritis (RA), juvenile idiopathic arthritis (JIA), Crohn's disease, undiagnosed recurrent fevers and HPFs themselves. Four of 67 patients with RA plus amyloidosis had MEFV variants compared with none of 34 RA patients without amyloid (P value=0.03). The E148Q variant of MEFV was present in two of the three patients with TNF receptor-associated periodic syndrome (TRAPS) complicated by amyloid in two separate multiplex TRAPS families containing 5 and 16 affected members respectively, and the single patient with Muckle-Wells syndrome who had amyloidosis was homozygous for this variant. The R92Q variant of TNFRSF1A was present in two of 61 JIA patients with amyloidosis, and none of 31 nonamyloidotic JIA patients. No HPF gene mutations were found in 130 healthy control subjects. Although allelic variants in HPFs genes are not major susceptibility factors for AA amyloidosis in chronic inflammatory disease, low-penetrance variants of MEFV and TNFRSF1A may have clinically significant proinflammatory effects.

Identifying mutations in autoinflammatory diseases: towards novel genetic tests and therapies?

Touitou I(1), Notarnicola C, Grandemange S.

Author information:

(1)Laboratoire de Génétique Moléculaire et Chromosomique, Hôpital Arnaud de Villeneuve, Montpellier, France.

Autoinflammatory diseases are defined as illnesses caused by primary dysfunction of the innate immune system. This new concept includes a broad number of disorders, but the spotlight has been focused for the past two years on periodic fevers (familial Mediterranean fever [FMF]; mevalonate kinase deficiency [MVK]; tumor necrosis factor [TNF] receptor-associated periodic syndrome [TRAPS]; cryopyrin-associated periodic syndrome [CAPS]), Crohn's disease and Blau

syndrome, thanks to the recent understanding of their molecular basis. Indeed, until recently, these conditions were defined only by phenotypical features, the main ones being recurrent attacks of fever, abdominal pain, arthritis, and cutaneous signs, which sometimes overlap, obscuring diagnosis. The search for distinguishing signs such as periorbital edema in TRAPS, and the use of specific functional tests where available, are valuable. Needless to say, molecular screening of the causative genes has dramatically improved patient quality-of-life by providing early and accurate diagnosis, subsequently allowing for the appropriate treatment. Some patients, however, remain hard to manage despite the advent of new genetic tests, and/or due to the lack of effective treatment. The original clinical link between the aforementioned diseases can now be confirmed by a molecular one, following the exciting discovery that most of the altered proteins are related to the death domain fold (DDF) superfamily involved in inflammation and apoptosis. These molecules mediate the regulation of nuclear factor-kappa B (NF-kappa B) activation, cell apoptosis, and interleukin-1 beta secretion through cross-regulated and, sometimes, common signaling pathways. Knowledge of the defective step in autoinflammation has already led to the elucidation of the mechanisms of action of existing drugs and may allow the development of new therapies.

Familial Mediterranean fever with massive recurrent ascites: a case report.

Cekin AH(1), Dalbudak N, Künefecı G, Gür G, Boyacıoğlu S.

Author information:

(1)Başkent University Faculty of Medicine, Department of Gastroenterology, Ankara, Turkey.

A 35-year-old woman had a history of recurrent massive ascites for 12 years. She had been examined to identify the etiology of ascites and was placed on antituberculous and subsequently steroid treatment at another center before admission to our hospital for fever, abdominal distention and abdominal pain. She had massive ascites with serum-ascites albumin gradient of 1.0 g/dl. We could not

find any cause for ascites including tuberculosis. We thus performed exploratory laparotomy of the abdomen. There was no evidence of tuberculosis, peritoneal diseases or of any gynecological reason for ascites. Biopsies taken from the peritoneum revealed fibrinous peritonitis. Since she had a history of attacks of abdominal pain in her childhood, she was screened for mutations causing familial Mediterranean fever and was found to be homozygous for M694V. After definitive diagnosis of familial Mediterranean fever, she was put on colchicine treatment and relief of symptoms and reduction in ascites were seen on follow-up. To our knowledge this is the first documented case of massive ascites due to familial Mediterranean fever.

A patient with hyper-IgD syndrome in Antalya, Turkey.

Coban E(1), Terzioğlu E.

Author information:

(1)Department of Internal Medicine, Faculty of Medicine, Akdeniz University, Arapsuyu, 07070, Antalya, Turkey. ecoban@akdeniz.edu.tr

Hyper-IgD syndrome is a periodic fever syndrome that presents with recurrent episodes of high fever accompanied by lymphadenopathy, abdominal distress,

arthralgias or arthritis, headache and skin lesions. The diagnosis is based on clinical grounds and elevated serum IgD levels (>100 U/ml), but requires a high index of suspicion, and a mevalonate kinase enzyme defect. Most patients are from western Europe but there are others identified in other countries. We describe a 17-year-old patient who had been followed with the diagnosis of familial Mediterranean fever for a long time before she was diagnosed with hyper-IgD syndrome.

[Autoinflammatory disorders: a new concept in hereditary periodic fever syndromes].

[Article in Spanish]

Horcada Rubio ML(1), Delgado Beltrán C, Armas Ramírez C.

Author information:

(1)Servicio de Reumatología, Hospital Clínico Universitario Lozano Blesa, Zaragoza.

At last year the great scientific advances in genetics and molecular biology have

led to a bigger knowledge about we nowadays call "Autoinflammatory syndromes", characterized by recurrent inflammatory episodes genetically determined and not mediated by autoimmunity. In this group, they are included the hereditary periodic fever syndromes: familial mediterranean fever (FMF), hyper Ig-D syndrome (HIDS), TNF-receptor-associated periodic syndrome (TRAPS), Muckle-Wells syndrome (MWS), familial cold autoinflammatory syndrome (FCAS), CINCA syndrome. The past 6 year have witnessed the identification of genes causing these diseases. Some of these genes encode proteins with a common domain (PYRIN domain). These protein are part of regulatory pathway of inflammation and apoptosis. The purpose of this article, is to carry out review of the genetic, clinical, molecular and rheumatologic aspect of these syndromes, in part unknown. Although they are not common, they are not absent in our diary clinical practise. Their study and research we will be able to obtain new knowledge that lead us to solve the complex inflammatory process.

(1)Department of Biochemistry, University of Lausanne, Chemin des Boveresses 155, CH-1066 Epalinges, Switzerland.

Comment in

Immunity. 2004 Mar;20(3):243-4.

Mutations within the NALP3/cryopyrin/CIAS1 gene are responsible for three autoinflammatory disorders: Muckle-Wells syndrome, familial cold autoinflammatory syndrome, and CINCA. The NALP3 protein is homologous to NALP1, which is a component of the inflammasome, a molecular platform that activates the proinflammatory caspases-1 and -5. NALP3 (and other members of the NALP family) lacks the C-terminal, CARD-containing sequence of NALP1, and its role in caspase

activation is unclear. Here, we report that NALP2 and NALP3 associate with ASC, the CARD-containing protein Cardinal, and caspase-1 (but not caspase-5), thereby forming an inflammasome with high proIL-1 $\beta$ -processing activity. Macrophages from Muckle-Wells patients spontaneously secrete active IL-1 $\beta$ . Increased inflammasome activity is therefore likely to be the molecular basis of the symptoms associated with NALP3-dependent autoinflammatory disorders.

Bafounta ML(1), Doumat-Batch F, Vasseur E, Staroz F, Clerici T, Saiag P.

Author information:

(1)Service de Dermatologie, CHU Ambroise Paré, UFR Paris-Ouest, Boulogne.

**BACKGROUND:** Familial mediterranean fever belongs to the periodic fever syndromes. During the attacks, fever is associated with abdominal pain, arthralgia, or both. Cutaneous involvement occurs in 7 to 46 p. 100 of cases and mainly consists in erysipelas-like erythema. We report on three patients treated for familial Mediterranean fever who developed unusual cutaneous lesions.

**OBSERVATIONS:** All the patients had long past history of familial mediterranean fever without cutaneous involvement except, for the third patient who had pseudo-erysipela. The first patient had diffuse Sweet's syndrome-like lesions, the second developed long lasting panniculitis of the thigh and the third had a persistent and lichenified erysipela-like plaque. In two patients, skin histology revealed an inflammatory infiltrate with neutrophils. In all cases, an increase in the colchicine dose led to the rapid resolution of the lesions.

**DISCUSSION:** In our 3 case reports, the lesions were particular because of their atypical clinical appearance, their long duration, and they differed from the usual pseudo-erysipela aspect. Histopathologically, the lesions were similar to pseudo-erysipela, which has led some authors to hypothesize that cutaneous lesions of familial mediterranean fever belong to neutrophilic dermatoses. This hypothesis is supported by the response to the increase in colchicine doses.

The west side story: MEFV haplotype in Spanish FMF patients and controls, and evidence of high LD and a recombination "hot-spot" at the MEFV locus.

Mutations at the MEFV gene cause, with various degrees of penetrance, familial

Mediterranean fever (FMF). This disease is more prevalent in the Middle East than elsewhere, and most studies have focused on those populations. However, FMF occurs also in the Western Mediterranean and these populations should be taken into account for a complete view of FMF. We have analyzed intragenic MEFV SNPs in Spanish and Chueta (descendants of converted Jews) FMF patients and controls, and this constitutes the first systematic survey of normal MEFV SNP haplotype structure and variability. Our findings have allowed us to systematize the nomenclature of MEFV haplotypes and show that there is strong linkage disequilibrium (LD) at the MEFV locus and an intragenic recombination hot spot. The high local LD, regardless the recombination hot spot, is responsible for the limited diversity of the MEFV control haplotypes found in the Spanish population and it suggests that it may be a common feature to all Mediterranean populations. The MEFV mutation spectrum in Spain is quite diverse, and similar to those of France and Italy. On the contrary, the Chueta spectrum was poorer and closer to that of North African Jews, suggesting a direct connection with the Jewish diaspora.

Author information:

(1)Department of Pathology and Comprehensive Cancer Center, The University of Michigan Medical School, Ann Arbor, Michigan 48109, USA.

Several autoinflammatory disorders are associated with missense mutations within the nucleotide-binding oligomerization domain of cryopyrin. The mechanism by which cryopyrin mutations cause inflammatory disease remains elusive. To understand the molecular bases of these diseases, we generated constructs to express three common cryopyrin disease-associated mutations, R260W, D303N, and E637G, and compared their activity with that of the wild-type protein. All cryopyrin mutant proteins tested were found to induce potent NF-kappaB activity when compared with the wild-type protein. This activation was dependent on the expression of ASC, an adaptor protein previously suggested to mediate cryopyrin signaling. When the disease-associated mutants were expressed in monocytic THP-1 cells (which express endogenous ASC), each induced spontaneous IL-1beta secretion, whereas wild-type protein did not. In the absence of stimuli, wild-type cryopyrin was unable to bind to ASC, whereas the three mutants coimmunoprecipitated with ASC, suggesting a mechanism involved in the constitutive activation of mutant proteins. The induction of cryopyrin activity by enforced oligomerization in THP-1 cells resulted in ASC binding and the secretion of IL-1beta, an effect that was abolished by the inhibition of ASC expression with small interfering RNAs. Thus, cryopyrin-mediated IL-1beta secretion requires ASC in monocytic cells. Further, these results indicate that cryopyrin disease-associated mutants are constitutively active and able to induce NF-kappaB activation and IL-1beta secretion at least in part by an increased ability to interact with ASC.

**BACKGROUND:** The MEFV gene is responsible for familial Mediterranean fever (FMF). Several disease associated mutations have been identified. The range of genetic variation in MEFV in Greek patients has not been determined.

**OBJECTIVE:** To describe a method that facilitates the routine screening of the entire coding sequence of MEFV (excluding exon 1).

**METHODS:** The non-isotopic RNase cleavage assay (NIRCA) was optimised and used as a first step screening method to screen exons 2 to 10 of MEFV. Exons 2 and 10 were analysed separately at DNA level, while exons 3 to 9 were analysed together at cDNA level. The sample group consisted of 26 FMF patients diagnosed using established clinical criteria, six asymptomatic relatives, 12 patients with atypical clinical manifestations, nine patients suffering from various inflammatory diseases, and three normal individuals. All were analysed by NIRCA for mutations in the MEFV gene and direct sequencing was applied subsequently to confirm the results.

**RESULTS:** MEFV mutations were identified in 25 of 26 typical FMF patients and in two of 12 patients with atypical manifestations. NIRCA results were in concordance with sequencing findings in all sequences analysed, suggesting that the method is highly reliable in this disease. Sixteen alterations of MEFV were identified (eight missense mutations and eight single nucleotide polymorphisms).

**CONCLUSIONS:** NIRCA can be used for rapid screening of the coding sequence of the MEFV gene in patients suspected of suffering from FMF.

Amyloidosis in familial Mediterranean fever patients: correlation with MEFV genotype and SAA1 and MICA polymorphisms effects.

Medlej-Hashim M(1), Delague V, Chouery E, Salem N, Rawashdeh M, Lefranc G, Loiselet J, Mégarbané A.

Author information:

(1)Unité de Génétique Médicale, Faculté de Médecine, Université Saint Joseph, Beirut, Lebanon. myrnahachem@hotmail.com

**BACKGROUND:** Familial mediterranean fever (FMF) is a recessively inherited disease characterized by recurrent crises of fever, abdominal, articular and/or thoracic pain. The most severe complication is the development of renal amyloidosis. Over 35 mutations have been discovered so far in the gene responsible for the disease, MEFV. This article aims at determining a correlation between the MEFV genotype and the occurrence of amyloidosis in FMF patients, in addition to the study of the modifying effects of the SAA1 (type 1 serum amyloid A protein) and MICA (Major Histocompatibility Complex (MHC) class-I-chain-related gene A) genes on this severe complication.

**METHODS:** Fourteen MEFV mutations were screened and the SAA1 and MICA polymorphisms tested in 30 FMF patients with amyloidosis and 40 FMF patients without amyloidosis.

**RESULTS:** The M694V and V726A allelic frequencies were, respectively, significantly higher and lower in the group with amyloidosis, compared to the control FMF group. The beta and gamma SAA1 alleles were more frequently encountered in the group without amyloidosis, whereas the alpha allele was significantly more observed in FMF patients with amyloidosis ( $p < 0.025$ ). All the MICA alleles were encountered in both patients' groups, but none of them was significantly associated with amyloidosis.

**CONCLUSIONS:** The results suggest a protective effect of the SAA1 beta and gamma alleles on the development of amyloidosis and show the absence of a MICA modifying effect on amyloidosis development. Testing these polymorphisms on a larger sample will lead to more definite conclusions.

Author information:

(1)Division of Pediatric Nephrology, University Children's Hospital, INF 150, 69120, Heidelberg, Germany.

Familial Mediterranean fever (FMF) is an autosomal recessive disorder characterized by recurrent and self-limited attacks of serosal inflammation with abdominal pain, chest pain, and arthritis usually accompanied by fever. Different vasculitides such as polyarteritis nodosa (PAN) and Henoch-Schönlein syndrome (HSS) may be associated with FMF. We report two sisters of a Turkish family with FMF who developed distinct vasculitides. The younger sister developed severe PAN with perirenal hematoma at the age of 13 years, the older sister presented with severe HSS and acute renal failure at the age of 19 years. Neither sister developed amyloidosis until the age of 30 years. This observation suggests that early events in the pathogenesis of PAN and HSS are generally quite similar.

**BACKGROUND:** To determine the surface expression of neutrophil beta2 integrin (CD11b/CD18) and L-selectin (LS) adhesion molecules in patients with familial Mediterranean fever (FMF) and to investigate the in vitro regulation of their expression in response to chemoattractant stimuli.

**METHODS:** Neutrophil surface expression of CD11b and LS molecules was analyzed by flow cytometry in anticoagulated whole blood drawn from FMF patients and normal controls, and the in vitro regulation of these molecules induced by the chemoattractant N-formyl-methionyl-leucyl-phenylalanine (FMLP) was assayed.

**RESULTS:** Patients during acute FMF attacks showed a statistically significant increased neutrophil surface CD11b compared with normal controls (mean fluorescence intensity: 22.8 +/- 13.7 vs 12.8 +/- 10.41, respectively; p = .03). There was no difference in LS expression between the groups. Neutrophils of FMF patients regulate CD11b and LS expression induced by chemoattractant (FMLP) stimulation to a degree similar to that in controls.

**CONCLUSIONS:** beta2 Integrin is up-regulated during an acute attack of FMF in dissociation with LS expression, suggesting a unique nonchemoattractant-mediated neutrophil activation.

Hereditary periodic fever syndromes are a group of diseases characterized by intermittent bouts of clinical inflammation with focal organ involvement, mainly of the abdomen, musculoskeletal system and skin. The most frequent is familial Mediterranean fever, which affects patients of Mediterranean descent all over the world. Three other types have recently been characterized clinically and genetically. A thorough diagnosis is warranted, as clinical and therapeutic management is specific for each of these diseases. The underlying mechanisms of these inflammatory diseases appear to be specific for each type, involving so far unknown proteins, and have already opened new avenues in our understanding of the inflammatory response.

**OBJECTIVES:** To identify the ethnic, clinical, genetic, and pharmacokinetic correlates of colchicine treatment failure in patients with familial Mediterranean fever (FMF).

**METHODS:** Fifty-nine FMF patients, unresponsive to a daily dose of  $> \text{or } = 2 \text{ mg}$  colchicine, were compared with 51 colchicine-responsive patients by clinical, demographic, and socioeconomic assessment, FMF gene (Mediterranean Fever [MEFV]) mutation and serum amyloid A1 (SAA1) gene polymorphism analysis, and plasma and white blood cell colchicine level determination.

**RESULTS:** Colchicine responders and nonresponders were comparable with respect to gender, age, duration and onset of the disease, and various demographic parameters. The 2 cohorts were found to carry mainly the M694V MEFV mutation and had a similar number of homozygotes or compound heterozygotes. Predominance of the alpha/beta alleles of SAA1 and comparable plasma and polymorphonuclear colchicine concentrations characterized both groups. Nonresponders were from lower socioeconomic backgrounds, had less education, and a more severe form of disease. A statistically significant 2-fold elevation of colchicine concentration in the mononuclear cells (MNC) of responders was found.

**CONCLUSIONS:** Colchicine treatment failure in FMF is associated with inadequate colchicine MNC concentration, probably resulting from a genetic defect unrelated to the underlying FMF.

Patterns of cardiovascular reactivity in disease diagnosis.

Naschitz JE(1), Rosner I, Rozenbaum M, Fields M, Isseroff H, Babich JP, Zuckerman E, Elias N, Yeshurun D, Naschitz S, Sabo E.

Author information:

(1)Departments of Internal Medicine A and Rheumatology, Bnai Zion Medical Center and Bruce Rappaport Faculty of Medicine, Technion-Israel Institute of Technology, Haifa, Israel. naschitz@tx.technion.ac.il

**BACKGROUND:** Aberrations of cardiovascular reactivity (CVR), an expression of autonomic function, occur in a number of clinical conditions, but lack specificity for a particular disorder. Recently, a CVR pattern particular to chronic fatigue syndrome was observed.

**AIM:** To assess whether specific CVR patterns can be described for other clinical conditions.

**METHODS:** Six groups of patients, matched for age and gender, were evaluated with a shortened head-up tilt test: patients with chronic fatigue syndrome (CFS) (n = 20), non-CFS fatigue (F) (n = 15), neurally-mediated syncope (SY) (n = 21), familial Mediterranean fever (FMF) (n = 17), psoriatic arthritis (PSOR) (n = 19) and healthy subjects (H) (n = 20). A 10-min supine phase was followed by recording 600 cardiac cycles on tilt (5-10 min). Beat-to-beat heart rate (HR) and pulse transit time (PTT) were measured. Results were analysed using conventional statistics, recurrence plot analysis and fractal analysis.

**RESULTS:** Multivariate analysis evaluated independent predictors of the CVR in each patient group vs. all other groups. Based on these predictors, equations were determined for a linear discriminant score (DS) for each group. The best sensitivities and specificities of the DS, consistent with disease-related phenotypes of CVR, were noted in the following groups: CFS, 90.0% and 60%; SY, 93.3% and 62.5%; FMF, 90.1% and 75.4%, respectively.

**DISCUSSION:** Pathological disturbances may alter cardiovascular reactivity. Our data support the existence of disease-related CVR phenotypes, with implications for pathogenesis and differential diagnosis.

Author information:

(1)Department of Pediatric Nephrology, Faculty of Medicine, Gazi University, Besevler, Ankara, Turkey. sevcan@gazi.edu.tr

We describe a 7-year-old boy with familial Mediterranean fever (FMF) complicated by polyarteritis nodosa (PAN) with distinct angiographic findings. On admission, he had abdominal pain, arthralgia, and severe fibromyalgia. During hospitalization, he displayed maculopapular eruptions, high blood pressure, gastrointestinal bleeding, and persistent constitutional symptoms mimicking a vasculitic process, most probably PAN. Renal angiography showed a perfusion defect compatible with a renal infarction secondary to a vasculitic process. He responded well to pulse methylprednisolone therapy with colchicine. We emphasize the rare association of FMF and PAN and the non-aneurysmal angiographic signs of PAN.

Arthritis Rheum. 2005 Jul;52(7):2226-7.

Arthritis Rheum. 2004 Nov;50(11):3738-9; author reply 3739-40.

OBJECTIVE: Mutations in the NALP3/CIAS1/PYPAF1 gene are associated with the autoinflammatory diseases Muckle-Wells syndrome (MWS), familial cold autoinflammatory syndrome (FCAS), and neonatal-onset multisystem inflammatory disease (NOMID), which is also known as chronic infantile neurologic, cutaneous, articular (CINCA) syndrome. Molecular studies suggest that NALP3 is involved in the processing of interleukin-1beta (IL-1beta), prompting us to investigate

whether IL-1 blockade may be therapeutic in patients with MWS.

**METHODS:** We reviewed the clinical features of 3 members of a family, all of whom had MWS associated with the NALP3 variant V200M (also designated V198M), and evaluated the response of their inflammatory disease to treatment with the recombinant human IL-1 receptor antagonist anakinra. The subjects kept a diary of symptoms and underwent fortnightly clinical and laboratory assessments, including measurement of the serum amyloid A protein concentration.

**RESULTS:** Each subject had fever, rashes, arthralgia, conjunctivitis, sensorineural deafness, and an intense acute-phase response characteristic of MWS. However, additional features were identified, including exacerbation of their disease by cold and neurologic manifestations, that have hitherto been described only in FCAS and NOMID, respectively. Clinical and serologic evidence of active inflammatory disease resolved rapidly and completely during treatment with anakinra.

**CONCLUSION:** The remarkable response of MWS to anakinra suggests that IL-1 $\beta$  has a fundamental role in the pathogenesis of inflammation associated with mutations in the NALP3 gene, and supports study of IL-1 inhibition in patients with NOMID/CINCA syndrome or FCAS. The clinical features of the various syndromes associated with mutations in the NALP3 gene may overlap to a greater extent than has previously been recognized.

**PURPOSE OF REVIEW:** To review the remarkable recent progress in our understanding of a range of inflammatory conditions in humans that until recently appeared unrelated. The term autoinflammatory disease has been proposed to describe a group of disorders characterized by attacks of seemingly unprovoked inflammation without significant levels of autoantibodies and autoreactive T cells.

**RECENT FINDINGS:** As the link between the innate immune response and disease susceptibility has become more apparent, some remarkable associations have emerged. The majority of hereditary periodic fevers are due to mutations in the pyrin and tumour necrosis factor receptor superfamilies of molecules, both of which are intimately involved in innate immunity. Pyrin/marenostrin protein is mutated in familial Mediterranean fever, while mutations in a related protein, cryopyrin, are associated with Muckle-Wells/familial cold urticaria and chronic infantile neurologic cutaneous and articular syndrome. Both of these proteins interact with the apoptotic speck-like protein involved in caspase-1 activation and regulation of nuclear factor kappa B transcription; furthermore cryopyrin contains regions of homology with the nucleotide-binding oligomerization domain 2 protein, which is associated with susceptibility to Crohn's disease. Variants in the leucine-rich repeat domain of nucleotide-binding oligomerization domain are found in approximately 20% of patients with Crohn's disease, depending on ethnic background, while mutations in the NACHT domain are associated with a rare dominant granulomatous disease called Blau syndrome.

**SUMMARY:** The study of autoinflammatory disease has progressed from genetics to definition of the functional defects in these patients. Although a direct association between defective innate immune responses to bacterial components and these diseases has not been formally established, much ongoing research is aimed towards confirmation of that hypothesis.

TMS1/ASC: the cancer connection.

McConnell BB(1), Vertino PM.

Author information:

(1)Department of Radiation Oncology and Winship Cancer Institute, Emory University School of Medicine, Atlanta, Georgia 30322, USA.

TMS1/ASC is a bipartite protein comprising two protein-protein interaction domains, a pyrin domain (PYD) and a caspase recruitment domain (CARD). Proteins containing these domains play pivotal roles in regulating apoptosis and immune response pathways, and mutations in a number of PYD- and CARD-containing proteins have been linked to autoinflammatory diseases and cancer. Indeed, one of the ways in which TMS1/ASC was identified was as a target of methylation-mediated silencing in breast cancer cells. This review discusses the mounting evidence supporting a correlation between the silencing of TMS1/ASC expression and cancer. In addition, it addresses the reported functions of TMS1/ASC that include apoptosis, activation of inflammatory caspases and regulation of NF-kappa B, and discusses the potential ways in which loss of TMS1/ASC contributes to carcinogenesis.

Pyrexia of unknown origin in children: a review of 102 patients from Turkey.

Ciftçi E(1), Ince E, Doğru U.

Author information:

(1)Department of Paediatric Infectious Diseases, University of Ankara Medical School, Ankara, Turkey. erginciftci@doctor.com

Pyrexia of unknown origin (PUO) has not been appropriately investigated in Turkish children and therefore a study was undertaken to determine the causes of PUO and to evaluate which clinical procedures are useful in establishing a diagnosis. A total of 102 children fitting the classical PUO criteria seen in our clinic between 1995 and 2002 were investigated retrospectively. Infections, collagen vascular disorders, malignancy and miscellaneous conditions constituted 44.2%, 6.8%, 11.7% and 24.5% of cases, respectively, while 12.8% of the cases remained undiagnosed. Enteric fever, brucellosis and respiratory tract infections were the most commonly encountered infections, whereas familial Mediterranean

fever was the commonest non-infectious disorder. Biopsy, aspiration, serology, bacteriology, radiology and observation of the clinical course were the most useful diagnostic procedures.

Benign cystic mesothelioma: a rare cause of ascites in a case with familial Mediterranean fever.

Curgunlu A(1), Karter Y, Tüfekci IB, Tunckale A, Karahasanoglu T.

Author information:

(1)Department of Internal Medicine, Cerrahpasa Medical Faculty, Istanbul University, Istanbul, Turkey. acurgunlu@hotmail.com

Benign cystic mesothelioma (BCM) is a rare neoplasm of the peritoneum, consisting of solitary or multiple cysts arising from mesothelial cells. Here we report a patient with a previous diagnosis of familial Mediterranean fever (FMF) presenting with abdominal distension and ascites which were found to be due to BCM. The co-existence of these two entities has not been reported previously. Ascites as the presenting feature of BMC is also a rare observation.

Colchicine-induced leukopenia in a patient with familial Mediterranean fever: the cause and a possible approach.

Ben-Chetrit E(1), Navon P.

Author information:

(1)Department of Medicine, Hadassah University Hospital, Jerusalem, POB12000, Israel. eldad@hadassah.org.il

A young patient with familial Mediterranean fever (FMF) developed leukopenia each time she took colchicine. However, when she discontinued the drug the white cell and the platelets counts increased but she experienced FMF attacks. Later it was found that the patient also had concomitant cytomegalovirus (CMV) infection. This

complex situation posed several diagnostic and therapeutic issues concerning the real cause for the leukopenia and the possible approach to take in such conditions. We propose that when an essential drug (such as colchicine for FMF) causes leukopenia, one should look for concurrent CMV or another viral infection. If there is no such infection, it is suggested that the mechanism leading to leukopenia be clarified. In the case of bone marrow suppression, colchicine should be continued with injections of G-CSF, whereas if the bone marrow is hypercellular it is suggested to use steroids and colchicine concomitantly.

MEFV mutations are increased in Behçet's disease (BD) and are associated with vascular involvement.

Atagunduz P(1), Ergun T, Direskeneli H.

Author information:

(1)Departments of Rheumatology and Dermatology, Marmara University School of Medicine, Istanbul, Turkey.

**OBJECTIVE:** A high prevalence of Behçet's disease (BD) among familial Mediterranean fever (FMF) patients has been described recently and a weak association of BD and certain MEFV gene mutations, originally linked to FMF, has been reported in an ethnically mixed population from France. We further investigated the presence of MEFV mutations in BD patients from Turkey, a country with a high prevalence of both disorders.

**METHODS:** The frequencies of three FMF-related MEFV mutations (M694V, M680I and V726A) were investigated in BD patients (n = 57) by molecular genetic studies using a polymerase chain reaction with the ARMS method. All patients fulfilled the International Study Group Criteria for the diagnosis of BD and patients with FMF-like symptoms or a chronic inflammatory disease were excluded.

**RESULTS:** Fifteen BD patients were found to carry one single MEFV mutation (26%), compared to 9.1% in the control group (p = 0.003, OR: 3.5, 95% CI: 1.6-7.6).

Among 20 BD patients with vascular involvement, 11 (55%) had MEFV mutations compared to 4 patients (11%) in the non-vascular group (p = 0.001, OR: 10, 95%

CI: 2.5-39.3). M694V was the dominant mutation in our study group (11 out of 15 patients with mutated alleles). Six out of 7 female patients with vascular involvement carried MEFV mutations in contrast to 5 out of 13 male patients (85.7% versus 38.4%,  $p = 0.07$ , OR: 0.1, 95% CI: 0.009-1.14). No association with other clinical manifestations was observed.

CONCLUSION: MEFV mutations, originally linked to FMF, may act as a genetic susceptibility factor for other inflammatory disorders such as vascular BD.

MEFV mutations in familial Mediterranean fever: association of M694V homozygosity with arthritis.

Olgun A(1), Akman S, Kurt I, Tuzun A, Kutluay T.

Author information:

(1)Department of Biochemistry and Clinical Biochemistry, Gülhane School of Medicine, Etlik-06018, Ankara, Turkey. aolgun@yahoo.com

OBJECTIVE: Familial Mediterranean fever (FMF) is an autosomal recessive recurrent polyserositis with a higher prevalence in some ethnic groups, including Turks. Mutations in the FMF gene (MEFV) were found associated with FMF. The aim of this study was to analyze MEFV gene mutations in FMF patients to gain insight into the mutation phenotype correlation.

OBJECTIVES: We analyzed the most frequent mutations (M680I, M694V, V726A, and E148Q) in a group of young male Turkish FMF patients using an amplification refractory mutation system and a commercial kit.

RESULTS: M694V mutation was detected in 80% of the patients. After making a strict diagnostic discrimination between arthralgia and arthritis, arthritis was present in 71% of homozygous and 29.4% of heterozygous patients for M694V mutation. Other mutations were not found to correlate with specific symptoms or findings.

CONCLUSION: The homozygosity of M694V mutation in the MEFV gene is associated with arthritis in FMF patients.

Decreased prevalence of atopy in paediatric patients with familial Mediterranean fever.

Sackesen C(1), Bakkaloglu A, Sekerel BE, Ozaltin F, Besbas N, Yilmaz E, Adalioglu G, Ozen S.

Author information:

(1)Hacettepe University Medical Faculty, Paediatric Allergy and Asthma Unit, Ankara, Turkey.

**BACKGROUND:** A number of inflammatory diseases, including familial Mediterranean fever (FMF), have been shown to be driven by a strongly dominated Th1 response, whereas the pathogenesis of atopic diseases is associated with a Th2 response.

**OBJECTIVE:** Because dominance of interferon gamma has the potential of inhibiting Th2 type responses-that is, development of allergic disorders, to investigate whether FMF, or mutations of the MEFV gene, have an effect on allergic diseases and atopy that are associated with an increased Th2 activity.

**METHOD:** Sixty children with FMF were questioned about allergic diseases such as asthma, allergic rhinitis, and atopic dermatitis, as were first degree relatives, using the ISAAC Study phase II questionnaire. The ISAAC Study phase II was performed in a similar ethnic group recruited from central Anatolia among 3041 children. The same skin prick test panel used for the ISAAC Study was used to investigate the presence of atopy in patients with FMF and included common allergens.

**RESULTS:** The prevalences of doctor diagnosed asthma, allergic rhinitis, and eczema were 3.3, 1.7, and 3.3%, respectively, in children with FMF, whereas the corresponding prevalences in the ISAAC study were 6.9, 8.2, and 2.2%, respectively. Only the prevalence of allergic rhinitis was significantly different between the two groups ( $p < 0.001$ ). The prevalence of atopy in these patients with FMF (4/60 (7%)) was significantly lower than in the children of the population based study (20.6%) ( $p < 0.001$ ).

**CONCLUSION:** Family Mediterranean fever seems to be protective against development of atopic sensitisation and allergic rhinitis.

Intravenous colchicine for treatment of patients with familial Mediterranean fever unresponsive to oral colchicine.

Lidar M(1), Kedem R, Langevitz P, Pras M, Livneh A.

Author information:

(1)Heller Institute of Medical Research, Sheba Medical Center, Tel-Hashomer 52621, Israel.

**OBJECTIVE:** To evaluate the efficacy and safety of weekly intravenous (IV) colchicine, in addition to oral colchicine therapy, in a subset of patients with familial Mediterranean fever (FMF) unresponsive to oral colchicine prophylaxis.

**METHODS:** Thirteen patients with frequent FMF attacks, despite oral doses of 2-3 mg/day colchicine, were treated with weekly IV injections of 1 mg colchicine for 12 weeks in an open-label pilot study. Patients were evaluated periodically for the number and severity of their attacks, use of analgesics, and erythrocyte sedimentation rate (ESR).

**RESULTS:** A 50% reduction in attack frequency and attack severity in at least one site was achieved by 10 and 6 of the 13 study patients, respectively ( $p < 0.001$  and  $p < 0.01$ ). Mean number of abdominal attacks declined significantly from  $4.2 \pm 3.0$  per patient at baseline to  $1.9 \pm 2.6$  attacks at the end of the third month of the study ( $p = 0.0002$ ). The mean severity of abdominal attacks declined from a baseline of  $6.1 \pm 0.95$  to  $3.9 \pm 2.8$  after 3 months ( $p = 0.02$ ). Comparable significant change was observed in chest attacks, ESR, and number of analgesic tablets used. Joint attacks were unrelieved during the study period. The treatment was safe and well tolerated, without side effects.

**CONCLUSION:** Treatment with weekly IV colchicine injections in addition to oral colchicine therapy is effective and safe in patients with FMF refractory to oral colchicine.

A case of familial Mediterranean fever and polyarteritis nodosa complicated by spontaneous perirenal and subcapsular hepatic hemorrhage requiring multiple arterial embolizations.

The association of familial Mediterranean fever (FMF) and polyarteritis nodosa (PAN) has been well established. These patients have been reported to have an overall better prognosis than other PAN patients. Herein we report a patient with FMF and PAN who died of sepsis following a severe course of recurrent bleeding episodes which required multiple embolization attempts. The 39-year-old Turkish male presented with abdominal pain of 1-month duration. He had been diagnosed with FMF at the age of 24. On admission, he had pallor with general ill appearance. Rebound tenderness was obtained in the right upper abdominal quadrant. He had mild anemia, leukocytosis, thrombocytosis, and hypoalbuminemia. On the 2nd day of his admission, he developed hypotension with a rapid decline in hemoglobin level. Abdominal angiography showed multiple aneurysms in the branches of renal arteries, superior mesenteric artery, and hepatic arterial system including left renal infarct, suggesting PAN. He was put on high-dose steroids and oral cyclophosphamide. Despite medical treatment, he developed intense abdominal pain, hypotension, tachycardia, and a rapid fall in hemoglobin on four occasions. Active bleeding sites were embolized in two different angiography sessions. Although the patient experienced no more recurrent bleeding, he died of multiorgan dysfunction syndrome resulting from sepsis 6 weeks after admission. Polyarteritis nodosa associated with FMF may follow a grave course despite immunosuppressive therapy. Arterial embolization should be considered in the presence of bleeding aneurysms in addition to immunosuppressive therapy.

Analysis of the modifying effects of SAA1, SAA2 and TNF-alpha gene polymorphisms on development of amyloidosis in FMF patients.

Yilmaz E(1), Balci B, Kutlay S, Ozen S, Ertürk S, Oner A, Beşbaş N, Bakkaloğlu A.

Author information:

(1)Department of Medical Biology, Hacettepe University Faculty of Medicine, Ankara, Turkey.

The aim of this study was to examine whether polymorphisms at serum amyloid A (SAA) and tumor necrosis factor-alpha (TNF-alpha) genes are associated with development of amyloidosis in familial Mediterranean fever (FMF) patients. Seventy-three FMF patients with amyloidosis and 100 other FMF patients without amyloidosis of known genotypes and 100 healthy control subjects were analyzed. There was a significant difference in the frequency of alpha/alpha genotype at the SAA1 locus between FMF patients with amyloidosis and controls and FMF patients without amyloidosis. The frequencies of the alpha/alpha genotype and alpha alleles at SAA1 locus were significantly higher in the FMF patients with amyloidosis. The frequencies of the alpha allele at SAA1 locus in FMF patients with amyloidosis, without amyloidosis and controls were 85.6%, 49.5% and 42.5%, respectively. We demonstrated that alpha/alpha genotype at SAA1 gene might have modifying effects on the development of amyloidosis. Determination of genotypes at SAA1 locus can play a key role in conferring genetic susceptibility and patient's prognosis to renal amyloidosis.

Abdominal and digestive system associations of familial Mediterranean fever.

Mor A(1), Gal R, Livneh A.

Author information:

(1)Heller Institute of Medical Research, Sheba Medical Center, Tel-Hashomer 52621, Israel.

Familial Mediterranean fever (FMF) is a hereditary episodic febrile syndrome that is expressed by acute spells of fever, painful manifestations in the abdomen, chest and joints, and slow development of nephropathic amyloidosis. Despite the

recent cloning of the FMF gene (MEFV) and the identification of about 40 disease-related mutations, the diagnosis is still clinically dependent, and the pathogenesis and most of the clinical heterogeneity remain to be explained. Because episodic abdominal pain affects 95% of FMF patients, most of them are seen by gastroenterologists and undergo complete or partial abdominal imaging before the diagnosis is made. Focusing on recent advances in FMF, this article reviews both common and infrequent manifestations that a gastroenterologist may encounter during workups of FMF patients. These include episodic abdominal pain, paralytic or mechanical ileus, constipation, diarrhea, ascites, malabsorption, bowel infarction, and bleeding, arising directly from FMF or secondary to FMF common associations such as amyloidosis, vasculitides, inflammatory bowel disease, irritable bowel syndrome, or colchicine side effects. This article will help the gastroenterologist to cope with most clinical situations related to the abdominal and alimentary tract in patients with FMF.

A severe autosomal-dominant periodic inflammatory disorder with renal AA amyloidosis and colchicine resistance associated to the MEFV H478Y variant in a Spanish kindred: an unusual familial Mediterranean fever phenotype or another MEFV-associated periodic inflammatory disorder?

Aldea A(1), Campistol JM, Arostegui JI, Rius J, Maso M, Vives J, Yagüe J.

Author information:

(1)Servei d'Immunologia, Institut Clínic d'Infeccions i Immunologia (ICII), c/Villaroel 170, 08036 Barcelona, Spain.

Familial Mediterranean fever (FMF) is an autosomal recessive disease characterized by recurring short attacks of fever and serositis. Secondary AA amyloidosis is the worst complication of the disease and often determines the prognosis. The MEFV gene, on chromosome 16p13.3, is responsible for the disease and around 30 mutations have been reported to date. Colchicine is the standard FMF treatment today, and prevents both attacks and amyloid deposition in 95% of patients. Here we describe a three-generation Spanish kindred with five family

members affected by a severe periodic inflammatory disorder associated with renal AA amyloidosis and colchicine unresponsiveness. Clinical diagnosis of definite FMF disease was made based on the Tel-Hashomer criteria set. Genetic analyses revealed that all subjects were heterozygous for the new H478Y MEFV variant, segregating with the disease. In addition, mutations in the TNFRSF1A and CIAS1/PYPAF1/NALP3 genes, related to the dominantly inherited autoinflammatory periodic syndromes, were ruled out. However, the dominant inheritance of the disease, the long fever episodes with a predominant joint involvement, and the resistance to colchicine in these patients raise the question of whether the periodic syndrome seen in this kindred is a true FMF disease with unusual manifestations or rather another MEFV-associated periodic syndrome. We conclude that the new H478Y MEFV mutation is the dominant pathological variant causing the inflammatory periodic syndrome in this kindred and that full-length analyses of the MEFV gene are needed to obtain an adequate diagnosis of patients with clinical suspicion of a hereditary periodic fever syndrome, especially those from non-ancestral populations.

Acute epididymitis in boys: evidence of a post-infectious etiology.

Somekh E(1), Gorenstein A, Serour F.

Author information:

(1)Pediatric Infectious Diseases Unit, Edith Wolfson Medical Center, Holon, Israel.

**PURPOSE:** We studied the etiology and management of pediatric epididymitis.

**MATERIAL AND METHODS:** We performed 1-year prospective study in children with epididymitis. All patients underwent an immediate sonographic study of the scrotum. Microbiological studies included throat and urine cultures as well as viral cultures of nasopharyngeal and stool specimens. Serological tests for group A streptococcus and *Mycoplasma pneumoniae* as well as for enteroviruses, adenoviruses, influenza and parainfluenza viruses in the appropriate seasons were performed in patients and controls.

**RESULTS:** A total of 44 patients 2 to 14 years old (mean age 9.8 +/- 3.2) were studied. Hospital admissions peaked during the summer and winter. The incidence of epididymitis was around 1.2/1,000 boys yearly. One patient had familial Mediterranean fever and another had Henoch-Schonlein purpura. Microbiological studies of the urine, throat, nasopharynx and stool yielded bacterial/viral growth in 9 patients (20.4%). Serological studies revealed significantly elevated titers to certain pathogens in patients with epididymitis compared with controls, including *M. pneumoniae* (53% vs 20%), enteroviruses (62.5% vs 10%) and adenoviruses (20% vs 0%). Most patients were treated with analgesics and 3 patients received antibiotics intravenously. Systemic and local signs and symptoms resolved gradually in 1 to 7 days.

**CONCLUSIONS:** Our results suggest that epididymitis in boys is not rare and it is mostly an inflammatory phenomenon (presumably post-infectious) with a benign course. The treatment of these patients is basically with analgesics with a little role for antibiotics.

Cutting edge: CIAS1/cryopyrin/PYPAF1/NALP3/CATERPILLER 1.1 is an inducible inflammatory mediator with NF-kappa B suppressive properties.

O'Connor W Jr(1), Harton JA, Zhu X, Linhoff MW, Ting JP.

Author information:

(1)Department of Microbiology and Immunology, Lineberger Comprehensive Cancer Center, University of North Carolina, Chapel Hill, NC 27599-7295, USA.

Mutations in the cold-induced autoinflammatory syndrome 1 (CIAS1) gene have been recently linked to three chronic autoinflammatory disorders. These observations point to an important role for CIAS1 in regulating inflammatory processes. We report that TNF-alpha and ligands recognized by multiple Toll-like receptors rapidly induce CIAS1 gene expression in primary human monocytes. Transfection of full-length CIAS1 or either of two shorter, naturally occurring isoforms dramatically inhibited TNF-alpha-induced activation of NF-kappaB reporter activity. Furthermore, CIAS1 suppressed TNF-alpha-induced nuclear translocation of endogenous p65. Transcriptional activity of exogenous NF-kappaB p65 was also blocked by CIAS1. The nucleotide-binding and leucine-rich repeat regions, but not the pyrin domain of CIAS1, are responsible for this inhibition. These data suggest CIAS1/cryopyrin may act as a key regulator of inflammation, induced to dampen NF-kappaB-dependent proinflammatory signals.

[Tumor necrosis factor receptor superfamily 1A-associated periodic syndrome (TRAPS)].

[Article in French]

Hentgen V(1), Granel B, Dodé C, Cuisset L, Delpech M, Grateau G.

Author information:

(1)Service de pédiatrie, centre hospitalier intercommunal, Créteil, France.

**PURPOSE:** Tumor necrosis factor receptor superfamily 1A associated periodic syndrome (TRAPS) belongs to the group of hereditary fever syndromes, also called hereditary auto-inflammatory syndromes.

**CURRENT KNOWLEDGE AND KEY POINTS:** The diagnosis of TRAPS should be evoked in presence of the following clinical signs, whatever the population of the affected patients. TRAPS acute inflammatory access, of 1 to 3 weeks' duration, is characterised by the presence of fever, abdominal pain, myalgias, various types of skin rash including erysepela-like erythema. Long term inflammatory response can lead to AA amyloidosis. Genetic testing will confirm the diagnosis when showing a mutation in the extracellular part of the TNFRSF1A receptor.

Therapeutic management of TRAPS is not definitely established. Daily colchicine does not seem to prevent efficiently inflammatory attacks. Corticosteroids, in contrast can attenuate the intensity and diminish the duration of attacks.

**FUTURE PROSPECTS AND PROJECTS:** The value of biological agents that inhibits TNF action is not yet completely determined in TRAPS. Mechanisms of the disease are not yet elucidated. In some families with specific mutations, a relative soluble TNF receptor deficiency has been found in the plasma. However this mechanism does not account for what is observed in other kindreds.

PFAPA syndrome mimicking familial Mediterranean fever: report of a Turkish child.

Ataş B(1), Caksen H, Arslan S, Tuncer O, Kirimi E, Odabaş D.

Author information:

(1)Department of Pediatrics, Yüzüncü Yıl University Faculty of Medicine, Van, Turkey.

The PFAPA (Periodic Fever, Aphthous stomatitis, Pharyngitis, Adenitidis) syndrome is characterized by periodic fever, adenitis, pharyngitis, and aphthous stomatitis. Herein, we present a Turkish child with PFAPA syndrome mimicking familial Mediterranean fever because of a rare presentation. A 9-year-old boy was admitted with recurrent fever, aphthous stomatitis, sore throat, headache, and

general body pains, lasting 2 to 3 days since 3.5 years of age. He was completely symptom-free between the attacks. He was diagnosed as having familial Mediterranean fever according to the clinical findings when he was 6 years of age and Colchicum tablet was administered. Despite colchicine therapy for 8 months, his attacks did not subside; therefore, the drug was discontinued. He had high fever, a painful cervical lymphadenopathy, aphthous stomatitis, and tonsillo-pharyngitis. The patient was then diagnosed as having PFAPA syndrome. He was given a single dose of prednisolone (0.35 mg/kg/dose). His complaints dramatically and completely disappeared 3 h after administration of the drug. During the 8th month of follow-up, a similar febrile attack lasting only 1 day was noted and it was controlled with a single dose of prednisolone (0.5 mg/kg/day). At this writing the patient is in the 12th month of follow-up, and there have been no symptoms after the second attack. In conclusion, our patient shows that PFAPA syndrome can be confused with familial Mediterranean fever. We also would like to emphasize that the typical PFAPA syndrome can be easily diagnosed by detailed history-taking and physical findings.

Familial Mediterranean fever with amyloidosis associated with novel exon 2 mutation (S1791) of the MEFV gene.

Timmann C(1), Mersinli O, Kuhne K, Sievertsen J, Griebel MA, Dieckerhoff J, Horstmann RD.

Author information:

(1)Bernhard Nocht Institute for Tropical Medicine, Bernhard-Nocht-Strasse 74, 20359 Hamburg, Germany. timmann@bni.uni-hamburg.de

Familial Mediterranean fever (FMF) is an autosomal recessive disorder characterized by recurrent attacks of fever, serositis, and a risk for AA amyloidosis. FMF is caused by mutations in the Mediterranean fever gene (MEFV), which is expressed in blood cells of the myelomonocytic differentiation pathway. We identified a novel mutation S1791 in exon 2 of MEFV in two members of a family of Turkish origin. In both cases, S1791 was in compound heterozygosity with MEFV

mutation M694V, and the characteristic clinical syndrome of FMF including amyloidosis was found. The location of S1791 in exon 2 is of interest because (1) amyloidosis in FMF has previously been found to be strongly associated with compound exon 10 mutations and (2) it supports the notion that the mechanism causing FMF is connected to the cytoplasmic rather than nuclear function of the molecule.

Colchicine-induced myopathy in a teenager with familial Mediterranean fever.

Sayarlioglu M(1), Sayarlioglu H, Ozen S, Erkoc R, Gul A.

Author information:

(1)Department of Internal Medicine, Division of Rheumatology, Medical Faculty, Yuzuncu Yil University, Van, Turkey. sayarli@hotmail.com

OBJECTIVE: To report a case of colchicine-induced myopathy in a teenager with

familial Mediterranean fever (FMF).

**CASE SUMMARY:** A 15-year-old boy of Turkish origin, diagnosed as having FMF at the age of 14 years, was treated with colchicine 1.5 mg/d. He had experienced only 2 mild peritonitis attacks with fever within 1 year. The patient used the recommended dose regularly, and he described progressive proximal muscle weakness and generalized myalgias, which started 1 month before presentation. Physical examination showed proximal muscle weakness in his arms and legs. Laboratory tests revealed elevated serum creatine kinase, aspartate aminotransferase, alanine aminotransferase, and lactate dehydrogenase. All other laboratory values were within normal range. Electromyographic investigation revealed a myopathic pattern in proximal muscles without any neuropathic changes. A biopsy of the deltoid muscle showed vacuolar degeneration of striated muscle fibers with no inflammatory findings.

**DISCUSSION:** Colchicine, the most important drug in treatment of FMF, can cause myopathy in patients with impaired renal and hepatic function. In our patient, an objective causality scale showed that therapeutic doses of colchicine for FMF were the definite cause of myopathy, even though his renal and hepatic function were normal. The treatment of FMF attacks in patients who cannot use colchicine is an important problem. There are insufficient data about the use of immunosuppressive agents in the treatment of FMF attacks; however, we now successfully control the attacks with colchicine 0.5 mg/d and azathioprine 2 mg/kg/d.

**CONCLUSIONS:** Colchicine-induced myopathy should be excluded in patients with FMF who present with generalized muscle weakness. Clinicians should be aware that myopathy can occur in patients with FMF who have normal renal and hepatic function.

NALP proteins are recently identified members of the CATERPILLER (CARD, transcription enhancer, R(purine)-binding, pyrin, lots of LRR) family of proteins, thought to function in apoptotic and inflammatory signaling pathways. Mutations in the CIAS1 gene, which encodes a member of the NALP (NACHT-, LRR-, and PYD-containing proteins) family, the cryopyrin/NALP3/PYPAF1 protein, expressed primarily in phagocytic cells, were recently found to be associated with a spectrum of autoinflammatory disorders. These include chronic infantile neurologic cutaneous and articular (CINCA) syndrome (also known as neonatal-onset multisystem inflammatory disease [NOMID]), Muckle-Wells syndrome (MWS), and familial cold urticaria (FCU). We describe herein 7 new mutations in 13 unrelated patients with CINCA syndrome and identify mutational hotspots in CIAS1 on the basis of all mutations described to date. We also provide evidence of genotype/phenotype correlations. A 3-dimensional model of the nucleotide-binding domain (NBD) of cryopyrin suggested that this molecule is structurally and functionally similar to members of the AAA+ protein family of ATPases. According to this model, most of the mutations known to affect residues of the NBD are clustered on one side of this domain in a region predicted to participate in intermolecular contacts, suggesting that this model is likely to be biologically relevant and that defects in nucleotide binding, nucleotide hydrolysis, or protein oligomerization may lead to the functional dysregulation of cryopyrin in the MWS, FCU, and CINCA/NOMID disorders.

Saarbrücken, Germany. maario.albrecht@mpi-sb.mpg.de

Sequence variations in the gene products PYPAF1/CIAS1 and NOD2/CARD15 have been associated with several autoinflammatory diseases that, although clinically different, share a similar inflammatory pathophysiology. A multiple sequence alignment of homologous proteins demonstrates that some of the missense variants are located in highly conserved regions of the NTPase domain and possibly impair NTP-hydrolysis. Intriguingly, one of the variations, which is found identically in PYPAF1 and NOD2, is located at the same alignment position. Our findings suggest that evolutionary gene duplication can give rise to disease families because variants affect conserved sequence in a similar fashion.

Familial Mediterranean fever (FMF) is a recessively inherited inflammatory disorder, characterised by recurrent attacks of fever and serositis. Since nitric oxide (NO) is an important mediator of inflammation, the production of NO (assessed as the accumulation of nitrate and nitrite and measured by capillary electrophoresis) in blood plasma of FMF patients during acute attacks (active) and attack-free periods (inactive) of the disease has been determined and compared with NO levels found in healthy volunteers (control group C). Thirty-six FMF patients were involved in a placebo-controlled double-blind study (group A received the drug, group B the placebo) of the effects of Immuno-Guard, a novel herbal preparation which relieves the severity and longevity of FMF attacks on NO blood levels. Thirty-two FMF patients (group D) being permanently treated with colchicine were also examined with respect to their NO blood level. No significant differences were found between the NO levels in blood of inactive FMF patients and those of control group C, or between inactive colchicine-treated group D patients and inactive patients of groups A and B, a finding which is atypical for chronic inflammatory disorders. Significantly lower plasma NO levels were found in active FMF patients in groups A and B compared with inactive patients in those groups ( $p=0.031$  and  $0.036$ , respectively) and with patients of group D and the control group C ( $p=0.0235$  and  $0.0453$ , respectively). The decrease of NO in blood of FMF patients may trigger the generation of fever by initiating the production of pro-inflammatory IL-6. Plasma NO levels in inactive FMF patients were significantly increased during attack-free periods following treatment with Immuno-Guard. The preparation has a normalising effect both on NO and IL-6 blood levels in FMF patients during attacks, demonstrating a relationship between the beneficial effect of Immuno-Guard in reducing the severity of inflammatory attacks in FMF patients and the increase in NO blood levels.

Author information:

(1)Max-Planck-Institute for Informatics, Stuhlsatzenhausweg 85, 66123 Saarbrücken, Germany. mario.albrecht@mpi-sb.mpg.de

Several autoinflammatory diseases with distinct clinical manifestations have been associated with sequence variations in the gene products PYPAF1/CIAS1 and NOD2/CARD15. Both proteins belong to the PYD/CARD-containing family of apoptosis regulators and activators of pro-inflammatory caspases. To gain insight into the dysfunctional role of sequence alterations, we assembled a structure-based multiple sequence alignment of family members and related proteins. This allowed us to analyze the putative effect of the alterations on the function of nucleotide-binding (NACHT) and leucine-rich repeat (LRR) domains shared by the family members. In support of this analysis, we carefully selected template structures for the NACHT and LRR domains and mapped the genetic variations onto 3D domain models. Additionally, we propose a model of the NACHT and LRR domain complex. Our study revealed that many of the disease-associated sequence variants are located close to highly conserved sequence regions of functional relevance and are spatially adjacent in the predicted 3D structure. The implications on the domain functions such as NTP-hydrolysis or oligomerization are discussed.

Erratum in

Ann Ital Med Int. 2003 Jul;11(7):550.

Familial Mediterranean fever (FMF) is an autosomal recessive disorder that mainly affects people living around the Mediterranean sea (i.e. Turks, Armenians, Arabs and Jews), but cases of FMF are now being increasingly diagnosed in every country of the world (including Italy). Described for the first time in 1945, it has recently become more relevant, after the discovery of the responsible gene, the MEFV gene which encodes a 781-aminoacid protein called pyrin that seems to play a role in the regulation of the inflammatory process. As the prototype of an emerging group of disorders fated to become more and more popular--the hereditary auto-inflammatory disorders--FMF is an under-diagnosed cause of fever of unknown origin. Fever is the main but not the only symptom; sterile serosites are the most common associated features. The classical clinical picture is being continuously enriched. Geno-phenotype correlations and interval-free symptoms are the new clinical insights, while fundamentally important studies attempt to enlighten its obscure pathogenesis. In spite of the introduction of alternative treatments, colchicine is still the only suitable drug for the prevention of acute episodes and the development of amyloidosis.

Prevalence and significance of mutations in the familial Mediterranean fever gene in Henoch-Schönlein purpura.

Gershoni-Baruch R(1), Broza Y, Brik R.

Author information:

(1)Department of Human Genetics, Rambam Medical Center, and the Bruce Rappoport Faculty of Medicine, Technion-Israel Institute of Technology, Haifa, Israel.  
rgershoni@rambam.health.gov.il

**OBJECTIVES:** Based on the fact that Henoch-Schönlein purpura (HSP) occurs in approximately 5% of persons with familial Mediterranean fever (FMF), we assessed the prevalence and significance of FMF gene mutations in children with one or more episodes of HSP.

**STUDY DESIGN:** Thirty-four boys and 18 girls treated for HSP at Rambam Medical Center were interviewed and asked to donate blood. Mean age at disease onset was 6.7+/-2.4 years, and mean follow-up was 3.8+/-1.3 years. Six predominant mutations (M694V, M680I, M694I, V726A, K695R, E148Q) in the MEFV gene were studied.

**RESULTS:** Nine heterozygotes, three homozygotes and two compound heterozygotes, were identified. Altogether, five persons (10%) carried two mutated MEFV alleles, a number significantly exceeding that determined for the general Israeli population (1%-2%). Of these, three displayed genotypes associated with a mild form of disease (M694V/E148Q and V726A/V726A), and two had genotypes normally observed in disease-free persons (E148Q/K695R and E148Q/E148Q).

**CONCLUSIONS:** Occult FMF cases much more numerous than expected were identified among children presenting with HSP. Such children should be closely monitored for renal complications, and treatment with colchicine should be considered.

Tumour necrosis factor receptor-associated periodic syndrome (TRAPS) is a dominantly inherited disorder characterised by recurrent episodes of sustained fever. Here we report a case of TRAPS with a novel TNFRSF1A mutation, C70S, in a Japanese family. The mutation disrupts one of the three disulphide bonds in cysteine-rich domain 2 of TNF receptor 1, similar to the reported mutations of the same cysteine residue (C70R, C70Y). This is the first confirmed case of TRAPS in an eastern Asian population. The patient's asymptomatic sister as well as their mother with mild symptoms had the same mutation. CONCLUSION: Although tumour necrosis factor receptor-associated periodic syndrome has been reported mainly in families of northern European ancestry, our case suggests the need to include it in the differential diagnosis of patients with recurrent fever even in ethnic groups in which no case has been documented.

Pyrin binds the PSTPIP1/CD2BP1 protein, defining familial Mediterranean fever and PAPA syndrome as disorders in the same pathway.

Pyrin, the familial Mediterranean fever protein, is found in association with the cytoskeleton in myeloid/monocytic cells and modulates IL-1beta processing,

NF-kappaB activation, and apoptosis. These effects are mediated in part through cognate interactions with the adaptor protein ASC, which shares an N-terminal motif with pyrin. We sought additional upstream regulators of inflammation by using pyrin as the bait in yeast two-hybrid assays. We now show that proline serine threonine phosphatase-interacting protein [PSTPIP1, or CD2-binding protein 1 (CD2BP1)], a tyrosine-phosphorylated protein involved in cytoskeletal organization, also interacts with pyrin. Recently, PSTPIP1/CD2BP1 mutations were shown to cause the syndrome of pyogenic arthritis, pyoderma gangrenosum, and acne (PAPA), a dominantly inherited autoinflammatory disorder mediated predominantly by granulocytes. Endogenous PSTPIP1/CD2BP1 and pyrin are coexpressed in monocytes and granulocytes and can be coimmunoprecipitated from THP-1 cells. The B box segment of pyrin was necessary and the B box/coiled-coil segment sufficient for this interaction, whereas the SH3 and coiled-coil domains of PSTPIP1/CD2BP1 were both necessary, but neither was sufficient, for pyrin binding. The Y344F PSTPIP1/CD2BP1 mutation, which blocks tyrosine phosphorylation, was associated with a marked reduction in pyrin binding in pervanadate-treated cells. PAPA-associated A230T and E250Q PSTPIP1/CD2BP1 mutations markedly increased pyrin binding as assayed by immunoprecipitation and, relative to WT, these mutants were hyperphosphorylated when coexpressed with c-Abl kinase. Consistent with the hypothesis that these mutations exert a dominant-negative effect on the previously reported activity of pyrin, we found increased IL-1beta production by peripheral blood leukocytes from a clinically active PAPA patient with the A230T PSTPIP1/CD2BP1 mutation and in cell lines transfected with both PAPA-associated mutants.

Familial Mediterranean fever is a multisystem disorder, usually seen in subjects of Mediterranean and Middle Eastern origin, characterized by recurrent bouts of fever and pain due to inflammation of the peritoneum, synovia, or pleura. In this article we report a case of Familial Mediterranean fever with recurrent abdominal pain and hyperbilirubinemia, review the literature and discuss whether the hyperbilirubinemia is co-existent or a feature of the disease.

Colchicine treatment in children with familial Mediterranean fever.

Ozkaya N(1), Yalçinkaya F.

Author information:

(1)Ankara University School of Medicine, Ankara, Turkey.

Prophylactic colchicine therapy has been shown to be a safe and effective method of eliminating the attacks and preventing the development of amyloidosis in patients with familial Mediterranean fever (FMF). However, information about effective dosages that control FMF attacks and prevent amyloidosis in childhood is not available. The aim of this study is to determine the 'effective colchicine dose' for children in terms of body weight and surface area. Sixty-two (34 male, 28 female) children with FMF were selected and colchicine treatment was initiated by giving 0.5-1 mg/day to each patient. The dose was gradually increased up to a maximum 2 mg/day in unresponsive patients; mean duration of therapy was 45.6 +/- 35.5 months. When the 'optimal effective dosage' (i.e. the one that reduced the frequency of attacks and ESR, CRP and fibrinogen levels during the attack-free period) was achieved, the optimal effective dose was calculated according to the body weight and body surface area for each patient. Based on these values 'mean colchicine dose' was computed for the study group and values for different age groups were evaluated. Mean colchicine doses according to the body weight and surface area of the whole group were found to be 0.03 +/- 0.02 mg/kg/day and 1.16 +/- 0.45 mg/m(2)/day, respectively. It was shown that children less than 5 years of age might need colchicine doses as high as 0.07 mg/kg/day or 1.9 mg/m(2)/day. These dosages are approximately 2.5-3 times more than the 'mean colchicine dose' for children aged 16-20 years. These results clearly show that small children need higher doses of colchicine in order to control their attacks. Thus, we conclude that colchicine, when given according to body weight or body surface area, would be more effective in childhood.

Familial Mediterranean fever mutation frequencies and carrier rates among a mixed Arabic population.

Al-Alami JR(1), Tayeh MK, Najib DA, Abu-Rubaiha ZA, Majeed HA, Al-Khateeb MS, El-Shanti HI.

Author information:

(1)Department of Biochemistry, School of Medicine, Jordan University of Science and Technology, Irbid, Jordan.

**OBJECTIVE:** Familial Mediterranean Fever (FMF) is an autoinflammatory periodic disorder characterized by febrile and painful attacks due to inflammation involving the serosal membranes. The gene implicated in this disorder, MEFV, has been cloned and mutations in its coding regions have been identified. We aimed at identifying the frequency of MEFV mutations and carrier frequency in a mixed Arabic population.

**METHODS:** We identified 29 probands from 29 unrelated sibships segregating the disorder and representing the affected individual cohort. We screened 200 anonymous deoxyribonucleic acid (DNA) samples, representing a healthy adult cohort, for the mutations found to be common in the affected individual cohort. We also, screened anonymous DNA samples from 4 Arabic countries, namely, Egypt (231), Syria (225), Iraq (176) and the Kingdom of Saudi Arabia (107) thus enlarging our healthy adult cohort. The study was carried out between 1999 and 2002 at Jordan University of Science and Technology, Irbid and the University of Jordan, Amman, Jordan.

**RESULTS:** Out of the 58 alleles of the 29 probands, only 31 mutations were identified and M694V and V726A are the most common. The mutation E148Q was the most common among the healthy adult cohort, but was not present in affected individuals. The collective mutant allele frequency "q" was 0.101. The expected carrier rate was 18.1% (one in 5.5) while the observed carrier rate was 18.4% (one in 5.4).

**CONCLUSION:** E148Q has reduced penetrance and thus, a proportion of the individuals genetically affected with FMF remain asymptomatic. M694I and M680I are more prevalent in the affected individuals cohort, which points to their higher penetrance. The overall carrier rate is one in 5, but the selective heterozygote advantage could not be demonstrated in this study due to the relatively small sample size.

alanaro@telefonica.net

Esparto grass (*Stipa tenacissima*), which is commonly found in the Mediterranean area, has a wide variety of uses. Five plaster workers from the same family developed cough, dyspnea, malaise, and fever after exposure to the esparto fiber used in their work for the previous few years. They showed a significant decrease in symptoms when away from work. Precipitating antibodies against an esparto extract were found in the sera of all patients. Specific IgG antibodies against *Aspergillus fumigatus* were detected. *A. fumigatus* was identified after microbiologic evaluation of esparto fiber samples. The dust derived from fungi-contaminated esparto fibers can cause hypersensitivity pneumonitis in exposed subjects. The causative antigen is *A. fumigatus*. When esparto fibers were strongly contaminated by fungi, all the workers developed a clinical picture compatible with hypersensitivity pneumonitis. The coincidental finding of an

occupational and a familiar condition is unusual.

An eleven year old girl from Turkey was diagnosed to have a periodic fever syndrome. The diagnosis of familial mediterranean fever was made by molecular analysis of a mutation in the MEFV-Gen which codes for pyrin. The disease is well-known in the mediterranean area and belongs to the periodic fever syndromes. These syndromes are discussed for their differential diagnosis focused to childhood.

Structure. 2003 Oct;11(10):1190-1.

Signaling in apoptosis and inflammation is often mediated by proteins of the death domain superfamily in the Fas/FADD/Caspase-8 or the Apaf-1/Caspase-9 pathways. This superfamily currently comprises the death domain (DD), death effector domain (DED), caspase recruitment domain (CARD), and pyrin domain (PYD) subfamilies. The PYD subfamily is most abundant, but three-dimensional structures are only available for the subfamilies DD, DED, and CARD, which have an antiparallel arrangement of six alpha helices as common fold. This paper presents the NMR structure of PYD of NALP1, a protein that is involved in the innate immune response and is a component of the inflammasome. The structure of NALP1 PYD differs from all other known death domain superfamily structures in that the third alpha helix is replaced by a flexibly disordered loop. This unique feature appears to relate to the molecular basis of familial Mediterranean fever (FMF), a genetic disease caused by single-point mutations.

## Evaluation of 80 children with prolonged fever.

Cogulu O(1), Koturoglu G, Kurugol Z, Ozkinay F, Vardar F, Ozkinay C.

### Author information:

(1)Faculty of Medicine, Department of Pediatrics, Ege University, Izmir, Turkey.  
cogulu@med.ege.edu.tr

**BACKGROUND:** Several studies have been published regarding the etiology and evaluation of a child with prolonged fever, however, the reasons for the prolonged fever have changed during the years. The present study aims to determine the causes of prolonged fever, to investigate the relationship of fever using some basic laboratory tests, and to establish guidelines for the approach in those children.

**METHODS:** The charts of 80 out of 17490 hospitalized children who were seen between 1996 and 2001 with prolonged fever of longer than 2 weeks and unknown origin were reviewed in the university hospital of Izmir, Turkey. Their charts were evaluated in respect of age, sex, growth curves, educational level of their families, the duration and the magnitude of fever, causes of fever, and basic laboratory investigations such as white blood cell, blood smear, hemoglobin, erythrocyte sedimentation rate, and C-reactive protein.

**RESULTS:** Forty-four (55.00%) were boys and 36 (45.00%) were girls. Forty-four children (55.00%) were aged between 1 month and 2 years, 21 (26.25%) were aged 3-6 years, seven (8.75%) were aged 7-10 years, and eight (10.00%) were older than 10 years. The mean age was 3.87 +/- 4.17 years (range 3 months-17 years). Forty-six children (57.50%) had a prolonged fever that had lasted from 15-30 days, 18 (22.50%) from 31-60 days, and 16 (20.00%) had fever lasting more than 60 days. Final diagnosis had been reached in 70 of the 80 children (87.50%). The most common causes were infection (47/80), followed by immune deficiency (6/80), collagen tissue disorder (5/80), neoplasia (2/80), and miscellaneous (10/80) such as central fever in three, diabetes insipidus in two, familial Mediterranean fever in two, Kawasaki disease, foreign body in the respiratory system, and Crohn disease in one patient each. Among the laboratory tests white blood cell count, hemoglobin level and blood smear distribution of infection group were statistically significant.

**CONCLUSIONS:** The most common cause of fever of unknown origin remains infection. The proportion of collagen tissue disorders and neoplasia have been found to be decreased. Unusual reasons such as diabetes insipidus and foreign body in the respiratory system in the miscellaneous group have been detected. Age plays

important role in the diagnosis of prolonged fever, while some basic laboratory tests might give clues in the evaluation and may suggest a diagnosis.

Haematopoietic stem cell transplantation for the treatment of systemic sclerosis and other autoimmune disorders.

Tyndall A(1), Matucci-Cerinic M.

Author information:

(1)Department of Rheumatology, University of Basle, Felix Platter-Spital, CH-4012, Basle, Switzerland. alan.tyndall@fps-basel.ch

Systemic sclerosis (SSc) with involvement of vital organs has up to 50% 5-year mortality and no treatment is known which changes the natural history. Although components of vascular, immunological and fibrotic processes are involved, drugs such as cyclophosphamide (CY), an alkylating agent and a potent immunosuppressive, have been partially effective in uncontrolled studies. The dose of such agents is limited by the inevitable toxicity on the bone marrow, but this threshold may be superseded by first removing the patient's own haematopoietic stem cells, followed by reconstitution of the marrow after high-dose myeloablative CY or other therapy. This autologous haematopoietic stem cell transplantation (HSCT) technique has been applied to approximately 650 patients with severe autoimmune diseases worldwide, > 100 of whom had SSc. Of these, 75 are included in the Basle registry. Around 70% of patients responded with a significant (> 25%) improvement of the thickened skin and stabilisation of vital organ involvement. Approximately a third achieved a durable remission. The treatment-related mortality was 8.5%. Based on these encouraging Phase I/II study results, several multi-centre, international, prospective randomised Phase III trials are running or being planned. The preliminary data suggest that through such a jolt of heavy immunosuppression, the dysregulated autoaggressive immune system may be re-regulated. It is hypothesised that this results in fewer autoinflammatory and unwanted stimulatory signals to other systems such as vascular endothelium and fibroblasts, and these mechanisms are currently under

study.

The tumor necrosis factor alpha-dependent activation of the human mediterranean fever (MEFV) promoter is mediated by a synergistic interaction between C/EBP beta and NF kappaB p65.

MEFV is a gene expressed specifically in myeloid cells and whose mutations underlie an autosomal recessive auto-inflammatory disease, called familial Mediterranean fever (FMF), characterized by recurrent episodes of serosal inflammation. This gene, which encodes a protein with unclear physiological functions, has been shown to be up-regulated by the pro-inflammatory cytokine tumor necrosis factor alpha (TNFalpha). However, the mechanism of this regulation is unknown, and the MEFV promoter is still to be characterized. Here, we show that 243 bp of the 5'-flanking region of the human MEFV gene are sufficient to direct high level expression of MEFV in TNFalpha-treated cells. The TNFalpha-induced expression of MEFV is dependent on both NFkappaB p65 and C/EBPbeta that bind to evolutionarily conserved sites located, in the human promoter, at positions -163 and -55, respectively. As shown by a series of transcription and gel shift assays performed with wild-type and mutated promoter sequences, these two transcription factors act differently on the TNFalpha-dependent transcription of MEFV: C/EBPbeta is the key regulatory factor required to confer cell responsiveness to TNFalpha, whereas NFkappaB p65 increases this response by means of a synergistic interaction with C/EBPbeta that is dependent on the integrity of the identified -55 C/EBP binding site. Given the phenotype of patients with FMF, this C/EBP-NFkappaB interaction may represent a key step in the control of an inflammatory response that is abnormally high in this disease. These data, which shed novel light on the pathophysiology of FMF,

represent an unusual example of cross-talk between C/EBP and NFkappaB pathways in TNFalpha signaling.

mrozenb@netvision.net.il

**OBJECTIVE:** The aim of this study was to assess the presence of dysautonomia, as manifested in abnormal cardiovascular reactivity, in patients with familial Mediterranean fever (FMF).

**METHODS:** Fifty-five consecutive patients with FMF and 23 age- and sex-matched healthy controls were evaluated. Cardiovascular reactivity was studied: (1) using recordings of blood pressure (BP) and heart rate (HR) during 10 min of recumbence and 30 min of head-up tilt test to identify clinical endpoints and (2) during tilt-test, identifying parameters acting as independent predictors of FMF reactivity and enabling computation of a cardiovascular reactivity score (CVRS).

**RESULTS:** Clinically, vasovagal reaction, postural tachycardia syndrome, and/or orthostatic hypotension were observed in ten patients (18.1%). Utilizing a derived equation, the group average CVRS in FMF was  $5.83 \pm 1.78$  (healthy group  $-7.60 \pm 5.41$ ) ( $P < 0.0001$ ). A CVRS of  $>3.25$  was associated with FMF, with 98% sensitivity and 100% specificity.

**CONCLUSION:** A very high percentage of FMF patients exhibit abnormal cardiovascular reactivity which is clinically occult but can be detected on autonomic challenge and application of the CVRS.

Favorable preliminary experience with etanercept in two patients with the hyperimmunoglobulinemia D and periodic fever syndrome.

Takada K(1), Aksentijevich I, Mahadevan V, Dean JA, Kelley RI, Kastner DL.

Author information:

(1)National Institute of Arthritis and Musculoskeletal and Skin Diseases, National Institutes of Health, Bethesda, Maryland 20892, USA.

**OBJECTIVE:** The hyperimmunoglobulinemia D and periodic fever syndrome (HIDS; MIM 260920) is caused by recessive mutations in the mevalonate kinase gene (MVK), which encodes an enzyme involved in cholesterol and nonsterol isoprenoid biosynthesis. HIDS is characterized by persistently elevated polyclonal IgD and recurrent febrile episodes. Although abnormalities in tumor necrosis factor alpha (TNF alpha) are not the primary cause of HIDS, plasma TNF alpha levels are elevated in HIDS patients during attacks and thus may be a therapeutic target. This study assessed the effects of etanercept, a soluble p75 TNF alpha receptor-Fc fusion protein, in 2 patients with HIDS.

**METHODS:** We performed biochemical and molecular genetic analyses on 2 girls with periodic episodes of fever, skin rash, abdominal pain, and arthralgia, of whom 1 had elevated levels of serum IgD. After the diagnosis of HIDS was made, treatment with etanercept was initiated in both patients. Clinical response was recorded in a standardized diary, and serum levels of cytokines and their decoy receptors were serially measured in 1 of the 2 patients.

**RESULTS:** Urinary mevalonate levels were elevated in both girls. Patient 1 was heterozygous for a known MVK missense mutation (V377I) and a novel mutation that led to skipping of exon 3. Patient 2 was found to have V377I and a new missense mutation, S329R. Neither patient had mutations in TNFRSF1A or MEFV, the genes for the TNF receptor-associated periodic syndrome and familial Mediterranean fever, respectively. Etanercept reduced the frequency and severity of symptoms in both patients, whereas the levels of serum IgD and urine mevalonate remained unchanged.

**CONCLUSION:** Our favorable experience with etanercept for the treatment of HIDS suggests that further investigation of this therapy is warranted.

Heterogeneity among patients with tumor necrosis factor receptor-associated periodic syndrome phenotypes.

Aganna E(1), Hammond L, Hawkins PN, Aldea A, McKee SA, van Amstel HK, Mischung C, Kusuvara K, Saulsbury FT, Lachmann HJ, Bybee A, McDermott EM, La Regina M, Arostegui JI, Campistol JM, Worthington S, High KP, Molloy MG, Baker N, Bidwell JL, Castañer JL, Whiteford ML, Janssens-Korpola PL, Manna R, Powell RJ, Woo P, Solis P, Minden K, Frenkel J, Yagüe J, Mirakian RM, Hitman GA, McDermott MF.

Author information:

(1)Barts and London, Queen Mary's School of Medicine and Dentistry, London, UK.

**OBJECTIVE:** To investigate the prevalence of tumor necrosis factor receptor-associated periodic syndrome (TRAPS) among outpatients presenting with recurrent fevers and clinical features consistent with TRAPS.

**METHODS:** Mutational screening was performed in affected members of 18 families in which multiple members had symptoms compatible with TRAPS and in 176 consecutive subjects with sporadic (nonfamilial) "TRAPS-like" symptoms. Plasma concentrations of soluble tumor necrosis factor receptor superfamily 1A (sTNFRSF1A) were measured, and fluorescence-activated cell sorter analysis was used to measure TNFRSF1A shedding from monocytes.

**RESULTS:** Eight novel and 3 previously reported TNFRSF1A missense mutations were identified, including an amino acid deletion (Delta D42) in a Northern Irish family and a C70S mutation in a Japanese family, both reported for the first time. Only 3 TNFRSF1A variants were found in patients with sporadic TRAPS (4 of 176 patients). Evidence for nonallelic heterogeneity in TRAPS-like conditions was found: 3 members of the "prototype familial Hibernian fever" family did not possess C33Y, present in 9 other affected members. Plasma sTNFRSF1A levels were low in TRAPS patients in whom renal amyloidosis had not developed, but also in mutation-negative symptomatic subjects in 4 families, and in 14 patients (8%) with sporadic TRAPS. Reduced shedding of TNFRSF1A from monocytes was demonstrated in vitro in patients with the T50M and T50K variants, but not in those with other

variants.

CONCLUSION: The presence of TNFRSF1A shedding defects and low sTNFRSF1A levels in 3 families without a TNFRSF1A mutation indicates that the genetic basis among patients with "TRAPS-like" features is heterogeneous. TNFRSF1A mutations are not commonly associated with nonfamilial recurrent fevers of unknown etiology.

Reproductive system in familial Mediterranean fever: an overview.

Ben-Chetrit E(1), Levy M.

Author information:

(1)FMF Unit, Department of Medicine, Hadassah University Hospital, Jerusalem, Israel. eldad@Hadassah.org.il

Familial Mediterranean fever (FMF), amyloidosis, and colchicine may affect the reproductive system of male and female patients. Colchicine treatment improves female fertility and the outcome of pregnancy and may prevent the development of amyloidosis. However, colchicine may induce oligospermia/azoospermia, but this effect is rare. Overall, colchicine treatment improves the prognosis of patients with FMF and increases their reproductive ability.

sezaozen@hacettepe.edu.tr

**OBJECTIVE:** To analyze 70 individuals who were found to have the Mediterranean fever (MEFV) gene for the presence of definite familial Mediterranean fever (FMF) and to assess if they were prone to clinical and laboratory inflammation. We also prospectively evaluated 72 patients with childhood rheumatic diseases for the presence of MEFV mutations.

**METHODS:** Seventy patients with one MEFV gene mutation were reevaluated for the presence of a clinical FMF phenotype using a new set of criteria. They were also questioned for the presence of musculoskeletal symptoms and rheumatic diseases. They were sampled for erythrocyte sedimentation rates and C-reactive protein levels. A second group with childhood rheumatic diseases were diagnosed according to international criteria.

**RESULTS:** Median age of the 70 heterozygous individuals was 12 years. About 1/3 (34.3%) were classified with clinical FMF phenotype according to the suggested criteria. Fifteen (21.4%) were classified as normal and 3 (4.3%) had recurrent abdominal pains but did not fulfill all criteria for clinical FMF. Overall, 28 (40.0%) had some form of rheumatic complaint and 15 (21.4%) had developed a rheumatic disease including Behçet's disease, a vasculitis, or acute rheumatic fever. The mean ESR and CRP levels were 45.47 +/- 33.05 mm/h and 4.00 +/- 6.73 mg/dl, respectively. Among the 72 patients with rheumatic diseases of childhood, 22 (30.5%) carried one or 2 mutations of the MEFV gene. The mutated allele frequency among patients with rheumatic diseases was significantly higher than those in controls ( $p < 0.05$ ). Within this group, among the 59 patients with juvenile idiopathic arthritis 15 had mutations in the heterozygous or homozygous form.

**CONCLUSION:** We confirm the acute phase response in the carriers for MEFV mutations. We suggest that these patients may have a tendency to develop certain manifestations due to an increased baseline of inflammation, and the presence of these mutations may affect their disease course when they develop rheumatic disease.

Th1 polarization in familial Mediterranean fever.

Aypar E(1), Ozen S, Okur H, Kutluk T, Besbas N, Bakkaloglu A.

Author information:

(1)Department of Pediatrics, Hacettepe University, 06100 Ankara, Turkey.

**OBJECTIVE:** Familial Mediterranean fever (FMF) is an autosomal recessive disease characterized by fever and serosal inflammation accompanied with an outburst of acute phase inflammatory products and cytokines. We studied the role of T helper (Th) 1 and 2 cells in FMF to elucidate the character of the inflammation. The cytokine products of Th1 and Th2, interferon-g (IFN-g) and interleukin 4 (IL-4), respectively, were analyzed by intracellular cytokine staining and FACS analysis.

**METHODS:** We studied 34 Turkish patients with FMF (18 asymptomatic, 8 during an attack, and 8 with amyloidosis) and 14 age matched controls, as well as 11 parents of the patients who were accepted as heterozygotes for MEFV (Familial Mediterranean gene) mutations. Peripheral blood mononuclear cells were isolated and stained with monoclonal antibodies for IFN-g and IL-4. The percentage of IL-4 positive T cells was not significantly different between the groups. However, the percentage of IFN-g positive T cells in FMF patients experiencing an attack (median 25.8%, range 8.9-50.5%) was significantly higher than asymptomatic FMF patients (median 12%, range 0.1-70.7) ( $p = 0.04$ ) and age matched controls ( $n = 7$ , median 0.4%, range 0-3.9%) ( $p = 0.0001$ ). The percentage of IFN-g positive T cells in asymptomatic FMF patients was also significantly higher than age matched controls ( $p = 0.008$ ). Heterozygotes for FMF had significantly higher IFN-g production (median 2.6%, range 0-42.4%) compared to age matched controls ( $n = 7$ , median 0.2%, range 0-1.4) ( $p = 0.001$ ). IFN-g production in FMF patients with

secondary amyloidosis was also markedly increased but had a large range of variation.

CONCLUSION: Inflammation in FMF shows a Th1 polarization. We suggest that in patients with FMF the IFN- $\gamma$  concentrations may remain higher because the defective pyrin is not able to inhibit this Th1 mediated inflammation.

The E148Q MEFV allele is not implicated in the development of familial Mediterranean fever.

Tchernitchko D(1), Legendre M, Cazeneuve C, Delahaye A, Niel F, Amselem S.

Author information:

(1)Service de Biochimie, hôpital Henri-Mondor, Créteil, France.

Familial Mediterranean fever (FMF) is an autosomal recessive disorder characterized by recurrent attacks of fever and serositis, common in populations of Armenian, Arab, Sephardic Jewish and Turkish origin. Early diagnosis is crucial to start colchicine therapy that prevents the occurrence of attacks and renal amyloidosis. In the absence of functional test for FMF, the diagnosis remains clinical and is generally confirmed by molecular analysis of the MEFV gene. More than 40 missense mutations and two in-frame deletions have been reported, most of them being located in exon 10 of the gene. The M694V (c.2080A>G) mutation, the most frequent defect, is responsible for a severe phenotype when present in the homozygous state. The E148Q (c.442G>C) sequence variant, which is situated in exon 2, is also common, but its role in FMF is controversial. In order to assess the implication of the E148Q variation in FMF, we investigated 233 patients of Sephardic Jewish origin living in France and 213 disease-free relatives of these patients. The frequency of the E148Q allele was found to be similar in the two groups (3.62% and 3.75%, respectively,  $p=0.93$ ). Most importantly, the frequency of the M694V/E148Q compound heterozygous genotype was comparable between the patients group (3.9%) and the healthy relatives group (4.2%,  $p=0.85$ ). This population-based study, therefore, strongly supports the hypothesis that E148Q is just a benign polymorphism and not a disease-causing

mutation. Considering this variant as a mutation may lead to set false positive diagnoses and to neglect the likely existence of genetic heterogeneity in FMF.

Safety of colchicine therapy during pregnancy.

Michael O(1), Goldman RD, Koren G; Motherisk Team.

Author information:

(1)Hospital for Sick Children, Toronto, Ont.

QUESTION: A 27-year-old patient in our clinic with familial Mediterranean fever (FMF) has been treated with colchicine for the last decade. She is planning her first pregnancy. What recommendations should we give her regarding use of colchicine before and during pregnancy, bearing in mind that discontinuation of colchicine could lead to complications from amyloidosis?

ANSWER: Colchicine passes through the placenta in humans, is teratogenic in animals, and raises rates of male and female infertility. Based on several patients with chromosomal anomalies, some authorities recommend that patients who require colchicine therapy during pregnancy undergo amniocentesis with karyotyping. In contrast, an increasing body of evidence suggests that colchicine use throughout pregnancy carries no substantial teratogenic or mutagenic risk when used at recommended doses. Its use prevents febrile attacks of FMF and reduces the frequency of renal complications.

aduzova@hacettepe.edu.tr

**OBJECTIVES:** 1) To compare the sensitivity of serum amyloid A protein (A-SAA) and other acute phase proteins (APPs) in determining subclinical inflammation in patients with familial Mediterranean fever (FMF) during an attack-free period; 2) to define those clinical, laboratory features that may modify the A-SAA level; and 3) to evaluate the effect of an increase in the colchicine dose on the A-SAA level.

**METHODS:** A-SAA, CRP, ESR, fibrinogen and ferritin levels were measured in 183 patients [88 F, 95 M; median age 11.0 years (1.0-20.0)] with FMF during an attack-free period. Mutational analysis was available in 157 patients. The colchicine dose was increased in 26 randomly chosen patients with no attacks within the last year; laboratory studies were repeated at the end of the second month.

**RESULTS:** During an attack-free period, the median A-SAA level was 74 (6-1,500) mg/L; other APPs were within normal ranges in 49-93% of the patients. Age, gender, age at onset, age at diagnosis, the duration of treatment and the frequency of attacks had no significant effect on the A-SAA level. Homozygous and compound heterozygous patients had higher A-SAA levels than heterozygous patients [129 mg/L (8-1,500) versus 29 mg/L (6-216);  $p < 0.005$ ]. There was a dramatic decrease in the A-SAA level [from 244 mg/L (16-1,400) to 35.5 mg/L (8-1,120);  $p < 0.001$ ] and an increase in the hemoglobin ( $1.89 \pm 0.10$  mmol/L to  $1.98 \pm 0.19$  mmol/L;  $p < 0.005$ ) after the increase in colchicine dose in 26 patients.

**CONCLUSION:** Subclinical inflammation continues during an attack-free period in FMF patients. A-SAA was the best marker of subclinical inflammation. Patients who are homozygous or compound heterozygotes of MEFV mutations had higher A-SAA levels. An increase in the colchicine dose resulted in a dramatic decrease in A-SAA and an increase in hemoglobin level. These findings favor the use of A-SAA in drug monitoring.

Comment on

Isr Med Assoc J. 2003 Aug;5(8):592-4.

**BACKGROUND:** Familial Mediterranean fever is an autosomal recessive disease characterized by recurrent attacks of fever and serositis. The disease is caused by mutations in the MEFV gene, presumed to act as a down-regulator of inflammation within the polymorphonuclear cells.

**OBJECTIVES:** To present the results of 412 FMF patients genotyped for three MEFV mutations, M694V, V726A and E148Q.

**RESULTS:** The most frequent mutation, M694V, was detected in 47% of the carrier chromosomes. This mutation, especially common among North African Jewish FMF patients, was not found in any of the Ashkenazi (East European origin) patients. Overall, one of the three mutations was detected in 70% of the carrier chromosomes. M694V/M694V was the most common genotype (27%), followed by M694V/V726A (16%). The full genotype could be assessed in 57% of the patients, and one disease-causing mutation in an additional 26%. Only one patient with the E148Q/E148Q genotype was detected despite a high carrier rate for this mutation in the Jewish population, a finding consistent with a low penetrance of this genotype. The M694V/M694V genotype was observed in 15 patients with amyloidosis compared to 4 amyloidosis patients with other genotypes ( $P < 0.0001$ ).

**CONCLUSIONS:** Because of low penetrance and as yet other undetermined reasons, mutation analysis of the most common MEFV mutations supports a clinical diagnosis in only about 60% of patients with definite FMF.

Behçet's disease: from Hippocrates to the third millennium.

Verity DH(1), Wallace GR, Vaughan RW, Stanford MR.

Author information:

(1)St Thomas's Hospital, London, UK. veritydh@hotmail.com

Behçet's disease (BD) is characterised by recurrent episodes of orogenital aphthae, systemic vasculitis, and systemic and retinal venous thrombosis. An association between HLA-B51 and BD was first identified over 20 years ago, but recently identified gene associations implicate regions both within and without the MHC in the immunological events underlying the lesions in BD. These include allelic variants within the tumour necrosis factor gene region and within the MHC class I chain related gene region, the factor V Leiden mutation, which is associated with retinal vascular occlusion, and alleles of the intercellular adhesion molecule gene. No single causative gene for BD has emerged; the evidence indicates that the underlying immune events in BD are triggered by a microbial antigen and subsequently driven by genetic influences which control leucocyte

behaviour and the coagulation pathways. Knowledge of these risk factors may permit a more accurate prognosis for a given patient, and identify new pathways for more targeted intervention than is currently available.

A Japanese case of familial Mediterranean fever with family history demonstrating a mutation in MEFV.

Yoshida K(1), Kanaoka S, Kajimura M, Kataoka H, Takahira K, Osawa S, Sano M, Hishida A.

Author information:

(1)First Department of Medicine, Hamamatsu University School of Medicine, Shizuoka.

We describe a 17-year-old woman with a family history of FMF who suffered from recurrent fever accompanied by pains in the left chest and abdomen. During a five-year period she experienced attacks about once every six months. The metaraminol provocative test was positive. Genomic DNA extracted from peripheral blood lymphocytes from both her and her parents were analyzed by polymerase chain reaction (PCR), followed by cycle sequencing. We detected a mutation (ATG to ATA) in codon 694 in exon 10 of the FMF gene, MEFV, that resulted in a substitution of isoleucine for methionine (M694I) in both her and her father. This is the first Japanese case of FMF with a mutation in MEFV identified in the family history.

Hyperimmunoglobulinemia D and periodic fever syndrome (HIDS) in a child with normal serum IgD, but increased serum IgA concentration.

Saulsbury FT(1).

Author information:

(1)Division of Immunology and Rheumatology, Department of Pediatrics, University of Virginia Health System, Charlottesville, Virginia 22908, USA. fts@virginia.edu

This report describes a boy with hyperimmunoglobulinemia D and periodic fever syndrome (HIDS). The serum IgD level was normal, but the serum IgA concentration was markedly elevated. In addition, he had a history of orchitis on two occasions, a previously unreported manifestation of HIDS. This report expands the clinical and laboratory features associated with HIDS and serves to emphasize that a normal serum IgD level does not exclude the diagnosis of HIDS.

yakcan@mynet.com

Familial Mediterranean fever (FMF) is an autosomal recessive disorder characterized by recurrent fever of unknown origin, renal amyloidosis, peritonitis, pleuritis and/or synovitis. There have been many studies to elucidate the etiopathogenesis of FMF. IL-6 is a cytokine that can induce the formation of serum amyloid A and C-reactive protein, both of which are important in development of amyloidosis. IL-6 was determined to be strongly associated in the etiopathogenesis of periodic fever in Chinese-pei dogs. The dogs with this syndrome experience periodic fever, arthritis, renal amyloidosis, a clinical picture very alike of human FMF. Here, we aimed to study mainly whether IL-6 had a similar etiopathogenetic role in human FMF as in Chinese-pei dogs syndrome. The median IL-6 blood levels were found to be higher in patients with acute (n=8) FMF attack (1.85 U/ml) compared to those (n=33) with asymptomatic ones (1.0 U/ml) (p=0.16). There are mainly two results: first; the study should be designed with a larger sample size of patients with acute attack in order to alleviate underestimation of significance, second; sampling time may give various results because of dynamic changes of cytokine levels during acute attack period.

pfisher002@md.northwestern.edu

**BACKGROUND:** Familial Mediterranean fever (FMF) is an autosomal recessive disease characterized by inflammatory serositis (fever, peritonitis, synovitis and pleuritis). The gene locus responsible for FMF was identified in 1992 and localized to the short arm of chromosome 16. In 1997, a specific FMF gene locus, MEFV, was discovered to encode for a protein, pyrin that mediates inflammation. To date, more than forty missense mutations are known to exist. The diversity of mutations identified has provided insight into the variability of clinical presentation and disease progression.

**CASE REPORT:** We report an individual heterozygous for the M680I gene mutation with a clinical diagnosis of FMF using the Tel-Hashomer criteria. Subsequently, the patient developed nephrotic syndrome with biopsy-confirmed fibrillary glomerulonephritis (FGN). Further diagnostic studies were unremarkable with clinical workup negative for amyloidosis or other secondary causes of nephrotic syndrome.

**DISCUSSION:** Individuals with FMF are at greater risk for developing nephrotic syndrome. The most serious etiology is amyloidosis (AA variant) with renal

involvement, ultimately progressing to end-stage renal disease. Other known renal diseases in the FMF population include IgA nephropathy, IgM nephropathy, Henoch-Schönlein purpura as well as polyarteritis nodosa.

CONCLUSION: To our knowledge, this is the first association between FMF and the M680I mutation later complicated by nephrotic syndrome and fibrillary glomerulonephritis.

Arthritis Rheum. 2004 Apr;50(4):1354-5; author reply 1355-6.

**OBJECTIVE:** Familial Mediterranean fever (FMF) is an autosomal-recessive disorder that is common in Armenian, Turkish, Arab, and Sephardic Jewish populations. Its clinical diagnosis is one of exclusion, with the patients displaying nonspecific symptoms related to serosal inflammation. MEFV gene analysis has provided the first objective diagnostic criterion for FMF. However, in the absence of an identified mutation (NI/NI genotype), both the sensitivity of the molecular analyses and the involvement of the MEFV gene in FMF are called into question. The present study was designed to further evaluate the diagnostic value of MEFV analysis in another population of Mediterranean extraction.

**METHODS:** The MEFV gene was screened for mutations in 50 patients living in Karabakh (near Armenia) who fulfilled the established criteria for FMF. In addition, we analyzed published series of patients from the above-mentioned at-risk populations.

**RESULTS:** The mutation spectrum in Karabakhian patients, which consisted of only 6 mutations (with 26% of NI alleles), differed from that reported in Armenian patients. Strikingly, among patients from Karabakh and among all classically affected populations, the distribution of genotypes differed dramatically from Hardy-Weinberg equilibrium ( $P = 0.0016$  and  $P < 0.00001$ , respectively). These results, combined with other population genetics-based data, revealed the existence of an FMF-like condition that, depending on the patients' ancestry, was shown to affect 85-99% of those with the NI/NI genotype.

**CONCLUSION:** These data illuminate the meaning of negative results of MEFV analyses and show that in all populations evaluated, most patients with the NI/NI genotype had disease that mimicked FMF and was unrelated to the MEFV gene. Our findings also demonstrate the high sensitivity of a search for very few mutations in order to perform a molecular diagnosis of MEFV-related FMF.

Long-term outcome of live donor kidney transplantation for renal amyloidosis.

Sherif AM(1), Refaie AF, Sobh MA, Mohamed NA, Sheashaa HA, Ghoneim MA.

Author information:

(1)Urology and Nephrology Center, Mansoura, Egypt.

**BACKGROUND:** The short-term outcome of kidney transplantation in patients with amyloidosis has been reported. The aim of this study is to investigate long-term results in patients with renal amyloidosis.

**METHODS:** We studied results of renal transplantation in 23 amyloidotic transplant recipients compared with those in a control group of 47 nonamyloidotic patients. Amyloidosis was secondary to familial Mediterranean fever (FMF) in 16 patients, whereas it was primary (idiopathic) in 7 transplant recipients. The 2 groups were homogeneous regarding age, sex, HLA matching, immunosuppression, and duration of transplantation.

**RESULTS:** Five- and 10-year actuarial graft survival rates were similar in both groups (79.35% versus 84.04% and 65.92% versus 56.61%, respectively ). Five- and 10-year actuarial patient survival rates also were similar (80% versus 94% and 68% versus 87%, respectively). Moreover, 72.4% of controls experienced at least 1 rejection episode, whereas only 43.5% of amyloidotic transplant recipients experienced 1 or more such events ( $P = 0.02$ ). Nonetheless, mean serum creatinine concentrations did not differ between the 2 groups during the observation period. Maintenance colchicine therapy prevented the recurrence of both FMF symptoms and amyloidosis. Recurrence was documented in only 1 amyloidotic transplant recipient (4.3%) 10 years posttransplantation. Significant gastrointestinal (GI) problems were more frequent in amyloidotic patients (65% versus 38%;  $P = 0.03$ ). Amyloidotic patients with GI problems, except for 2 patients, were administered cyclosporine. Eleven of these patients had FMF, which appeared to reflect the effects of both cyclosporine and colchicine. Infections were similar in the groups; whereas amyloidotic patients had significantly lower blood pressures.

**CONCLUSION:** In our experience, long-term (5 to 10 years) outcome of live related donor kidney transplantation in patients with amyloidosis is similar to that in the general transplant population.

PFAPA syndrome: with regard to a case.

Hernández-Bou S(1), Giner M, Plaza AM, Sierra JI, Martín Mateos MA.

Author information:

(1)Sección Inmunoalergia. Unidad Integrada de Pediatría Hospital Clínic-Hospital Sant Joan de Déu. Universidad de Barcelona, Spain.

**BACKGROUND:** PFAPA syndrome (Periodic Fever, Aphthas, Pharyngitis and cervical Adenopathies) is one of the causes of periodic fever in pediatrics and it is characterised by high fever, pharyngitis, cervical adenitis and aphthous stomatitis. Its etiopathogeny is unknown. The diagnosis is clinical and the findings of laboratory are unspecified. One or two doses (1 mg/kg) of oral prednisone are enough for a fast resolution of the clinic. It is a benign syndrome and no sequels have been noticed after its disappearance, usually in four years from its beginning.

**CLINICAL CASE:** We present the case of a 10-year-old patient who has been diagnosed of PFAPA syndrome after 3 years and a half of characteristic clinical bouts, with the fulfilment of diagnostic criteria and after having excluded other entities of similar presentation.

**CONCLUSIONS:** Periodic episodes of high fever, pharyngitis and cervical adenitis with a bad response to the conventional treatment should alert us to the PFAPA syndrome. The recognition of this entity will help us to improve the diagnostic and therapeutical focusing, lowering also the anxiety that these cases produce.

iislek@omu.edu.tr

Amyloidosis (A) related to familial Mediterranean fever (FMF) causes serious morbidity and mortality in children. Our study evaluates serum levels of apolipoprotein (Apo) AI, AII, B, and E and Apo AII/AI ratios as a non-invasive diagnostic tool for amyloidosis in children with FMF and FMF-A. Results were compared with those of patients with childhood nephrotic syndrome (NS) and healthy children (controls). Significantly lower serum levels of Apo AI (90.20+/-28.30 mg/dl) were documented in patients with FMF-A than in all other groups (FMF 126.89+/-51.07 mg/dl, NS 140.38+/-33.73 mg/dl, and controls 134.67+/-12.73 mg/dl) (  $P<0.01$ ). Diagnostic sensitivity, specificity, and predictive value for this test were 85%, 80%, and 85%, respectively. Apo AII/AI ratio results were essentially equal in all groups (  $P>0.05$ ). It is concluded that a decreased Apo AI serum level, but not Apo AII/AI ratio, is a useful, non-invasive test for the early diagnosis of FMF-A in children.

End-stage renal disease in North Africa.

Barsoum RS(1).

Author information:

(1)Department of Medicine, Cairo University, Cairo, Egypt. rbarsoum@msn.com

There are many similarities in the profile of chronic renal disease in the five North African countries, reflecting their close resemblance in ethnic background, bioecology and socioeconomic standards. The incidence of renal disease is much higher than that in the West, yet the prevalence is relatively lower, which mirrors the inadequacy of medical care facilities. The principal causes of end-stage chronic renal disease (ESRD) are interstitial nephritis (14 to 32%), often attributed to environmental pollution and inadvertent use of medications; glomerulonephritis (11 to 24%), mostly mesangioproliferative and focal segmental sclerosis; diabetes (5 to 20%) and nephrosclerosis (5 to 21%). Obstructive/reflux nephropathy, attributed to urinary schistosomiasis, is common in Egypt (7%), Libya and Southern Algeria. Primary urolithiasis is a frequent cause of obstructive nephropathy in the western (hyperoxaluria) and middle (cystinuria) regions. The incidence of tuberculosis is increasing, particularly the diffuse interstitial and hematogenous forms. It is responsible also for 10 to 40% of renal amyloidosis. The latter is also frequently associated with familial Mediterranean fever. Sickle cell anemia is an important health problem in the west, leading to a wide range of glomerular and tubulointerstitial nephropathies. Takayasu disease is increasingly recognized as a cause of ischemic nephropathy and renovascular hypertension. The management of ESRD is largely influenced by late referral, co-morbidities and lack of dialysis facilities. Hemodialysis is the most frequent modality of renal replacement therapy (RRT). CAPD is used sporadically. Renal transplantation, largely from live (often unrelated) donors, is offered to less than 5% of patients with ESRD. The reported outcome of RRT generally conforms with international standards.

Isoprenoid biosynthesis in hereditary periodic fever syndromes and inflammation.

Houten SM(1), Frenkel J, Waterham HR.

Author information:

(1)Laboratory Genetic Metabolic Diseases, Department of Pediatrics, Emma Children's Hospital, and Academic Medical Center, University of Amsterdam, Amsterdam, The Netherlands. smhouten@igbmc.u-strasbg.fr

Mevalonate kinase (MK) is an essential enzyme in the isoprenoid biosynthesis pathway which produces numerous biomolecules (isoprenoids) involved in a variety of cellular processes. The indispensability of MK and isoprenoid biosynthesis for human health is demonstrated by the identification of its deficiency as the biochemical and molecular cause of the inherited autoinflammatory disorders mevalonic aciduria and hyperimmunoglobulinemia D and periodic fever syndrome. Since the discovery of the genetic defect, considerable progress has been made in understanding the molecular, biochemical and immunological basis of MK deficiency. Important questions such as which specific protein(s) and/or signaling pathway(s) are affected, however, remain unanswered. Resolving the complete pathophysiology of this disorder is a major challenge, but eventually will give insight into the in vivo role of MK and isoprenoid biosynthesis in inflammation and fever. This may open novel options for antiinflammatory therapies in general. Here, we give a general introduction on isoprenoid biosynthesis, the regulation thereof and deficiencies therein. We review the molecular, biochemical and immunological aspects of MK deficiency and discuss the relations between isoprenoid biosynthesis and inflammation. Finally, we compare MK deficiency with other autoinflammatory syndromes.

[Systemic urticarias].

[Article in French]

Hachulla E(1).

Author information:

(1)Service de Médecine Interne, Hôpital Claude Huriez, 59037 Lille Cedex.

Systemic urticaria remains a challenge in terms of etiology, investigation and management. Most of cases are urticarial vasculitis consequence of inflammatory injury of capillaries and postcapillary venules in the skin. If hypocomplementemic urticarial vasculitis syndrome is a classical cause, the majority of patients have an underlying systemic disease like systemic lupus erythematosus, Sjögren's syndrome, mixed cryoglobulinemia, Still disease or cancer. Others systemic urticaria have been reported without clearly evidence of vasculitis like in primary or acquired angioedema, hereditary periodic fever syndromes and in some thyroiditis. Diagnosis needs a step to step procedure. Treatment depends the underlying disease. Some patients respond to nonsteroidal antiinflammatory drugs, some other need corticosteroids or immunosuppression. If urticarial vasculitis seems isolated in the absence of chronic obstructive pulmonary disease, antihistamines, nonsteroidal antiinflammatory drugs, colchicine, dapsone or hydroxychloroquine must be first used.

[Familial Mediterranean fever (familial paroxysmal polyserositis)].

[Article in German]

Dlugosch J(1), Altrock G, Klepzig H.

Author information:

(1)Medizinische Klinik I, Klinikum Offenbach/Main, Offenbach.

**HISTORY AND ADMISSION FINDINGS:** A 48-year-old Iranian man had suffered since the age of 15 from repetitive periods of fever and abdominal pain, which had led to appendicectomy and cholecystectomy. He was admitted because of pain in the left chest and fever. He showed himself to be a personality fixed on his chronic pain. He reported pressure in the left chest and slight tenderness in the abdomen. His body temperature was about 38.5 degrees C axillary.

**INVESTIGATIONS:** All routine laboratory tests were normal except CRP (183 mg/l), microalbuminuria (20 mg/l) and amyloid A-protein in serum (865 mg/l). In an X-ray of the chest a small amount of fluid was seen on both sides. A gene test confirmed mutation of the Marenostin/Pyrin gene at chromosome 16.

**DIAGNOSIS, TREATMENT AND CLINICAL COURSE:** The diagnosis of familial Mediterranean fever was based on the typical clinical history, the ethnographical background and the result of the gene test. We initiated therapy with colchicine (3 x 0.5 mg/d) that resulted in rapid improvement of the symptoms and the patient has had no further pain.

**CONCLUSION:** Mediterranean fever should be considered in cases of repeated periods of abdominal or chest pain and fever in patients with typical ethnographical background. An early diagnosis and therapy may shorten the course of the disease and prevent unnecessary surgery, prolonged periods of hospitalization, a personality structure fixed on chronic pain, and the development of amyloidosis.

Familial Mediterranean fever.

Bakkaloglu A(1).

Author information:

(1)Department of Pediatrics, Pediatric Nephrology and Rheumatology Unit, Faculty of Medicine, Hacettepe University, Ankara 06100, Turkey. aysin@hacettepe.edu.tr

Familial Mediterranean fever (FMF) is the most frequent periodic syndrome characterized by recurrent attacks of polyserositis. Fever, abdominal pain, chest

pain, and arthritis/arthralgia are the leading symptoms. It is an autosomal recessive disorder, which primarily affects Jewish, Armenian, Turkish, and Arab populations. The FMF gene (MEFV) has recently been cloned to chromosome 16p, which encodes pyrin. Genotype-phenotype correlation is not well established. Amyloidosis is the most severe complication of FMF. The SAA1-alpha/alpha genotype was associated with an increased risk of amyloidosis. Colchicine treatment not only decreases the frequency and severity of attacks, but also prevents amyloidosis. Certain vasculitides, namely Henoch-Schonlein purpura and polyarteritis nodosa, are more frequent among FMF patients.

Familial Mediterranean fever (FMF) and renal AA amyloidosis--phenotype-genotype

correlation, treatment and prognosis.

Ben-Chetrit E(1).

Author information:

(1)Department of Medicine, FMF Clinic, Hadassah University Hospital, Jerusalem, Israel. eldad@hadasah.org.il

Familial Mediterranean fever (FMF) is an autosomal recessive disease, which primarily affects the population surrounding the Mediterranean basin. It is characterized by recurrent attacks of fever and peritonitis, pleuritis, arthritis or erysipelas-like erythema. Amyloidosis, causing renal failure, is one of the most severe complications of the disease. The gene associated with FMF (MEFV) has been recently isolated. Phenotype-genotype correlation studies revealed that amyloidosis was more common in FMF patients originating from North-Africa who were homozygous for the M694V mutation. Such a correlation was not found in Turkish patients. The risk of amyloidosis is increased in male FMF patients and in patients bearing polymorphism a/a in the SAA1 gene. Colchicine is the chosen drug for the treatment of FMF and can prevent amyloidosis.

From renal amyloid deposits to the identification of the culprit genes.

Pirson Y(1).

Author information:

(1)Nephrology Department, Cliniques St Luc, Université Catholique de Louvain, Brussels, Belgium. pirson@nefr.ucl.ac.be

Hereditary amyloidoses with renal involvement are classified in two groups. The first group is a growing family of autoinflammatory disorders characterized by recurrent fever attacks. Amyloidosis is caused by the deposition of amyloid A (AA) protein, which is a degradation product of a normal serum acute-phase protein: serum amyloid A (SAA). The prototype is familial Mediterranean fever

(FMF). TNF Receptor Associated Periodic Syndrome (TRAPS) is a recently recognized periodic fever syndrome, differing from FMF in several characteristics: autosomal-dominant transmission, longer duration of attacks, and lack of response to colchicine prophylaxis. The second group comprises a variety of disorders, each characterized by the deposition of a specific mutant protein. The prototype is transthyretin amyloidosis (TTR). Identification of the form of amyloidosis has clinical implications. Therefore, in a patient with a history of recurrent fever attacks and AA amyloidosis, a diagnosis of FMF or TRAPS dictates appropriate genetic counseling and management. In patients with renal amyloidosis without a history of fever, identification of the mutant protein is therapeutically crucial; therefore, when the cell type that produces the precursor is (exclusively or mainly) the hepatocyte, a liver transplantation is to be considered.

Four children of Turkish origin, three boys aged 12, 8 and 7 years, and a girl aged 5 years, presented with clinical symptoms of familial Mediterranean fever. They had the characteristic episodes of fever combined with abdominal pain, thoracic pain, general malaise or arthralgia. Familial Mediterranean fever is an

autosomal recessive genetic disorder restricted to people originating from the Middle East. The causative gene (MEFV) and many missense mutations have been identified. The clinical syndrome is characterised by self-limiting febrile episodes accompanied by inflammation of the serous membranes, resulting in peritonitis, pleuritis or synovitis. In untreated patients systemic amyloidosis may develop, which manifests as renal insufficiency. The diagnosis is based on the characteristic medical history and is confirmed by DNA analysis. Meanwhile, treatment with colchicine can be started. This is effective in 90% of affected patients. Being aware of the prevalence of familial Mediterranean fever in immigrant populations can improve the quality of life and prevent long-term complications.

Hereditary periodic fever syndromes are defined as recurrent attacks of generalized inflammation for which no infectious or auto-immune cause can be identified. Minimal clinical variations, a unique biochemical-specific abnormality and the mode of genetic inheritance distinguish the four main diseases: familial Mediterranean fever, hyper-immunoglobulinemia D, TNF-receptor-associated periodic syndrome (TRAPS) and Muckle Wells syndrome. It presents with prolonged attacks of fever and severe localized inflammation. TRAPS is caused by dominantly inherited mutations in the gene encoding the first TNF receptor, which result in decreased serum levels of soluble TNF-receptor leading

to inflammation due to unopposed TNF-alpha action. Corticosteroid treatment is not completely effective in most TRAPS patients. Preliminary experiences with recombinant TNF-receptor analogues in the treatment appear be promising.

Acute vasculitis with multiorgan involvement in a patient with familial Mediterranean fever.

Braun E(1), Schapira D, Guralnik L, Azzam ZS.

Author information:

(1)Department of Internal Medicine, Rambam Medical Center and B. Rappaport Faculty of Medicine, Technion, Haifa, Israel.

We report a rare case of a patient with long-standing familial Mediterranean fever who presented with sudden onset of dyspnea, abdominal pain, and cutaneous manifestations. Chest CT and histologic preparations disclosed pulmonary hemorrhage and signs of systemic vasculitis. Cyclophosphamide and steroid therapy were initiated, with marked improvement. Based on this and 1 other case, we propose that systemic vasculitis should be included as a clinical manifestation of FMF.

Double blind, randomized, placebo controlled pilot study of ImmunoGuard--a standardized fixed combination of *Andrographis paniculata* Nees., *Eleutherococcus senticosus* Maxim., *Schizandra chinensis* Bail., and *Glycyrrhiza glabra* L. special extracts standardized for the content of Andrographolide (4 mg/tablet), Eleuteroside E, Schisandrins and Glycyrrhizin, was carried out in two parallel groups of patients. The study was conducted in 24 (3-15 years of both genders) patients with Familial Mediterranean Fever (FMF), 14 were treated with tablets of series A (verum) and 10 patients received series B product (placebo). The study medication was taken three times of four tablets daily for 1 month. Daily dose of the andrographolide--48 mg. The primary outcome measures in physician's evaluation were related to duration, frequency and severity of attacks in FMF patients (attacks characteristics score). The patient's self-evaluation was based mainly on symptoms--abdominal, chest pains, temperature, arthritis, myalgia, erysipelas-like erythema. All of 3 features (duration, frequency, severity of attacks) showed significant improvement in the verum group as compared with the placebo. In both clinical and self evaluation the severity of attacks was found to show the most significant improvement in the verum group. Both the clinical and laboratory results of the present phase II (pilot) clinical study suggest that ImmunoGuard is a safe and efficacious herbal drug for the management of patients with FMF.

(1)Department of Obstetrics & Gynaecology, VU University Medical Center, De Boelelaan 1117, 1081 HV, Amsterdam, The Netherlands. mijatovic@xs4all.nl

Familial Mediterranean fever (FMF) is a recessively inherited disease of episodic fever in combination with severe abdominal pain, pleurisy, arthritis or erysipelas-like skin rashes. The disease is mainly prevalent in Sephardic Jews, Armenians, Turks and Arabs. The gene responsible for FMF was cloned in 1997. The

gene expresses a protein called pyrin which is believed to play a role in the downregulation of mediators of inflammation. Several mutations have been identified of which the homozygous form of the M694V mutation is associated with a more severe expression of FMF. Prophylactic administration of colchicine is effective in relieving most patients from their attacks and preventing the development of amyloidosis, which usually leads to end-stage renal disease. Unfortunately, there is little awareness of the disease in gynaecological practice although a FMF full blown episode may mimic an acute abdominal calamity suggesting several possible gynaecological diagnoses. FMF is also associated with subfertility. In females, infertility was mainly related to oligomenorrhea although the causes remain unclear. In male FMF patients, progression of the disease may induce testicular impairment, consequently affecting spermatogenesis. Some controversy exists as to the adverse effects of colchicine on sperm production and function although the impression is that the occurrence of sperm pathology in FMF patients, using the recommended dosage of colchicine, is very low. In pregnant FMF patients, an increased occurrence of miscarriage has been found. However, the mechanisms involved remain unclear. Although colchicine is a mitotic inhibitor and transplacental crossing of colchicine has been demonstrated, no increased risk of foetal abnormalities in colchicine-treated pregnant FMF patients has been found. Therefore, amniocentesis should not be done for reassurance alone.

Psychosocial correlates of incidence of attacks in children with Familial Mediterranean Fever.

Gidron Y(1), Berkovitch M, Press J.

Author information:

(1)Department of Sociology of Health, Faculty of Health Sciences, Ben-Gurion University, Beer-Sheva, Israel. yorig@bgumail.bgu.ac.il

This study tested the relationship between psychosocial factors and incidence of Familial Mediterranean Fever (FMF) attacks. Forty-five children with FMF were

studied retrospectively. Parents assessed their child's hostility, perceived-control, illness-behavior encouragement (IBE), family dysfunction, and reported number of attacks during the last 12 months. Hostility was positively correlated with number of attacks, especially in children below age 10 and in girls. Family dysfunction was positively correlated with attacks in girls and in children at or above age 10. IBE was inversely correlated with attacks in older children. In children below age 10, number of siblings was positively correlated with attacks, and negatively correlated with attacks in the older group. Psychosocial factors explained 27% of the variability in attacks, after controlling for age and number of siblings, with hostility remaining the only significant predictor of attacks. These findings, if replicated in a prospective study, may guide interventions for preventing FMF attacks.

Serum amyloid A1 and tumor necrosis factor-alpha alleles in Turkish familial Mediterranean fever patients with and without amyloidosis.

Akar N(1), Hasipek M, Akar E, Ekim M, Yalçinkaya F, Cakar N.

Author information:

(1)Departments of Pediatric Molecular Genetics and Pediatric Nephrology, University of Ankara, Ankara, Turkey. nejatakar@hotmail.com

The major complication of familial Mediterranean fever (FMF) is AA amyloidosis. The influence of FMF gene (MEFV) mutations and/or unknown environmental factors and other genetic modifiers are likely to affect the phenotypic variations of the disease and the development of amyloidosis. Serum amyloid A is a serum precursor of AA amyloid that is induced by inflammatory cytokines including TNF-alpha. Our analysis of SAA1.1 frequency in Turkish FMF-amyloidosis patients, revealed a higher frequency compared to non FMF-amyloidosis patients but the difference was not significant. On the other hand, the distribution of SAA1.1 homozygosity among FMF-amyloidosis patients was 55.5% compared to FMF-non-amyloidosis patients (30.8%) which was statistically significant revealing a 2.5 fold risk for the occurrence of amyloidosis. There was no significant difference between the

controls and FMF patients with and without amyloidosis for the TNF-alpha-308 G-A allele. It is worth noting that all TNF-alpha-308 G-A carriers (n = 6) in FMF-amyloidosis group have SAA1.1 homozygosity compared to 2/11 in FMF-non-amyloidosis group. Further evaluation of these polymorphisms may have importance and need further study.

Familial mediterranean fever: revisiting an ancient disease.

Ozen S(1).

Author information:

(1)Department of Paediatric Nephrology and Rheumatology, Hacettepe University Faculty of Medicine, 06100, Ankara, Turkey. sezaozen@hacettepe.edu.tr.

Familial Mediterranean fever (FMF) is an auto-inflammatory disease characterised by periodic attacks of fever and serositis. Recent genetic and epidemiological research have highlighted the importance of this disease. FMF is the most frequent periodic fever syndrome and is transmitted in an autosomal recessive fashion. The disease is caused by mutations in the gene on the short arm of chromosome 16, coding for the protein "pyrin". Pyrin is mainly expressed in neutrophils and monocytes and is among the proteins involved in the interleukin-1

inflammatory pathway. The recurrent attacks of fever are accompanied by severe abdominal pain, arthritis and/or chest pain along with a marked increase in acute phase reactants. Among these, serum amyloid A protein is especially important since it is the precursor of the amyloid A fibrils deposited in secondary renal amyloidosis. Renal amyloidosis has a grave prognosis. Differential diagnosis from other periodic fever syndromes is especially important in western European countries. Among these hyper IgD syndrome is common in Netherlands and the tumour necrosis factor receptor-associated periodic syndrome is especially common among Scottish and Irish families. Mutation analysis of the gene may be helpful in diagnosing FMF; however, if this is not possible, a trial of colchicine is a helpful diagnostic tool. The indications for life-long colchicine treatment should be discussed with the family. CONCLUSION: Familial mediterranean fever and other auto-inflammatory syndromes should be suspected in children with recurrent febrile attacks. Early diagnosis will save the child from unnecessary work-up and kidney involvement.

[r\\_brik@rambam.health.gov.il](mailto:r_brik@rambam.health.gov.il)

Familial Mediterranean fever (FMF) is characterized by recurrent episodes of peritonitis, pleuritis, and synovitis. Among the pulmonary manifestations of FMF, pleuritis is the most common. Long-term sequelae of the respiratory system have not been described in FMF patients. We describe the pulmonary manifestations and function tests in a group of children who were found by genetic screening to be homozygous for the FMF gene. We surveyed 48 patients of Mediterranean extraction (aged 6-18 years) who were evaluated for a variety of pulmonary symptoms, and in whom clinical and genetic studies confirmed a diagnosis of FMF. All patients underwent complete pulmonary function tests, which included spirometry, body plethysmography, and single-breath carbon monoxide diffusion (Dlco). Forty percent of the Jewish patients, but only 8% of the Arab patients ( $P < 0.001$ ), suffered from pulmonary manifestations during an attack of FMF. Jewish patients who were homozygotes for the M694V mutation suffered significantly more from episodes of pleuritis, cough, and rapid, shallow breathing than Arab patients, who were either homozygotes for the V726A mutation or bore any other combination of mutations. Three patients (6%) had mild restrictive lung disease, all of them homozygotes for the M694V mutation. In 3 further patients, obstructive lung impairment was found. Pulmonary manifestations during FMF attacks are significantly more common in the Jewish population bearing the M694V mutation. Restrictive lung impairment was found in a small number of these patients with a severe course of the disease; however, the series is too small to draw conclusions about long-term sequelae of the respiratory system in FMF patients.

Behçet's syndrome: an update.

Yazici H(1).

Author information:

(1)Division of Rheumatology, Department of Medicine, Cerrahpa Medical Faculty, University of Istanbul, Aksaray 34303, Istanbul, Turkey. hyazici@attglobal.net

The pathogenic mechanisms in Behçet's syndrome are largely unknown. An autoantigen role for human leukocyte antigen B51 has been proposed. The reasons behind the thrombophilia are also not clear. Endothelial pathology could be the main culprit. The recently proposed association between familial Mediterranean fever and Behçet's syndrome might not be well founded. The long-term prognosis is more guarded among the young and among males. However, the disease burns out in many cases. Clinicians are getting better at management, and have better understanding of the old drugs, such as colchicine, and have new and potent drugs like tumor necrosis factor-alpha inhibitors.

Serum sIL-2r, IL-6, IL-10 and TNF-alpha level in familial Mediterranean fever patients.

Baykal Y(1), Saglam K, Yilmaz MI, Taslipinar A, Akinci SB, Inal A.

Author information:

(1)Department of Internal Medicine,Gulhane School of Medicine, Hacettepe University, Etlik-Ankara 06018, Turkey.

In this study we investigated cytokine levels in patients with familial Mediterranean fever (FMF). Twenty patients and 20 healthy controls were included. Ten patients had acute attacks of FMF, whereas the other 10 were in the silent period. Patients with the acute exacerbation of FMF had higher soluble interleukin-2 receptor (sIL-2r), interleukin-6 (IL-6), tumour necrosis factor-alpha, erythrocyte sedimentation rate (ESR), C-reactive protein (CRP) and fibrinogen levels than those in the silent period (  $P<0.001$ ) and controls (  $P<0.001$ ). In patients with acute attacks of FMF, interleukin-10 (IL-10) levels were not significantly different from those in the other patients or the controls (  $P>0.05$ ). In FMF patients IL-6, TNF-alpha, sIL-2r, ESR, CRP and fibrinogen levels increased with the acute-phase reaction, especially in the attack period. On the other hand, anti-inflammatory cytokine IL-10 levels did not increase as much as did the inflammatory cytokines. The balance between the cytokines may help us to understand the pathophysiology of FMF and to develop therapies. We conclude that the levels of the acute-phase reactants and the cytokines could be useful for diagnosis of acute exacerbations, follow-up and treatment. However, the cost of cytokine measurement analyses seems disadvantageous at present.

Familial Mediterranean fever presenting as recurrent acute pelvic inflammatory disease.

Adair R(1), Colon JM, McGovern PG.

Author information:

(1)Department of Obstetrics, Gynecology, and Women's Health, UMD-New Jersey Medical School, Newark, NJ 07103, USA.

**BACKGROUND:** Recurrent acute episodes of pelvic inflammatory disease (PID) often present a diagnostic dilemma. The differential diagnosis should include reinfection, appendicitis, endometriosis, irritable bowel syndrome, colitis,

persistent ovarian cyst, and antibiotic-resistant bacterial strains.

CASE: NA young Palestinian woman presented with recurrent episodes of pelvic pain with rebound tenderness, fever, and elevated white blood cell count, erythrocyte sedimentation rate, and C-reactive protein. The patient underwent extensive workup, multiple courses of intravenous and oral antibiotics, and diagnostic laparoscopies, with continued recurrent episodes. Treatment with colchicine for suspected familial Mediterranean fever resulted in resolution of symptoms.

CONCLUSION: In patients of Mediterranean ancestry who have symptoms of recurrent PID that are refractory to conventional treatment, familial Mediterranean fever should be included in the differential diagnosis.

Author information:

(1)Department of Pediatric Otorhinolaryngology, Spedali Civili, University of Brescia, Brescia, Italy.

Marshall's syndrome or PFAPA (periodic fever, aphthous stomatitis, pharyngitis, cervical adenitis) syndrome is a recently described pediatric periodic disease characterized by recurrent febrile episodes associated with head and neck symptoms. The origin of this syndrome is unknown, and it can last for several years. During healthy periods, patients grow normally. The differential diagnosis includes other diseases characterized by periodic fevers, such as familial Mediterranean fever, familial Hibernian fever, hyperglobulinemia D syndrome, Behçet's disease, cyclic neutropenia, juvenile rheumatoid arthritis, and several infectious diseases. Many treatments have been used, with various results, including antibiotics, nonsteroidal anti-inflammatory drugs, acetylsalicylic acid, colchicine, antiviral medicines, steroids, cimetidine, and tonsillectomy. We describe 5 new patients affected by PFAPA syndrome who were observed at the Department of Pediatric Otorhinolaryngology, Spedali Civili, Brescia, Italy, from

November 2000 to August 2001. All children underwent physical examination, bacterial, fungal, and viral cultures, chest radiography, and several laboratory studies. The patients were treated by successful tonsillectomy, and after a mean follow-up of 10 months, no recurrence was observed. An analysis of the literature is also presented with particular emphasis on the differential diagnosis of this rare illness and the results of the different therapeutic options.

Cisplatin treatment triggers familial Mediterranean fever attacks.

Toubi E(1), Gershoni-Baruch R, Kuten A.

Author information:

(1)Clinical Immunology, Bnai Zion Medical Center, Haifa, Israel.

A 42-year-old familial Mediterranean fever (FMF) patient who was treated with cisplatin-based chemotherapy for adenocarcinoma of the lung developed severe and frequent attacks of FMF during treatment. Abdominal pain, arthralgia and fever occurred for a few days following each cisplatin cycle. His FMF worsened, the abdominal pain and fever lasted longer and treatment with colchicine was ineffective. It has been hypothesized that the link between cisplatin treatment and FMF attacks lies in an increased production of serotonin, IL-6, IL-1, IL-8 and TNF-alpha. These inflammatory cytokines have been reported to be overproduced during cisplatin treatment and are known to play an important role in FMF relapse. The oncologist should be made aware of the possibility of disease aggravation in FMF patients during cisplatin-based chemotherapy.

Common mutations in the familial Mediterranean fever gene associate with rapid

progression to disability in non-Ashkenazi Jewish multiple sclerosis patients.

Shinar Y(1), Livneh A, Villa Y, Pinhasov A, Zeitoun I, Kogan A, Achiron A.

Author information:

(1)Heller Institute of Medical Research, Sheba Medical Center, Tel Hashomer, Israel. yshinar@sheba.health.gov.il

Ancient founder mutations in the Mediterranean fever gene, MEFV, are associated with familial Mediterranean fever, a recessive, episodic, inflammatory disease. Since these mutations are reported to express with above normal levels of acute phase reactants in healthy heterozygotes we postulated that the heterozygous phenotype could aggravate the clinical expression of ongoing autoimmune diseases. This study evaluated progression to disability in relapsing-remitting multiple sclerosis (RR-MS) patients of non-Ashkenazi and Ashkenazi origin carrying an MEFV mutation, particularly the detrimental M694V, using the expanded disability status scale (EDSS). In the non-Ashkenazi patients group (n=48), carriers (n=17) presented with a two-fold higher fraction which reached EDSS=3.0 and 6.0 compared to noncarriers (n=31) despite a comparable mean of MS duration. The median time to reach EDSS=3.0 was 2 years in the carriers vs 10 years in noncarriers (P=0.007); The median time to reach EDSS=6.0 was 6 years vs 23 years, respectively (P=0.003). M694V heterozygous patients reached both EDSS milestones earlier than other patients. Progression to disability was not enhanced in Ashkenazi RR-MS carriers (n=12, noncarriers n=59). In conclusion, non-Ashkenazi MS patients carrying one mutated MEFV gene, particularly M694V, expressed rapid progression to disability. The expressed mutation may increase inflammatory damage inflicted by autoimmune responses.

Efficacy of colchicine therapy in amyloid nephropathy of familial Mediterranean fever.

Oner A(1), Erdoğan O, Demircin G, Bülbül M, Memiş L.

Author information:

(1)Department of Pediatric Nephrology, Dr. Sami Ulus Children's Hospital, Ankara, Turkey. ayseoner99@hotmail.com

Comment in

Pediatr Nephrol. 2003 Dec;18(12):1311-2.

The aim of this study was to investigate the effect of colchicine therapy on the outcome of amyloid nephropathy of familial Mediterranean fever (FMF) in childhood. The diagnosis of amyloidosis type AA was confirmed by renal biopsy in 38 patients. During a mean follow-up period of 30.5 months (range 6-88 months), the patients received colchicine therapy. While 24 of these patients were compliant with the treatment, 14 patients remained non-compliant. Of the 24 compliant patients, 19 had normal renal function at the onset; in 13 the proteinuria improved, in 5 patients it remained stable, and in 1 patient it deteriorated from a proteinuric to nephrotic stage. Partial resolution of amyloidosis was demonstrated by repeat renal biopsy in 1 patient who showed complete resolution of proteinuria. In contrast, none of 14 non-compliant patients improved, and while only 1 patient was in renal failure initially, 10 patients deteriorated to renal failure during the follow-up period. The presence of tubulointerstitial injury at presentation adversely affected the prognosis. In conclusion, when used appropriately, colchicine can improve proteinuria and prevent chronic renal failure in patients with amyloid nephropathy of FMF. The presence of renal failure or tubulointerstitial injury at presentation and non-compliance with therapy are the factors decreasing the success of therapy.

kkonstan@med.uoa.gr

**OBJECTIVE:** To search for pyrin mutations associated with familial Mediterranean fever (FMF) in Greece.

**PATIENTS AND METHODS:** 62 patients fulfilling the Tel Hashomer diagnostic criteria for definite (33) or probable (29) FMF diagnosis were studied. Eight point mutations of pyrin gene were tested by standard methods. Of the 62 patients tested, 48 were Greek, four were Jewish, seven were Armenian, and three were Arab.

**RESULTS:** 42 patients were found to be homozygotes for pyrin mutations; 11 patients were found to carry only one of the tested mutations; in nine patients no mutations were detected.

**CONCLUSION:** Molecular detection of pyrin gene mutations seems useful in confirming suspected cases, and in detecting asymptomatic cases, of Mediterranean fever in Greece. It may also be used as a screening tool within affected families.

Urinary glycosaminoglycans in the course of familial Mediterranean fever.

Baskin E(1), Saatçi U, Ciliv G, Bakkaloglu A, Besbas N, Topaloglu R, Ozen S.

Author information:

(1)Baskent University Hospital, Department of Paediatric Nephrology, 6. Cadde, 72/3 Bahcelievler, 06490, Ankara, Turkey. esrabaskin@hotmail.com

Familial Mediterranean fever (FMF) is characterised by recurrent fever and serositis. The most important complication of the disease is amyloidosis. Cheap and non-invasive methods would be important in predicting or establishing the early diagnosis of amyloidosis. For this purpose, we studied the role of urinary glycosaminoglycans (GAG). The study group included 123 FMF patients without an attack and 11 patients with FMF associated amyloidosis. Ten healthy children and ten patients with primary nephrotic syndrome served as controls. In patients with

amyloidosis, urinary GAG were lower than in patients with FMF, patients with nephrotic syndrome and controls (median and range: 8.54 mg hexuronic acid/g creatinine (1.87-25.5), 5.8 (1.7-17.26), 23.12 (8.74-28.06) and 19.25 (14.2-26.9) respectively,  $P < 0.01$ ). There was a significant negative correlation between the duration of the disease and urinary GAG ( $r = -0.43$ ,  $P = 0.002$ ). In 49 FMF patients with a low GAG, urinary GAG increased significantly after an increase in the colchicine dose (median and range: 6.64 mg hexuronic acid/g creatinine (1.77-19.39) and 9.45 mg hexuronic acid/g creatinine (2.36-28.9),  $P < 0.01$ ). **CONCLUSION:** These results suggest that urinary glycosaminoglycan levels may be a predictor of amyloidosis in patients with familial Mediterranean fever. We also suggest that effective colchicine doses may be monitored by following urinary glycosaminoglycan excretion.

The contribution of genotypes at the MEFV and SAA1 loci to amyloidosis and disease severity in patients with familial Mediterranean fever.

Gershoni-Baruch R(1), Brik R, Zacks N, Shinawi M, Lidar M, Livneh A.

Author information:

(1)Rambam Medical Center, Haifa, Israel. rgershoni@rambam.health.gov.il

**OBJECTIVE:** The clinical profile in familial Mediterranean fever (FMF), including its major manifestation, amyloidosis, is influenced by MEFV allelic heterogeneity and other genetic and/or environmental factors. In this study, we analyzed the contribution of genotypes at the MEFV and SAA1 loci to disease severity and to the development of amyloidosis, and further defined the factors affecting the clinical profile of FMF.

**METHODS:** We investigated a sample of 277 FMF patients (154 men and 123 women), including 62 patients with nephropathic amyloidosis, in whom both FMF alleles had been identified. A detailed chart review, interview, and physical examination were undertaken to determine the patients' demographic characteristics, medical history, clinical manifestations, and treatment. The disease severity score was calculated from the Tel-Hashomer key. Genotypes at the SAA1 locus (isoforms

alpha, beta, and gamma) were determined in all patients. The SAA1 13C/T polymorphism of the SAA1 promotor was analyzed in a subset of cases.

RESULTS: The male:female ratio (154:123, or 1.3) was higher among patients with amyloidosis (40:22, or 1.8) compared with patients without amyloidosis (114:101, or 1.1). Logistic regression analysis showed that homozygosity for the M694V allele (odds ratio [OR] 4.27, 95% confidence interval [95% CI] 2.01-9.07), the presence of the SAAalpha/alpha genotype (OR 2.99, 95% CI 1.47-6.09), the occurrence of arthritis attacks (OR 2.43, 95% CI 1.17-5.06), and male sex (OR 1.73, 95% CI 0.90-3.33) were significantly and independently associated with renal amyloidosis. Disease severity was mainly influenced by MEFV mutations and was not associated with genotypes at the SAA1 locus. The SAA1 13T allele was rare, being associated mainly with the SAA gamma isoform, and not related to renal amyloidosis.

CONCLUSION: Overall, disease severity and the development of amyloidosis in FMF are differentially affected by genetic variations within and outside the MEFV gene.

Familial Mediterranean fever (FMF) is an inherited disorder characterized by recurrent episodes of fever and inflammation. Most patients with FMF carry missense mutations in the C-terminal half of the pyrin protein. To study the physiologic role of pyrin, we generated mice expressing a truncated pyrin molecule that, similar to FMF patients, retains the full PYRIN domain. Bacterial lipopolysaccharide (LPS) induces accentuated body temperatures and increased lethality in homozygous mutant mice. When stimulated, macrophages from these mice produce increased amounts of activated caspase-1 and, consequently, elevated levels of mature IL-1beta. Full-length pyrin competes in vitro with caspase-1 for binding to ASC, a known caspase-1 activator. Apoptosis is impaired in macrophages from pyrin-truncation mice through an IL-1-independent pathway. These data support a critical role for pyrin in the innate immune response, possibly by acting on ASC, and suggest a biologic basis for the selection of hypomorphic pyrin variants in man.

**PURPOSE:** The study aimed to determine whether detectable concentrations of colchicine are present in the tear fluid of treated patients with familial Mediterranean fever (FMF) and thus demonstrate a possible route by which colchicine reaches the corneal surface.

**METHODS:** Tear fluid samples (50-100 microL) were collected from eight FMF patients on long-term colchicine treatment. Colchicine tear fluid concentrations were determined in all patients by radioimmunoassay using goat anticolchicine antibodies and [3H]colchicine (Dupont, Wilmington, DE).

**RESULTS:** Detectable concentrations of colchicine, with no apparent effect on the ocular surface, were found in all tear fluid samples (median, 0.46 ng/mL; range, 0.24-1.05 ng/mL).

**CONCLUSIONS:** This study provides evidence of the route by which colchicine, given systemically, reaches the corneal surface and thus gives credence to the possible inhibitory effect of this drug on corneal wound healing in the cases described in the literature.

ASC is a pro-apoptotic protein containing a pyrin domain (PD) and a caspase-recruitment domain (CARD). A previous study suggests that ASC interacts with Ipaf, a member of the Apaf-1/Nod1 protein family. However, the functional relevance of the interaction has not been determined. Here, we report that co-expression of ASC with Ipaf or oligomerization of ASC induces both apoptosis and NF-kappa B activation. Apoptosis induced through ASC was inhibited by a mutant form of Caspase-8 but not by that of Caspase-1. The PD of ASC physically interacted with Caspase-8 as well as with pyrin, the familial Mediterranean fever gene product. Caspase-8 deficiency rescued mouse fibroblasts from apoptosis induced by ASC oligomerization. Pyrin disrupted the interaction between ASC and Caspase-8, and inhibited both apoptosis and NF-kappa B activation induced by ASC. These findings suggest that ASC is a mediator of NF-kappa B activation and Caspase-8-dependent apoptosis in an Ipaf signaling pathway.

Carrier frequency of the V377I (1129G>A) MVK mutation, associated with Hyper-IgD and periodic fever syndrome, in the Netherlands.

Houten SM(1), van Woerden CS, Wijburg FA, Wanders RJ, Waterham HR.

Author information:

(1)Laboratory Genetic Metabolic Diseases, Department of Pediatrics/Emma Children's Hospital, Academic Medical Center, University of Amsterdam, Amsterdam, The Netherlands.

Hyper-IgD and periodic fever syndrome (HIDS) and mevalonic aciduria (MA) are two autosomal recessive disorders that both are caused by a deficient activity of the enzyme mevalonate kinase (MK) due to mutations in the encoding gene (MVK). The most frequently occurring MVK mutation, V377I (1129G>A), has been identified exclusively in HIDS patients. Other common mutations have been associated with both HIDS and MA. To estimate the incidence of MK deficiency in the Netherlands, we determined the carrier frequency of the V377I mutation in genomic DNA

extracted from anonymised newborn screening cards by PCR-RFLP. We found 14 carriers among 2138 analysed samples (1 : 153). Based on the V377I allele frequency of 42% in patients diagnosed with MK deficiency, the carrier frequency of any MVK mutation in the Dutch population can be calculated as 1 : 65. This predicts a disease incidence between 1 in 5196 and 1 in 53 656, which is far more than actually observed. Although under-diagnosis of patients with MK deficiency remains possible, this discrepancy probably is due to a reduced penetrance of V377I homozygosity. Analysis of the distribution of the V377I allele within patients carrying MVK mutations revealed that this was not according to the Hardy-Weinberg equilibrium principle, most probably due to an under-representation of V377I homozygotes in HIDS. Homozygotes for V377I might exhibit a much milder phenotype of MK deficiency or no disease-phenotype at all.

Author information:

(1)Max-Planck-Institute for Informatics, Stuhlsatzenhausweg 85, 66123 Saarbrücken, Germany. mario.albrecht@mpi-sb.mpg.de

PYRIN- and CARD-containing proteins belong to a recently identified protein family involved in the regulation of apoptosis and inflammatory processes. Variations in the gene products of the family members PYPAF1 and NOD2/CARD15 have been associated with several autoinflammatory diseases. We could identify the mouse orthologs of PYPAF1, PYPAF5, NOD1, NOD2 and the rat ortholog of PYPAF5. Intriguingly, we found that PYPAF5 has been reported previously not only as regulator of NF-kappaB and caspase-1, but also as angiotensin II and vasopressin receptor. In particular, based on a comprehensive sequence analysis, we propose a structural model for this hormone receptor that is different from the model suggested previously.

Author information:

(1)Department of Pathology and Comprehensive Cancer Center, The University of Michigan Medical School, Ann Arbor, MI 48109, USA.

Cryopyrin, a member of the Nod protein family mutated in familial cold urticaria and Muckle-Wells syndrome, has been recently implicated in inflammation. However, the mechanism of activation and regulation of the cryopyrin signaling pathway remains poorly understood. We report here that co-expression of cryopyrin with its binding partner, ASC, induced both apoptosis and NF-kappaB activation. This signaling was mimicked by oligomerization of ASC, suggesting that cryopyrin activates downstream targets as reported for other Nod family members. Notably, pyrin, the product of the familial Mediterranean fever gene, inhibited cryopyrin-mediated apoptosis and NF-kappaB activation by disrupting the cryopyrin-ASC interaction. These results provide evidence for a cryopyrin signaling pathway activated through the induced proximity of ASC, which is negatively regulated by pyrin.

Seronegative spondyloarthropathy of familial Mediterranean fever.

Incel NA(1), Saraçoğlu M, Erdem HR.

Author information:

(1)nincel@hotmail.com

Familial Mediterranean fever (FMF) is characterized by an autosomal inheritance pattern, Mediterranean ancestry, and history of recurrent fever. We present a 30-year-old Turkish man with FMF and accompanying seronegative spondyloarthropathy. His diagnose depended on the clinical course of his disease: recurrent fever accompanied by abdominal pain attacks together with a positive family history and his ethnic origin and sacroiliitis. We review the common manifestations of FMF and remind physicians that sacroiliac joint involvement must be kept in mind in presence of articular symptoms in a FMF patient.

[The association of polyarteritis nodosa and familial Mediterranean fever].

[Article in French]

Bosacki C(1), Richard O, Freycon F, Mosnier JF, Cathébras P.

Author information:

(1)Service de médecine interne, Hôpital Nord, Saint-Etienne.

INTRODUCTION: Some necrotizing vasculitis may be associated with familial Mediterranean fever (FMF). We report a new case of polyarteritis nodosa (PAN) that preceded the diagnosis of FMF.

**OBSERVATION:** A young woman of Turkish origin had a long childhood history of inflammatory arthralgia and myalgia, leading to the provisional diagnosis of chronic juvenile arthritis, then, after a confirmative muscle biopsy, to the diagnosis of PAN, whose outcome remained benign. At the age of 19, she was diagnosed as having FMF on clinical and genetic grounds, and colchicine led to the regression of most symptoms.

**DISCUSSION:** As with Henoch-Schönlein's purpura, PAN seems significantly associated with FMF. Its characteristics are a younger age at onset, more frequent peri-renal hematoma, overlap between classical PAN and micropolyangeitis, and overall better prognosis. In its muscular form, PAN is difficult to distinguish from protracted febrile myalgia, a recently described manifestation of FMF, in which pathological findings are poorly documented.

A large kindred with familial cold autoinflammatory syndrome.

Johnstone RF(1), Dolen WK, Hoffman HM.

Author information:

(1)Allergy-immunology Section, Department of Pediatrics, Medical College of Georgia, Augusta, Georgia, USA.

**BACKGROUND:** Familial cold autoinflammatory syndrome (FCAS), formerly known as familial cold urticaria, is a rare condition characterized by fever, rash, and arthralgias elicited by exposure to cold. Recently, mutations responsible for FCAS were identified in a novel gene (CIAS1), making it possible to confirm the diagnosis in most patients.

**OBJECTIVE:** We present a summary of clinical data from a large family with FCAS to further define the characteristics of the disorder and to validate previously proposed clinical criteria.

**METHODS:** A total of 73 participants were evaluated by interview and questionnaire, including 36 affected individuals. Responses from the questionnaire were analyzed and comparisons of proportions were made using the Z test. DNA was isolated and genotyping was performed on all subjects. Affected

haplotypes (genotype patterns) were identified and used to confirm the diagnosis. Sequencing of the CIAS1 gene was performed in selected patients to confirm the mutation.

RESULTS: The prevalence of rash, fever/chills, joint complaints, nausea, headache, and thirst were not significantly different from previously reported proportions. There was statistically significant differences in conjunctivitis, sweating, and drowsiness with  $\alpha = 0.01$ . The mean temperature required to produce symptoms was 22 degrees C, and the average earliest onset of symptoms after exposure was 1.5 hours.

CONCLUSIONS: Applying the proposed clinical criteria, 41% of affected subjects met all six criteria, 90% met five criteria, and 100% met four criteria for FCAS. None of the unaffected subjects met more than two criteria. Using a threshold of 4 of 6 clinical criteria, the data support the diagnostic validity of the proposed clinical criteria.

Familial Mediterranean fever.

Odabas AR(1), Cetinkaya R, Selcuk Y, Bilen H.

Author information:

(1)Department of Nephrology, Ataturk University School of Medicine, Erzurum, Turkey.

BACKGROUND: The pathogenesis of familial Mediterranean fever (FMF) is unknown, and since no specific laboratory test is yet available, the diagnosis of FMF remains clinical. The purpose of this study was to review clinical characteristics of patients with FMF.

METHODS: A total of 96 patients with FMF were evaluated either retrospectively (for those diagnosed before 1997) or prospectively (for those after 1997).

RESULTS: The records of 54 male and 42 female patients were studied. All patients were Turks. Family history was positive in 72 patients (75%). Involved site was peritoneum in 73 (76%), joints in 65 (68%), and pleura in 16 (17%). Febrile myalgia occurred in 3 patients (3%), and erysipelas-like skin lesions were

observed in 2 (2%). Fever was found in 93 patients (97%). Reactive systemic (AA) amyloidosis was found in 38 patients (40%).

CONCLUSIONS: Diagnostic problems persist despite increased understanding of the pathogenesis of FMF. Amyloidosis, the most important complication of FMF, is often seen.

liz.drewe@nottingham.ac.uk

Erratum in

Rheumatology (Oxford). 2003 May;42(5):711.

OBJECTIVE: To assess the effects prospectively of tumour necrosis factor (TNF) receptor superfamily (TNFRSF) fusion proteins TNFRSF1B (etanercept) and TNFRSF1A (p55TNFr-Ig) in patients with TNF receptor associated periodic syndrome (TRAPS).

METHODS: Seven patients with a clinical and genetic diagnosis of TRAPS received subcutaneous etanercept for 24 weeks. One of these patients had previously received an intravenous infusion of p55TNFr-Ig. Therapeutic response was assessed by comparing corticosteroid requirement, acute-phase response and an established scoring system over 20 weeks, both on and off etanercept.

RESULTS: Etanercept was well tolerated. The five corticosteroid-responsive patients required significantly less corticosteroids and demonstrated reductions in acute-phase reactants on etanercept. The two patients not requiring corticosteroids had small reductions in disease activity scores. The effect of p55TNFr-Ig in a single patient with TRAPS remains unclear.

CONCLUSIONS: Etanercept does not abolish inflammatory attacks but improves disease activity allowing corticosteroid reduction. Etanercept may be clinically useful in replacing or reducing steroid requirements in the treatment of TRAPS. A formal trial of etanercept to establish its role in clinical management is indicated.

CT findings in patients with familial Mediterranean fever during an acute abdominal attack.

Zissin R(1), Rathaus V, Gayer G, Shapiro-Feinberg M, Hertz M.

Author information:

(1)Department of Diagnostic Imaging, Sapir Medical Center, Kfar Saba 44281, Israel.

The aim of this study is to present the abdominal CT findings of patients with familial Mediterranean fever (FMF) examined during an acute abdominal attack. CT scans of 17 patients (10 women and 7 men; age range 11-45 years) were retrospectively reviewed. Attention was directed to mesenteric or peritoneal abnormalities and to the presence of appendiceal pathology. Patients were divided into two groups; group A (n=14) consisted of patients with an acute abdominal attack caused by FMF, and group B (n=3) consisted of patients whose attack proved to be owing to a separate pathology requiring surgery. Characteristic CT findings of acute abdomen in FMF included mesenteric pathology (n=12), mainly of engorged vessels with thickened mesenteric folds, mesenteric lymphadenopathy (n=6) and ascites (n=6). Signs of focal peritonitis were found in four patients.

Radiologists should be familiar with such CT findings of peritoneal irritation in patients with FMF during an acute attack, and may suggest this clinical diagnosis in the proper clinical setting in a patient who has not been previously diagnosed. Alternatively, the radiologist should be aware of the possibility of a concurrent acute appendicitis or other acute abdominal pathology in patients with known FMF and should search for it.

Comment in

QJM. 2003 May;96(5):379-80.

QJM. 2003 Jun;96(6):454.

**BACKGROUND:** Studying patients with chronic fatigue syndrome (CFS), we have developed a method that uses a head-up tilt test (HUTT) to estimate BP and HR instability during tilt, expressed as a 'haemodynamic instability score' (HIS).

**AIM:** To assess HIS sensitivity and specificity in the diagnosis of CFS.

**DESIGN:** Prospective controlled study.

**METHODS:** Patients with CFS (n=40), non-CFS chronic fatigue (n=73), fibromyalgia (n=41), neurally mediated syncope (n=58), generalized anxiety disorder (n=28), familial Mediterranean fever (n=50), arterial hypertension (n=28), and healthy subjects (n=59) were evaluated with a standardized head-up tilt test (HUTT). The HIS was calculated from blood pressure (BP) and heart rate (HR) changes during the HUTT.

**RESULTS:** The tilt was prematurely terminated in 22% of CFS patients when postural symptoms occurred and the HIS could not be calculated. In the remainder, the median(IQR) HIS values were: CFS +2.14(4.67), non-CFS fatigue -3.98(5.35), fibromyalgia -2.81(2.62), syncope -3.7(4.36), generalized anxiety disorder -0.21(6.05), healthy controls -2.66(3.14), FMF -5.09(6.41), hypertensives -5.35(2.74) (p<0.0001 vs. CFS in all groups, except for anxiety disorder, p=NS). The sensitivity for CFS at HIS >-0.98 cut-off was 90.3% and the overall specificity was 84.5%.

DISCUSSION: There is a particular dysautonomia in CFS that differs from dysautonomia in other disorders, characterized by HIS >-0.98. The HIS can reinforce the clinician's diagnosis by providing objective criteria for the assessment of CFS, which until now, could only be subjectively inferred.

J Pediatr. 2003 Feb;142(2):99-101.

We describe four members in a family of 8 individuals over 3 generations with the autosomal dominant inherited periodic fever syndrome tumor necrosis factor receptor-associated periodic syndrome (TRAPS). The patients had recurrent

episodes of fever, abdominal pain, arthritis, and rash. We examined the gene coding for the tumor necrosis factor receptor TNFRSF1A in all first-degree family members. In all 4 symptomatic members of the family, a hitherto undescribed mutation C98Y (380G-->A) in the TNFRSF1A gene was identified. In contrast, this mutation was not found in the 4 family members reported to be healthy nor in 50 normal control patients. The youngest member of the family, a 2-year-old boy, was treated successfully with etanercept.

Increased soluble FAS suggests delayed apoptosis in familial Mediterranean fever complicated with amyloidosis.

Kiraz S(1), Ertenli I, Oztürk MA, Haznedaroglu IC, Calgüneri M, Atalar E, Ozbalkan Z, Kirazli S, Celik I.

Author information:

(1)Department of Rheumatology, Hacettepe University School of Medicine, Ankara, Turkey.

**OBJECTIVE:** Interactions of the FAS with FAS ligand have been proposed as a major regulatory mechanism of immune homeostasis. Soluble FAS (sFAS) acts as a competitive antagonist to FAS, thereby inhibiting FAS mediated apoptosis. sFAS concentrations have been studied in various autoimmune diseases, with controversial results. In this cross sectional study, we investigated the role of sFAS protein in attack-free patients with familial Mediterranean fever (FMF) with and without amyloidosis.

**METHODS:** Twelve FMF patients without amyloidosis (male/female: 7/5; median age 23.5 yrs, range 17-38), 10 FMF patients with amyloidosis (male/female: 5/5; median age 41.5 yrs, range 33-51), and 14 controls (male/female: 6/8; median age 46 yrs, range 38-57) were enrolled in the study. Serum sFAS concentrations were studied by ELISA.

**RESULTS:** Median serum sFAS concentrations were 4630 (2580-12,270), 1338 (453-3240), and 3430 (2110-5960) pg/ml in FMF patients without amyloidosis, FMF patients with amyloidosis, and controls, respectively. Intergroup differences were all statistically significant ( $p < 0.05$ ).

**CONCLUSION:** Elevated serum sFAS concentrations in attack-free FMF patients might be due to dysregulated apoptosis of polymorphonuclear leukocytes together with the ongoing subclinical inflammatory activity. On the other hand, decreased sFAS concentrations could contribute to the augmented apoptosis together with the alterations in immune response leading to the amyloidosis.

Male sex coupled with articular manifestations cause a 4-fold increase in susceptibility to amyloidosis in patients with familial Mediterranean fever homozygous for the M694V-MEFV mutation.

Gershoni-Baruch R(1), Brik R, Lidar M, Shinawi M, Livneh A.

Author information:

(1)Department of Human Genetics, Rambam Medical Center, Haifa, Israel.  
r.gershoni@rambam.health.gov.il

**OBJECTIVE:** Familial Mediterranean fever (FMF) is an autosomal recessive disorder

characterized by attacks of fever, serositis, and a predisposition to the development of amyloidosis. The wide clinical variability of the disease has been partly attributed to MEFV allelic heterogeneity and partly to the influence of additional genetic and/or environmental modifiers. Of these, male sex was found to influence disease penetrance and susceptibility to amyloidosis. We investigated the role of sex as an independent contributor to the phenotypic profile in FMF and further defined the factors affecting disease expression and severity.

**METHODS:** A total of 124 patients with FMF who were all homozygous for the M694V mutation, including 47 patients with nephropathic amyloidosis, were identified. A detailed chart review and physical examination were undertaken to determine demographic characteristics, history, clinical manifestations, and treatment, and we calculated the disease severity score from the Tel-Hashomer key.

**RESULTS:** A preponderance of male patients was documented (73:51; 1.4). The overall male:female ratio was significantly higher among patients with amyloidosis (32:15; 2.1) compared to patients without amyloidosis (41:36; 1.1). FMF severity scores, independently calculated for male and female patients, were equally high (9.5 +/- 3.0 and 9.7 +/- 2.8, respectively). The frequency of arthritic attacks, significantly higher in women than men ( $p = 0.015$ ), remained notably higher in male FMF patients with amyloidosis compared to male FMF patients without amyloidosis ( $p = 0.002$ ). Significant correlation between arthritis attacks and amyloidosis was found ( $R > 0.285$ ,  $p < 0.001$ ).

**CONCLUSION:** Susceptibility to renal amyloidosis is influenced both by sex and the occurrence of joint attacks, acting as 2 MEFV independent factors (OR 2.37, 95% CI 1.06-5.26 and OR 3.27, 95% CI 1.23-8.68, respectively).

Hip involvement in patients with familial Mediterranean fever. A review of ten cases.

Younes M(1), Kahn MF, Meyer O.

Author information:

(1)Rheumatology Department (Professor O. Meyer), Bichat Teaching Hospital, 46,

rue Henri-Huchard, 75018 Paris, France.

Hip involvement is uncommon in familial Mediterranean fever (FMF) and can result either from a process specific to this disease or from a coexisting chronic inflammatory joint disease, usually suggestive of ankylosing spondylitis (AS). We report ten cases of FMF with radiologically-documented inflammatory hip disease. Five patients had AS and one had juvenile idiopathic arthritis. There were six men and four women, with a mean age of 34.4 years  $\pm$  17.6 (range, 15-70 years). Onset of the inflammatory hip disease occurred after bouts of acute hip symptoms in one of the patients with isolated FMF and after protracted hip arthritis in another; the two other patients had no history of hip symptoms. The HLA-B27 antigen was looked for in two of the five patients with FMF and AS, with negative results in both; another patient in this subgroup had severe ulcerative colitis. Total hip replacement or replacement of the acetabulum was required in six patients, including two with isolated FMF. Chronic joint disease has been estimated to contribute fewer than 5% of the joint manifestations in FMF. In previous studies, the hips and knees were affected in 75% of patients with chronic joint disease related to FMF. The association of FMF and AS (usually without the HLA-B27 antigen) has been well documented, although the pathogenic mechanisms that link these two conditions remain unknown.

Comment in

Eur J Hum Genet. 2004 Feb;12(2):85-6.

Familial Mediterranean fever (FMF) is an autosomal recessive disorder,

characterised by short, recurrent attacks of fever with abdominal, chest or joint pain and erysipelas-like erythema. It is an ethnically restricted genetic disease, found commonly among Mediterranean populations, as well as Armenians, Turks, Arabs and Jews. Traditionally, Italians have been considered little affected by FMF, despite the geographical position of Italy (northern Mediterranean basin) and the migratory changes in its population. The objective was to characterise the demographic, clinical and genetic features of FMF in Italy. Patients of Italian origin were recruited from those referred to Italian-French medical centres for FUO (Fever of Unknown Origin) or 'surgical' emergencies; clinical history, genealogy and physical examination were recorded; all other possible infectious, neoplastic, auto-immune and metabolic diseases were excluded. Mutational analysis of the gene responsible for FMF (MEFV on 16p13.3) was performed, after which geno-phenotypical correlations were established. Italian FMF patients, 40 women and 31 men, aged from 3 to 75 years, have shown all the clinical manifestations indicative of FMF described in the literature, but with a lower incidence of amyloidosis. The genetic tests have been contributive in 42% of cases. The frequency of each different mutation has been similar to that found in a series of 'endemic' countries. The geno-phenotypical correlations have suggested the existence of genetic and/or environmental modifier-factors. Among Italians FMF seems to be more frequent than was believed in the past. The data presented are consistent with their geographical location and their history.

hahoffman@ucsd.edu

Familial cold autoinflammatory syndrome (FCAS) is an autosomal dominant inflammatory disease with a high degree of penetrance that is characterized by episodes of rash, arthralgia, fever, conjunctivitis, and leukocytosis after generalized exposure to cold. FCAS was previously mapped to a 10-cM region on chromosome 1q44, and subsequently the gene ( CIAS1) responsible for FCAS was identified. In this paper, we describe the physical and genetic mapping of the FCAS locus, and we report a large ancestral haplotype and a new disease-causing mutation. A BAC contig of approximately 3 Mb was developed and subsequently used for high throughput sequencing. We identified a critical region of 4 cM using rare crossover events in four large North American FCAS families. An unusually large shared haplotype (40 cM) was identified in three of the four families. We found a single heterozygous missense mutation (T1058C=L353P) in exon 3 of CIAS1 in all four families that is responsible for the large majority of FCAS cases described in the literature. We also report a comprehensive list of intragenic single nucleotide polymorphisms. The data provided here will assist others

researching the 1q44 region and will aid clinicians in the diagnosis of FCAS.

The MetaFMF website: a high quality tool for meta-analysis of FMF.

Pugnère D(1), Ruiz M, Sarrauste de Menthère C, Masdoua B, Demaille J, Touitou I.

Author information:

(1)Institute of Human Genetics-CNRS UPR 1142, 141, rue de la Cardonille, 34396 Montpellier Cedex 5, France. denis.pugnere@igh.cnrs.fr

We present here the MetaFMF database (freely accessible at [http://fmf.igh.cnrs.fr/metaFMF/index\\_us.html](http://fmf.igh.cnrs.fr/metaFMF/index_us.html)) that attempts to gather and unify, in a common resource, data on phenotype-genotype correlation in familial Mediterranean fever (FMF). A single accession form, including a large number of quality controls, has been implemented such that data, collected worldwide, are included in an homogeneous manner. The inclusion criterion has the objective to avoid interpretational bias: patients will be included only if they bear at least two mutations. The clinical form has been set up by an International editorial board (12 FMF expert centres), which guarantees the validity of the data. Data are anonymous and submitted by a secure interface, in which the researcher is logged in with a specific ID and password. A pilot study on 211 patients has shown the feasibility and relevance of this project. We anticipate that the use of MetaFMF will enable reliable assessment of phenotype-genotype correlations in FMF, and define a set of severe versus mild mutations/genotypes. It should also highlight reasons for previous inconsistencies in such correlations.

INFEVERS: the Registry for FMF and hereditary inflammatory disorders mutations.

Sarrauste de Menthère C(1), Terrière S, Pugnère D, Ruiz M, Demaille J, Touitou I.

Author information:

(1)Institute of Human Genetics-CNRS UPR 1142, 141, rue de la Cardonille, 34396 Montpellier Cedex 5, France. cyril.sarrauste@igh.cnrs.fr

We have established the INFEVERS--Internet periodic FEVERS--website (which is freely accessible at <http://fmf.igh.cnrs.fr/infevers/>). Our objectives were to develop a specialist site to gather updated information on mutations responsible for hereditary inflammatory disorders: i.e. Familial Mediterranean Fever (FMF), TRAPS (TNF Receptor 1A Associated Syndrome), HIDS (HyperIgD Syndrome), MWS (Muckle-Wells Syndrome)/FCU (Familial Cold Urticaria)/CINCA (Chronic Infantile Neurological Cutaneous and Articular Syndrome). Contributors submit their novel mutations through a 3 step form. Depending on the disease concerned, a member of the editorial board is automatically solicited to overview and validate new submissions, via a special secured web interface. If accepted, the new mutation is available on the INFEVERS web site and the discoverer, who is informed by email, is credited by having his/her name and date of the discovery on the site. The INFEVERS gateway provides researchers and clinicians with a common access location for information on similar diseases, allowing a rapid overview of the corresponding genetic defects at a glance. Furthermore, it is interactive and extendable according to the latest genes discovered.

**OBJECTIVE:** Familial Mediterranean fever (FMF) is an autosomal recessive disease with diverse clinical presentation. The FMF gene (MEFV) has recently been cloned and 30 point mutations causing the disease have been identified. We appraised the value of mutation analysis as a diagnostic test for FMF in symptomatic pediatric patients, and explored the possible correlations between MEFV genotypes and the diverse phenotypic expression of the disease.

**METHODS:** Two hundred sixteen children who met the clinical criteria for FMF underwent molecular genetic studies to detect the 3 most common mutations in the Israeli FMF patient population (M694V, V726A, E148Q). The mutations found were related to clinical presentation and disease severity, using the Tel-Hashomer severity score.

**RESULTS:** Of the 216 children who fulfilled the diagnostic criteria for FMF, 82 (38.0%) had 2 of the tested mutations, 73 (33.8%) had only one mutation, and 61 (28.2%) had none of the mutations studied. The M694V was the most frequent mutation, detected in 174 of 432 MEFV alleles (40.0%). The V726A mutation was found in 39 alleles (9.0%) and the E148Q mutation in 25 (5.8%). The severity score correlated with the number of mutations. Children with no mutations presented at an older age compared to children with one or 2 mutations. Children homozygous for the M694V mutation presented at a younger age, had a higher severity score, and more commonly had arthritis.

**CONCLUSION:** Limited genetic molecular testing for MEFV mutations may explain some of the FMF clinical variability, but is diagnostically ineffective. The use of clinical criteria remains essential in establishing the diagnosis of FMF.

Ontario, Canada. jagdish.butany@uhn.on.ca

Endothelial cell dysfunction plays an important role in the development and progression of cardiovascular and other disease. The purpose of this review is to discuss some of the genetic diseases known to adversely affect endothelial function. Although the list is exhaustive, we focus our discussion on primary pulmonary hypertension, diabetes mellitus, Alzheimer's disease, Crohn's disease, Von-Hippel-Lindau disease, familial Mediterranean fever, thrombotic microangiopathy, and key vascular malformations. Endothelial dysfunction results from a complex interplay between genetic and environmental factors. This review highlights some of the growing body of evidence implicating endothelial dysfunction as an important mediator of diverse diseases.

The authors review the genes, and their respective proteins, responsible for eight autoinflammatory conditions. Familial Mediterranean fever is caused by mutations in pyrin, which is the prototype of a new family of proteins belonging to the death-domain superfamily. This new group of proteins, which regulate apoptosis, inflammation, and cytokine processing, share an approximately 90-amino-acid N-terminal sequence called the PYRIN domain. Mutations in another PYRIN domain protein, termed cryopyrin, are responsible for three clinically defined illnesses, Muckle-Wells syndrome, familial cold autoinflammatory syndrome, and NOMID/CINCA. A related protein encoded by the gene is responsible for the Mendelian disorder, Blau syndrome, and also predisposes to Crohn disease. The gene responsible for PAPA syndrome has recently been identified as, and preliminary results from the authors' laboratory also implicate its protein product in these pathways. Lastly, the authors discuss the broadening genetic and clinical spectrum of TRAPS, an autoinflammatory syndrome resulting from mutations in the 55-kDa receptor for tumor necrosis factor.

De novo CIAS1 mutations, cytokine activation, and evidence for genetic heterogeneity in patients with neonatal-onset multisystem inflammatory disease (NOMID): a new member of the expanding family of pyrin-associated autoinflammatory diseases.

Aksentijevich I(1), Nowak M, Mallah M, Chae JJ, Watford WT, Hofmann SR, Stein L, Russo R, Goldsmith D, Dent P, Rosenberg HF, Austin F, Remmers EF, Balow JE Jr, Rosenzweig S, Komarow H, Shoham NG, Wood G, Jones J, Mangra N, Carrero H, Adams BS, Moore TL, Schikler K, Hoffman H, Lovell DJ, Lipnick R, Barron K, O'Shea JJ, Kastner DL, Goldbach-Mansky R.

Author information:

(1)National Institute of Arthritis and Musculoskeletal and Skin Diseases, NIH, Bethesda, Maryland 20892, USA.

**OBJECTIVE:** Neonatal-onset multisystem inflammatory disease (NOMID; also known as chronic infantile neurologic, cutaneous, articular [CINCA] syndrome) is characterized by fever, chronic meningitis, uveitis, sensorineural hearing loss, urticarial skin rash, and a characteristic deforming arthropathy. We investigated whether patients with this disorder have mutations in CIAS1, the gene which causes Muckle-Wells syndrome and familial cold autoinflammatory syndrome, two dominantly inherited disorders with some similarities to NOMID/CINCA syndrome.

**METHODS:** Genomic DNA from 13 patients with classic manifestations of NOMID/CINCA syndrome and their available parents was screened for CIAS1 mutations by automated DNA sequencing. Cytokine messenger RNA (mRNA) levels were assessed by real-time polymerase chain reaction on peripheral blood leukocyte mRNA, and serum cytokine levels were assayed by enzyme-linked immunosorbent assay. Protein expression was assessed by Western blotting of lysates from plastic-adherent peripheral blood mononuclear cells.

**RESULTS:** In 6 of the 13 patients, we found 6 heterozygous missense substitutions in CIAS1. Five of the 6 mutations are novel. None of these sequence changes was observed in a panel of >900 chromosomes from healthy controls. Two distinct nucleotide changes in a single codon in unrelated patients resulted in the same amino acid change. In 4 mutation-positive children whose parental DNA was available, no mutation was found in the parental DNA, supporting the conclusion that the mutations arose de novo. Consistent with the recently discovered role of CIAS1 in the regulation of interleukin-1 (IL-1), we found evidence of increased

IL-1beta, as well as tumor necrosis factor, IL-3, IL-5, and IL-6, but not transforming growth factor beta, in a mutation-positive patient compared with normal controls.

CONCLUSION: Our data increase the total number of known germline mutations in CIAS1 to 20, causing a spectrum of diseases ranging from familial cold autoinflammatory syndrome to Muckle-Wells syndrome to NOMID/CINCA syndrome. Mutations in CIAS1 were only found in approximately 50% of the cases identified clinically as NOMID/CINCA syndrome, which raises the possibility of genetic heterogeneity. IL-1 regulation by CIAS1 suggests that IL-1 receptor blockade may constitute a rational approach to the treatment of NOMID/CINCA syndrome.

Tuberculous ileitis in a renal transplant recipient with familial Mediterranean fever: Gray-scale and power Doppler sonographic findings.

Yilmaz E(1), Balci A, Sal S, Cakmakci H.

Author information:

(1)Department of Radiology, Dokuz Eylül University School of Medicine, Inciralti, 35340 Izmir, Turkey.

The ileocecal area is the most common site of involvement of intestinal tuberculosis. We report the case of a 26-year-old renal transplant recipient with familial Mediterranean fever who developed tuberculous ileitis. Gray-scale sonography and CT showed circumferential thickening of the bowel wall and enlargement of the mesenteric lymph nodes. Power Doppler sonography revealed markedly increased vascularity in the wall of the affected ileal segment and in the mesenteric nodes. Some nodes had no flow at the center owing to caseation necrosis, a finding consistent with the diagnosis of tuberculous ileitis.

Colonoscopy was performed, and histopathologic examination of biopsy specimens revealed acute inflammatory changes. Cultures of the specimens confirmed the presence of Mycobacterium tuberculosis. We conclude that findings on power Doppler sonography may support a diagnosis of tuberculous ileitis and avoid

clinical mismanagement.

Genetic clues to understanding periodic fevers, and possible therapies.

McDermott MF(1).

Author information:

(1)Dept of Diabetes and Metabolic Medicine, Unit of Molecular Medicine, Barts and the London, Queen Mary's School of Medicine and Dentistry, University of London, UK. m.f.mcdermott@qmul.ac.uk

Significant breakthroughs in our understanding of the molecular basis of the inflammatory response have been achieved in the past five years, with the successive identification of the genetic basis of all known hereditary periodic-fever syndromes. Impaired cytokine recognition and defective signalling molecules have been implicated in the inception of recurrent attacks of fever with acute-phase protein response. Disorders of interleukin-1 processing and of regulation of nuclear factor kappaB transcription factor, and possibly defective apoptosis, might be involved in the pathogenesis of all but one of these disorders. Mutations in genes of both the pyrin and tumour-necrosis-factor-receptor superfamilies are postulated to lead to the survival of leukocytes that would ordinarily undergo apoptosis, and ultimately to a prolonged inflammatory response. Improved therapies have reduced the incidence of systemic amyloidosis, but this complication remains the most frequent cause of death.

The significance of paired MEFV mutations in individuals without symptoms of familial Mediterranean fever.

Tunca M, Akar S, Hawkins PN, Booth SE, Sengül B, Yavuzşen TU, Oktem S, Soytürk M, Akkoç N, Booth DR.

The majority of patients with familial Mediterranean fever (FMF) have identifiable mutations in both alleles of the MEFV gene, while some individuals with paired MEFV mutations do not have clinical symptoms of the disease. During family studies we identified nine such individuals from six kindreds, most of whom either subsequently developed FMF or had other clinically significant inflammatory disease; one case benefiting substantially from colchicine therapy. Four individuals remained asymptomatic. Two further asymptomatic subjects with paired MEFV mutations were identified among 49 healthy controls from western Turkey, of whom a further 18.4 per cent were simple heterozygotes. This carrier rate was higher than would be expected from prevalence of FMF in this region, suggesting that penetrance of paired recognised pathogenic MEFV mutations may frequently be incomplete. MEFV genotyping results must be interpreted with due caution, and follow-up of apparently asymptomatic subjects with paired mutations is advisable.

Tubular functions in familial Mediterranean fever.

Akkuş S(1), Çalışkan S, Kasapçopur O.

Author information:

(1)Department of Pediatrics, Istanbul University Cerrahpaşa Faculty of Medicine, Istanbul, Turkey.

In this study, we aimed to evaluate renal tubular function in familial Mediterranean fever (FMF). Urinary N-acetyl-beta-D glucosaminidase (U-NAG, beta2-microglobulin (U-beta2M) and microalbumin (Ua) levels were measured in children with different clinical stages of FMF (58 patients with FMF, 9 patients with amyloidosis secondary to (FMF). Control groups were healthy children (n=21), children with upper respiratory tract infection (URTI) (n=21) and with steroid sensitive nephrotic syndrome (SSNS) (n=18). U-NAG was significantly increased in patients with a recent diagnosis of FMF compared to patients with FMF on colchicine and to healthy controls. In patients with recently diagnosed FMF, a marked decrease in U-NAG, U-beta2M and Ua were determined after three months on colchicine therapy. On the other hand, U-NAG and Ubeta2M levels were increased in patients with FMF during attacks and then decreased in the post-attack period. U-beta2M in patients with FMF during attacks was significantly different from patients with URTI. Finally, U-NAG and U-beta2M were increased significantly in patients with FMF-amyloidosis and SSNS when compared with other FMF groups and healthy controls, respectively. In conclusion, the high U-NAG value in newly diagnosed patients compared to that of patients taking colchicine and the decline of U-NAG and U-beta2M levels after attack to the levels observed in colchicine users (without a significant change in Ua value) suggest that the renal injury early in the course of FMF might be dominantly at the level of the tubuli.

# Detrimental effects of cyclosporin A on long-term graft survival in familial Mediterranean fever renal allograft recipients: experience of two transplantation centers.

Shabtai M(1), Ben-Haim M, Zemer D, Malinger-Saavedra P, Rosin D, Kuriansky J, Lustig S, Shabtai EL, Shapira Z, Ayalon A.

## Author information:

(1)Departments of Surgery and Transplantation, Sheba Medical Center, Tel Hashomer, Israel. mshabtai@post.tau.ac.il

**BACKGROUND:** Cyclosporin A has been associated with severe toxic side effects in patients with familial Mediterranean fever who underwent renal transplantation.

Nevertheless, the impact on graft function and survival is not well documented.

**OBJECTIVE:** To compare long-term graft function and survival, between CsA-based vs. CsA free immunosuppressive protocols in FMF recipients of renal allograft.

**METHODS:** Data of FMF recipients were analyzed retrospectively. Graft survival and function and the incidence of acute rejection were correlated to graft source (living donor vs. cadaveric donor), colchicine dose, presence of proteinuria, and immunosuppression protocol (CsA-based triple drug therapy vs. azathioprine-prednisone alone).

**RESULTS:** There were 35 FMF patients with primary renal grafts (13 from living donors and 22 from cadaveric donors). Mean follow-up was 10.6 +/- 6.05 years. Sixteen patients were on CsA-based triple drug therapy and 19 patients on AZA-Pred alone. Mean overall graft survival was 11.2 +/- 0.6 years and 9.4 +/- 1.36 vs. 11.6 +/- 0.4 years for CsA-treated and AZA-Pred groups respectively (P = 0.05). One-year survival was 94% and 96.6% for CsA-treated vs. non-CsA patients (not significant), but 5 and 10 years survival were 76% and 46%, compared to 94.5% and 86% respectively (P = 0.05 at 5 years and 0.001 at 10 years). Mean serum creatinine at time of data collection was 2.3 +/- 1.5 mg/dl in the CsA group vs. 1.6 +/- 0.7 mg/dl in the AZA-Pred group (P = 0.02). There were 14 and 13 reversible rejection episodes in the AZA-Pred and CsA groups respectively (not significant).

**CONCLUSION:** It is suggested that CsA exerts detrimental effects on long-term renal graft function and survival in FMF patients.

Hyper IgD syndrome (HIDS) associated with in vitro evidence of defective monocyte TNFRSF1A shedding and partial response to TNF receptor blockade with etanercept.

Author information:

(1)Academic Unit of Child Health, St Mary's Hospital, Manchester, UK.  
peter\_arkwright@lineone.net

Hereditary periodic fever syndromes comprise a group of distinct disease entities linked by the defining feature of recurrent febrile episodes. Hyper IgD with periodic fever syndrome (HIDS) is caused by mutations in the mevalonate kinase (MVK) gene. The mechanisms by which defects in the MVK gene cause febrile episodes are unclear and there is no uniformly effective treatment. Mutations of the TNFRSF1A gene may also cause periodic fever syndrome (TRAPS). Treatment with the TNFR-Fc fusion protein, etanercept, is effective in some patients with TRAPS, but its clinical usefulness in HIDS has not been reported. We describe a 3-year-old boy in whom genetic screening revealed a rare combination of two MVK mutations producing clinical HIDS as well as a TNFRSF1A P46L variant present in about 1% of the population. In vitro functional assays demonstrated reduced receptor shedding in proband's monocytes. The proband therefore appears to have a novel clinical entity combining Hyper IgD syndrome with defective TNFRSF1A homeostasis, which is partially responsive to etanercept.

Comparison of synovial MMP-1 and TIMP-1 levels in patients with various inflammatory arthritides: is there any difference between rheumatoid arthritis, Behçet's disease and familial Mediterranean fever?

Pay S(1), Erdem H, Serdar M, Dinç A, Simşek I, Turan M.

Author information:

(1)Gülhane Military Medical Academy, Ankara, Turkey. salihp@yahoo.com

The purpose of this study was to investigate synovial levels of matrix metalloproteinase-1 (MMP-1), known to break down collagen, and tissue inhibitor of metalloproteinase (TIMP-1), its natural antagonist, in patients with various inflammatory disorders. Eighty-five patients with different inflammatory arthritides (20 Behçet's disease, 20 familial Mediterranean fever, 26 rheumatoid arthritis and 19 osteoarthritis) were enrolled in the study. Synovial MMP-1 and TIMP-1 levels were measured by two-step sandwich ELISA. There were significant differences between study and control groups regarding erythrocyte sedimentation rate, C-reactive protein, MMP-1 and TIMP-1 values. The synovial MMP-1 levels of patients with Behçet's disease and familial Mediterranean fever were no different from those in patients with rheumatoid arthritis, but significantly higher than those of patients with osteoarthritis. The synovial TIMP-1 levels in patients with osteoarthritis were higher than those of patients with the other three diseases, among which the difference was not statistically significant, and the difference between osteoarthritis and the others was statistically significant. Because of the detection of similar levels of synovial MMP-1 in patients with familial Mediterranean fever, Behçet's disease and rheumatoid arthritis, we conclude that the absence of erosions in patients with familial Mediterranean fever and Behçet's disease may be explained by MMP-1 being a marker of cytokine-driven inflammation, or by the short-lived and transient nature of the arthritis observed in these patients.

Familial Mediterranean fever (FMF) is a hereditary disease, the most threatening complication of which is systemic amyloidosis. The thyroid gland may be asymptotically involved in most patients with systemic amyloidosis secondary to FMF. However, clinically detectable thyroid goitre is quite rare, and until now only nine cases of thyroid goitre secondary to amyloid deposition in FMF have been reported. Of 1,100 FMF patients regularly followed up at our centre, thyroid goitre due to the accumulation of amyloid substance could be detected in only three (0.27%). In this report, we summarise the clinical and laboratory features of these patients. All three patients were euthyroid. Total thyroidectomy was performed for compressive symptoms in one patient and for aesthetic purposes in the other two. In countries with a high prevalence of FMF, such as Turkey, secondary amyloidosis of the thyroid gland should be borne in mind in long-standing FMF patients.

Temperature dependence of mutant mevalonate kinase activity as a pathogenic factor in hyper-IgD and periodic fever syndrome.

Houten SM(1), Frenkel J, Rijkers GT, Wanders RJ, Kuis W, Waterham HR.

Author information:

(1)Departments of Paediatrics/Emma Children's Hospital and Clinical Chemistry, Academic Medical Centre, University of Amsterdam, Amsterdam, The Netherlands.

Hyper-IgD and periodic fever syndrome (HIDS) and mevalonic aciduria are autosomal recessive disorders characterized by recurrent episodes of fever and generalized inflammation. Both syndromes are caused by specific mutations in the gene encoding mevalonate kinase (MK), resulting in a depressed enzymatic activity mainly due to reduced protein levels. We studied the effect of temperature on the activity of wild-type and several mutant MKs in fibroblasts. All fibroblast cell lines from HIDS patients and harbouring the common V377I MVK allele displayed substantially higher MK activities at 30 degrees C as compared to 37 degrees C. As shown by temperature inactivation experiments this resulted in a protein nearly as stable as in control cell lines, indicating that primarily the maturation of the protein is affected. Accordingly, when HIDS cell lines were cultured at 39 degrees C, MK activity decreased further. This triggered a compensatory increase in 3-hydroxy-3-methylglutaryl-CoA reductase activity, indicating that MK becomes progressively rate-limiting. A similar phenomenon occurs in vivo. MK activity in peripheral blood mononuclear cells drops 2-8-fold when HIDS patients experience febrile attacks. Our results suggest that minor elevations in temperature can set off a chain of events with MK becoming progressively rate-limiting, leading to a temporary deficiency of isoprenoid end-products, which induces inflammation and fever.

Crohn disease and familial Mediterranean fever (FMF) are inflammatory diseases characterized by abdominal pain and fever. The concurrence of the 2 diseases

(FMF-CD) may pose a challenge to diagnosis and treatment. We undertook the present study to determine the prevalence of Crohn disease in FMF and to characterize FMF-CD patients clinically and genetically. Using a computerized search, the patients of our FMF clinic were screened for a concomitant diagnosis of Crohn disease. Patients and their medical records were thoroughly examined, and their DNA was genotyped for mutations in the MEFV gene. Control groups of ethnically and sex-matched patients suffering from each of the diseases alone, either Crohn disease or FMF, were used for comparison. We identified 7 patients with concomitant Crohn disease and FMF, which is more than the expected prevalence in the general population ( $p = 0.03$ ). Crohn disease presented at a significantly later age in the FMF-CD group ( $40.6 \pm 10.0$  yr versus  $26.2 \pm 11.4$  yr;  $p < 0.004$ ). Disease severity and other characteristics of Crohn disease were comparable to the Crohn disease control group. Contrary to the FMF control group patients, FMF in FMF-CD patients was characterized by a higher attack frequency ( $p < 0.05$ ) and increased prevalence of amyloidosis ( $p < 0.02$ ). The overall severity score was similar in both groups. In conclusion, Crohn disease appears to be more prevalent in FMF and presents later than in patients without FMF. FMF in this group of patients shows a higher attack frequency and is more often complicated by amyloidosis.

Comment in

Nephrol Dial Transplant. 2003 May;18(5):1031; author reply 1032.

**BACKGROUND:** Secondary amyloidosis is the most frequent of the various types of systemic amyloidosis, the epidemiology of which is not yet fully known. The aim of our study was to evaluate retrospectively the collective data for the aetiological distribution, clinical findings and approaches to the management of secondary amyloidosis in Turkey.

**METHODS:** Data from a simple questionnaire addressing aetiology, and demographic and clinical characteristics of patients with biopsy-proven secondary amyloidosis was retrospectively analysed. Eleven nephrology clinics contributed data for this study.

**RESULTS:** The 11 contributing centres provided a total of 287 cases (102 female, 185 male). The aetiological distribution was as follows: familial Mediterranean fever (FMF) 64%, tuberculosis 10%, bronchiectasis and chronic obstructive lung disease 6%, rheumatoid arthritis 4%, spondylarthropathy 3%, chronic osteomyelitis 2%, miscellaneous 4%, unknown 7%. Oedema accompanied by proteinuria was present in 88% of the cases, hepatomegaly in 17%, and splenomegaly in 11%. The mean systolic and diastolic blood pressures were 115+/-26 and 73+/-15 mmHg respectively. The family history was positive in 16%; 73% of the cases were on colchicine treatment when the questionnaire was administered. Thirty-eight per cent of the cases had progressed to ESRD and were on renal replacement therapy.

**CONCLUSIONS:** FMF is the leading cause of secondary amyloidosis in Turkey, followed by tuberculosis. Oedema accompanied by proteinuria is the most prominent presenting finding, and hypotension seems to be common among these patients.

Author information:

(1)Department of Medical Biology, Faculty of Medicine, University of Hacettepe, Ankara, Turkey.

**BACKGROUND:** Familial Mediterranean fever (FMF) is an autosomal recessive disease characterized by recurring attacks of fever and serositis. The definition of the mutated gene has allowed molecular diagnosis of the disease. The most important complication of FMF is the development of AA type secondary amyloidosis. In a group of patients clinically designated as phenotype II amyloidosis patients, renal amyloidosis develops without being preceded by typical attacks of the disease. In this study, the mutations of the MEFV gene were analysed in a group of patients clinically recognized as phenotype II.

**METHODS:** DNA samples were obtained from tissue samples of the subjects. PCR-RFLP methods were used to analyse the M694V, M680I, V726A and E148Q mutations that have been previously defined by us to be the most common mutations in our Turkish cohort.

**RESULTS:** The distribution of the four most common mutations among phenotype II patients was 38% for M694V, 8% for M680I, 4% for V726A and 4% for E148Q.

**CONCLUSIONS:** In phenotype II amyloidosis patients, the distribution of the four common MEFV mutations was not significantly different from that found in all FMF patients with typical symptoms who do or do not develop amyloidosis. We therefore suggest that secondary genetic or environmental factors are operative in the development of secondary amyloidosis in patients with FMF.

[Periodic fever].

[Article in Spanish]

Mongil Ruiz I(1), Canduela Martínez V.

Author information:

(1)Hospital de Laredo. Cantabria. España. imongil@hlrd.insalud.es

Periodic fever can be defined as recurrent episodes of fever lasting from a few days to several weeks separated by symptom-free intervals of variable duration, recurring throughout several months. Although these clinical pictures are unusual

in clinical practice, in some instances the differential diagnosis with recurrent infections, malignancies and connective tissue diseases is difficult. The aim of this review is to group together these different clinical pictures, which are dispersed in the literature, to obtain an overall and detailed perspective. We classified these processes in two categories: hereditary (familial Mediterranean fever, hyper-IgD syndrome, tumor necrosis factor-receptor-associated periodic syndrome, Muckle-Wells syndrome and familial cold urticaria) and non-hereditary (periodic fever, aphthous stomatitis, pharyngitis, and adenopathy syndrome [PFAPA syndrome], cyclic neutropenia, chronic infantile neurological cutaneous and articular syndrome [CINCA syndrome], Castleman's disease, early onset sarcoidosis and Blau syndrome). Although diagnosis is essentially clinical, in recent years many advances have been made in the knowledge of the molecular and genetic bases of hereditary diseases, which may be of considerable help in establishing the diagnosis and improving treatment.

Overt and occult rheumatic diseases: the child with chronic fever.

Frenkel J(1), Kuis W.

Author information:

(1)Department of General Pediatrics, Wilhelmina Children's Hospital, University Medical Center Utrecht, Suite KE.04.133.1, P.O. Box 85090, The Netherlands.

Identification of the genes involved in hereditary periodic fever syndromes has led to the recognition of a new pathophysiological category, the autoinflammatory disorders. The main non-hereditary autoinflammatory disease in childhood is systemic juvenile idiopathic arthritis (SJIA), others being the chronic infantile neurological cutaneous arthropathy (CINCA) syndrome and the periodic fever, aphthous stomatitis, pharyngitis and adenopathy (PFAPA) syndrome. Familial Mediterranean fever (FMF) has been traced to mutations in the MEFV gene. Mutations in the MVK gene, encoding the enzyme mevalonate kinase, cause the hyper-IgD periodic fever syndrome (HIDS). The tumour necrosis factor(TNF)-receptor-associated periodic syndromes (TRAPS) have been linked to mutations in the TNFRSF1A gene, encoding a TNF-alpha receptor, and the CIAS1 gene is mutated in familial cold autoinflammatory syndrome. We discuss how this knowledge has influenced diagnosis and treatment of these rare genetic disorders and how it might change our approach to the more common rheumatic diseases.

Lack of isoprenoid products raises ex vivo interleukin-1beta secretion in hyperimmunoglobulinemia D and periodic fever syndrome.

Frenkel J(1), Rijkers GT, Mandey SH, Buurman SW, Houten SM, Wanders RJ, Waterham HR, Kuis W.

Author information:

(1)Division of Pediatrics, Wilhelmina Children's Hospital, KE.04.133.1, University Medical Center Utrecht, PO Box 85090, 3580 AB Utrecht, The Netherlands. j.frenkel@wkz.azu.nl

OBJECTIVE: To investigate whether the increased interleukin-1beta (IL-1beta) secretion in hyperimmunoglobulinemia D and periodic fever syndrome is due to the accumulation of mevalonate kinase (MK), the substrate of the deficient enzyme, or

the lack of its products, the isoprenoid compounds.

**METHODS:** The effects of lovastatin and farnesol (FOH), geranylgeraniol (GGOH), and mevalonate on peripheral blood mononuclear cells (PBMCs) from 8 patients with MK deficiency and from 13 controls were studied. Lovastatin inhibits isoprenoid biosynthesis by reducing the production of mevalonate. FOH and GGOH restore isoprenoid biosynthesis downstream from MK. Culture supernatants were collected for cytokine analysis 48 hours after stimulation with monoclonal antibodies against CD2 + CD28.

**RESULTS:** Lovastatin induced a 15-fold rise in IL-1 $\beta$  secretion by normal anti-CD2 + CD28-stimulated cells ( $P < 0.001$ ). This effect could be countered by mevalonate and, to a lesser extent, by FOH and GGOH. In the absence of lovastatin, mevalonate did not change IL-1 $\beta$  secretion. Stimulated MK-deficient cells secreted 9-fold more IL-1 $\beta$  than control PBMCs ( $P < 0.005$ ), rising 2.4-fold in the presence of lovastatin. The effect of lovastatin on IL-1 $\beta$  secretion was reduced by mevalonate, FOH, and GGOH. Isoprenoid biosynthesis in PBMCs from patients was impaired due to the endogenous MK deficiency. Bypassing this defect with FOH, in the absence of lovastatin, led to a 62% reduction ( $P < 0.02$ ) in IL-1 $\beta$  secretion by these cells.

**CONCLUSION:** In this model, shortage of isoprenoid end products contributes to increased IL-1 $\beta$  secretion by MK-deficient PBMCs, whereas excess mevalonate does not.

Reduced MEFV messenger RNA expression in patients with familial Mediterranean fever.

Notarnicola C(1), Didelot MN, Koné-Paut I, Seguret F, Demaille J, Touitou I.

Author information:

(1)Laboratoire de Génétique Moléculaire et Chromosomique, Hôpital Arnaud de Villeneuve, 371 Avenue du Doyen Gaston Giraud, 34295 Montpellier Cedex 5, France.

**OBJECTIVE:** Familial Mediterranean fever (FMF) is the most common inherited periodic syndrome. The disease phenotype and the almost exclusive expression of

the causative gene, MEFV, in leukocytes suggest that this gene plays an important role in the inflammatory cascade. Since most of the known mutations are conservative, we sought to determine how minor DNA defects can give rise to the dramatic phenotypic features seen in FMF.

**METHODS:** To address whether the molecular basis of the phenotype-genotype correlation could be related to altered MEFV messenger RNA (mRNA) expression, we quantified the relative abundance of MEFV transcripts in peripheral blood leukocytes from patients with FMF, healthy carriers of a single MEFV mutation, and healthy control subjects.

**RESULTS:** We found significantly lower expression of MEFV mRNA in genetically ascertained FMF patients than in healthy controls (0.7 versus 1.1;  $P = 0.00001$ ). In healthy carriers, the mRNA levels were intermediate, suggesting a true dose-response relationship between the number of mutations and the abundance of MEFV transcripts. The difference between healthy controls and healthy carriers was significant (1.1 versus 0.8;  $P = 0.008$ ), demonstrating that the decrease in mRNA expression is related to a molecular defect independent of FMF symptoms. MEFV mRNA expression was also found to be a function of the type of mutations. The lowest MEFV levels were found in healthy carriers and patients with M694V. Moreover, we observed an inverse correlation with the clinical severity score ( $r = -0.6$ ,  $P = 0.04$  and  $r = -0.6$ ,  $P = 0.004$  in patients with 1 and 2 M694V mutations, respectively).

**CONCLUSION:** Our results demonstrate that MEFV message levels are related to both the genotype and the phenotype, and suggest that the pathophysiology of FMF relies on a quantitative defect of MEFV mRNA expression.

Early blunted cortisol response to insulin induced hypoglycaemia in familial Mediterranean fever.

Korkmaz C(1), Colak O, Alatas O, Ozarslan A, Ergül B.

Author information:

(1)Department of Rheumatology, Medical School of Osmangazi University, Eskisehir, Turkey. ckorkmaz@ogu.edu.tr

**OBJECTIVE:** To study cortisol, adrenocorticotrophic hormone and C-reactive protein responses to specific stimuli in familial Mediterranean fever (FMF).

**METHODS:** For the purpose of measuring cortisol, ACTH, and CRP responses to insulin induced hypoglycaemia during attack-free periods, 14 FMF patients, 11 patients with ankylosing spondylitis or Behçet's disease as disease controls (DC), and a further 10 healthy control subjects (HC) were involved in this study. None of the subjects had ever received corticosteroids before this study. Cortisol and ACTH levels were measured by chemiluminescence enzyme immunoassay.

**RESULTS:** No attack was observed among FMF patients during the test. No significant difference in the mean cortisol values after insulin induced hypoglycaemia was observed between the groups involved at any stage of the test. The integral cortisol response to hypoglycaemia expressed as the AUC (0-90 min) was found not to differ among the study groups (1827 +/- 115.6 in FMF; 2196 +/- 205.4 in DC,  $p = 0.12$ ; 1771 +/- 98.4 in HC,  $p = 0.9$ ). The delta response of cortisol to insulin induced hypoglycaemia was found to be statistically lower ( $-4 \pm 0.8$  mg/dl vs.  $-1.9 \pm 0.7$  microg/dl;  $p < 0.03$ ) only for the 0 to 30 min interval in patients with FMF compared to HC respectively. Similar results, though of no statistical significance, were also found for the 0 to 45 min interval ( $1.17 \pm 2.2$  microg/dl in FMF patients vs.  $3.3 \pm 2$  microg/dl in HC;  $p = 0.6$ ). The mean basal CRP level of patients with FMF was remarkably higher than that in HC. Although the mean CRP level at 90 min for FMF cases with cortisol levels under 12 microg/dl at 30 min was found to be higher than those with cortisol levels over 12 microg/dl at 30 min, no significant difference was observed.

**CONCLUSION:** An early blunted cortisol response observed in a stressful situation in FMF patients may well account for the curious relationship between stress and an inflammatory reaction and/or attack. Furthermore, the fact that the CRP level was relatively higher in FMF patients with lower cortisol levels might also highlight the importance of endogen cortisol in the inflammatory feature of this disease.

Fire and ICE: the role of pyrin domain-containing proteins in inflammation and apoptosis.

Gumucio DL(1), Diaz A, Schaner P, Richards N, Babcock C, Schaller M, Cesena T.

Author information:

(1)Department of Cell and Developmental Biology, University of Michigan, Ann Arbor 48109-0616, USA. dgumucio@umich.edu

The genetic bases for several human autoinflammatory syndromes have recently been identified, and the mutated proteins responsible for these diseases are rapidly being characterized. Here, we examine two of these newly identified proteins, pyrin (also called marenostin, product of the familial Mediterranean fever locus, MEFV) and cryopyrin (product of the CAIS1 locus, and mutated in familial cold urticaria, Muckle Wells syndrome and chronic infantile neurological cutaneous and articular syndrome). Both pyrin and cryopyrin contain an N-terminal domain that encodes a death domain-related structure, now known as the pyrin domain, or PyD. We trace the molecular interactions mediated by these PyDs, examine the evolution of the family of molecules containing this domain, and discuss the function of PyD-containing proteins and their homologues. Synthesis of the available data indicates that both pyrin and cryopyrin interact via their PyDs with a common adaptor protein, ASC. ASC itself participates in at least three important cellular processes: apoptosis, recruitment and activation of pro-caspase-1 (with associated processing and secretion of IL-1beta), and activation of NF-kappaB (a transcription factor involved in both initiation and

resolution of the inflammatory response). Through PyD:PyD interactions, pyrin and cryopyrin, as well as several related, but still uncharacterized PyD containing proteins, appear to modulate the activity of all three of these processes, each of which plays a crucial role in the inflammatory pathways that characterize the innate immune system.

Successful treatment of familial Mediterranean fever attacks with thalidomide in a colchicine resistant patient.

Seyahi E(1), Ozdogan H, Masatlioglu S, Yazici H.

Author information:

(1)Department of Rheumatology, Cerrahpasa Medical Faculty, University of Istanbul, Turkey.

Colchicine is the treatment of choice in familial Mediterranean fever (FMF) both for attacks and for prevention of secondary amyloidosis. The overall non-responder rate varies from 5-10 to 40%. Thalidomide is known to blunt the acute phase response. We report the efficacy of the addition of thalidomide to colchicine in controlling the febrile attacks and acute phase response in a patient with FMF resistant to 2 mg colchicine per day.

Molecular diagnosis of FMF: lessons from a study of 446 unrelated individuals.

Ben-Chetrit E(1), Urieli-Shoval S, Calko S, Abeliovich D, Matzner Y.

Author information:

(1)Department of Medicine, Hadassah University Hospital in Ein Kerem, Jerusalem, Israel. eldad@hadassah.org.il

**BACKGROUND:** Traditionally, the diagnosis of familial Mediterranean fever (FMF) has been based on clinical manifestations and the physician's experience.

Following the cloning of the gene associated with this disease (MEFV), genetic analysis of its mutations has become available, providing a new tool for the establishment or confirmation of the diagnosis of FMF.

**OBJECTIVES:** We analyzed the results of molecular testing for MEFV mutations in 600 individuals. We wished to determine how many of them bore mutations and what percentage had clinically active FMF. We also compared the rate of genetic confirmation of the FMF diagnosis in referrals with suspected FMF seen by general practitioners with that of persons sent for genetic analysis by FMF experts.

**METHODS:** Of 600 individuals tested for FMF mutations, we analyzed separately 446 unrelated persons for the combination of their mutations, epidemiological data, and clinical manifestations. The five most common mutations in the present cohort were analyzed using the amplification refractory mutation system (ARMS).

**RESULTS:** Of the 446 subjects analyzed, 249 (55%) bore mutations: 147 of these were homozygotes or compound heterozygotes, all of whom had FMF according to clinical criteria. Of the remaining 102 heterozygotes, 72 had FMF according to clinical criteria. Two patients with none of the five mutations also had FMF:

North African Jews bore mainly mutations M694V and E148Q. The M694V mutation was found exclusively in Palestinian Arabs. The rate of confirmation of FMF diagnosis by mutation analysis in subjects sent by FMF experts was significantly higher than that of persons referred by general practitioners. Analysis of the molecular testing of the multicase families (154 individuals) revealed that 141 of them bore MEFV mutations and that 4 persons homozygous for E148Q were asymptomatic.

**CONCLUSIONS:** Molecular analysis of FMF mutations confirmed the diagnosis in about 60% of the referrals with suspected FMF. Some (33%) of the patients were heterozygotes, and there were also FMF patients with none of the 5 mutations analyzed. A second opinion by an FMF expert may decrease the need for mutation analysis in subjects suspected of having FMF.

Colchicine neuromyopathy: a report of six cases.

Altıparmak MR(1), Pamuk ON, Pamuk GE, Hamuryudan V, Ataman R, Serdengeçti K.

Author information:

(1)Department of Nephrology, Cerrahpasa Medical School, University of Istanbul, Turkey. gepamuk@yahoo.com

Colchicine has been in use for therapeutic purposes for many years. It can, however, cause subacute onset muscle and peripheral nerve toxicity in patients with chronic renal failure. In this report we describe 6 patients who developed neuromyopathy after the administration of colchicine. All patients presented with proximal muscle weakness, elevated serum creatine kinase (CK) levels, and neuropathy and/or myopathy on electromyography (EMG). The diagnosis of colchicine toxicity was confirmed in all cases by the normalization of CK levels and EMG after discontinuation of the drug. Toxicity developed in 4 renal failure patients on therapeutic doses of the drug, while one patient took a massive dose for suicidal reasons, and the other was on high-dose therapy. Patients using colchicine--especially those with renal failure--should be warned about the side effects of the drug and physicians should be careful in the administration of the drug.

Author information:

(1)Department of Pediatric Cardiology, Ankara University Medical School, Turkey.

The aetiologies, clinical features and follow-up data of 62 children with pericarditis admitted to a university hospital during a 6-year period were retrospectively assessed. Uraemic pericarditis was the most frequent and infections the second most frequent cause. In this series, the proportion of children with purulent pericarditis is less than in previous reports from developing countries. Familial Mediterranean fever, neoplasias, acute rheumatic fever and post-pericardiotomy syndrome were other important causes of pericarditis.

*Clin Auton Res.* 2002 Aug;12(4):228-30.

This study aimed to develop a method to distinguish between the cardiovascular reactivity in chronic fatigue syndrome (CFS) and other patient populations. Patients with CFS (n = 23), familial Mediterranean fever (n = 15), psoriatic arthritis (n = 10), generalized anxiety disorder (n = 12), neurally mediated syncope (n = 20), and healthy subjects (n = 20) were evaluated with a shortened head-up tilt test (HUTT). A 10-minute supine phase of the HUTT was followed by recording 600 cardiac cycles on tilt, i. e., 5 to 10 minutes. Beat-to-beat heart rate (HR) and pulse transit time (PTT) were acquisitioned. Data were processed by recurrence plot and fractal analysis. Fifty-two variables were calculated in each subject. On multivariate analysis, the best predictors of CFS were HR-tilt-R/L, PTT-tilt-R/L, HR-supine-DET, PTT-tilt-WAVE, and HR-tilt-SD. Based on these predictors, the 'Fractal & Recurrence Analysis-based Score' (FRAS) was calculated:  $FRAS = 76.2 + 0.04 \times HR\text{-supine-DET} - 12.9 \times HR\text{-tilt-R/L} - 0.31 \times HR\text{-tilt-SD} - 19.27 \times PTT\text{-tilt-R/L} - 9.42 \times PTT\text{-tilt-WAVE}$ . The best cut-off differentiating CFS

from the control population was FRAS = + 0.22. FRAS > + 0.22 was associated with CFS (sensitivity 70 % and specificity 88 %). The cardiovascular reactivity received mathematical expression with the aid of the FRAS. The shortened HUTT was well tolerated. The FRAS provides objective criteria which could become valuable in the assessment of CFS.

Erratum in

Arthritis Rheum 2002 Dec;46(12):3398.

**OBJECTIVE:** Familial cold urticaria (FCU) and Muckle-Wells syndrome (MWS) are dominantly inherited autoinflammatory disorders that cause rashes, fever, arthralgia, and in some subjects, AA amyloidosis, and have been mapped to chromosome 1q44. Sensorineural deafness in MWS, and provocation of symptoms by cold in FCU, are distinctive features. This study was undertaken to characterize the genetic basis of FCU, MWS, and an overlapping disorder in French Canadian, British, and Indian families, respectively.

**METHODS:** Mutations in the candidate gene NALP3, which has also been named CIAS1 and PYPAF1, were sought in the study families, in a British/Spanish patient with apparent sporadic MWS, and in matched population controls. Identified variants were sought in 50 European subjects with uncharacterized, apparently sporadic periodic fever syndromes, 48 subjects with rheumatoid arthritis (RA), and 19

subjects with juvenile idiopathic arthritis (JIA).

RESULTS: Point mutations, encoding putative protein variants R262W and L307P, were present in all affected members of the Indian and French Canadian families, respectively, but not in controls. The R262W variant was also present in the subject with sporadic MWS. The V200M variant was present in all affected members of the British family with MWS, in 2 of the 50 subjects with uncharacterized periodic fevers, and in 1 of 130 Caucasian and 2 of 48 Indian healthy controls. No mutations were identified among the subjects with RA or JIA.

CONCLUSION: These findings confirm that mutations in the NALP3/CIAS1/PYPAF1 gene are associated with FCU and MWS, and that disease severity and clinical features may differ substantially within and between families. Analysis of this gene will improve classification of patients with inherited or apparently sporadic periodic fever syndromes.

The TNF receptor-associated periodic syndrome (TRAPS): emerging concepts of an autoinflammatory disorder.

Hull KM(1), Drewe E, Aksentijevich I, Singh HK, Wong K, McDermott EM, Dean J, Powell RJ, Kastner DL.

Author information:

(1)Office of the Clinical Director, National Institute of Arthritis and Musculoskeletal and Skin Diseases, National Institutes of Health, Bethesda, Maryland 20892, USA. hullk@mail.nih.gov

The present report describes and expands the clinical and genetic spectrum of the autoinflammatory disorder, tumor necrosis factor (TNF) receptor-associated periodic syndrome (TRAPS). A total of 20 mutations have been identified since our initial discovery of 6 missense mutations in TNF receptor super family 1A (TNFRSF1A) in 1999. Eighteen of the mutations result in amino acid substitutions within the first 2 cysteine-rich domains (CRDs) of the extracellular portion of the receptor. A single splicing mutation also affects the first CRD by causing the insertion of 4 amino acids. Haplotype analysis of the most commonly occurring

and ethnically heterogeneous mutation, R92Q, demonstrates an ancient founder; however, analysis of the T50M mutation, another commonly occurring mutation in Irish and Scottish families, does not, suggesting that T50M is a recurring mutation. Mutations that result in cysteine substitutions demonstrate a higher penetrance of the clinical phenotype (93% versus 82% for noncysteine residue substitutions), and also increase the probability of developing life-threatening amyloidosis (24% versus 2% for noncysteine residue substitutions). Retrospective and prospective evaluation of more than 50 patients, representing 10 of the 20 known mutations, allows us to expand and better define the clinical spectrum of TRAPS. Recurrent episodes of fever, myalgia, rash, abdominal pain, and conjunctivitis that often last longer than 5 days are the most characteristic clinical features of TRAPS. Defective shedding of TNFRSF1A can only partially explain the pathophysiologic mechanism of TRAPS, since some mutations have normal shedding. Consequently, other mechanisms may be mediating the observed phenotype. We are currently investigating other possible mechanisms using stable and transiently transfected cell systems in vitro, as well as developing a knockin mouse model. Preliminary data suggest that etanercept may be effective in decreasing the severity, duration, and frequency of symptoms in TRAPS patients. Additionally, it provides a viable therapeutic alternative to glucocorticoid therapy, which has numerous serious, long-term adverse effects. Two clinical trials are being conducted to evaluate the efficacy of etanercept in decreasing the frequency and severity of symptoms in TRAPS. Lastly, we have summarized data that R92Q and P46L, and probably as yet undiscovered substitutions, represent very low penetrance mutations that may play a much larger role in more broadly defined inflammatory diseases such as rheumatoid arthritis. Our laboratories are currently undertaking both clinical and basic research studies to define the role of these mutations in more common inflammatory diseases.

Familial Mediterranean fever (FMF) is an autosomal recessive disorder. Although the pathogenesis of the disease is not yet completely understood, enhanced acute-phase responsiveness is considered to be one of the most important mechanisms. The presence of high levels of antistreptolysin O (ASO) antibodies and streptococcus-associated diseases, such as acute poststreptococcal glomerulonephritis (AGN) and acute rheumatic fever (ARF), has been reported in patients with FMF. In order to better understand the effect of FMF on antistreptococcal antibody response, we measured ASO and antideoxyribonuclease B (anti-DNAse B) levels in patients with FMF and compared them with those in healthy controls. The study consisted of two parts. In the first step, antistreptococcal antibody levels were analysed in 44 patients with FMF and 165 healthy children who had no history or clinical evidence of upper respiratory tract infection (URTI) for the last 4 months. In the second step, antistreptococcal antibody levels were measured in 15 patients with FMF and 22 healthy controls in response to documented group A beta-haemolytic streptococcal pharyngitis. In the first part of the study, ASO and anti-DNAse B levels in patients with FMF were found to be significantly higher than those in healthy controls ( $P<0.001$ ). In the second part, ASO and anti-DNAse B titres were found to be significantly higher in patients with FMF than in controls ( $P<0.001$  and  $<0.05$ , respectively) 4 weeks after a positive throat culture. We concluded that patients with FMF have an exaggerated response to streptococcal antigens and might be prone to poststreptococcal non-suppurative complications, such as ARF.

Plasma levels of the von Willebrand factor-cleaving protease in physiological and pathological conditions in children.

Kavakli K(1), Canciani MT, Mannucci PM.

Author information:

(1)Ege University Hospital, Department of Pediatric Hematology, Izmir, Turkey.  
kkavakli@med.ege.edu.tr

The hemolytic uremic syndrome (HUS) and thrombotic thrombocytopenic purpura (TTP) are rare disorders characterized by thrombocytopenia, hemolytic anemia, and ischemic organ failure due to thrombotic occlusions in arterioles. The recent observation that a von Willebrand factor-cleaving protease (VWF-CP) is low in the plasma of patients with TTP but normal in those with HUS has potentially offered a new specific tool for differential diagnosis. In this study, the authors evaluated the plasma levels of the VWF-CP during the neonatal state and healthy childhood and in some pathological pediatric conditions. The protease was measured in 16 healthy newborns, 20 healthy children aged 5-18 years, patients with diabetes mellitus type 1 (n = 7), acute viral hepatitis (n = 10), chronic viral hepatitis (n = 10), transfusion-dependent beta-thalassemia major (n = 10), acute varicella infection (n = 11), the nephrotic syndrome (n = 11), and familial Mediterranean fever (n = 10). Mean protease levels were significantly lower in newborns than in healthy children (50.5 +/- 16.1% vs. 83.3 +/- 16.3%)(p = .0001). In patients with acute viral hepatitis, protease levels were also significantly reduced (40.2 +/- 27% v s. 83.3 +/- 16.3% in healthy children)(p = .0001). Other patient groups had normal protease levels. In conclusion, low protease levels are far from being a specific beacon for TTP. The current paradigm that a single laboratory test may enable physicians to distinguish TTP from HUS seems to be challenged by these and other findings.

[DNA comet assay for evaluation of genotoxic effects in risk groups].

[Article in Russian]

Arutiunian RM, Oganessian GG, Nersesian AK.

DNA comet assay (CA), gel electrophoresis of single cells, is effective in evaluating the genetic (genotoxic) effects of endogenous and exogenous agents. CA was used to study the extent of spontaneous or UV-induced DNA damages in the

leukocytes in two groups at genetic risk: in Chernobyl accident liquidators and patients with familial Mediterranean fever (FMF). There was a significant increase in the number of UV-induced and excision repair-mediated DNA breaks in both risk groups as compared to control samples. The spontaneous extent of DNA breaks in the cells of the liquidators and FMF patients were similar to those in the controls. The extent of oxidative DNA damages detected during incubation with the endonuclease enzymes formamidopyrimidine glycosylase and endonuclease III were also determined in FMF patients. There were no statistically significant differences in the extent of oxidative DNA damage in the cells of FMF patients as compared to the controls. The findings give grounds to recommend CA for biomonitoring of genotoxic effects.

Tumor necrosis factor receptor-associated periodic syndrome (TRAPS) is a dominantly inherited autoinflammatory syndrome that results from mutations in TNFRSF1A, the gene that encodes the 55-kd tumor necrosis factor receptor. Clinically, patients present with recurrent episodes of fever in conjunction with localized inflammation at various sites. Myalgia is one of the most characteristic features of this syndrome and is frequently associated with an overlying erythematous, macular rash that, together with the myalgia, displays centrifugal migration. This has previously been believed to occur as a result of myositis. We describe herein the case of a 60-year-old man with TRAPS, in whom

magnetic resonance imaging of the left thigh demonstrated edematous changes in the muscle compartments and surrounding soft tissues. A full-thickness wedge biopsy was performed, and hematoxylin and eosin staining and immunohistochemistry analysis of the specimen demonstrated normal myofibrils but a severely destructive monocytic fasciitis. These results suggest that the myalgia experienced by individuals with TRAPS is due to a monocytic fasciitis and not to myositis.

**OBJECTIVE:** To characterize the frequency, clinical signs, and genotypic features of tumor necrosis factor receptor-associated periodic syndrome (TRAPS) in a series of 394 patients of various ethnic origins who have recurrent inflammatory syndromes.

**METHODS:** Sequencing of the coding region of the TNFRSF1A gene was performed in 128 patients in whom there was a high suspicion of TRAPS, and denatured high-performance liquid chromatography was used to systematically screen for TNFRSF1A in 266 patients with recurrent inflammatory syndrome and no or only 1 Mediterranean fever gene (MEFV) mutation.

**RESULTS:** TNFRSF1A mutations were found in 28 (7.1%) of 394 unrelated patients. Nine (32%) of the 28 patients had a family history of recurrent inflammatory

syndromes. In 13 patients, the length of the attack of inflammation was fewer than 5 days. Three of the mutations (Y20H, L67P, and C96Y) were novel. Two mutations, R92Q and (mainly) P46L, found in 12 and 10 patients, respectively, had lower penetrance compared with other mutations. TNFRSF1A mutations were found in patients of various ethnic origins, including those at risk for familial Mediterranean fever (FMF): Armenians, Sephardic Jews, and especially Arabs from Maghreb. Only 3 (10.7%) of the 28 patients had amyloidosis.

CONCLUSION: TRAPS is an underdiagnosed cause of recurrent inflammatory syndrome. Its presence in the population of persons of Mediterranean ancestry and the short duration of the attacks of inflammation can lead to a fallacious diagnosis of FMF. Because an accurate diagnosis in patients with recurrent inflammatory syndromes is crucial for proper clinical management and treatment, genetic screening for TNFRSF1A is warranted.

Effects of intravenous immunoglobulins on T cell and oligodendrocyte apoptosis in high-dose antigen therapy in experimental autoimmune encephalomyelitis.

Weishaupt A(1), Kuhlmann T, Schönrock LM, Toyka KV, Brück W, Gold R.

Author information:

(1)Department of Neurology, Neuroimmunology Branch and Clinical Research Group for Multiple Sclerosis, Julius-Maximilians Universität, Josef-Schneider-Strasse 11, 97080 Würzburg, Germany. a.weishaupt@mail.uni-wuerzburg.de

Intravenous immunoglobulins (IVIg) are purified preparations of immunoglobulins from plasma of healthy human donors containing polyclonal IgG and various immunomodulatory contaminants. IVIg may exert its therapeutic effect at several levels of the immune network. Antigen-specific therapy of adoptive transfer-(AT)-EAE in Lewis rats leads to elevated serum levels of tumor necrosis factor-alpha (TNF-alpha). TNF-alpha release at sites of inflammation increased apoptosis of autoaggressive T cells in spinal cord in situ and oligodendrocyte apoptosis. In addition, autoinflammatory T cells in liver were destroyed and caused liver damage by TNF-alpha release. To explore a possible neutralizing

effect of IVIg on TNF-alpha secreted by antigen-specific T cells, we analyzed T cell and oligodendrocyte apoptosis as well as liver damage in rats that had been injected with myelin basic protein (MBP) and co-treated intravenously with human IVIg. As in our earlier studies, we found that TNF-alpha serum levels were raised by antigen therapy and decreased with concomitant IVIg administration. Using IVIg treatment, antigen-induced T cell apoptosis in inflamed spinal cord and liver of MBP/IVIg-treated animals was significantly reduced compared to control rats treated with MBP/albumin. T cell apoptosis decreased to levels observed in EAE rats receiving albumin only. In addition, serum levels of liver enzymes were raised after MBP/albumin administration and decreased by co-treatment with IVIg, indicating protection of hepatocytes by the neutralization of TNF-alpha. In contrast, oligodendrocyte apoptosis in animals receiving MBP/IVIg was significantly higher than in EAE controls. This indicates that IVIg may have different tissue-specific effects. Besides neutralization of TNF-alpha-mediated cell death, IVIg may also interfere with the network of local immune cells, thus modulating survival of glial cells.

Cranial nerve lesions and abnormal visually evoked potentials associated with the M694V mutation in familial Mediterranean fever.

Finsterer J(1), Stöllberger C, Shinar Y.

Author information:

(1)NKH Rosenhügel, Vienna, Austria.

A 52-year-old Turkish man with familial Mediterranean fever (FMF) due to the homozygous M694V mutation in the MEFV-gene on chromosome 16p13.3, newly developed hemicrania, blurred and double vision, ptosis, ophthalmoparesis and peripheral facial nerve palsy. Except for double vision, all the other abnormalities disappeared spontaneously within 10 days after onset. Markedly prolonged latencies of the visually evoked potentials were also found. At follow-up, 8 months after onset of the neurological abnormalities, right-sided bradydiadochokinesia, right-sided discrete weakness and right-sided hypaesthesia were found. After the exclusion of other hereditary fever syndromes, migraine, stroke, Molaret's meningitis, Behçet's syndrome and mitochondriopathy by clinical, serological, CSF investigations, funduscopy, electroencephalography, and cerebral MRI and MRI angiography, the described neurological abnormalities were regarded as CNS and PNS manifestation of vasculitis or amyloidosis in FMF.

Familial Mediterranean Fever (FMF) is an autosomal recessive disease of high prevalence within Mediterranean countries and particularly common in four ethnic populations: Arabs, non-Ashkenazi Jews, Armenians, and Turks. The responsible

gene MEFV has been assigned to chromosome 16p13.3. Our aim was to establish the frequencies of the most common mutations in Greek-Cypriots. We found that 1 in 25 is a carrier of one of three mutations. V726A, M694V, and F479L. In 68 Grek-Cypriot FMF chromosomes analyzed, we found V726A (25%), F479L (20.6%), M694V (17.6%), and others (36.8%). Mutation F479L, relatively common in this population, is very rare elsewhere. Our study indicates that FMF is not a rare condition in Cyprus and that, because of the significant morbidity associated with this disorder, which is often diagnosed only after unnecessary surgeries, a newborn screening program to detect affected in this population may be warranted.

[Genetic diagnosis of periodic diseases (familial mediterranean fever or FMF)].

[Article in French]

Touitou I.

Periodic disease is the prototype of a group of hereditary disorders characterised by recurrent inflammatory attacks. Since the discovery of the causing gene (MEFV) in 1997, three hospital laboratories in France, and around 20 throughout the world, propose a specific genetic test, based on the search of the common MEFV mutations on DNA extracted from a simple blood sample. This strategy allows definitive confirmation of periodic disease if one mutation is detected on each of the two chromosomes (around 30 mutations are reported today), but do not exclude the diagnosis in the other cases (one or no mutation detected). A non-contributive test shows the existence of rare MEFV mutations, or the involvement of another gene responsible for inflammatory hereditary syndrome; important differential diagnosis to be done, because their mode of management may be different from that of periodic disease.

Clinical and biochemical outcome of renal amyloidosis.

Odabas AR(1), Cetinkaya R, Selcuk Y, Erman Z, Bilen H.

Author information:

(1)Department of Nephrology, Ataturk University, School of Medicine, Erzurum, Turkey.

AA amyloidosis is a relatively rare disease which complicates chronic inflammatory diseases, chronic infections, familial Mediterranean fever (FMF) and malignant diseases. Although amyloid deposition may be found in many organs, renal involvement dominates the clinical picture. We reviewed 63 patients with AA amyloidosis who presented to our nephrology department between 1995 and 2000. Prognostic markers, detailed history, physical examination and laboratory tests were evaluated. The causes of AA amyloidosis were as follows: FMF 42 (66.6%), pulmonary tuberculosis 9 (14.2%), chronic osteomyelitis 4 (6.3%), bronchiectasia 4 (6.3%), rheumatoid arthritis 1 (1.5%), juvenile idiopathic arthritis 1 (1.5%), inflammatory abdominal aortic aneurysm 1 (1.5 %), unknown aetiology 1 (1.5%). The diagnosis was made on renal biopsies in 63.4% of the patients, while the remaining 36.6% were diagnosed as a result of rectal biopsies. Sixteen patients died. A low serum albumin, high creatinine and high 24-hour urine albumin

excretion were associated with high mortality.

Blood. 2003 Feb 1;101(3):1205; author reply 1205-6.

We describe data on a 7-year-old girl with congenital dyserythropoietic anemia (CDA), who also had familial Mediterranean fever (FMF). Repeated transfusions required since the age of 6 months to treat her CDA led to iron overload and a persistently high ferritin level. Her relapsing FMF made effective iron chelation therapy very difficult. Consequently, at the age of 4 years, she underwent allogeneic, sibling bone marrow transplantation (BMT). During conditioning for her BMT, symptoms of FMF, including splenomegaly, arthritis, and recurrent

abdominal pain, began to resolve and she was gradually weaned off colchicine. Now, 2 years after the transplantation, she remains free from FMF symptomatology and is off all immunosuppressants. This case demonstrates that symptoms of FMF can be alleviated by the therapy used during allogeneic BMT. In this patient it is likely that the missing factor in FMF is now being provided by granulocytes derived from the stem cells within transplanted bone marrow.

[Fibril-forming proteins: the amyloidosis. New hopes for a disease that cardiologists must know].

[Article in Italian]

Arbustini E(1), Gavazzi A, Merlini G.

Author information:

(1)Laboratorio di Diagnostica Molecolare, Area Trapiantologica di Ricerca, IRCCS Policlinico San Matteo, Dipartimento di Biochimica, Università degli Studi, Pavia. e.arbustini@smatteo.pv.it

Several proteins share the property of conforming as antiparallel beta-sheets, and forming insoluble amyloid fibrils that deposit in the interstitium of organs/tissues and cause systemic amyloidosis. Cardiac involvement is frequent

and constitutes a major predictor of poor outcome. Its typical phenotype is that of restrictive cardiomyopathy. The biochemical classification of the amyloidogenic proteins provides the bases for innovative therapeutic approaches. Primary systemic amyloidosis (AL) is a protein conformation disorder in which monoclonal immunoglobulin light chains (kappa or lambda) produced by clonal plasma cells, are deposited as amyloid in kidneys, heart, liver, and other organs. The recent evidence that chemotherapy reduces or even eradicates the amyloidogenic clone with consequent functional improvement of the affected organs raises new hopes for a treatment, whose key of success is early diagnosis. Heart transplantation can be proposed in patients < 60 years of age in association with autologous stem cell transplantation. In serum amyloid A amyloidosis, fibrils are constituted of the acute phase serum amyloid A protein that is produced in excess in chronic inflammatory diseases such as familial mediterranean fever, autoimmune disorders and chronic infections. The strategy is to treat the underlying inflammatory disease, but new molecules inhibiting amyloid formation and promoting amyloid resorption are facing the clinical scenario and trials are in progress. In transthyretin (TTR) amyloidosis, the non-senile forms are autosomal dominant diseases caused by defective proteins synthesized by mutated TTR genes (more than 70 known mutations with different genotype-phenotype correlations). The treatment is based on transplantation of the TTR-producing liver; exceptionally, liver plus heart or kidney are transplanted. Apolipoprotein A1 amyloidosis is an inherited autosomal dominant disease that benefits from the transplantation of the most impaired organs, usually heart, liver or kidney, either single or combined. The diagnosis of apolipoprotein A1 and TTR amyloidosis relies on positive family history, immunocharacterization of the amyloid fibrils in a tissue biopsy, gene defect detection and absence of light chains in serum and urines. Vice versa, non-familial primary amyloidoses are diagnosed when kappa or lambda light chains are identified with immunofixation in serum or urines. Tissue studies provide the gold standard for the diagnosis and immunocharacterization of amyloid protein. Heart involvement is diagnosed with a multiparametric approach that includes clinical, electrocardiographic and echocardiographic evaluation. The fine-needle biopsy of the periumbilical fat is the preferral procedure for amyloid detection and immunocharacterization of amyloid protein. This approach excludes, with a few exceptions, the need of endomyocardial biopsy.

Recurrent urticaria as a rare manifestation of familial Mediterranean fever.

Alonso R(1), Cisteró-Bahima A, Enrique E, San Miguel-Moncín MM.

Author information:

(1)Allergy and Clinical Immunology Unit, Institut Universitari Dexeus, Barcelona, Spain.

Familial Mediterranean fever (FMF) is a genetic disorder characterized by acute episodes of fever with some combination of severe abdominal pain, pleurisy, arthritis, and skin rash. The case of a patient with recurrent urticaria referred for study of drug allergy is presented. After allergy had been ruled out, the urticaria was attributed to previously undiagnosed symptoms of an underlying systemic disease: FME. Urticaria is the least frequent cutaneous manifestation of this disease, and genetic analysis was required to confirm the diagnosis.

Periodic fever is defined as a series of unexplained febrile episodes, most often starting during childhood. The febrile episodes last usually few days, are of fixed or variable duration, and regress spontaneously, the intervals between episodes being asymptomatic. Fever is accompanied by clinical manifestations

affecting peritoneal, pleural and/or mucous membranes, joints and skin. Four different etiologies are presently known. Three are hereditary diseases: familial mediterranean fever and periodic fever with hyperimmunoglobulinemia D which have a recessive autosomal transmission, and TNF receptor associated periodic syndrome or TRAPS which has a dominant autosomal transmission. One is sporadic: periodic fever with aphthous stomatitis, pharyngitis and adenopathy or PFAPA. Other etiologies are yet to be identified as many cases of periodic fever remain unexplained.

Mutational spectrum in the MEFV and TNFRSF1A genes in patients suffering from AA amyloidosis and recurrent inflammatory attacks.

Dodé C(1), Hazenberg BP, Pêcheux C, Cattan D, Moulin B, Barthélémy A, Gubler MC, Delpech M, Grateau G.

Author information:

(1)Laboratoire de biochimie et génétique moléculaire, Hôpital Cochin, Assistance Publique-Hôpitaux de Paris (AP-HP), Paris, France.

**BACKGROUND:** Among hereditary fevers characterized by recurrent attacks of fever and organ localized inflammation, familial Mediterranean fever (FMF), and tumour necrosis factor receptor superfamily 1A (TNFRSF1A) receptor associated periodic syndrome (TRAPS) are diseases with identified genes that can be associated with renal amyloidosis of the AA type. In this study we have characterized FMF and TRAPS genotypes in 38 unrelated patients suffering from amyloidosis AA and recurrent inflammatory attacks.

**METHODS:** Mutations of the MEFV and TNFRSF1A genes, responsible respectively for FMF and TRAPS, were searched for by amplifying, using polymerase chain reaction (PCR), genomic DNA, and direct sequencing.

**RESULTS:** Twenty-seven patients (71%) carried mutations in MEFV (22 patients with two mutations, two patients with a single mutation) or TNFRSF1A genes (three patients). Patients with MEFV mutations belonged to the classical at-risk ethnic group for FMF: Sephardic Jews, Turks, Armenians, and Arabs from the Maghreb. The main genotype encountered was M694V/M694V (19/22), one Turkish patient was M680I/M680I, and two Arab patients from the Maghreb were M694I/M694I. We found three Caucasian patients with the C55S, C70Y, R92Q mutations in the TNFRSF1A gene.

**CONCLUSIONS:** In this series we observed that FMF is the main cause of AA amyloidosis in Sephardic Jews and Turks. MEFV and TNFRSF1A mutations were found in only 6 of 14 Arab patients from the Maghreb. We found three families (one Caucasian and two from Maghreb) with AA amyloidosis without MEFV or TNFRSF1A mutations, suggesting that other genetic cause(s) exist(s). The characterization of mutations in MEFV and TNFRSF1A is important for the therapeutic behaviour of AA amyloidosis associated with inherited recurrent fever.

Thoracic and lung involvement in familial Mediterranean fever (FMF).

Lidar M(1), Pras M, Langevitz P, Livneh A.

Author information:

(1)Heller Institute of Medical Research, Sheba Medical Center, Tel-Hashomer, Israel.

Lung involvement in FMF is limited mainly to transient pleuritis during acute attacks. Amyloidosis of the lung is rare and is associated with symptomatic involvement of other organs while remaining subclinical in itself. Vasculitis of the lung in FMF is possible because of the strong association between FMF and a variety of vasculitides. With the exception of one case of isolated pulmonary vasculitis, vasculitis of the lung in FMF has not been described. The claim that FMF protects against asthma has not been established, but this inverse association, if present, may be traced to linkage disequilibrium in which MEFV modifies the effect of asthma and atopic-related genes, or to eosinophil function. Mesothelioma has been reported in at least four patients with FMF and is related to chronic or recurrent stimulation of the serous membrane. Three patients had peritoneal mesothelioma, while one developed mesothelioma of the lung. Finally, thromboembolism should be considered, particularly in patients with FMF amyloidosis who present with respiratory distress.

Genotype/phenotype correlations in Arab patients with familial Mediterranean fever.

Majeed HA(1), El-Shanti H, Al-Khateeb MS, Rabaiha ZA.

Author information:

(1)Department of Pediatrics, Faculty of Medicine, University of Jordan, Amman. pal@go.com.jo

**OBJECTIVES:** To study the phenotype/genotype correlations in Arab patients with familial Mediterranean fever (FMF).

**PATIENTS AND METHODS:** The study was performed in a 3-year period (February

1998-February 2001). Patients were seen in the pediatric FMF clinic of Jordan University Hospital, and the diagnosis of FMF was made according to published criteria. Screening for mutations was carried out by direct sequencing of the entire coding sequence of exon 10 and its donor splice site and by restriction endonuclease testing for mutations in exon 2. A total of 278 patients with clinically positive FMF were screened.

RESULTS: Of the 278 patients, 50 (18%) had 2 mutations identified, and 76 (27%) other patients had only 1 mutation identified. The 50 patients with 2 mutations are the subject of this report. The M694V/M694V and the M694V/V726A and M694I/M694I genotypes were the most common (30%, 16%, and 14%, respectively). Three homozygous genotypes (M694V/M694V, V726A/V726A, and M694I/M694I) and 2 compound heterozygous genotypes (M694V/V726A and V726A/M680I) accounted for 78% of mutations. The difference in the mean severity score ( $14 \pm 2$ ) of the M694V/M694V group and the V726A/V726A (mean severity score,  $10 \pm 3$ ) and M694I/M694I (mean severity score,  $6 \pm 1$ ) groups was statistically significant ( $P = .003$  and  $0$ , respectively). The difference between the M649V/M694V group and the M694V/V726A (mean severity score,  $15 \pm 2$ ) was not statistically significant ( $P = 0.31$ ).

CONCLUSIONS: The genotypes M694V/M694V and M694V/V726A have a severe clinical course in Arab patients with FMF, whereas the M694I/M694I is associated with mild disease.

We describe 3 Japanese patients in 2 families with familial Mediterranean fever

(FMF) as determined by gene analysis. FMF is an ethnically related, genetic disease, occurring commonly in some Mediterranean populations. The FMF gene (MEFV) mutation found in our patients is M694I. The patients may be remote from East Asian extraction.

Parvoviral infection of endothelial cells and its possible role in vasculitis and autoimmune diseases.

Magro CM(1), Crowson AN, Dawood M, Nuovo GJ.

Author information:

(1)Department of Pathology, Ohio State University, Columbus 43210, USA.

**OBJECTIVE:** To analyze a series of biopsies from 16 patients who, on the basis of clinical and dermatopathologic findings, had a spectrum of connective tissue diseases (CTD), autoinflammatory or CTD-like syndromes for parvoviral DNA, RNA, and protein.

**METHODS:** Most of the patients were initially screened for parvoviral-related IgG and IgM antibodies. Parvoviral DNA was analyzed by solution phase polymerase chain reaction (PCR). In situ localization of viral VP1 RNA was accomplished by in situ reverse transcriptase (RT) PCR; viral protein (VP2) was detected by immunohistochemistry and these results correlated with the histologic findings. (J Rheumatol 2002;29:xxxx)

**RESULTS:** Of 11 people tested, 10 had either IgG or IgM specific antibodies against parvovirus. Common histologic features of the 16 cases included an interface dermatitis, interstitial histiocytic infiltration with variable collagen necrobiosis, a mononuclear cell dominant vasculitis, and interstitial neutrophilia. Detection of parvoviral RNA by in situ RT-PCR in 14 of 16 cases corroborated solution phase PCR data and demonstrated that the endothelial cells and surrounding mononuclear cells were the viral target. Viral protein as revealed by immunohistochemistry showed an equivalent histologic distribution. Anti-tumor necrosis factor-alpha (TNF-alpha) therapy (etanercept) yielded dramatic improvement after worsening of symptoms with traditional

immunosuppressive therapy in the 3 patients in whom this drug was administered; TNF-alpha mRNA was detected by in situ RT-PCR in the area of parvoviral infected cells.

CONCLUSION: Parvoviral induced endothelialitis may be responsible for cases of "idiopathic" CTD.

ASC is an adaptor protein that is composed of two protein-protein interaction domains, a PYRIN domain (PYD), and a caspase-recruitment domain (CARD). Recently, ASC was identified as a binding partner of pyrin, which is the product of MEFV, a gene causing familial Mediterranean fever (FMF). Mutations in MEFV result in defects in control of neutrophil-mediated inflammation. Thus we focused on the expression of ASC in neutrophils. Immunohistochemical study showed that ASC is increased in neutrophils in severe inflammatory sites of gangrenous appendicitis. We, then, tested whether proinflammatory mediators induce ASC using peripheral

blood neutrophils in vitro. ASC expression was transiently up-regulated by IL-1alpha, IL-1beta, IFN-alpha, IFN-gamma, TNFalpha, and LPS. ASC was also increased by incubation with either anti-Fas antibody or recombinant soluble Fas ligand. The Fas-mediated induction of ASC was inhibited by a general caspase inhibitor, z-VAD-fmk, and an immunocytochemical study showed that ASC was increased in neutrophils exhibiting characteristic phenotypes for apoptosis. These findings suggest that up-regulation of ASC is closely associated with inflammation and apoptosis in neutrophils.

yalcinkaya@tr-net.net.tr

The clinical spectrum of arthritis in 124 children with well-documented familial Mediterranean fever (FMF) was investigated in a retrospective study. Seven mutations in the FMF gene (MEFV) were also screened using restriction enzyme digestion and amplification refractory mutation system techniques in 110 patients. Mean age at the onset of FMF arthritis was 5.93+/-3.50 years, 75% of the patients being under 10 years of age. Arthritis in the lower extremities, upper extremities, and small joints of the hands and feet was noted in 122 (98%), 17 (14%), and 15 (12%) patients, respectively. Three patients had atypical arthritis involving temporomandibular, sacroiliac, and sternoclavicular joints. Although most of the arthritic attacks resolved within a few weeks, 12 (10%) patients developed protracted arthritis persisting for months. Amyloidosis was demonstrated in 17 (14%) patients who had not received colchicine treatment. Mutation analysis confirmed the diagnosis of FMF in 77 (62%) children. The clinical presentations of arthritis in FMF may be an important source of diagnostic confusion in FMF. Mutation analysis is of value in situations of diagnostic uncertainty.

**OBJECTIVE:** To compare the hemodynamic responses to autonomic challenge evoked by upright tilt table testing in patients with familial Mediterranean fever (FMF).

**METHODS:** Forty consecutive patients with FMF and 25 age and sex matched healthy controls were evaluated using the head-up tilt test (HUTT). The main outcome measures were the values of blood pressure (BP) and heart rate (HR) recorded during recumbence and tilt. The endpoints of vasodepressor and cardioinhibitory reactions, orthostatic tachycardia, and postural tachycardia syndrome were recorded.

**RESULTS:** Patients with FMF exhibited significantly higher diastolic BP during supine and tilt measurements ( $p = 0.003$  and  $0.04$ , respectively). In response to tilt, patients showed significant increases in HR compared to healthy subjects ( $p = 0.02$ ). Pathological endpoints on tilt were observed in the FMF group in 7 patients (17%) and in no controls. FMF severity, genotype, duration of illness, response to therapy, and associated amyloidosis did not correlate with pathological reactions on HUTT.

**CONCLUSION:** FMF patients exhibit an abnormal cardiovascular reactivity, which is clinically occult, but can be detected on autonomic challenge. The abnormal autonomic activity in FMF is similar to dysautonomia described in a variety of rheumatic disorders.

A young boy from nonconsanguineous Palestinian parents presented with short stature, motor developmental delay, wide nasal bridge, bilateral periorbital edema, everted lower lip, brachydactyly, large interphalangeal articulations, drumstick extremities of the fingers, bilateral simian crease, clinodactyly of the 5th fingers, painful joints, subcutaneous nodules all over his body and recurrent episodes of fever of unknown origin. Differential diagnoses such as the hyperimmunoglobulinemia D syndrome, tumor necrosis factor receptor associated periodic syndrome (TRAPS), the chronic infantile neurological cutaneous and articular (CINCA) syndrome, and the newly recognized nodulosis, arthropathy, and osteolysis (NAO) syndrome are discussed. This syndrome may not have been previously reported.

Colchicine is a unique anti-inflammatory drug with respect to its limited clinical usefulness and its mode of action. Colchicine is mainly indicated for the treatment and prophylaxis of gout and familial Mediterranean fever. Its mode of action includes modulation of chemokine and prostanoid production and inhibition of neutrophil and endothelial cell adhesion molecules by which it interferes with the initiation and amplification of the joint inflammation. This paper discusses its adverse effects and indications.

Late diagnosis of severe colchicine intoxication.

Güven AG(1), Bahat E, Akman S, Artan R, Erol M.

Author information:

(1)Department of Pediatrics, Akdeniz University Medical Faculty, 07070 Antalya, Turkey. gur@med.akdeniz.edu.tr

A 4-year-old Turkish girl was referred to our hospital with the findings of encephalopathy and pancytopenia. She had a history of severe abdominal cramps and gastrointestinal bleeding. A confused state, muscle pain and weakness, erythema-bullous and erythema-nodosum-like skin lesions, and alopecia were observed at her hospitalization. All of these symptoms resolved on follow-up. On laboratory investigation severe thrombocytopenia and leukopenia, mild anemia, a moderate increase in aspartate aminotransferase and alanine aminotransferase levels were detected. After reevaluating her medical history, it was learned that she had accidentally taken 1.3 to 1.5 mg/kg of colchicine 3 to 4 days before her first hospitalization. The possibility of misdiagnosis of colchicine intoxication should be borne in mind, and pediatricians must be aware of its toxic effects, especially in areas where patients with familial Mediterranean fever are present.

Familial Mediterranean fever: the segregation of four different mutations in 13 individuals from one inbred family: genotype-phenotype correlation and intrafamilial variability.

Gershoni-Baruch R(1), Shinawi M, Shamaly H, Katsinetz L, Brik R.

Author information:

(1)Institute of Human Genetics, Rambam Medical Center, Haifa, Israel.  
rgershoni@ramba.health.gov.il

Familial Mediterranean fever (FMF) is an autosomal recessive disease

characterized by recurring attacks of fever and serositis. Six sequence alterations (M694V, V726A, K695R, M680I, M694I, and E148Q), in the MEFV gene, account for the majority of FMF chromosomes. Differences in the clinical expression have been mainly attributed to MEFV allelic heterogeneity. Homozygotes for the M694V mutation have a more severe form of the disease and more frequently demonstrate articular and renal complications. The clinical manifestations associated with mutation M680I are considered less severe. Mutations E148Q, K695R and V726A have reduced penetrance, and many individual homozygotes or compound heterozygotes for these mutations remain asymptomatic. Here we report on one inbred family with 13 individuals (one grandparent, three parents, and nine grandchildren), either homozygotes or compound heterozygotes, for one or two of four mutations (V726A, M694V, M680I, and K695R). Three parents and one grandparent who each carried two mutated alleles remained asymptomatic. Of nine grandchildren who were compound heterozygotes for two mutations in the MEFV gene, only those with either the M694V/V726A or the M694V/M680I genotypes manifested the disease, bearing further evidence to the severity of mutation M694V in individuals sharing a similar genetic and environmental background. Nevertheless, one father and one grandmother who carried the M694V/V726A compound heterozygous genotype were symptom-free, while the four grandchildren with the same genotype manifested the disease from early age, providing further evidence for the role of additional environmental and genetic modifiers. The occurrence of four different mutations in two sets of consanguineous parents merits consideration per se.

Mutations in CD2BP1 disrupt binding to PTP PEST and are responsible for PAPA syndrome, an autoinflammatory disorder.

Wise CA(1), Gillum JD, Seidman CE, Lindor NM, Veile R, Bashiardes S, Lovett M.

Author information:

(1)Sarah M. and Charles E. Seay Center for Musculoskeletal Research, Texas Scottish Rite Hospital for Children, Dallas, TX, USA. carol.wise@tsrh.org

PAPA syndrome (pyogenic sterile arthritis, pyoderma gangrenosum, and acne, OMIM #604416) and familial recurrent arthritis (FRA) are rare inherited disorders of early onset, primarily affecting skin and joint tissues. Recurring inflammatory episodes lead to accumulation of sterile, pyogenic, neutrophil-rich material within the affected joints, ultimately resulting in significant destruction. We recently localized the genes for PAPA syndrome and FRA to chromosome 15q and suggested that they are the same disorder. We have now established this by the identification of co-segregating disease-causing mutations in the CD2-binding protein 1 (CD2BP1; GenBank accession no XM 044569) gene in the two reported families with this disorder. E250Q or A230T amino acid substitutions occur within a domain highly homologous to yeast cleavage furrow-associated protein CDC15. CD2BP1 and its murine ortholog, proline-serine-threonine phosphatase interacting protein (PSTPIP1), are adaptor proteins known to interact with PEST-type protein tyrosine phosphatases (PTP). Yeast two-hybrid assays demonstrate severely reduced binding between PTP PEST and both the E250Q and A230T mutant proteins. Previous evidence supports the integral role of CD2BP1 and its interacting proteins in actin reorganization during cytoskeletal-mediated events. We hypothesize that the disease-causing mutations that we have identified compromise physiologic signaling necessary for the maintenance of proper inflammatory response. Accordingly we suggest classification of PAPA syndrome as an autoinflammatory disease. This CD2BP1-mediated biochemical pathway(s) may function in common inflammatory disorders with apparent etiological overlap, such as rheumatoid arthritis and inflammatory bowel disease.

Author information:

(1)Helsinki University Central Hospital, Helsinki, Finland.

**OBJECTIVE:** To investigate the presence of TRAPS (tumor necrosis factor receptor-associated periodic syndrome), which is a recently defined, dominantly inherited autoinflammatory syndrome caused by mutations in the tumor necrosis factor receptor superfamily 1A gene (TNFRSF1A, CD120a), in a Finnish family with recurrent fever.

**METHODS:** The TNFRSF1A gene was sequenced in both affected and unaffected family members. Flow cytometry and enzyme-linked immunosorbent assay analyses were used to assess membrane expression and serum levels of the TNFRSF1A protein, respectively.

**RESULTS:** A missense mutation in exon 4, located in the third extracellular domain of TNFRSF1A and resulting in an amino acid substitution (F112I) close to a conserved cysteine, was found in all 4 affected family members and in 1 asymptomatic individual. The mutation was clearly associated with low levels of soluble TNFRSF1A as well as with the clinical symptoms of recurrent fever and abdominal pain. Impaired shedding of TNFRSF1A after phorbol myristate acetate stimulation was detected in blood granulocytes and monocytes from the 3 adult family members with the mutation, but in the child bearing the mutation and showing clinical symptoms of recent onset, the shedding defect was less marked.

**CONCLUSION:** TRAPS should be suspected in any patient who presents with a history of intermittent fever accompanied by unexplained abdominal pain, arthritis, or skin rash, particularly in the presence of a family history of such symptoms. Screening for low serum levels of soluble TNFRSF1A identifies individuals who are likely to have TNFRSF1A mutations.

rgershoni@rambam.health.gov.il

Familial Mediterranean fever (FMF) is an autosomal recessive disorder characterised by recurring attacks of fever and serositis. Five sequence alterations (M694V, V726A, M680I, M694I and E148Q), in the MEFV gene, account for the majority of FMF chromosomes. The wide clinical variability of the disease has been related to MEFV allelic heterogeneity. M694V homozygotes have a severe form of the disease. Mutations E148Q and V726A have reduced penetrance. The clinical features, associated with the M680I and the complex V726A-E148Q allele, are not well defined. This study aims to further characterise the phenotypic profile associated with the major MEFV mutations. We investigated 220 FMF patients, in whom both FMF alleles have been identified, and found that different genotypes are characterised by a specific allelic related clinical profile and penetrance. Homozygotes for the M694V mutation and the complex V726A-E148Q allele are the most severely affected and often endure renal amyloidosis. Homozygotes for the M680I and V726A alleles and compound heterozygotes for either the M694V or the V726A-E148Q alleles in combination with either the E148Q, the V726A or the M680I alleles are significantly less severely affected. The morbidity associated with the complex V726A-E148Q allele by far outweighs that associated with the V726A allele, bearing evidence to the fact that the E148Q mutation is not a benign polymorphism. These findings increase our understanding of the role of allelic variability in disease expression.

A 39-year-old man had been suffering from periodic fever since childhood. He was started on hemodialysis due to secondary amyloidosis on December 2000. The patient was believed to have Familial Mediterranean fever (FMF) because of recurrent fever with peritonitis, arthritis and inflammatory changes and secondary amyloidosis in his kidneys, heart and colon. No other family member had recurrent fever. IL-6, TNF, and dopamine beta-hydroxylase were not increased in the febrile phase. The patient was homozygous for the M694I mutation. We report the first Japanese case of FMF associated with amyloidosis and confirmed by a gene mutation.

[The spectrum and level of low-weight molecular compounds of microbial origin in familial Mediterranean fever].

[Article in Russian]

Ktsoian ZhA, Beloborodova NV, Osipov GA, Sarkisian NN, Karagezian KG.

Familial Mediterranean fever (FMF) is a disease whose etiopathogenesis is not clarified yet. The infectious theory of FMF has not been confirmed either. Nevertheless, the involvement of microbes in the trigger of an inflammatory process cannot be excluded since today's well-known pathogenetic processes in FMF are to be directly related to the key cells of an inflammatory response. According to the existing concept, homeostasis of small molecules originating from microbes (SMOM) in healthy individuals is achieved due to adequate immune

system function with the preserved biocenosis of a macroorganism whose disturbance with resultant immune shifts triggers a cascade of inflammatory reactions in the body. An attempt was taken to reveal the participation of microorganisms at the onset of an inflammation in case of FMF by using chromatographic mass spectrometry to detect chemical components of microorganisms and their vital activity products. The method allows one to screen a large number of microbial markers in a clinical sample. Pronounced impairments in the homeostasis of non-protein SMOM were found in the blood of examined patients with FMF (n = 16). There was a uniformity of deviations from the normal values in all the examinees in the episodes and episode-free periods. These qualitative and quantitative deviations basically differ from the direction of changes with other diseases (n 59) or healthy individuals (n = 18). All significant deviations affect non-traditional participants of an inflammatory process in the host. The similar microecological breakages in the human body and their consequences have not been earlier detected and investigated. The findings show it necessary to continue studies to receive an answer to the question as to whether the detected homeostatic features of SMOM in patients with FMF are primary or what is their role in the etiopathogenesis.

Recurrent fevers in children are common, mainly due to viral (particularly in day care centers), or to bacterial (urinary tract upper and lower respiratory) infections. The diagnosis of recurrent hereditary fever is now possible on the basis of clinical features, biochemical and genetic tests. Familial Mediterranean

Fever (FMF) remains the most frequent disorder of this group, which includes now three other entities: TNF receptor associated periodic syndrome (TRAPS), the hyperIgD syndrome (HIDS) and the Muckle-Wells syndrome.

Familial Mediterranean fever is no more the sole hereditary disease characterized by recurrent inflammatory attacks. Three other main entities have now been defined, both at clinical and genetic levels: a dominant disease due to mutations of one of the tumour necrosis factor receptor, called TRAPS for tumour necrosis factor receptor associated periodic syndrome, the hyper-immuno-globulinaemia D and periodic fever syndrome (HIDS), which is a metabolic disorder and the Muckle-Wells syndrome. A thorough diagnosis of these diseases is crucial for appropriate management and treatment.

Familial mediterranean fever is a hereditary inflammatory disease, with autosomal recessive transmission, due to mutations in the MEFV gene. The MEFV gene, located on the short arm of chromosome 16, codes an anti-inflammatory protein, marenostine or pyrin. The disease is characterised by paroxysmal bouts of fever with acute and painful serositis. Appearance of renal amyloidosis indicates severe prognosis. The disease appeared several thousands of years ago in an ancestor common to Sephardic Jews, Turks, Armenians and Arabs. The full clinical description, including renal complications and familial forms, was made by two French investigators and dates from the 1950s. That this description is relatively recent is due to the scarcity of medical treatment and the poor living conditions in the regions concerned, which also explains the occurrence of endemic diseases (in particular tuberculosis), the frequency of acute rheumatic fever, malaria and pyogenic infections. Prophylactic treatment by colchicine, suggested by Turkish authors and one American author, has been demonstrated to avoid not only inflammatory episodes but also the development of amyloidosis.

Familial mediterranean fever and Behçet's disease--are they associated?

Ben-Chetrit E(1), Cohen R, Chajek-Shaul T.

Author information:

(1)Department of Medicine, Hadassah University Hospital, Jerusalem, Israel. eldad@hadassah.org.il

**OBJECTIVE:** To test whether the coexistence of familial Mediterranean fever (FMF) and Behçet's disease (BD) is more frequent than expected and whether each disease affects the severity of the other.

**METHODS:** We screened 353 charts of patients with FMF to detect individuals with concomitant BD. Of these, 152 patients with FMF over the age of 18 years were also interviewed and examined specifically. We also studied 53 patients with BD, looking for FMF and for their MEFV mutations. We compared BD patients with MEFV mutations to those without them.

**RESULTS:** None of 353 patients with FMF was found to have concomitant BD. Sixteen patients with BD bore MEFV mutations, 2 of whom were symptomatic homozygotes and had concomitant FMF. No patient with BD with a single MEFV mutation had FMF. Both BD groups (with or without MEFV mutations) were similar in their clinical manifestations and disease course.

**CONCLUSION:** BD and FMF are 2 separate entities that have a mild trend toward a higher than expected association. However, there was no mutual effect of FMF on BD or vice versa.

Enhanced cytokine mRNA levels in attack-free patients with familial Mediterranean fever.

Notarnicola C(1), Didelot MN, Seguret F, Demaille J, Touitou I.

Author information:

(1)Laboratory of Genetics, Arnaud de Villeneuve Hospital, Montpellier, France.

Familial Mediterranean fever (FMF) is a recessively inherited inflammatory disorder, characterized by recurrent attacks of fever and serositis. Screening of mutations in the causing gene (MEFV) now allows accurate diagnosis of FMF among other inflammatory conditions. It is well documented that secreted levels of some pro-inflammatory cytokines are elevated in FMF. Here, we investigated cytokine expression at the transcriptional level, in patients that could be genetically ascertained. We have measured the transcript abundance of tumor necrosis factor alpha, interleukin-1beta, interleukin-6 and interleukin-8, in circulating leukocytes and shown that these were more elevated in attack-free FMF patients than in controls ( $P=0.01$ ,  $P=0.008$ ,  $P=0.02$ ,  $P=0.001$  respectively). There was no significant difference according to MEFV genotype or colchicine treatment. Our results suggest that cytokine transcriptional pathways are misregulated in attack-free FMF patients, and further supports the hypothesis that these patients have subclinical inflammation between attacks.

Value of testis biopsy in the diagnosis of systemic amyloidosis.

Ozdemir BH(1), Ozdemir OG, Ozdemir FN, Ozdemir AI.

Author information:

(1)Department of Pathology, Başkent University Faculty of Medicine, Ankara, Turkey.

**OBJECTIVES:** To evaluate testis biopsy as a diagnostic tool in systemic amyloidosis, to assess how amyloidosis affects testicular tissue, and to examine the relationship between testicular amyloidosis and infertility.

**METHODS:** Testicular biopsies from 72 patients with confirmed systemic amyloidosis were examined for amyloid deposition after Congo red and crystal violet staining. A rectal biopsy was also done in each case, and the results were compared with the testicular biopsy findings.

**RESULTS:** Testicular amyloid deposition was detected in 62 (86.1%) of 72 patients. Fifty-one (85%) of 60 patients with secondary amyloidosis, 11 (91.7%) of 12 patients with primary amyloidosis, and 28 (87.5%) of 32 patients with familial Mediterranean fever showed amyloid deposition in the testis. Rectal biopsies were positive in 40 cases (55.6%). Only 4 of the 62 patients with testicular amyloid showed normal spermatogenesis. The remaining 58 exhibited abnormal spermatogenesis, and 77.7% of patients had seconder infertility. Of 62 patients with positive testis biopsies, 30 had serum creatinine levels less than 1.5 mg/dL, and 29 patients with testicular amyloid manifested nephrotic syndrome.

**CONCLUSIONS:** The testis biopsy is a valuable and more sensitive method than rectal biopsy for diagnosing systemic amyloidosis. The results also showed that testicular amyloidosis causes infertility at a higher rate than expected.

An Israeli Arab patient with a de novo TNFRSF1A mutation causing tumor necrosis factor receptor-associated periodic syndrome.

Aganna E(1), Zeharia A, Hitman GA, Basel-Vanagaite L, Allotey RA, Booth DR, Hawkins PN, Thacker C, Syndercombe-Court D, McDermott MF.

Author information:

(1)MRCPI: Barts and the London, Queen Mary's School of Medicine and Dentistry, University of London, UK.

**OBJECTIVE:** To investigate genetic susceptibility to recurrent fevers, generalized severe myalgia, and migratory erythema in an Israeli Arab child with no family history of similar disease.

**METHODS:** DNA sequencing of exons 1-6 of the TNFRSF1A gene (formerly TNFR1) was performed in the patient and his parents to determine the presence of the autosomal-dominant tumor necrosis factor receptor-associated periodic syndrome (TRAPS); informative markers spanning the TNFRSF1A locus were used to genotype all available members of the patient's family. The TNFRSF1A gene was subsequently screened in 69 healthy Arab controls and 96 Caucasian controls. Formal forensic paternity testing was performed on the child.

**RESULTS:** We found a de novo missense mutation in exon 3 of the TNFRSF1A gene, involving a novel C-->T transition encoding a Cys70Arg (C70R) variant, in the Israeli Arab patient. Eight of the common familial Mediterranean fever (FMF) gene MEFV mutations were excluded. This mutation was not present in the parents or siblings, or among the 69 healthy Arab controls. However, another TNFRSF1A variant, Pro46Lys (P46L), was present in 1 of the Arab controls.

**CONCLUSION:** We have identified a TNFRSF1A mutation associated with periodic fever in an Arab patient, and a TNFRSF1A variant, which is variably pathogenic in Caucasians, in an Arab control. This is the first report of a de novo mutation in periodic fevers in general, and also of TRAPS in the Arab population. These findings demonstrate the need to include TRAPS in the differential diagnosis of recurrent fevers in this population.

# Effect of colchicine and cytokines on MEFV expression and C5a inhibitor activity in human primary fibroblast cultures.

Abedat S(1), Urieli-Shoval S, Shapira E, Calko S, Ben-Chetrit E, Matzner Y.

Author information:

(1)Hematology Unit, Hadassah Hospitals, Mount Scopus, Israel.

**BACKGROUND:** Familial Mediterranean fever is an autosomal recessive disease characterized by sporadic attacks of inflammation affecting the serosal spaces. The gene associated with FMF (MEFV), mainly expressed in neutrophils, was recently found to be expressed also in primary cultures of serosal origin (peritoneal and synovial fibroblasts). A C5a inhibitor, previously detected in normal serosal fluids, was recently identified in serosal cultures as well, and was found to be deficient in serosal fluids and cultures obtained from FMF patients.

**OBJECTIVE:** To investigate the effect of colchicine (the main therapeutic agent for FMF patients) and certain inflammatory cytokines (IL-1 beta, TNF-alpha, IFN-alpha, IFN-gamma) on MEFV expression and C5a inhibitor activity in neutrophils and primary peritoneal fibroblast cultures.

**METHODS:** Human primary peritoneal fibroblast cultures and neutrophils were studied for MEFV expression and C5a inhibitor activity, using reverse transcription-polymerase chain reaction and C5a-induced myeloperoxidase assay, respectively, in the presence and absence of colchicine and cytokines.

**RESULTS:** MEFV expression in neutrophils was high and could not be induced further. Its expression in the peritoneal fibroblasts was lower than in neutrophils and could be induced using colchicine and cytokines parallel with induction of C5a inhibitor activity. Semi-quantitative RT-PCR assays enabled estimation of MEFV induction by the cytokines at 10-100-fold and could not be further increased by concomitant addition of colchicine.

**CONCLUSION:** Serosal tissues, which are afflicted in FMF, express colchicine and cytokine-inducible MEFV and contain inducible C5a inhibitor activity. The relation between the ability of colchicine to induce MEFV and C5a inhibitor activity, and its efficacy in FMF treatment, require further investigation.

Familial Mediterranean Fever: association of elevated IgD plasma levels with specific MEFV mutations.

Medlej-Hashim M(1), Petit I, Adib S, Chouery E, Salem N, Delague V, Rawashdeh M, Mansour I, Lefranc G, Naman R, Loiselet J, Lecron JC, Serre JL, Mégarbané A.

Author information:

(1)Unité de Génétique Médicale, Faculté de Médecine, Université Saint Joseph, Beirut, Lebanon.

Familial Mediterranean Fever (FMF) is a recessively inherited disorder, characterized by episodic fever, abdominal and arthritic pain, as well as other forms of inflammation. Some FMF patients present higher IgD serum levels, and it is not yet known whether such an elevation is related to specific genotypes or correlated with a specific phenotype. In order to evaluate the association between known FMF-related mutations and IgD levels in confirmed patients, as well as the correlation between those levels and the presence of specific clinical signs, genotypic analysis and IgD plasma measurements were performed for 148 Lebanese and Jordanian FMF patients. Most common mutational patterns were M694V heterozygotes (19%) and homozygotes (17%), and V726A heterozygotes (18%) and homozygotes (5%), with an additional 11% combining both mutations. Twenty-one patients had higher IgD levels (superior to 100 microg/ml). The risk for higher IgD levels was significantly associated with M694V homozygote status (OR = 6.25) but not with heterozygotic one (OR = 1). Similarly, the risk for higher IgD was also found with V726A homozygotes (OR = 2.2) but not with heterozygotes (OR = 1.05). The use of colchicine was not statistically associated with IgD levels. Clinically, hyper IgD was also found significantly associated with arthritis (OR = 18). Thus, homozygotic status for M694V, and to a lesser extent V726A, is associated with increased risk for higher IgD plasma levels, regardless of colchicine use. Elevated IgD plasma levels are also correlated with the severity of FMF manifestations, and especially with arthritis.

Acute phase response in familial Mediterranean fever.

Korkmaz C(1), Ozdogan H, Kasapçopur O, Yazici H.

Author information:

(1)Department of Rheumatology, Medical School of Osmangazi University, Eskisehir, Turkey.

**OBJECTIVE:** To test the hypothesis that not all acute phase reactants respond in the same way during attacks of familial Mediterranean fever (FMF) and that there is a subclinical acute phase response (APR) in a proportion of patients during the interval between attacks.

**METHODS:** Blood and urine samples were obtained from 49 patients with FMF during an attack and the attack-free period that followed, to test for erythrocyte sedimentation rate, C reactive protein (CRP), fibrinogen, white blood cell count, platelet count, factor VIII related antigen, haptoglobin, protein electrophoresis, ferritin, proteinuria, and haematuria. Control groups comprised 29 patients with juvenile idiopathic arthritis, 10 patients with various infectious diseases, and 19 healthy subjects.

**RESULTS:** A marked APR was seen during the FMF attacks which was comparable with that obtained in the diseased control groups. CRP was the only acute phase protein that was raised during all attacks. Neither thrombocytosis nor an increase in ferritin levels (except one) was noted in any attack. Serum albumin levels remained unchanged. In two thirds of the patients with FMF a continuing APR was seen in between the attacks.

**CONCLUSION:** Platelet, ferritin, and albumin responses are not part of the significant APR seen during short lived attacks of FMF, and inflammation continues in about two thirds of the patients during an attack-free period.

Author information:

(1)Departments of Pediatrics and Rheumatology, Cerrahpasa Medical Faculty, Istanbul University, Istanbul, Turkey.

**OBJECTIVE:** To evaluate growth process and insulin like growth factor-1 (IGF-1) levels in children with familial Mediterranean fever (FMF).

**METHODS:** This prospective study group consisted of 51 children with FMF under colchicine therapy (20 boys, 31 girls) and 42 healthy children (22 boys, 20 girls). All children were prepubertal. Bone ages and IGF-1 levels were determined in all cases. Height velocity (HV), height standard deviation score (SDS), target height and target height SDS were calculated.

**RESULTS:** There was no statistical difference in age, HSDS, target height SDS and bone ages between healthy and diseased subjects. HV of children with FMF did not differ significantly from the control group. There was no statistical difference in age, HSDS, target height SDS and bone ages between healthy and FMF subjects. HV of children with FMF did not differ significantly from the control group. There was no significant correlation between disease duration, number of attacks, erythrocyte sedimentation rate and HV, HSDS and IGF-1 levels of FMF patients. There was positive correlation between cumulative colchicine dose and HV ( $r = 0.29$ ).

**CONCLUSION:** Growth and IGF-1 levels of children with FMF do not differ from their healthy peers. However, there was positive correlation between HV and cumulative colchicine dose. This study suggests that colchicine not only has no adverse influence on growth, but more by suppressing disease activity and inflammation it has an enhancing role.

Increased neutrophil apoptosis during attacks of familial Mediterranean fever.

Ozen S(1), Uckan D, Baskin E, Besbas N, Okur H, Saatci U, Bakkaloglu A.

Author information:

(1)Department of Pediatric Nephrology and Rheumatology, Hacettepe University Faculty of Medicine, Sıhhiye 06100 Ankara, Turkey.

**AIM:** Apoptosis is a programmed form of cell death. Recently much attention has been devoted to the role of apoptosis in rheumatological diseases. We have aimed to analyze apoptosis in the inflammatory pathway of familial Mediterranean fever (FMF).

**METHODS:** 26 FMF patients and 12 age and sex matched controls were the subject of the study. Twelve of the patients were analyzed during an FMF attack whereas samples were obtained at least a week after an attack in 14. Four of the patients had renal amyloidosis. Whole blood was treated with ammonium chloride for RBC lysis. Subsequently the cells were stained with propidium iodide and annexin. Neutrophils and lymphocytes were gated separately for analysis by flow cytometry. We have also analyzed cellular Fas and Fas-ligand expression in these cells.

**RESULTS:** The mean age of the patients was  $12.00 \pm 3.17$ , and was not different than the control subjects. Erythrocyte sedimentation rate and CRP levels were significantly elevated in the attack group as compared to the attack-free group. The mean levels of neutrophil apoptosis in the FMF patients with an attack, attack-free and controls were  $12.94 \pm 11.78$ ,  $6.60 \pm 7.83$  and  $3.98 \pm 4.27$ , respectively. Lymphocyte apoptosis in the same groups were  $7.84 \pm 8.63$ ,  $2.75 \pm 2.33$ , and  $1.22 \pm 0.93$ , respectively. Neutrophil and monocyte apoptosis was significantly increased during the attack as compared to the controls ( $p < 0.05$ ). However lymphocyte apoptosis was not different between the aforementioned groups. On the other hand, lymphocyte apoptosis was significantly increased in the SLE patients ( $p < 0.05$ ), whereas neutrophil apoptosis was not. Fas staining of neutrophils were not different between the groups ( $p > 0.05$ ). On the other hand the difference between the groups for FasL was significant ( $p < 0.05$ ).

**CONCLUSION:** Neutrophil and monocyte but not lymphocyte apoptosis was significantly increased during FMF attacks reminding us that FMF is an autoinflammation of certain peripheral cells. The increased apoptosis in these patients maybe regarded as a response to clear the unwanted inflammatory cells. On the other hand the increased apoptosis maybe the explanation of the self-limited nature of the FMF attacks. Future studies will enlighten us on the

significance of this increased apoptosis in the process of inflammation.

Familial Mediterranean fever (FMF)-associated amyloidosis in childhood. Clinical features, course and outcome.

Cakar N(1), Yalçinkaya F, Ozkaya N, Tekin M, Akar N, Koçak H, Misirlioğlu M, Akar E, Tümer N.

Author information:

(1)Department of Pediatric Nephrology, Ankara Social Security Children's Hospital, Ankara, Turkey. nilguncakar@hotmail.com

**OBJECTIVE:** Familial Mediterranean fever (FMF) is an autosomal recessive disorder of childhood characterized by attacks of fever and serositis. Renal amyloidosis is the most important complication of the disease that determines the prognosis.

**METHODS:** Forty-eight Turkish FMF patients with amyloidosis who have been followed at the two hospitals in Ankara were included in this study.

**RESULTS:** All patients with amyloidosis had been symptomatic for FMF at the time of the diagnosis (Phenotype I), none had received regular colchicine therapy and all presented with proteinuria. Ten of them had asymptomatic proteinuria; 38 had nephrotic syndrome and 8 of them had renal insufficiency (CRI) as well, at the time of the diagnosis. Regular colchicine therapy was commenced to all of the patients. At the end of observation period of 4.5 +/- 2.23 years (range 2-12 yrs) on treatment, nephrotic syndrome resolved in 13 patients and proteinuria was lost in 5 of them. None but 2 of the patients who were diagnosed at proteinuric stage progressed to end stage renal failure (ESRF). Seven MEFV mutations (M694V, M680I, V726A, M694I, K695R, R761H, E148Q) were systematically investigated in 32 patients. Six of the seven studied mutations were found in these patients and clinical diagnosis was confirmed by mutation analysis in 24 patients. Eight patients were found to have mutations on one of the alleles.

**CONCLUSION:** Amyloidosis is the most serious complication of FMF. Colchicine treatment ameliorates the progression of renal disease in the patients who presented with proteinuria and even with nephrotic syndrome. No correlation

between the outcome of the patients with nephrotic syndrome and the degree of proteinuria and/or serum albumin levels at the initiation of treatment were noted. Progression to ESRF seems inevitable despite colchicine therapy after the development of CRI in patients with FMF associated amyloidosis.

A reassessment of the International Study Group criteria for the diagnosis (classification) of Behçet's syndrome.

Tunç R(1), Uluhan A, Melikoğlu M, Ozyazgan Y, Ozdoğan H, Yazici H.

Author information:

(1)Department of Internal Medicine, Faculty of Medicine, Selcuk University, Konya, Turkey.

**OBJECTIVE:** Patients with ulcerative colitis (UC) and Crohn's disease (CD) were not represented in the diseased controls group that had been utilised in the development of the International Study Group (ISG) criteria for the diagnosis of Behçet's syndrome (BS). Having similar features, both of these conditions can pose problems in the differential diagnosis of BS. Moreover, there has been a recent awareness of coexistence of BS and familial Mediterranean fever (FMF). The aim of this study was to reassess the performance of ISG criteria among patients with BS and other rheumatological conditions, specifically including those with CD, UC, and FMF.

**METHODS:** 302 consecutive patients with BS and 438 patients with other rheumatological conditions were surveyed for the presence or absence of the features of BS by means of a standard form which had been prepared according to ISG criteria. All control patients with a history of oral ulcer had a pathergy test and an eye examination by an experienced ophthalmologist with a slit lamp. The sensitivity and specificity of the ISG criteria were calculated.

**RESULTS:** Seven of 302 patients with BS (2%) did not fulfill the ISG criteria while 5 of 438 controls (1%) fulfilled the ISG criteria.

**CONCLUSION:** In this study ISG criteria performed well in correctly classifying BS. Further specificity studies might be considered in CD.

Nailfold capillary abnormalities in patients with familial Mediterranean fever.

Dinç A(1), Melikoğlu M, Korkmaz C, Fresko I, Ozdoğan H, Yazici H.

Author information:

(1)Division of Rheumatology, Department of Medicine, Cerrahpasa Medical Faculty, University of Istanbul, Turkey.

**OBJECTIVE:** To determine the frequency and the degree of the nailfold capillary abnormalities in patients with familial Mediterranean fever (FMF).

**METHODS:** We studied 67 (M/F: 28/39) patients with FMF. Thirty-seven healthy subjects (16/21), 19 patients (0/19) with systemic lupus erythematosus (SLE), and 8 patients (0/8) with scleroderma (PSS) were also studied. All participants were questioned for the presence of Raynaud's phenomenon (RP). Capillary loops of eight fingers were evaluated and scored with respect to avascular areas, tortuosity, enlargement and extravasations by the conventional capillary microscopy. Both FMF patients and healthy controls were examined in a blind manner.

**RESULTS:** FMF patients differed from healthy controls by the presence of increased tortuosity and enlargement of capillary loops, but not by microhemorrhages. Being female and the presence of RP were the factors that correlated with the capillaroscopic findings.

**CONCLUSION:** Capillary abnormalities are seen in patients with FMF.

Familial mediterranean fever - a review and update.

Orbach H(1), Ben-Chetrit E.

Author information:

(1)Departments of Medicine, Bikur Cholim, Jerusalem, Israel.

Familial Mediterranean fever (FMF) is an autosomal recessive disease, which primarily affects populations surrounding the Mediterranean basin. The disease occurs predominantly in Turks, Armenians, Arabs, and Sephardic Jews. FMF is

characterized by recurrent attacks of fever and peritonitis, pleuritis, arthritis or erysipelas-like erythema. Amyloidosis causing renal failure is one of the most severe complications of the disease. In 1997, the gene associated with FMF (MEFV) was isolated. It encodes a protein consisting of 781 amino acids and is expressed mainly in leukocytes. It was named "pyrin" indicating its relation to fever or "marenostrin" (our sea), referring to the Mediterranean focus of the disease. The exact pathogenesis of FMF is not known. Since the MEFV gene encodes a protein that resembles cytokines, which can down-regulate inflammation, it was suggested that pyrin may also have a similar effect. Thus, in FMF patients lacking this protein (or its activity) due to hereditary defects, there is no suppression or inhibition of the inflammatory process, thereby leading to a full-blown attack. Current studies suggest a limited phenotype-genotype correlation. It seems that other genetic and environmental modifiers influence the expression of FMF. Colchicine has been the drug of choice for FMF. It controls the FMF attacks and prevents the development of amyloidosis. Nevertheless, about 5-10% are non-responders and new therapies and approaches for these cases are currently under investigation. The prognosis of FMF patients is favorable, provided they are treated continuously with colchicine. Under this treatment most of the patients are free of acute inflammatory attacks and they will not develop amyloidosis.

**BACKGROUND:** Familial Mediterranean fever is a genetic disease in which some characteristic gene mutations have been found.

**OBJECTIVES:** To analyze the phenotype-genotype correlations in North African Jews and Armenians with FMF.

**METHODS:** We studied MEFV gene mutations and phenotype-genotype correlations in North African Jews and Armenians with Familial Mediterranean Fever living in France.

**RESULTS:** M694V mutation was the most common mutation in Jews and in Armenians. Patients with M680I homozygosity or M680I/M694V compound heterozygosity had a phenotype as severe as patients with M694V homozygosity.

**CONCLUSIONS:** This study characterizes the phenotype-genotype in specific ethnic

groups of patients with FMF.

Familial Mediterranean fever (FMF) is 1 of the major causes of secondary amyloidosis. Renal involvement is the main clinical complication and it mostly presents with nephrotic syndrome and chronic renal failure. Although deposition of amyloid has been reported in several endocrine glands such as the adrenal, thyroid, and testes, clinically significant functional impairment is uncommon. Herein, we describe a patient in whom the diagnosis of FMF was based on molecular screening and who presented with recurrent hypoglycemic attacks and extensive amyloid deposition affecting various organ function including adrenal, thyroid, parathyroid, testes, intestinal system, and the heart.

We describe a 22-year-old Turkish woman with nephrotic syndrome who had a history of acute myelocytic leukemia. After careful clinical evaluation, the patient underwent a renal biopsy. Light microscopic examination showed deposition of Congo-positive material both in the mesangium and around the small vessels. By histochemical analyses, the deposited material was proved to be amyloid A (AA). Because the patient's history did not reveal any event that might explain the development of secondary amyloidosis, she was screened for mutations causing familial Mediterranean fever (FMF) and was found to be homozygous for the M694V mutation by denaturing gradient gel electrophoresis. We recommend that FMF-Phenotype II and the development of amyloid nephropathy, before or without other symptoms of FMF, should be kept in mind in the face of unexplained proteinuria/amyloidosis, especially in high-risk ethnic groups.

Amyloid goiter in Familial Mediterranean Fever (FMF): a clinicopathologic study of 10 cases.

Ozdemir BH(1), Akman B, Ozdemir FN.

Author information:

(1)Department of Pathology, Baskent University Faculty of Medicine, Ankara, Turkey.

FMF Amyloidosis is an important etiological factor of end stage renal disease (ESRD) in Mediterranean Countries. Apart from major target organs as cardiovascular, respiratory and gastrointestinal system, endocrine organs can also be involved. We planned to investigate the thyroid involvement in our amyloidosis group. The aim of this study was to determine clinical characteristics of amyloid goiter in FMF patients and the abnormalities of thyroid function, as well as to identify pathologic characteristics. Twenty-two hemodialysis patients (mean age 34.1 +/- 14 years, range 17-68) whose ESRD

secondary to FMF amyloidosis were evaluated with physical examination, serum levels of thyroid hormones, ultrasound examination of thyroid glands, thyroid syntigraphic studies. Goiter was found in 10 patients (4 male, 6 female) having enlarged neck mass (mean age 35 +/- 14 years, range 23-64). The serum levels of thyroid hormones and TSH were normal in 4 patients. Other four cases had euthyroid sick syndrome. Only one patient developed tender enlarged neck mass with subacute thyroiditis symptoms and one had primary hyperthyroidism. Ultrasound examination showed; hypoechoic nodules in 6 patients diffuse multinodular enlargement in 4 patients. Thyroid syntigraphic studies revealed hypoactive nodules in 7 patients and hyperactive nodules in 3 patients. After the laboratory tests were completed, in 10 patients diagnosis were made with fine needle aspiration biopsy. Of 10 patients 5 underwent subtotal thyroidectomy. Immunohistochemical evaluation demonstrated the presence of amyloid AA immunoreactivity in all cases. In conclusion fine needle aspiration from the thyroid when enlarged is useful in the diagnosis of suspected amyloidosis, especially since it is a safe, easily performed procedure. With the help of amyloid goiter diagnosis the patient's prognosis on hemodialysis and with renal transplantation can be predicted. Amyloid goiter must be searched in hemodialysis patients especially in Mediterranean Countries.

Arch Intern Med. 2001 Nov 12;161(20):2406-8.

We describe 2 Dutch patients with recurrent fever attacks undiagnosed for more than 40 years. The diagnosis of periodic fever was made when molecular analysis

revealed novel mutations in the tumor necrosis factor (TNF) receptor gene (TNFRSF1A), establishing the diagnosis of TNF receptor-associated periodic syndrome. This syndrome is an autosomal dominant disorder characterized by recurring episodes of fever, arthralgia, and skin lesions that is caused by mutations in the 55-kd TNFRSF1A gene. This finding has facilitated treatment for TNF receptor-associated periodic syndrome because blocking of TNF signaling seems to alleviate the symptoms. Use of a short course of recombinant p75TNFR:Fc fusion protein (etanercept) induced prolonged remission in one patient.

TNF-receptor-associated periodic syndrome (TRAPS) is a recently recognized disorder characterized by prolonged attacks of high fever and severe localized inflammation. TRAPS is caused by dominant mutations in the 55 kDa TNF receptor gene (TNFRSF1A). We here describe three German TRAPS patients of two families with Cys30-->Arg and Thr50-->Met mutations, respectively. Both mutations have already been observed before in other nonrelated families. The Thr50-->Met amino acid exchange, caused by an ACG-->ATG transition, has been reported in two other families of different ethnic background. The possibility that the ACG-->ATG sequence alteration is a mutational hot spot causing TRAPS is discussed. Furthermore, we describe and discuss the symptoms of our patients, possible inducers of febrile attacks, and treatments which the patients had received when their diagnoses were still unknown.

Pulmonary hypertension in patients with amyloidosis.

Dingli D(1), Utz JP, Gertz MA.

Author information:

(1)Division of Hematology and Internal Medicine, Mayo Clinic and Mayo Foundation, Rochester, MN 55905, USA.

Pulmonary hypertension (PH) with right-sided cardiac failure is a rare complication of amyloidosis, and its natural history is not well-defined. The aim of our study was to evaluate patients who were seen at our institution who had PH and amyloidosis and to describe the natural history of this complication. The study was a retrospective chart review of patients seen at the Mayo Clinic with both PH and amyloidosis listed as major diagnoses between January 1, 1980, and December 31, 1999. Patients with known causes of PH were excluded. Five patients met our criteria (four women and one man). Four patients had light-chain amyloidosis and one had amyloid A deposition secondary to familial Mediterranean fever. All patients had symptoms related to PH without echocardiographic evidence of left ventricular dysfunction. The median survival time after the diagnosis of amyloidosis was 2.8 years, and PH was found a median of 73 days before death. Five patients died of cardiac complications, including one with sudden cardiac death. PH is an unusual complication of amyloidosis. Patients develop PH late in the disease process and do not have a worse prognosis compared to other patients with cardiac amyloidosis. PH is a marker of advanced amyloidosis.

Nat Genet. 2001 Nov;29(3):241-2.

Familial cold autoinflammatory syndrome (FCAS, MIM 120100), commonly known as familial cold urticaria (FCU), is an autosomal-dominant systemic inflammatory disease characterized by intermittent episodes of rash, arthralgia, fever and conjunctivitis after generalized exposure to cold. FCAS was previously mapped to a 10-cM region on chromosome 1q44 (refs. 5,6). Muckle-Wells syndrome (MWS; MIM 191900), which also maps to chromosome 1q44, is an autosomal-dominant periodic fever syndrome with a similar phenotype except that symptoms are not precipitated by cold exposure and that sensorineural hearing loss is frequently also present. To identify the genes for FCAS and MWS, we screened exons in the 1q44 region for mutations by direct sequencing of genomic DNA from affected individuals and controls. This resulted in the identification of four distinct mutations in a gene that segregated with the disorder in three families with FCAS and one family with MWS. This gene, called CIAS1, is expressed in peripheral blood leukocytes and encodes a protein with a pyrin domain, a nucleotide-binding site (NBS, NACHT subfamily) domain and a leucine-rich repeat (LRR) motif region, suggesting a role in the regulation of inflammation and apoptosis.

Familial cold autoinflammatory syndrome: phenotype and genotype of an autosomal dominant periodic fever.

Hoffman HM(1), Wanderer AA, Broide DH.

Author information:

(1)Department of Medicine, University of California at San Diego, La Jolla, 92093-0635, USA.

**BACKGROUND:** Familial cold autoinflammatory syndrome (FCAS), commonly known as familial cold urticaria, is a rare autosomal dominant inflammatory disorder with episodic symptoms precipitated by exposure to cold.

**OBJECTIVE:** The goal of this study was to formulate clinical diagnostic criteria for FCAS in a large cohort in whom the diagnosis of FCAS was supported by genetic linkage to chromosome 1q44.

**METHODS:** We assessed 45 affected and 68 unaffected members from 6 American families. DNA analysis was performed to confirm linkage to chromosome 1q44. Clinical characteristics were determined by means of analysis of detailed questionnaires and medical histories.

**RESULTS:** Pedigree and genetic analyses confirmed autosomal dominant transmission and linkage to chromosome 1q44 in all families. The most consistent symptoms during attacks were rash (100%), fever (93%), arthralgia (96%), and conjunctivitis (84%). Age of onset was within the first 6 months of life in 95% of affected subjects. The average delay between cold exposure and onset of symptoms was 2.5 hours, and the average duration of an episode was 12 hours. Renal disease with amyloidosis occurs infrequently in FCAS (2%).

**CONCLUSION:** The most consistent clinical characteristics of FCAS that discriminate it from other periodic fevers are association with cold exposure, conjunctivitis, age of onset, duration of episodes, and an autosomal dominant inheritance pattern. On the basis of the analysis of genotype and phenotype of FCAS, we formulated clinical diagnostic criteria that can be used to distinguish FCAS from other hereditary periodic fever syndromes.

(1)Centre for Amyloidosis and Acute Phase Proteins, Department of Medicine, Royal Free and University College Medical School, Royal Free Campus, London, UK.

Comment in

QJM. 2002 May;95(5):332-3.

Familial Mediterranean fever (FMF) is caused by more than 25 mutations in the gene MEFV, which encodes pyrin (marennostatin), a protein implicated in the regulation of neutrophil activity. Pyrin Q148, is one of the five most common variants in populations in which FMF typically occurs. Our identification of the pyrin Q148 allele in several patients from ethnic groups in which FMF is not classically recognized who had longstanding fevers or AA amyloidosis prompted us to study the prevalence of pyrin Q148 in healthy British, Indian and Chinese subjects. The gene frequency was also sought in 50 British Caucasian patients with inflammatory arthritis, 25 of whom had AA amyloidosis, five Punjabi Indians with AA amyloidosis complicating inflammatory arthritis, and seven British Caucasian patients with uncharacterized longstanding fever syndromes. The allele frequency for pyrin Q148 was 21%, 15% and 0%, respectively, among Punjabi Indian, Chinese and Caucasian British controls, and was significantly increased among the patients with AA amyloidosis and the patients with obscure fever syndromes ( $p < 0.01$ ). Pyrin Q148 is a polymorphism and occurs widely in global terms, and, although it may cause FMF when associated with certain other MEFV mutations, homozygosity for Q148 alone must usually be insufficient to produce FMF in the populations studied. The association of pyrin Q148 with AA amyloidosis and with obscure chronic inflammatory diseases suggests the variant may augment

inflammation non-specifically, which might have been beneficial during evolution, but could potentially exacerbate many chronic inflammatory disorders.

Hereditary periodic fever syndromes.

McDermott MF(1), Frenkel J.

Author information:

(1)Unit of Molecular Medicine, Department of Diabetes and Metabolic Medicine, Barts and the London, Queen Mary's School of Medicine and Dentistry, University of London, UK.

Hereditary periodic fever syndromes are defined by recurrent attacks of generalised inflammation for which no infectious or auto-immune cause can be identified. For most of these disorders, the molecular basis has recently been elucidated. This has opened the prospect of novel therapeutic approaches. Familial Mediterranean fever (FMF) is caused by mutations in the MEFV gene. Pathogenesis is poorly understood. The clinical severity is in part related to the mutations involved. Tumour necrosis factor receptor-1-associated periodic syndrome (TRAPS) is caused by mutations in the TNFRSF1A gene. This results in decreased serum levels soluble TNF-receptor leading to inflammation due to unopposed TNF-alpha action. Results of treatment with recombinant TNF-receptor analogues are promising. The hyper IgD periodic fever syndrome (HIDS) is caused by mutations in the MVK gene, leading to mevalonate kinase deficiency. The pathogenesis remains unclear. Muckle-Wells syndrome (MWS) and familial cold urticaria (FCU) are probably allelic disorders. The gene has been located, but not identified.

Plasma fibronectin- and thrombospondin-adhesive molecules during acute attacks and attack-free periods of familial Mediterranean fever.

Ertenli I(1), Kiraz S, Oztürk MA, Haznedaroglu IC, Celik I, Kirazli S, Calgüneri M.

Author information:

(1)Department of Rheumatology, Hacettepe University School of Medicine, Ankara, Turkey.

We assessed plasma concentrations of fibronectin (FN) and thrombospondin (TSP) during acute attacks and attack-free periods of patients with familial Mediterranean fever (FMF). Seven female and three male FMF patients (mean age 34+/-7 years) were enrolled in the study. Plasma samples were obtained during acute FMF attacks and after 3 months of freedom from attacks. Erythrocyte sedimentation rate, C-reactive protein, and white blood cell count were evaluated concurrently. Plasma levels of FN and TSP were assayed by enzyme-linked immunosorbent assay (ELISA). Both FN and TSP concentrations were found to increase during acute attacks. Levels of adhesive molecules decreased during attack-free periods ( $P < 0.05$ ). Significant correlations were found between FN and TSP levels and the concentrations of acute-phase response indicators ( $P < 0.05$ ). This study disclosed for the first time significantly higher increments in the plasma levels of FN and TSP during acute FMF attacks than in attack-free periods. Therefore, the two matrix glycoproteins may play precipitating and/or regulatory roles in the inflammatory processes of these attacks.

Genetically determined recurrent fevers.

Delpech M(1), Grateau G.

Author information:

(1)Génétique et Physiopathologie des Maladies Inflammatoires, Institut National  
de la Santé et de la Recherche Médicale (INSERM) EMI 00-05, Faculté de Médecine  
Cochin Port-Royal, 24 rue du fg St Jacques, 75014, Paris, France.  
delpech@cohin.inserm.fr

The usefulness of molecular diagnosis is now well established for genetically  
determined recurrent fevers. In familial Mediterranean fever, the severity of the  
disease and the risk of renal amyloidosis are correlated with mutations in MEFV,  
and the serum amyloid-associated protein (SAA)1 alpha/alpha allele is a modifying  
factor for amyloidosis. Study of the genes in various species shows that the  
human mutations represent a reappearance of the ancestral amino acid state and  
the B30-2 domain, where most human mutations are localized, is absent in the rat

and mouse proteins. Since the discovery of the responsible gene, TNF-receptor-associated periodic syndrome seems to be more frequent than previously considered. Among the new mutations described, some are associated with an incomplete penetrance.

**BACKGROUND:** The hyper-IgD and periodic fever syndrome (HIDS) is characterized by recurrent attacks of fever, abdominal distress, and arthralgia and is caused by mevalonate kinase mutations.

**OBJECTIVE:** To ascertain the role of mevalonate kinase and the usefulness of molecular diagnosis in HIDS.

**DESIGN:** Cross-sectional study.

**SETTING:** The international Nijmegen HIDS registry.

**PATIENTS:** 54 patients from 41 families who met the clinical criteria for HIDS.

**MEASUREMENTS:** Clinical symptoms and signs, immunoglobulin concentration, leukocyte count, erythrocyte sedimentation rate, mutation analysis, and mevalonate kinase enzyme activity assay.

**RESULTS:** There were two groups of patients: 41 patients with mevalonate kinase mutations (classic-type HIDS) and 13 patients without mutations (variant-type HIDS). Patients with classic-type HIDS had a lower mevalonate kinase enzyme activity, a higher IgD level, and more additional symptoms with attacks. The IgD level did not correlate with disease severity, mevalonate kinase enzyme activity, or genotype.

**CONCLUSION:** Genetic heterogeneity exists among patients with a clinical diagnosis of HIDS.

FMF is widely distributed in populations inhabiting the Mediterranean basin. It is mainly attributed to five founder mutations (M680I, M694V, M694I, V726A, E148Q) in the MEFV gene. The frequencies and distribution of these mutations in 146 FMF patients, of Arab and Jewish descent, were compared to that observed in 1173 healthy individuals of pertinent ethnic groups. Five mutations accounted for

91% of FMF chromosomes in our patients. Mutation M694V, predominant in North African Jews, was observed in all patients other than Ashkenazi Jews; mutation V726A was prevalent among all patients other than North African Jews; mutations M694I and M680I were mainly confined to Arab patients. Overall carrier rates, for four mutations (M680I, M694V, V726A, E148Q), were extremely high in our healthy cohort composed of Ashkenazi (n=407); Moroccan (n=243); Iraqi Jews (n=205); and Muslim Arabs (n=318); calculated at 1 : 4.5; 1 : 4.7; 1 : 3.5 and 1 : 4.3 respectively. The V726A allele prevalent among Ashkenazi and Iraqi Jews and Muslim Arabs (carrier rates: 7.4, 12.8 and 7.3%, respectively) was not found among Moroccan Jews. The M694V allele detected among Moroccan and Iraqi Jews and Muslim Arabs (carrier rates 11.1, 2.9 and 0.6%, respectively) was not observed among Ashkenazim. The overall frequency of mutations V726A and E148Q in Ashkenazim, Iraqi Jews and Arabs indicates that the bulk of individuals that comply with the genetic definition of FMF remain asymptomatic.

Colchicine is often used in the treatment of diseases such as familial Mediterranean fever (FMF) and gout. We have previously reported that patients with FMF who had colchicine on a daily basis and who had a total hip arthroplasty showed no heterotopic ossification after surgery. The mechanism by which colchicine causes this clinical phenomenon has never been elucidated. We therefore evaluated the effect of various concentrations of colchicine on cell proliferation and mineralisation in tissue culture, using rat and human cells with and without osteogenic potential. Cell proliferation was assessed by direct cell counts and uptake of (3H)thymidine, and mineralisation by measuring the amount of staining by Alizarin Red. Our findings indicate that concentrations of colchicine of up to 3 ng/ml did not affect cell proliferation but inhibition was observed at 10 to 30 ng/ml. Mineralisation decreased to almost 50%, which was the maximum inhibition observed, at concentrations of colchicine of 2.5 ng/ml. These results indicate that colchicine at low concentrations, of up to 3 ng/ml, has the capacity to inhibit selectively bone-like cell mineralisation in culture, without affecting cell proliferation. Further clinical and laboratory studies are necessary to evaluate the effects of colchicine on biological processes involving the proliferation of osteoblasts and tissue mineralisation in vivo, such as the healing of fractures, the formation of heterotopic bone and neoplastic bone growth.

Many insights have been gained into cytokine-regulated control of inflammatory processes and host defence in recent years. Evidence has also gradually accumulated that cytokine cascades play a central role in events regulating cell death and differentiation. Further developments include an understanding that the biological effects of the tumor necrosis factor-alpha (TNF-alpha or TNFSF) cytokine may be regulated by soluble TNF receptor binding and that modulation of receptor levels may permit physiological inhibition of TNF action. There has been a gradual realisation of the value of TNF/TNFR ratios as predictors of disease outcome, and the discovery of functional regulatory polymorphisms of the TNF gene and mutations of TNFRSF1A (TNFR1 receptor) have led to conceptual breakthroughs in our understanding of the genetic control of inflammation. However the exact mechanisms by which TNFRSF1A mutations give rise to disease susceptibility are not yet well understood. Over the past 10 years these concepts have been used as the basis for successful anti-TNF therapy of autoimmune diseases like rheumatoid arthritis (RA) and Crohn's disease.

Interaction between pyrin and the apoptotic speck protein (ASC) modulates ASC-induced apoptosis.

Richards N(1), Schaner P, Diaz A, Stuckey J, Shelden E, Wadhwa A, Gumucio DL.

Author information:

(1)Department of Cell and Developmental Biology, The University of Michigan Medical School, Ann Arbor, Michigan, 48109-0616, USA.

Patients with familial Mediterranean fever suffer sporadic inflammatory attacks characterized by fever and intense pain (in joints, abdomen, or chest). Pyrin, the product of the MEFV locus, is a cytosolic protein whose function is unknown. Using pyrin as a "bait" to probe a yeast two-hybrid library made from neutrophil cDNA, we isolated apoptotic speck protein containing a caspase recruitment domain (CARD) (ASC), a proapoptotic protein that induces the formation of large cytosolic "specks" in transfected cells. We found that when HeLa cells are transfected with ASC, specks are formed. After co-transfection of cells with ASC plus wild type pyrin, an increase in speck-positive cells is found, and speck-positive cells show increased survival. Immunofluorescence studies show that pyrin co-localizes with ASC in specks. Speck localization requires exon 1 of pyrin, but exon 1 alone of pyrin does not result in an increase in the number of specks. Exon 1 of pyrin and exon 1 of ASC show 42% sequence similarity and resemble death domain-related structures in modeling studies. These findings link pyrin to apoptosis pathways and suggest that the modulation of cell survival may be a component of the pathophysiology of familial Mediterranean fever.

Familial Mediterranean fever (FMF) is an autosomal recessive disease, characterized by recurrent attacks of fever and inflammation of serosal membranes and gradual development of nephropathic amyloidosis. The recent cloning of the FMF gene (MEFV) and identification of disease-associated mutations in most patients made the direct determination of FMF carrier frequency feasible. The aim of the present study was to investigate the carrier rate of the most common MEFV mutations among different Jewish ethnic groups in Israel. Further, an attempt was made to elucidate the possible biological advantage that the heterozygote state may confer. Three hundred Ashkenazi, 101 Iraqi, and 120 Moroccan Jews were screened for the E148Q, V726A, and M694V mutations (at least two most common mutations per group), with a resulting overall carrier frequency in the respective ethnic group of 14%, 29%, and 21%. No difference in morbidity between Ashkenazi carriers and non-carriers of MEFV mutations was discerned, although an excess of febrile episodes in carriers of the V726A and in carriers of either V726A or E148Q was evident ( $P < 0.02$  and  $P < 0.05$ , respectively). The frequency of subjects with two MEFV mutations but not expressing FMF (phenotype III) was 1:300 in Ashkenazi Jews and 1:25 in Iraqi Jews, exceeding the reported rate of overt FMF in these ethnic groups by 40-240 fold. These results affirm the high carrier rate among the studied Jewish ethnic groups in Israel and suggest that most subjects with FMF mutations are unaffected.

Familial Mediterranean fever is a rare disease characterized by cyclic attacks of fever, serositis and strong family background. Here we report a 22-year-old man who suffered from recurrent fever accompanied by chest and abdominal pain for more than 10 years. The attack frequency was about once per 2-3 weeks. Although he consulted many clinics and even received appendectomy at the age of 15, no definite diagnosis was given. During the admission, many laboratory examinations failed to show any abnormality except mild leukocytosis and elevated C-reaction protein. Image studies including chest X ray and abdominal CT scan showed negative result but, interestingly, Gallium-67 scan showed a hot spot in right lower chest and right lower abdomen. After prophylaxis with colchicine 1.0 mg per day, he has enjoyed more than 2 years without the above symptoms.

Author information:

(1)Heller Institute of Medical Research and Department of Orthopedics, Sheba Medical Center, Tel Hashomer, Israel.

Amyloidogenesis consists of two stages. In the first, amyloid enhancing factor

(AEF) is generated, and in the second, deposition of amyloid fibrils occurs. Colchicine is a known inhibitor of amyloidosis of familial Mediterranean fever (FMF) and of mouse experimental amyloidosis, but the timing and mechanism of its effect are still unclear. The aim of this study is to determine whether colchicine inhibits the second phase of amyloidogenesis and to study the time correlate of such an effect. To that end, amyloid was induced in Swiss male mice with AEF and AgNO(3) (an inflammatory stimulus), a method that skips the first phase of amyloidogenesis. Two amyloid induction protocols were used: a standard protocol, in which AEF and AgNO(3) were administered concurrently, and a prolonged protocol, in which the administration of AgNO(3) was delayed by 24 hours or 7 days. To study the inhibitory effect of colchicine on the second phase of amyloidogenesis, a single dose of colchicine (30 microg) was injected intravenously before, during, or after administration of AgNO(3) in both the standard and prolonged amyloid induction protocols. The amount of amyloid deposition in the spleens was determined with the crush-and-smear technique and a 5-grade scale. Colchicine was found to inhibit the second phase of amyloidogenesis. Its best effect was achieved when administered 48 hours after initiation of AgNO(3) injections. The pattern of colchicine-inhibition-in-time in the standard and the prolonged amyloid induction protocols was similar, indicating that colchicine exerts inhibition through its effect on the inflammatory stimulus (AgNO(3)). These findings suggest that (1) colchicine suppresses amyloidogenesis in the late (second) stage and that (2) this suppression is possibly related to the anti-inflammatory effect of colchicine.

Familial Mediterranean fever (FMF) is an autosomal recessive disorder caused by mutations in the Mediterranean fever gene (MEFV). We describe two novel missense mutations in MEFV, R653H and E230K. Both were found in compound heterozygosity with the mutation M694V in single Turkish patients with clinical syndromes characteristic for FMF. DNA sequencing and PCR-RFLP typing of the families confirmed the mutations and verified recessive modes of inheritance.

Familial Mediterranean fever (FMF) is a recessive disorder characterized by episodes of fever and intense inflammation. FMF attacks are unique in their sensitivity to the microtubule inhibitor colchicine, contrasted with their refractoriness to the anti-inflammatory effects of glucocorticoids. The FMF gene, MEFV, was recently identified by positional cloning; it is expressed at high levels in granulocytes and monocytes. The present study investigated the subcellular localization of the normal gene product, pyrin. These experiments did not support previously proposed nuclear or Golgi localizations. Instead fluorescence microscopy demonstrated colocalization of full-length GFP- and epitope-tagged pyrin with microtubules; this was markedly accentuated in paclitaxel-treated cells. Moreover, immunoblot analysis of precipitates of stabilized microtubules with recombinant pyrin demonstrated a direct interaction in vitro. Pyrin expression did not affect the stability of microtubules. Deletion constructs showed that the unique N-terminal domain of pyrin is necessary and sufficient for colocalization, whereas disease-associated mutations in the C-terminal B30.2 (rfp) domain did not disrupt this interaction. By phalloidin staining, a colocalization of pyrin with actin was also observed in perinuclear filaments and in peripheral lamellar ruffles. The proposal is made that pyrin regulates inflammatory responses at the level of leukocyte cytoskeletal organization and that the unique therapeutic effect of colchicine in FMF may be dependent on this interaction. j.frenkel@wkz.azu.nl

**BACKGROUND:** The hyperimmunoglobulinaemia D and periodic fever syndrome is a hereditary periodic fever, caused by deficiency of the enzyme mevalonate kinase. It is unclear how this defect leads to recurrent fever episodes.

**AIM:** To assess the involvement of cysteinyl leukotrienes in the pathogenesis of fever attacks as reflected by urinary leukotriene E(4) (LTE(4)) excretion.

**METHODS:** Urinary LTE(4) was measured in seven patients while febrile and afebrile.

**RESULTS:** LTE(4) was raised during fever in all subjects (46-199 nmol/mol creatinine, mean 92; normal <40). Urinary LTE(4) was normal between attacks, as well as in normal children with fever as a result of miscellaneous causes.

**CONCLUSION:** Our results suggest that cysteinyl leukotrienes play a role in the pathophysiology of this disorder. As no effective treatment is yet available, leukotriene receptor antagonists might offer a new therapeutic approach for patients with the hyperimmunoglobulinaemia D and periodic fever syndrome.

Familial Mediterranean Fever (FMF) is a recessive disorder characterised by episodes of fever and neutrophil-mediated serosal inflammation. The FMF gene (MEFV) was recently identified and four common mutations characterised. The aim of this study was to determine the carrier rate in the Turkish population and the mutation frequency in the clinically diagnosed FMF patients. We found a high frequency of carriers in the healthy Turkish population (20%). The distribution of the five most common MEFV mutations among healthy individuals (M694V 3%, M680I

5%, V726A 2%, M694I 0% and E148Q 12%) was significantly different ( $P<0.005$ ) from that found in patients (M694V 51.55%, M680I 9.22%, V726A 2.88%, M694I 0.44% and E148Q 3.55%).

The spectrum of Familial Mediterranean Fever (FMF) mutations.

Touitou I(1).

Author information:

(1)Hopital A de Villeneuve, Montpellier, France. isabelle.touitou@igh.cnrs.fr

Familial Mediterranean Fever (FMF) is the prototype of a group of inherited inflammatory disorders. The gene (MEFV) responsible for this disease, comprises 10 exons and 781 codons. Twenty-nine mutations, most located in the last exon, have been identified so far. It is unclear whether all are true disease-causing mutations. Five founder mutations, V726A, M694V, M694I, M680I and E148Q account for 74% of FMF chromosomes from typical cases (Armenians, Arabs, Jews, and Turks). Rare mutations are preferentially found in populations not usually affected by FMF (eg Europeans not from the above ancestries). The various combinations of MEFV mutations define severe to mild genotypes. The trend is that genotypes including two mutations located within mutational 'hot-spots' (codons 680 or 694) of the gene are associated with severe phenotypes, whereas mild phenotypes are associated with some other mutations, E148Q being the mildest and least penetrant. Understanding the correlation between the FMF phenotype and genotype is further obscured by the existence of complex alleles, modifier loci, genetic heterogeneity and possible epigenetic factors. Additionally, mutations in the MEFV gene are thought to be involved in non FMF disorders. Carrier rates for FMF mutations may be as high as 1:3 in some populations, suggesting that the disease is underdiagnosed. This review update emphasises that both clinical and genetic features are to be taken into account for patient diagnosis, colchicine treatment and prognosis.

Author information:

(1)Department of Medical Chemistry, Institute for Inflammation and Inflammatory Diseases, Faculty of Medicine, Vrije Universiteit, Amsterdam, The Netherlands.

**BACKGROUND:** Familial Mediterranean fever (FMF) is a periodic febrile disorder, characterised by fever and serositis. The acute phase response during attacks of FMF results from the release of cytokines, which in turn induce increased expression and changed glycosylation of acute phase proteins. A recent study indicated that attacks in FMF are accompanied by a rise of plasma concentrations of serum amyloid A (SAA) and C reactive protein (CRP), which remain significantly raised during remission relative to healthy controls. Another study suggested that obligatory heterozygotes also display an inflammatory acute phase response.

**OBJECTIVE:** To determine the state of inflammation in homozygotic and heterozygotic MEFV genotypes.

**METHODS:** CRP and SAA were studied by enzyme linked immunosorbent assay (ELISA). The glycosylation of the acute phase protein, alpha(1)-acid glycoprotein (AGP), was visualised with crossed affinoimmuno-electrophoresis with concanavalin A as diantennary glycan-specific component and Aleuria aurantia lectin as fucose-specific affinity component.

**RESULTS:** FMF attacks were associated with an increase ( $p<0.05$ ) in the serum inflammation parameters CRP, SAA, and AGP. The glycosylation of AGP showed an increase ( $p<0.05$ ) in fucosylated AGP glycoforms, whereas the branching of the glycans remained unaffected. The glycosylation of AGP in the MEFV carrier group, compared with that in a healthy control group, was characterised by a significant increase ( $p<0.05$ ) in branching of the glycans, whereas the fucosylation remained unaffected.

**CONCLUSION:** The findings suggest an FMF-specific release of cytokines, resulting in a different glycosylation of AGP between a homozygotic and heterozygotic MEFV genotype.

Erratum in

Am J Hum Genet 2001 Nov;69(5):1160.

Mutations in the extracellular domain of the 55-kD tumor-necrosis factor (TNF) receptor (TNFRSF1A), a key regulator of inflammation, define a periodic-fever syndrome, TRAPS (TNF receptor-associated periodic syndrome [MIM 142680]), which is characterized by attacks of fever, sterile peritonitis, arthralgia, myalgia, skin rash, and/or conjunctivitis; some patients also develop systemic amyloidosis. Elsewhere we have described six disease-associated TNFRSF1A mutations, five of which disrupt extracellular cysteines involved in disulfide bonds; four other mutations have subsequently been reported. Among 150 additional patients with unexplained periodic fevers, we have identified four novel TNFRSF1A mutations (H22Y, C33G, S86P, and c.193-14 G-->A), one mutation (C30S) described by another group, and two substitutions (P46L and R92Q) present in approximately 1% of control chromosomes. The increased frequency of P46L and R92Q among patients with periodic fever, as well as functional studies of TNFRSF1A, argue that these are low-penetrance mutations rather than benign polymorphisms. The c.193-14 G-->A mutation creates a splice-acceptor site upstream of exon 3, resulting in a transcript encoding four additional extracellular amino acids. T50M and c.193-14 G-->A occur at CpG hotspots, and haplotype analysis is consistent with recurrent mutations at these sites. In contrast, although R92Q also arises at a CpG motif, we identified a common founder chromosome in unrelated individuals with this substitution. Genotype-phenotype studies identified, as carriers of cysteine mutations, 13 of 14 patients with TRAPS and amyloidosis and indicated a lower penetrance of TRAPS symptoms in individuals with noncysteine mutations. In two families with dominantly inherited disease and in 90 sporadic cases that presented with a compatible clinical history, we have not identified any TNFRSF1A mutation, despite comprehensive genomic sequencing of all of the exons, therefore suggesting further genetic heterogeneity of the periodic-fever syndromes.

The B-box gene family represents a large number of genes involved in functions such as axial patterning, growth control, differentiation, and transcriptional regulation. These genes possess several conserved motifs that always include a B-box zinc binding motif associated with various other motifs such as the RING zinc finger, an alpha-helical coiled-coil, the rfp or B30.2 motif, propeller domain, and the NHL motif in various combinations. Mutations or rearrangements in several B-box family members are associated with human diseases and cancers such as familial Mediterranean fever (FMF), Optiz/BBB syndrome, acute promyelocytic

leukemia, mulibrey nanism, and thyroid carcinomas. This suggests that members of this gene family play important roles in fundamental biological processes. Here we discuss the known members of this rapidly expanding protein family.

Arthritis in familial Mediterranean fever.

Uthman I(1), Hajj-Ali RA, Arayssi T, Masri AF, Nasr F.

Author information:

(1)American University of Beirut, Medical Center, Lebanon. iuthman@aub.edu.lb

We studied the rheumatic and various clinical manifestations of familial Mediterranean fever (FMF) in Lebanon. A retrospective review was performed of the medical records of 74 FMF patients seen at the American University of Beirut Medical Centre (AUB-MC) from 1979 to 1996. We also reviewed the medical literature from 1968 to 2000 using MEDLINE and the key words "familial Mediterranean fever" and "arthritis". Arthritis was the presenting symptom in 12 cases (16.2%). Twenty-three patients (31%) had definite arthritis during the course of the disease that was monoarticular in 16 (70%), oligoarticular in six (26%), and polyarticular (rheumatoid-like) in one (4%). Arthritis of the large joints of the knees and ankles was the most frequent articular involvement. The arthritis was transient, monoarticular, nonerosive, and nondeforming in the majority of cases. Four patients (5.4%) had chronic arthritis, with one requiring total hip replacement. As in previous reports on arthritis of FMF, the majority of FMF patients studied in Lebanon had a transient monoarticular nonerosive and nondeforming type of arthritis affecting predominantly the large joints of the lower extremities.

Cardiac and intestinal amyloidosis in a renal transplant recipient with familial Mediterranean fever.

Yildiz A(1), Akkaya V, Kiliçaslan I, Türkmen A, Görçin B, Atilgan D, Sever MS.

Author information:

(1)Department of Internal Medicine and Division of Nephrology, University of Istanbul, Istanbul Faculty of Medicine, Istanbul, Turkey. alaattiny@hotmail.com

In Turkey, familial Mediterranean fever (FMF) is an important cause of nephrotic syndrome and endstage renal disease due to renal deposition of AA type amyloid. We report a case of living-related donor renal transplant recipient with FMF and renal AA type amyloidosis, who died of progressive heart failure due to cardiac involvement. The patient also had intractable diarrhea caused by biopsy-proven intestinal amyloidosis. The patient was on 1 mg/day colchicine. Although he was attack-free throughout the post-transplant period, intestinal and clinically

significant cardiac amyloidosis, which implied the presence of sustained inflammation and continuing amyloid deposition, appeared three years after renal transplantation. Cardiac deposition of AA amyloid may cause clinically significant heart disease, leading to cardiovascular mortality after renal transplantation for end-stage renal disease in FMF patients.

The musculoskeletal manifestations of familial Mediterranean fever in children genetically diagnosed with the disease.

Brik R(1), Shinawi M, Kasinetz L, Gershoni-Baruch R.

Author information:

(1)Rambam Medical Center and Technion-Israel Institute of Technology Faculty of Medicine, Haifa.

**OBJECTIVE:** Familial Mediterranean fever (FMF) is characterized by recurrent episodes of peritonitis, pleuritis, and synovitis. Its most common musculoskeletal manifestation is acute recurrent monarthritis, but other manifestations have also been described. We describe the articular and musculoskeletal manifestations in a group of patients who were found by genetic screening to be homozygous for the FMF gene.

**METHODS:** We surveyed 136 pediatric patients of Mediterranean extraction who were evaluated for a variety of musculoskeletal symptoms, and in whom genetic studies confirmed a diagnosis of FMF. Two groups of patients emerged: group 1 contained 107 patients who displayed a classic picture of FMF, and group 2 comprised 29 patients whose symptoms did not fulfill the criteria for a clinical diagnosis of FMF. Fifty-nine patients were Sephardic Jews and 77 were Arabs. The Jewish patients were all homozygous or compound heterozygous for the M694V mutation, while the Arab patients were homozygous or compound heterozygous for any 1 of the 5 mutations tested (M694V, V726A, M680I, M694I, and E148Q).

**RESULTS:** Acute episodes of monarthritis occurred in 42 (71%) of the Jewish children and 31 (40%) of the Arab children; 70% of these patients had the M694V mutation. Acute monarthritis occurred in 73 (68%) of the patients of group 1, but

in none of the patients from group 2. Ten (34%) of the 29 patients from group 2 exhibited diverse musculoskeletal manifestations. Thirteen patients in our series (10%) presented with a variety of musculoskeletal symptoms, including febrile myalgia syndrome in 6 patients.

CONCLUSION: Acute episodes of monoarthritis are the most common musculoskeletal manifestation of FMF in children bearing the M964V mutation, which predominates among Sephardic Jews, although children with the M694V mutation may also present with diverse nonspecific musculoskeletal manifestations. Genetic screening for FMF appears indicated in the evaluation of unexplained musculoskeletal symptoms in children of Mediterranean extraction.

Azoospermia due to testicular amyloidosis in a patient with familial Mediterranean fever.

Haimov-Kochman R(1), Prus D, Ben-Chetrit E.

Author information:

(1)Department of Obstetrics and Gynecology, Hadassah University Hospital, Mount Scopus, Israel.

We describe a patient suffering from familial Mediterranean fever (FMF) who presented to our clinic with secondary infertility of 2 years due to amyloid A amyloidosis. His spermiogram disclosed azoospermia. A testicular biopsy revealed hyalinized tubules devoid of full spermatogenesis and containing abundant amyloid, confirmed by Congo red stain. We suggest that testicular amyloidosis be taken into consideration when dealing with azoospermic FMF patients. In view of the progressive nature of amyloid accumulation in the testis we propose to follow routinely the spermiogram of FMF patients with renal amyloidosis. Furthermore, consideration of sperm cryopreservation is suggested in these cases. In FMF patients with azoospermia consideration of testicular biopsy is recommended as early as possible in order to increase the chance of sperm retrieval.

Subtalar arthritis as a presenting symptom of Familial Mediterranean fever: case report and literature review.

Dudkiewicz I(1), Chechik A, Blankstein A, Salai M.

Author information:

(1)Department of Orthopedic Surgery, Chaim Sheba Medical Center, Tel Hashomer, Israel.

Familial Mediterranean fever (FMF) is an autosomal, recessive disease affecting mainly people of Mediterranean origin. The primary pattern of FMF is acute, self-resolving periodic attacks of high-grade fever, accompanied by either peritonitis, pleuritis, or arthritis and sometimes typical ankle rash that simulates erysipelas. Rare manifestations, such as pericarditis or massive knee effusion, have been reported in the literature as a presenting symptom of FMF. The final diagnosis has recently become more accurate by identification of the gene for FMF. We describe a unique presenting symptom of subtalar arthritis with no former personal or family history of FMF. A genetic evaluation revealed a 694/726 genetic variant that confirmed the diagnosis of FMF. Treatment with daily colchicine, 1 mg/day, resulted in complete resolution of all complaints.

Clinical and molecular variability in childhood periodic fever with hyperimmunoglobulinaemia D.

Frenkel J(1), Houten SM, Waterham HR, Wanders RJ, Rijkers GT, Duran M, Kuijpers TW, van Luijk W, Poll-The BT, Kuis W.

Author information:

(1)Departments of General Paediatrics, Wilhelmina Children's Hospital, University Medical Centre Utrecht, P.O. Box 85090, 3508AB Utrecht, The Netherlands.

**OBJECTIVES:** The hyperimmunoglobulinaemia D and periodic fever syndrome (HIDS) was found recently to be caused by a deficiency of mevalonate kinase (MK). The aim of this study was to examine whether a relationship exists between the clinical expression of HIDS and the extent of MK deficiency.

**METHODS:** The medical records of children diagnosed with HIDS were reviewed for clinical features and serum immunoglobulin values. The mevalonic acid excretion in urine and MK enzyme activity in patients' cells were measured and the cDNA of the MVK gene was sequenced.

**RESULTS:** Fifteen patients with recurrent fever and raised serum immunoglobulin (Ig) D were included. Their clinical features varied. Eleven patients had a deficiency of MK, caused by mutations in the MVK gene. One mutation (V377I) was common to all 11 patients. Nine patients were compound heterozygotes for V377I and various other MVK mutations. There was no apparent relationship between the observed mutations and the clinical features. Surprisingly, four boys had normal MK activity and no MVK mutations.

**CONCLUSIONS:** Most HIDS patients have mutations in the MVK gene. The clinical variability observed cannot be explained by genotypic differences. Periodic fever and elevated IgD can result from other, still unknown, causes. Hence, testing for MK deficiency is necessary in patients with unexplained periodic fever.

Amyloid goiter as the initial manifestation of systemic amyloidosis due to familial mediterranean fever with homozygous MEFV mutation.

Sbai A(1), Wechsler B, Leenhardt L, Beaufils H, Hoang C, Ménégaux F, Piette JC.

Author information:

(1)Department of Internal Medicine, University Hospital Pitié-Salpêtrière, Paris, France.

We describe a case of amyloid goiter revealing a systemic amyloidosis secondary to familial Mediterranean fever (FMF) with homozygous MEFV mutation, and we review the literature. A 45-year-old euthyroid Sephardic man, known to suffer from FMF, developed a goiter with cold nodule, after which a subtotal thyroidectomy was performed. Histologic evaluation revealed diffuse AA amyloid deposition without any associated thyroid neoplasia. At that time, no other organ was found to be affected by amyloidosis. Colchicine and levothyroxine were prescribed. Eight years later, the patient presented with a rapidly growing neck enlargement. He reported that he had discontinued colchicine therapy 2 years earlier. The serum thyrotropin (TSH) and calcitonin levels were normal. Renal, digestive, and salivary gland biopsies confirmed the presence of systemic AA amyloidosis. Despite the reintroduction of colchicine, the onset of compressive symptoms led to the completion of the total thyroidectomy. The histopathology again demonstrated amyloid deposition, and excluded a malignant neoplasm. Nine cases of amyloid goiter associated with FMF have been reported in the literature; none of them had an amyloid goiter as the first manifestation of systemic amyloidosis. To our knowledge, this is the first case of FMF in which an amyloid goiter preceded the development of secondary systemic amyloidosis. The cessation of colchicine therapy may have played a role in local relapse and the secondary spread of amyloid deposits.

Prevalence of ischemic heart disease in patients with familial Mediterranean fever.

Langevitz P(1), Livneh A, Neumann L, Buskila D, Shemer J, Amolsky D, Pras M.

Author information:

(1)Heller Institute of Medical Research, Sheba Medical Center, Tel-Hashomer, Israel.

**BACKGROUND:** Familial Mediterranean fever is a genetic disorder manifested by recurrent attacks of peritonitis, pleuritis and arthritis, and characterized by clinical, histological and laboratory evidence for localized and systemic inflammation. Colchicine treatment usually prevents the attacks and the associated inflammation. Inflammation may play an important role in the initiation and progression of atherosclerosis and ischemic heart disease.

**OBJECTIVE:** To study the effect of inflammation and its prevention on the occurrence of IHD, using FMF as a model.

**METHODS AND PATIENTS:** We studied the presence of IHD and its risk factors in 290 FMF patients aged 40 years or more, and in two control groups--233 spouses of the FMF patients, and 126 patients with inflammatory diseases obtained from other outpatient clinics, FMF patients were also compared with age and gender-matched individuals from the population reference data of the Israel Ministry of Health.

**RESULTS:** The prevalence of IHD in FMF patients was significantly lower than in the group of controls from other outpatient clinics (15.5% vs. 30.2%,  $P < 0.05$ ) and comparable with their spouses (11.2%) and with the matched general population in Israel (16%).

**CONCLUSIONS:** These findings suggest that despite the evidence of recurrent inflammation, colchicine-treated FMF patients are not more predisposed to IHD than the normal population.

Study of the mutation M694V of familial Mediterranean fever in Jews.

Lucotte G(1).

Author information:

(1)LCL Laboratory, Irvy-sur-Seine, France.

Familial Mediterranean fever (FMF) is a recessively inherited disorder characterized by episodes of fever with abdominal pain, pleurisy, or arthritis. The familial Mediterranean fever gene, designated MEFV, was recently cloned, and the missense mutation M694V accounting for most of the patients with this disease was identified. The objective of the present study was to establish frequencies of the M694V mutation in three groups of Jews. The subjects studied were 381 Sephardi, 256 Ashkenazi, and 65 Oriental Jews, all male subjects, previously

collected for an anthropological study, independent of their FMF status. The M694V mutation in the 702 samples was assessed by amplifying genomic DNA with the use of primers that selectively amplify the normal or altered DNA sequence of the M694V mutation, by the amplification refractory mutation system (ARMS). In our sample of Sephardi Jews, the frequency of the M694V mutation is elevated (10.9%), and this is also the case for Oriental Jews (9.2%). In our sample of Ashkenazis, the M694V allele frequency is very low (0.8%).

Characterization of mevalonate kinase V377I, a mutant implicated in defective isoprenoid biosynthesis and HIDS/periodic fever syndrome.

Ríos SE(1), Cho YK, Miziorko HM.

Author information:

(1)Biochemistry Department, Medical College of Wisconsin, Milwaukee, WI 53226, USA.

The list of diseases linked to defects in lipid metabolism has recently been augmented by the addition of hyperimmunoglobulinemia D and periodic fever syndrome (HIDS: MIM 260920), which are correlated with depressed levels of mevalonate kinase activity [1,2] and protein [1]. More specifically, a V377I substitution has been proposed to account for this disease. We observed that V377

appears to be far from invariant in eukaryotic mevalonate kinases. Prokaryotic mevalonate kinases are lower in molecular weight and several terminate prior to residue 377 of the eukaryotic proteins. These observations prompted our direct test of the impact of V377 on activity and protein stability by engineering a V377I mutation in a recombinant human mevalonate kinase. The mutant protein has been isolated and kinetically characterized. In comparison with wild-type enzyme, V377I exhibits only modest differences (notably  $\geq$  6-fold inflation of  $K(m(MVA))$ ) that do not account for the diminished mevalonate kinase activity assayed in HIDS cell extracts. Moreover, thermal inactivation (50 degrees C) of isolated wild-type and V377I enzymes demonstrates little difference in stability between these proteins. We conclude that a single V377I substitution is unlikely to explain the observation of depressed mevalonate kinase stability and catalytic activity in HIDS.

[Diagnostic criteria for erysipelas].

[Article in French]

Vaillant L(1).

Author information:

(1)Service de Dermatologie, Université François-Rabelais et CHU, Tours, France.

Diagnosis of erysipelas is based upon the association of an acute inflammatory plaque with fever, lymphagitis, adenopathy and hyperleukocytosis. These associated symptoms are variable (20-70 p. 100 of cases). Bacteriology is not helpful for the diagnosis of erysipelas because of a low sensitivity (hemoculture 5 p. 100, standard examinations 5-41 p. 100), or delayed positivity (serology). Moreover cutaneous bacteriology is difficult to assess when other bacteria than streptococci are isolated. Erysipelas have to be distinguished from non-necrotizing cellulitis by peculiar clinical features (such as erysipeloid, facial staphylococcal infection, Pasteurella, Haemophilus influenzae) and from necrotizing fasciitis. Some non-infectious diseases may mimic erysipelas such as

venous thrombosis, familial Mediterranean fever, prosthesis intolerance, and compartment syndrome. Because the diagnostic value of clinical symptoms is not known and no diagnostic gold standard has been established, it is impossible to be sure that non-streptococcal erysipelas (especially staphylococcal) really exists. Thus, the first line treatment for all erysipelas must be an antistreptococcal antibiotic. Before prescribing a treatment, hemoculture and blood cell count could be useful. If antistreptococcal antibiotherapy is inefficient, all the differential diagnoses must be reviewed.

Autosomal-dominant periodic fever with AA amyloidosis: Novel mutation in tumor necrosis factor receptor 1 gene Rapid Communication.

Jadoul M(1), Dodé C, Cosyns JP, Abramowicz D, Georges B, Delpech M, Pirson Y.

Author information:

(1)Department of Nephrology, Cliniques Universitaires St. Luc, Université Catholique de Louvain, Brussels, Belgium. jadoul2nefr.ucl.ac.be

**BACKGROUND:** The recent identification of genes responsible for syndromes of periodic fever with amyloidosis has opened the way to a molecular diagnosis of hereditary AA amyloidosis.

**METHODS:** A Belgian woman presented for genetic counseling. Three first-degree relatives had a diagnosis of renal amyloidosis with a history of recurrent fever and inflammatory episodes. Medical records and pathological specimens were obtained from all physicians who had been in charge of her three relatives. Immunohistochemical staining was performed on paraffin-embedded material. A mutation search was performed in the MEFV (Mediterranean fever) and tumor necrosis factor receptor 1 (TNFR1 or TNFRSF1A) genes causing familial Mediterranean fever (FMF) and tumor necrosis factor receptor-associated periodic syndrome (TRAPS), respectively.

**RESULTS:** The family history was consistent with autosomal-dominant transmission of periodic fever with arthralgias, abdominal pain, and eventual AA amyloidosis involving the kidneys, digestive tract, and thyroid. Recurrent amyloidosis in

kidney graft was demonstrated in one patient and was suspected in the other. A novel heterozygous mutation (C55S) in TNFRSF1A was identified in the affected patient available for genetic testing but not in the asymptomatic woman requiring counseling. No mutation was detected in MEFV.

CONCLUSIONS: We report a novel mutation (C55S) in TNFRSF1A, resulting in autosomal-dominant periodic fever and AA amyloidosis. This condition, known as TRAPS, should be added to the differential diagnosis of hereditary renal amyloidosis, with obvious implications for management and genetic counseling.

Hyperimmunoglobulinaemia D and periodic fever syndrome (HIDS) is an autosomal recessive inflammatory disorder characterised by recurrent episode of fever associated with lymphadenopathy, abdominal distress, joint involvement and skin lesions. We recently demonstrated that mutations in the mevalonate kinase gene (MVK) are associated with HIDS. Direct DNA sequencing was done to screen the entire coding region of MVK in 25 unrelated patients with HIDS. Mutations were detected in the coding region of the gene including 11 missense mutations, one deletion, the absence of expression of one allele, as well as three novel polymorphisms. Seven of these mutations are novel. The large majority of the patients were compound heterozygotes for two mutations. Of these, V377I (G-->A) is the most common mutation occurring in 20 unrelated patients and was found to be associated with I268T in six patients. Mutations were associated with a decrease of mevalonate kinase (MK) (ATP:mevalonate 5-phosphotransferase, EC 2.7.1.36) enzymatic activity but not as profound as in mevalonic aciduria, a syndrome also caused by a deficient activity of MK. In HIDS the mutations are located all along the protein which is different from mevalonic aciduria where MK mutations are mainly clustered to a same region of the protein. On the basis of this study, we propose that the diagnostic screen of MVK in HIDS should be first directed on V377I and I268T mutations. Three patients are also described to illustrate the genotypic and phenotypic overlap with mevalonic aciduria.

Erratum in

Eur J Hum Genet 2001 Aug;9(8):651.

Mevalonic aciduria (MA) and hyperimmunoglobulinaemia D and periodic fever syndrome (HIDS) are two autosomal recessive inherited disorders both caused by a deficient activity of the enzyme mevalonate kinase (MK) resulting from mutations in the encoding MVK gene. Thus far, disease-causing mutations only could be detected by analysis of MVK cDNA. We now describe the genomic organization of the human MVK gene. It is 22 kb long and contains 11 exons of 46 to 837 bp and 10 introns of 379 bp to 4.2 kb. Three intron-exon boundaries were confirmed from natural splice variants, indicating the occurrence of exon skipping. Sequence analysis of 27 HIDS and MA patients confirmed all previously reported genotypes based on cDNA analysis and identified six novel nucleotide substitutions resulting in missense or nonsense mutations, providing new insights in the genotype/phenotype relation between HIDS and MA.

Although familial Mediterranean fever (FMF) is an autosomal recessive disorder, preliminary partial mutation analysis suggested that about 60% of FMF patients, who also suffer from Behçet's disease (FMF-BD), have only a single mutated FMF gene (MEFV). In this study, the possibility that patients with FMF-BD may indeed be carriers of a single mutated MEFV is further analysed. The presence of mutations in the coding region of MEFV of eight patients with FMF-BD, representing six families with 47 members, was determined by sequencing. A

possible role for the non-carrier chromosome and for BD in the expression of FMF in patients with a single mutated MEFV allele was determined by analysing the association between these variables and the presence of FMF in heterozygous kin. Sequence analysis revealed that all eight patients had indeed only one mutation in the coding region of MEFV. The patients' non-carrier chromosomes converged into three different MEFV haplotypes and were shared by heterozygous unaffected kin in five of six families. BD was found in 10 of 11 carriers with FMF vs one of 16 carriers without FMF ( $P < 0.001$ ). These results suggest that FMF may be expressed in individuals harbouring only one coding mutation in MEFV. The findings argue against a role for the non-carrier chromosome in the induction of FMF, and suggest that the FMF phenotype in this cohort was associated with the simultaneous presence of BD. These findings may mirror a more generalised rule, that FMF may be precipitated in carriers of a single mutated FMF gene by factors unrelated to the other MEFV allele.

Current aspects of colchicine therapy -- classical indications and new therapeutic uses.

Lange U(1), Schumann C, Schmidt KL.

Author information:

(1)Kerckhoff Clinic and Foundation, Department of Rheumatology, University Giessen, Ludwig Str. 37-39, D-61231 Bad Nauheim, Germany.

Uwe.Lange@Kerckhoff.med.uni-giessen.de

Colchicine has been traditionally used for the treatment of gout. At present there is no generally accepted alternative to colchicine for the treatment of acute attacks or for the prevention of further attacks. The complex actions of this substance, which are mainly attributable to its stabilising action on the cytoskeleton and cell membranes, and its special pattern of distribution form the basis for the results presented here regarding the prophylactic or therapeutic actions of colchicine in a whole range of other diseases. This is all the more significant in that in several instances it concerns diseases that have so far been unsatisfactorily controlled by other treatments. Because of its astonishing absence of side effects, some authors consider that low dose colchicine may be considered as an alternative to previous therapies or even a means of first choice. It is therefore incorrect to think that medical research has shown little interest in this long-known potential and has not sought to confirm promising options by means of controlled studies. Fibrotic and inflammatory systemic diseases and those in which leucocytic chemotaxis play a role seem to be particularly predestined for this.

The recent discovery of the mutated gene responsible for Familial Mediterranean Fever (FMF) is supposed to facilitate its diagnosis which up till now is a

clinical one because there are no specific laboratory tests. The sensitivity of genetic testing is limited because these tests search only for known mutations. In this case report we describe a patient with periodic abdominal pain in whom the diagnosis of FMF was wrongly discarded because of lack of a durable effect of colchicine and negative genetic testing. Diffuse peritoneal inflammation was nicely demonstrated by a FDG-PET (fluoro-deoxy-glucose positron-emission tomography) performed during a typical crisis. We discuss the possible diagnostic pitfalls and conclude that a crisis-PET might upgrade the level of diagnostic certainty in equivocal cases.

Familial Mediterranean fever and menstruation.

Ben-Chetrit E(1), Ben-Chetrit A.

Author information:

(1)Department of Medicine, Hadassah Hebrew University Hospital, Jerusalem, Israel.

**OBJECTIVE:** To study the prevalence, the nature and the genotype correlation of menstruation associated familial Mediterranean fever attacks.

**METHODS:** One hundred and forty-one female patients with familial Mediterranean fever were studied. A questionnaire regarding the presence and nature of menstruation associated with familial Mediterranean fever was designed and filled in by the authors during the patients' visits to the familial Mediterranean fever clinic. The patients who had a positive history for this manifestation were analysed for their familial Mediterranean fever mutations.

**RESULTS:** Ten out of 141 familial Mediterranean fever female patients (7%) had menstruation-associated familial Mediterranean fever attacks. These patients varied in their disease age of onset and disease duration. Increase of colchicine dose, daily or during the perimenstrual period or oral contraceptives were beneficial in preventing these familial Mediterranean fever attacks. No correlation was found with specific mutations causing familial Mediterranean fever.

CONCLUSIONS: Menstruation-associated familial Mediterranean fever attacks are relatively uncommon. They are not related to the age of the women, the chronicity of their disease or to the mutations they bear. Various therapeutic approaches have to be tried in order to abolish these attacks. A decrease in oestrogen level during menstruation may have a role in this unique manifestation of familial Mediterranean fever.

BACKGROUND: Familial Mediterranean fever (FMF) is characterized by febrile attacks, acute abdominal pain, pleuritis or arthritis and predominantly observed in ethnic groups of the Mediterranean area (Sephardic Jews, Turks, Armenians).

Its most ominous manifestation is amyloidosis potentially leading to chronic renal failure. FMF is an inherited disorder caused by mutations of the FMF-gene, which first was described in 1997.

CASE REPORT: We report a 10-year old turkish boy and his family presenting with an increased blood sedimentation rate (WBC) and recurrent attacks of acute abdominal pain. A molecular analysis was carried out, confirming a typical mutation of the FMF-gene. The patient remained free of symptoms after starting therapy with colchicine.

CONCLUSION: Investigation of the FMF gene enables an early diagnosis in case of clinical suspect findings, subsequent colchicine administration may prevent amyloidosis.

Familial Mediterranean Fever is a genetic disorder frequently diagnosed among the Arabs. It is also prevalent among Jews, Armenians and Turks. The clinical picture consists of febrile and painful attacks that differ in quality across patients and even within the same patient. There may be accompanying joint pain, chest pain, skin manifestations and other findings, and amyloidosis may occur in some patients as a complication. The primary treatment is Colchicine, which decreases the frequency of the attacks and prevents the occurrence of amyloidosis. The gene responsible for Familial Mediterranean Fever, MEFV, has been mapped and cloned and mutations were identified within its coding sequence. It encodes a protein that is expected to be a down regulator of inflammation. The spectrum of mutations in the Arabic population is partially studied. There are still several issues to be solved before we fully understand the disorder, and to enable us to confront it and decrease the morbidity and mortality inflicted by it.

apter@post.tau.ac.il

To evaluate the abdominal CT features of reactive amyloidosis, abdominal CT scans of 20 patients with amyloidosis of familial Mediterranean fever (FMF) were reviewed and compared with abdominal CT scans of 2 control groups: 22 patients with chronic renal failure (CRF) due to non-amyloidotic kidney diseases and 40 patients with normal kidney function. The kidney size of patients with amyloidosis of FMF were found to vary during the course of the disease from normal or slightly larger than normal at the proteinuric phase, to smaller than normal and comparable to kidney size in CRF, at the uremic stage. Compared to kidney disease of other causes, more patients with FMF-amyloidosis had dense kidneys with coarse parenchymal calcification and calcification in other abdominal organs. Patients with FMF-amyloidosis had fewer aortic calcifications than patients with non-amyloidotic kidney disease. These findings suggest that kidney disease of reactive amyloidosis may have abdominal CT findings distinguishing it from other types of kidney diseases.

The amyloidoses represent a heterogeneous group of disorders characterized by the pathologic deposition as fibrils of at least 20 different precursor molecules. To establish definitively the specific type of amyloid protein contained in fibrillar deposits, such material must be extracted, purified, and subjected to amino acid sequence analysis. Heretofore, the chemical identification of amyloid components has required gram quantities of tissue. Given the often-limited amounts of sample available, e.g., that derived from diagnostic needle biopsies, we have developed a micro-method to isolate and purify amyloid from minute tissue specimens. The procedure involves micro-extraction of the amyloid with subsequent purification by SDS-PAGE, electroblotting onto PVDF membranes, excision and elution of amyloid protein-related bands, and reversed phase HPLC. Chemical and immunologic studies of isolated amyloid components have demonstrated the purity achieved with this technique and have provided information on the molecular mass, heterogeneity, and immunoreactivity of the amyloid. Further, using this methodology, it has been possible to obtain sufficient material for amino acid sequencing and thus to establish unequivocally the chemical and molecular composition of the fibrillar deposits. Our microtechnique has clinical import and also is applicable to analyses of the amyloid found in experimental small animal models of these disorders.

Author information:

(1)Cellular and Molecular Biology Program, University of Michigan, Ann Arbor, Michigan, USA.

Familial Mediterranean fever (FMF; MIM 249100) is an autosomal recessive disease characterized by recurrent attacks of fever with synovial, pleural or peritoneal inflammation. The disease is caused by mutations in the gene encoding the pyrin protein. Human population studies have revealed extremely high allele frequencies for several different pyrin mutations, leading to the conclusion that the mutant alleles confer a selective advantage. Here we examine the ret finger protein (rfp) domain (which contains most of the disease-causing mutations) of pyrin during primate evolution. Amino acids that cause human disease are often present as wild type in other species. This is true at positions 653 (a novel mutation), 680, 681, 726, 744 and 761. For several of these human mutations, the mutant represents the reappearance of an ancestral amino acid state. Examination of lineage-specific dN/dS ratios revealed a pattern consistent with the signature of episodic positive selection. Our data, together with previous human population studies, indicate that selective pressures may have caused functional evolution of pyrin in humans and other primates.

This report describes a patient with Familial Mediterranean Fever (FMF) associated with renal amyloidosis, bilarectal surrenal haematomas and hypoaldosteronism which was clinically asymptomatic. The deposition of AA amyloide was found on the renal and bone marrow biopsies. Bilateral surrenal haematoma regressed after six month from the first events. Colchicine therapy controlled the attacks of the disease.

Familial Hibernian fever (FHF) is a rare hereditary syndrome that causes periodic attacks of fever and inflammation. It is an autosomal dominantly inherited disorder. The gene involved in FHF encodes for a receptor for tumour necrosis factor (TNFR1). These mutations are thought to result in impaired shedding of the receptor from the cell membrane, leading to deficient curtailing of the inflammatory reaction. The acronym TRAPS (TNF-receptor associated periodic syndrome) has been proposed as a more accurate name.

[Immunological indices in development of periodic disease].

[Article in Russian]

Karagezian KG, Nazaretian EE, Zavrodniaia AM, Ovnanian KO.

AIM: To specify immune changes in periodical disease (PD) in different periods of PD development as well as peculiarities of their changes in colchicin therapy.

MATERIAL AND METHODS: Clinicoimmunological investigations including blast transformation of lymphocytes with lymphocytic mitogen and renal antigen, leukocyte migration inhibition with renal antigen, spontaneous and complementary rosette formation were made in 828 PD patients and 43 donors.

RESULTS: Decreased functional activity and quantity of T-lymphocytes, their suppressory subpopulation was found in PD. The indices did not correlate with the

disease variants and gender but with age and PD complication. In amyloidosis immunological indices deteriorate with positive trend after colchicin treatment.  
CONCLUSION: PD is characterized by strain in immunological process.

Author information:

(1)Laboratory of Genetics, Arnaud de Villeneuve Hospital, Montpellier, France.

OBJECTIVE: Familial Mediterranean fever (FMF) is a genetically recessive inflammatory disease caused by mutations in the MEFV gene. Most patients of non-Ashkenazi Jewish ancestry or those who are homozygous for M694V manifest a severe disease course, but some express a mild form of the disease. We therefore

searched for other genes which could possibly be implicated in the disease phenotype. We tested MICA (major histocompatibility complex class I chain-related gene A) because it has been associated with a number of other inflammatory disorders.

**METHODS:** One hundred fifty FMF probands and their family members were evaluated. The MEFV gene was screened by a combination of denaturing gradient-gel electrophoresis, restriction fragment length polymorphism, and amplification refractory mutation system. The MICA transmembrane polymorphism in exon 5 was analyzed after biotin-labeled polymerase chain reaction products were loaded onto sequencing gels and subjected to autoradiography.

**RESULTS:** The contribution of MICA to the FMF phenotype was confirmed after adjustment for the patient's ancestry and for the MEFV genotype. MEFV was individually the most important prognostic factor for the disease. However, the impact of M694V homozygosity on the age at disease onset (OR 2.3) was aggravated if patients also inherited MICA-A9 (OR 6.3). In contrast, the frequency of attacks was found to be dramatically reduced (OR 0.16) in patients with MICA-A4.

**CONCLUSION:** We have identified the first FMF modifier locus, MICA. FMF is the first model of a Mendelian disease associated with MICA. These results clarify, at least partly, the inconsistent phenotype-MEFV correlation in FMF.

Familial Mediterranean fever is an autosomal recessive hereditary disease characterised by recurrent fever, poliserositis, chest and/or abdominal pain. Up to date diagnosis is based on clinical symptoms, familial anamnesis and response

to colchicine. It is an inflammatory reaction affecting serosal tissues but until recently different hypotheses have been suggested to explain the greatly increased chemotactic activity of the polymorfonuclear leucocytes. Identification of the function of the MEFV gene on chromosome 16 and its protein allows us to understand the pathogenesis of familial Mediterranean fever as well as provides a new diagnostic test and therapeutic measures. We describe a case of a young patient and review the literature.

Polyarteritis nodosa in patients with Familial Mediterranean Fever (FMF): a concomitant disease or a feature of FMF?

Ozen S(1), Ben-Chetrit E, Bakkaloglu A, Gur H, Tinaztepe K, Calguneri M, Turgan C, Turkmen A, Akpolat I, Danaci M, Besbas N, Akpolat T.

Author information:

(1)Department of Pediatrics, Hacettepe University, Ankara, Turkey. sozen@gen.hun.edu.tr

BACKGROUND: Familial Mediterranean Fever (FMF) is caused by mutations in the gene

encoding pyrin and is characterized by self-limited, recurrent attacks of fever and serositis. Vasculitis has been increasingly reported in FMF. A study evaluating the prognosis in FMF and polyarteritis nodosa (PAN) patients has not been reported previously.

**OBJECTIVES:** To determine the special characteristics and the prognosis of PAN in FMF patients.

**METHODS:** A questionnaire was used for the present survey. The setting was 7 referral centers from Turkey and Israel. Seventeen patients who were diagnosed with FMF and who developed PAN were included. PAN was diagnosed in those who met the Chapel Hill consensus criteria for microscopic polyarteritis or classic PAN. The clinical features of these 17 patients and the outcomes of their vasculitis were analyzed.

**RESULTS:** The age at diagnosis of PAN in these FMF patients ranged from 3.5 to 37 years. All patients had constitutional symptoms, elevated acute phase reactants, and myalgia at the time PAN was diagnosed. The diagnosis of PAN was confirmed by renal angiography in 8 patients, by renal biopsy in 6 patients, and by muscle and/or nodule biopsies in 6 patients. A number of patients had definite features of both classic PAN and microscopic polyarteritis.

**CONCLUSIONS:** When compared with other PAN patients, those with FMF tended to have a younger age at PAN onset, more frequent perirenal hematomas, and an overall better prognosis. The cases with overlapping features of microscopic and classic PAN pose a problem for the current classification of vasculitis. We suggest that the clinical representation of PAN in FMF patients has certain characteristics and may be a feature of FMF per se.

Familial Mediterranean fever in Lebanon: mutation spectrum, evidence for cases in Maronites, Greek orthodoxes, Greek catholics, Syriacs and Chiites and for an association between amyloidosis and M694V and M694I mutations.

Mansour I(1), Delague V, Cazeneuve C, Dodé C, Chouery E, Pêcheux C, Medlej-Hashim M, Salem N, El Zein L, Levan-Petit I, Lefranc G, Goossens M, Delpech M, Amselem S, Loiselet J, Grateau G, Mégarbane A, Naman R.

Author information:

(1)Unité de Génétique Médicale, Université Saint Joseph, Faculté de Médecine, Beirut, Lebanon. CTSHD@cyberia.net.lb

Seventy-nine unrelated Lebanese patients were tested for 15 mutations in the MEFV gene: A761H, A744S, V726A, K695R, M694V, M694I, M694del, M680I (G --> C), M680I (G --> A) in exon 10, F479L in exon 5, P369S in exon 3, T267I, E167D and E148Q in exon 2, using PCR digestion, ARMS, DGGE and/or sequencing. Mutations were detected in patients belonging to all communities, most interestingly the Maronite, Greek orthodox, Greek catholic, Syriac and Chiite communities. The most frequent mutations are M694V and V726A (27% and 20% of the total alleles respectively). M694I, E148Q and M680I mutations account respectively for 9%, 8% and 5%. Each of the K695R, E167D and F479L mutations was observed once and all the remaining mutations were not encountered. Of the alleles 33% do not carry any of the studied mutations. The mutation spectra, clinical features and severity of the disease differed among the Lebanese communities. The genotype-phenotype analysis showed a significant association ( $P < 0.001$ ) between amyloidosis and the presence of mutations at codon 694 in exon 10 (both M694V and M694I). None of the patients carrying other mutations developed amyloidosis.

Report on 59 patients with renal amyloidosis.

Paydas S(1).

Author information:

(1)Cukurova University Faculty of Medicine, Department of Internal Medicine, Adana, Turkey.

We studied a group of 59 patients with renal amyloidosis. Mean age (45 male, 14 female) was 33.05+/-13.04 years. All of the cases had secondary amyloidosis. The causes of secondary amyloidosis were as follows: familial Mediterranean fever (FMF) 18 (30.5%), pulmonary tuberculosis 12 (20.33%), chronic osteomyelitis 8 (13.55%), bronchiectasia 9 (15.25%), rheumatic diseases 4 (6.4%), Castleman's

disease 1 (1.6%), unknown aetiology 7 (11.86%). Hypertension was detected in 15.3% of the cases. In patients with less than 20 ml/min creatinine clearance (Ccr) hypertension was found in 20%. Hypotension was detected in 6 patients and all of these cases had severe hypoalbuminaemia (<2.1 g/dl). Nephrotic range proteinuria (>3.5 g/day) was found in 75% of cases. Daily proteinuria was correlated with serum levels of albumin, total lipid and cholesterol, haematocrit and duration of disease. The mean Ccr was 51.03+/-40.60 ml/min. Twenty-nine per cent of patients had Ccr less than 20 ml/min. Renal, subcutaneous fat and rectal biopsies demonstrated amyloid in 100%, 20% and 57.6%, respectively, of patients tested. Patients with secondary amyloidosis were treated with colchicine in addition to the therapy of primary disease (in 6 patients). Nine patients died, and end-stage renal disease developed in 12 patients during four years of follow-up. Proteinuria disappeared or decreased in patients with secondary amyloidosis except secondary to collagen tissue disease, without advanced renal failure. Colchicine did not affect amyloid deposition in 2 patients with normal renal function and negative proteinuria, who were rebiopsied. It can be questioned that "Colchicine may have effect(s) for decrement on proteinuria". At least colchicine can be of use in secondary amyloidosis.

Amyloidosis induced, end stage renal disease in patients with familial Mediterranean fever is highly associated with point mutations in the MEFV gene.

Ben-Chetrit E(1), Backenroth R.

Author information:

(1)Rheumatology Unit, Department of Medicine, Hadassah University Hospital, Jerusalem, Israel. eldad@hadassah.org.il

**BACKGROUND:** Familial Mediterranean fever (FMF) is an autosomal recessive disease characterised by recurrent attacks of fever and serositis. Amyloidosis is the most significant complication of FMF, leading to end stage renal disease (ESRD). Recently the gene (MEFV) causing this disease was cloned and more than 18 mutations have been identified. The hypothesis that the development of

amyloidosis is associated with one of these mutations was tested.

**METHODS:** 23 patients with FMF and ESRD were analysed for their MEFV mutations and correlated with their corresponding rectal and renal biopsies. As case controls 23 patients with FMF free of renal disease, but with similar origin, sex, age, and age at onset of FMF, were chosen.

**RESULTS:** All the patients with ESRD induced by amyloidosis were homozygous for the M694V or M694I mutations. This finding was significantly different from that seen in the control group.

**CONCLUSIONS:** Amyloidosis is highly associated with the 694 substitution in the MEFV gene causing FMF. It seems that genetic predisposition plays a part in the development of this complication of FMF.

Comment in

Hum Mutat. 2003 Jan;21(1):96-7.

Progressive systemic amyloidosis is the most important complication of familial Mediterranean fever that inevitably leads to chronic renal failure. Initial studies have suggested that the presence of the Met694Val mutation carry a significant risk for the development of amyloidosis. On the contrary, our data revealed that there was no dominance of any MEFV mutation in relation to amyloidosis. The difference between our mutation data and others led us to study a polymorphism in Turkish population that might be a risk factor for the occurrence of amyloidosis. As some of the previously reported exonic polymorphisms in other disease states found to increase the genetic susceptibility, we aimed to study Ala138Gly of the MEFV gene. Our study group consisted of 124 FMF patients, of which 47 had amyloidosis. Eighty-one individuals without any familial history of FMF were included as control group. There was no statistically significant difference between healthy controls and FMF patients for the Ala138Gly polymorphism ( $p=0.9$ ). However, when FMF/amyloidosis patients ( $n:47$ ) were taken as another group, the difference was significant ( $p= 0.01$ ) indicating that the carriers of 138Gly are more prone to amyloidosis [odds ratio 3.1 (CI 95% 1.57-5.75)].

An 8-year-old child with familial Mediterranean fever exhibited signs of colchicine intoxication while receiving prophylactic doses of the drug. She developed gastrointestinal, central nervous system, cardiovascular and haematological disturbances. Over 2 months she had been drinking high doses of natural grapefruit juice which, combined with long-term colchicine therapy and a viral upper respiratory tract infection, increased her susceptibility to the drug. CONCLUSION: To the best of our knowledge, this is the first time colchicine intoxication in this age group has been described in the English literature.

Mutations in MEFV, a gene encoding a protein (marenostin/pyrin) of unknown function, are associated with familial Mediterranean fever, a genetic condition characterized by febrile episodes of serosal inflammation. Based on its primary structure, this 781 residue protein is thought to function as a nuclear effector molecule. However, recent transient expression studies indicated a perinuclear cytoplasmic localization. Here, we describe the isolation and expression of a novel human MEFV isoform, MEFV-d2, generated by in-frame alternative splicing of exon 2. This transcript, expressed in leukocytes, predicts a 570 residue protein designated marenostin-d2. To investigate differences in subcellular localization

between the full-length protein (marenostin-fl) and marenostin-d2, while providing against the overexpression of transiently expressed proteins, we have generated CHO cell lines stably expressing these two isoforms fused to the green fluorescent protein. The localization pattern of marenostin-d2 differs dramatically from that of marenostin-fl. Marenostin-fl is homogeneously distributed over the entire cytoplasm, whereas marenostin-d2 concentrates into the nucleus. To map the critical domain(s) specifying these differences, deletion mutants have been generated. Deletion of the putative nuclear localization signals (NLS) does not alter the nuclear localization of marenostin-d2 whereas, despite the lack of discernible NLS in the domain encoded by the exon 1-exon 3 splice junction, deletion of this domain indeed disrupts this localization. These data, which challenge the current domain organization model of marenostin, strongly suggest that MEFV encodes a nuclear protein and raises the possibility that MEFV alternative splicing may control functions of wild-type and mutant marenostin proteins by regulating their translocation to the nucleus.

Tumor necrosis factor receptor-associated periodic syndrome: a novel syndrome with cutaneous manifestations.

Toro JR(1), Aksentijevich I, Hull K, Dean J, Kastner DL.

Author information:

(1)National Cancer Institute, National Institutes of Health, Bldg 10, Room 12N-238, 10 Center Dr, MSC 1908, Bethesda, MD 20892-1908, USA.  
torojo@exchange.nih.gov

**BACKGROUND:** Tumor necrosis factor receptor-associated periodic syndrome (TRAPS) is an inflammatory disorder characterized by prolonged episodes of periodic fever and localized inflammation and dominantly inherited mutations in TNFRSF1A, the gene encoding the 55-kDa tumor necrosis factor receptor. To our knowledge, the cutaneous pathologic characteristics of TRAPS have not been described previously. **OBJECTIVES:** To characterize the dermatologic manifestations of TRAPS by clinical, microscopic, and molecular methods, and to investigate its immunophenotype.

**DESIGN, SETTING, AND PATIENTS:** At the National Institutes of Health Clinical Center, Bethesda, Md, a tertiary care referral center, 25 patients with a clinical and molecular diagnosis of TRAPS were evaluated clinically and 10 biopsy specimens of lesional skin were examined by light microscopy and immunohistochemistry. Patients were screened for mutations in TNFRSF1A, the gene coding for the p55 tumor necrosis factor receptor.

**MAIN OUTCOME MEASURES:** Clinical, light microscopic, and immunohistochemical features.

**RESULTS:** The skin eruption usually lasted 4 to 21 days (mean, 13 days). Of 25 patients, 21 (84%) presented with migratory erythematous macules and patches and 10 (40%) had edematous dermal plaques. Conjunctivitis, characterized by pain and redness and/or periorbital edema, was present in 11 patients (44%). Most patients had their first skin eruption during the first 2 years of life. All patients had fever associated with the skin eruption. Most patients had associated abdominal pain (22 [88%]) and myalgia (20 [80%]). Other symptoms included arthralgia (13 [52%]), pleuritic chest pain (10 [40%]), and headache (17 [68%]). Microscopic examination of 10 biopsy specimens of lesional skin showed a superficial and deep perivascular and interstitial infiltrate of lymphocytes and monocytes. None of the biopsy specimens showed multinucleated macrophages or granulomatous or leukocytoclastic vasculitis. The results of immunohistochemistry showed a perivascular infiltrate of CD3+, CD4+, CD8+, CD68+, CD79a-, and CD20- cells. All the mutations were missense mutations in exons 2 through 4 of TNFRSF1A, directly affecting the extracellular domain of the protein.

**CONCLUSIONS:** TRAPS is characterized by a spectrum of dermatologic findings, including migratory patches, edematous plaques, periorbital edema, and/or conjunctivitis. TRAPS is characterized by a perivascular dermal infiltrate of lymphocytes and monocytes.

Mevalonate kinase (MK) is an essential enzyme in the mevalonate pathway which produces numerous cellular isoprenoids. The enzyme has been characterized both at the biochemical and the molecular level in a variety of organisms. Despite the fact that mevalonate kinase is not the rate-limiting enzyme in isoprenoid biosynthesis, its activity is subject to feedback regulation by the branch-point intermediates geranyldiphosphate, farnesyldiphosphate and geranylgeranyldiphosphate. Recently, the importance of mevalonate kinase was demonstrated by the identification of its deficiency as the biochemical and molecular cause of the inherited human disorders mevalonic aciduria and hyperimmunoglobulinemia D and periodic fever syndrome. The pathophysiology of these disorders is not yet understood, but eventually will give insight into the in vivo role of mevalonate kinase and isoprenoid biosynthesis with respect to the acute phase response and fever. The subcellular localization of mevalonate kinase is still a matter of debate. The enzyme could be localized predominantly in the cytosol, or in peroxisomes, or it is associated differentially with peroxisomes. Here we review the biochemical and molecular properties of MK, and discuss its biological significance, the regulation of its enzyme activity and finally its subcellular localization.

Familial Mediterranean fever (FMF) is characterised by recurrent episodes of fever and painful serositis. It is inherited as an autosomal recessive disease,

predominantly in people from the Eastern Mediterranean area. The patient described here was followed-up for 6 years. He had FMF diagnosed primarily on clinical grounds, which is now verified by a gene test.

FMF is a hereditary disorder characterised by periodic fever and acute abdominal, chest, or joint pain. In the long term, amyloidosis may develop and eventually result in kidney failure. A 26-year-old man from Lebanon was diagnosed with FMF by genetic testing and treated with colchicine for two months. Colchicine reduced the frequency, duration, and intensity of his attacks, and thus minimised the risk of amyloidosis developing.

Familial Mediterranean fever (FMF) is an autosomal, recessively inherited disease, mainly affecting patients from the Mediterranean basin. Owing to the recessive transmission, the disease in most of the affected families only occurs in the members of one generation. However, high consanguinity rates in populations with carrier frequencies as much as 1:5 may account for the occurrence of FMF in two or more successive generations, so-called pseudodominant inheritance. We report a case of pseudodominant inheritance in a Turkish family living in Denmark.

The term periodic fever syndrome has been used in a restricted sense to denote two diseases in which episodic fevers occur with a regular periodicity: cyclic neutropenia and the periodic fever, aphthous stomatitis, pharyngitis, and adenopathy (PFAPA) syndrome. Other authors have used the term in a more general sense to encompass a larger group of disorders characterized by recurrent episodes of fever that do not necessarily follow a strictly periodic pattern. These include familial Mediterranean fever, the autosomal dominant familial fevers (also known as Hibernian fever), and the hyperimmunoglobulin D syndrome. This article follows the latter usage, and reviews recent advances in our understanding of the genetics and molecular pathology of this group of diseases, as well as their clinical characterization and treatment.

Familial Mediterranean Fever (FMF) is a genetically defined disease affecting mostly families of jewish, turkish or armenian origin whose ancestors originate from the mediterranean basin. The first officially acknowledged description was given by SIEGAL in 1945 but previous cases were reported since 1908. The main clinical signs which are very varying in intensity and appearance are periodic attacks of fever with peritonitis, pleurisy and arthritis. The classical but not always found complication is amyloidosis with renal failure which is preventable by lifelong colchicine therapy. By using a novel genetest it is now possible to definitely diagnose FMF instead of relying on a diagnosis made merely by exclusion. This will emphasize the use of colchicine and should bring us nearer to the pathophysiology of this interesting disease.

Phenotype-genotype correlation in 91 patients with familial Mediterranean fever reveals a high frequency of cutaneomucous features.

Koné Paut I(1), Dubuc M, Sportouch J, Minodier P, Garnier JM, Touitou I.

Author information:

(1)Service de Pédiatrie, Hôpital Nord, chemin des Bourrellys, 13915 Marseille cedex 20, France.

**OBJECTIVES:** To describe the clinical manifestations of familial Mediterranean fever (FMF) in 91 patients from 47 families and provide data from the genetic study. **P:atients and methods.** We conducted a retrospective chart review of 91 patients (including 83 children aged <15 yr) from 47 families through a questionnaire and a specific database. The genetic analysis included complete screening of known mutations of the MEFV gene on chromosome 16p13.3. A positive diagnosis required at least two mutations, one on each chromosome.

**RESULTS:** Our panel included 52 females and 39 males, with a mean age of 7.27 yr. Of the 47 families, 31 were non-Ashkenazi Jews, 10 were Armenians and six were from other ethnic groups. Clinical features included fever (100%), peritonitis (86%), pleuritis (56%), arthritis (34%) and myalgias (27%). We observed a high rate of cutaneous manifestations (47%); erythema, oedema and recurrent oral ulcers were the most frequent. Phenotype-genotype correlations showed a significant association of M694V homozygosity with earlier age of onset ( $P = 0.044$ ), fever >39 degrees C ( $P = 0.002$ ), pleural crisis ( $P = 0.0044$ ), splenomegaly ( $P = 0.0005$ ) and arthritis ( $P = 0.001$ ). Associations with mucocutaneous features were as follows: erysipelas-like erythema ( $P = 0.012$ ), oedema ( $P = 0.61$ , not significant) and oral ulcers ( $P = 0.45$ , not significant).

**CONCLUSION:** New phenotype-genotype correlations emerged from our study: homozygosity for the M694V mutation was associated with intensity of fever, splenomegaly and with erysipelas-like erythema. Apart from erysipelas-like erythema, no significant association was found between other cutaneous features and the genotype.

The clinical patterns of myalgia in children with familial Mediterranean fever.

Majeed HA(1), Al-Qudah AK, Qubain H, Shahin HM.

Author information:

(1)Department of Pediatrics, Faculty of Medicine, University of Jordan.

**OBJECTIVES:** To study the frequency and clinical patterns of myalgia in a defined group of children with familial Mediterranean fever (FMF).

**METHODS:** A prospective 4-year (September 1995-September 1999) study of children with FMF seen in the pediatric FMF clinic of Jordan University teaching hospital.

Diagnosis of FMF was made according to published criteria. Once the diagnosis of FMF and myalgia was made, details about myalgia were collected by interview with the child and his/her parents and entered into a special study form.

**RESULTS:** Of 264 children with FMF seen over the study period, 65 (25%) developed myalgia. Three clinical patterns of myalgia were identified: the spontaneous pattern, the exercise-induced pattern, and the protracted febrile myalgia syndrome (PFMS), seen in 8%, 81%, and 11% of patients, respectively. The three patterns differed in the severity of pain, height of fever, and duration of the episode. In 33 children with the exercise-induced myalgia, in which response to colchicine could be reliably assessed, a favorable response was achieved in 97%. Three children with the PFMS had a dramatic response to corticosteroids.

**CONCLUSIONS:** Myalgia in children with FMF is common and can follow three different clinical patterns.

Familial Mediterranean fever. A review of the disease and clinical and laboratory findings in 105 patients.

Ozel AM(1), Demirtürk L, Yazgan Y, Avşar K, Günay A, Gürbüz AK, Gültepe M.

Author information:

(1)Department of Gastroenterology, Gülhane Military Medical Academy, Haydarpaşa Training Hospital, Istanbul, Turkey. melihozel@ixir.com

**BACKGROUND:** The diagnosis of familial Mediterranean fever still remains clinical, since no specific laboratory test exists, other than a molecular genetic test which is not widely available.

**AIM:** To evaluate the clinical findings in 105 Turkish patients; to compare these findings with those in the literature; and to make a brief review of the disease.

**METHODS:** A total of 105 familial Mediterranean fever patients were evaluated either retrospectively (for those diagnosed before 1997), or prospectively (for those after 1997). A diagnostic criteria set was used in addition to the clinical and laboratory findings that can be seen in familial Mediterranean fever, including the newly described manifestations. Previously selected clinical and laboratory parameters were observed for three consecutive days.

**RESULTS:** Of our patients, 88.5% were of Turkish, 3.8% of Armenian and 7.6% of Jewish origin. Family history was positive in 87 (82.8%) patients. Involved site was peritoneum in 97 (92%), joints in 45 (42.8%) and pleura in 19 (18%).

Frequency of myalgia/arthralgia was 24.7%, and skin findings were observed in 16.1% of patients. Splenomegaly, not related to amyloidosis, was present in 21 (20%)

patients. Meningeal, retinal or ovarian/testicular involvement was not observed.  
CONCLUSION: Identification of familial Mediterranean fever gene has led to the application of a molecular genetic test for the diagnosis of Familial Mediterranean Fever. Until genetic methods become widely available, diagnosis will remain clinical. Thus, awareness of various clinical forms and of the correct usage of diagnostic criteria in various patient populations is important.

A survey of phenotype II in familial Mediterranean fever.

Melikoğlu M(1), Ozdoğan H, Korkmaz C, Kasapçopur O, Arisoy N, Akkuş S, Fresko Z, Yazici H.

Author information:

(1)Department of Rheumatology, Cerrahpaşa Medical School, University of Istanbul, Istanbul, Turkey.

OBJECTIVE: Phenotype II in familial Mediterranean fever (FMF) is the onset of amyloidosis before the onset of FMF with its typical attacks, or as an isolated finding in a member of an FMF family. Its presence was investigated by looking for proteinuria among the asymptomatic relatives of patients with FMF complicated by amyloidosis and among the asymptomatic relatives of patients with juvenile chronic arthritis (JCA) complicated by amyloidosis, used as controls.

METHODS: The relatives of the index patients (13 with FMF and amyloidosis) and controls (6 with JCA and amyloidosis) were screened for proteinuria. Rectal biopsies were performed when proteinuria was significant ( $\geq 300$  mg/d).

RESULTS: 461 relatives were screened in the FMF group and 269 among the controls. Two of the FMF relatives and one JCA relative had no symptoms of FMF but had significant proteinuria. Rectal biopsy for amyloidosis was negative in all instances of significant proteinuria.

CONCLUSION: Phenotype II is uncommon among the relatives of patients with FMF and amyloidosis.

[Article in Russian]

Karagezian KG, Nazaretian EE, Zavgorodniaia AM, Ovnanian KO.

The examination of 404 patients with periodic disease (301 with uncomplicated form and 104 with amyloidosis complication) has detected decreased functional activity of T-lymphocytes and their suppressor subpopulation, their subnormal quantity. There was a rise in T-helper/T-suppressor index, level of B- and O-lymphocytes, sensitivity to the renal antigen. Colchicin therapy stopped the attacks and stimulated T-suppressor activity. Combined treatment with tactivin is proposed.

High frequency of amyloid lymphadenopathy in uremic patients.

Güz G(1), Ozdemir BH, Sezer S, Yakupoglu U, Demirhan B, Ozdemir FN, Haberal M.

Author information:

(1)Department of Nephrology, Baskent University Faculty of Medicine, Ankara, Turkey. galip\_guz@hotmail.com

Amyloid lymphadenopathy has only been reported in case report form, or in small groups of patient groups within large series. We believe that amyloid lymphadenopathy is common in uremic patients, and thus designed this study to determine the frequency of this condition in hemodialysis patients, and to assess its types and patterns. We reevaluated 46 uremic patients' lymph node biopsies

for amyloid deposits. We also immunohistochemically identified the protein origin of these deposits using Amyloid A, kappa, lambda, beta2 microglobulin, and transthyretin antibodies. Histopathologically, we observed for vascular involvement, follicular deposition, and diffuse deposition. We detected amyloid deposits in 10 of the 46 (22%) patients' lymph nodes. The patterns of deposition were vascular involvement alone in six specimens, vascular involvement plus follicular deposition in three, and vascular involvement plus diffuse deposition in one specimen. Amyloid AA type protein was present in seven nodes, beta2 microglobulin-related amyloid in two nodes, and immunoglobulin-derived protein (AL) in one node. We assessed these 10 patients for causes of end-stage renal disease (ESRD) and other conditions that might relate to amyloidosis. The cause of ESRD in the seven patients with AA amyloid were renal amyloidosis secondary to Familial Mediterranean Fever in four, glomerulonephritis in one patient who had bronchiectasis and Castleman's disease, unknown in one patient who had bronchial asthma, and pyelonephritis in one patient who had no characteristics that could be linked with AA type amyloidosis. The causes of ESRD in the two individuals with beta2 microglobulin-related amyloidosis who had been on long-term hemodialysis were pyelonephritis and glomerulonephritis. The cause of ESRD in the patient with AL type protein was glomerulonephritis, and this patient had no systemic disease. We conclude that amyloid lymphadenopathy is, indeed, common in uremic patients. Amyloid type AA is the most prevalent form of amyloid protein in uremic patients, but amyloid type does not always correspond with underlying cause of renal failure, or with the presence of systemic disease.

Pregnancy and amyloidosis: II. Suppression of amyloidogenesis during pregnancy.

Shtrasburg S(1), Pras M, Dolitzky M, Pariente C, Gal R, Livneh A.

Author information:

(1)Heller Institute of Medical Research, and the Department of Obstetrics and Gynecology, Sheba Medical Center, Tel-Hashomer, Israel.

The observation of a deleterious effect of pregnancy on kidney function in

amyloidosis of familial Mediterranean fever suggests that pregnancy may enhance amyloidogenesis. To determine whether pregnancy may indeed affect amyloidogenesis, pregnant mice were made amyloidotic by administration of amyloid-enhancing factor (AEF) and AgNO<sub>3</sub> at different points in time from conception, and amyloid- deposition was studied with the crush-and-smear technique. A possible effect of exogenous female sex hormones (beta-estradiol and progesterone) on amyloidogenesis was studied by administration of these hormones during amyloid induction in nonpregnant female mice. Amyloidogenesis was found to be significantly suppressed in mice during pregnancy. The reduction was possibly related to the effect of pregnancy on the inflammatory stimulus (AgNO<sub>3</sub>) and not on the administered AEF. Exogenous estrogen and progesterone failed to inhibit amyloidogenesis in nonpregnant mice. These findings suggest that pregnancy may suppress amyloidogenesis in mice. The suppression is caused by an anti-inflammatory effect of pregnancy. Estrogen and progesterone are probably unrelated to this finding.

We compared the frequencies of seven MEFV mutations (M694V, M680I, V726A, M694I, K695R, R761H, E148Q) and the clinical findings in 20 Turkish FMF patients who had not developed amyloidosis by the age of 40 years in the absence of colchicine therapy, with those in 27 Turkish amyloidosis patients. No mutation frequency, including that of M694V, was different between the two groups. Family history of amyloidosis and parental consanguinity were noted to be higher in the amyloidosis group. The seven mutations do not appear to be sufficient to explain the development of amyloidosis in Turkish FMF patients. Other genetic factors may be

important for this association.

Familial Mediterranean fever (FMF) is a recessively inherited disorder predisposing to renal amyloidosis and associated with mutations in MEFV, a gene encoding a protein of unknown function. Differences in clinical expression have been attributed to MEFV-allelic heterogeneity, with the M694V/M694V genotype associated with a high prevalence of renal amyloidosis. However, the variable risk for patients with identical MEFV mutations to develop this severe complication, prevented by lifelong administration of colchicine, strongly suggests a role for other genetic and/or environmental factors. To overcome the

well-known difficulties in the identification of modifying genetic factors, we investigated a relatively homogeneous population sample consisting of 137 Armenian patients with FMF from 127 independent families living in Armenia. We selected the SAA1, SAA2, and APOE genes-encoding serum amyloid proteins and apolipoprotein E, respectively-as well as the patients' sex, as candidate modifiers for renal amyloidosis. A stepwise logistic-regression analysis showed that the SAA1alpha/alpha genotype was associated with a sevenfold increased risk for renal amyloidosis, compared with other SAA1 genotypes (odds ratio [OR] 6.9; 95% confidence interval [CI] 2.5-19.0). This association, which was present whatever the MEFV genotype, was extremely marked in patients homozygous for M694V (11/11). The risk for male patients of developing renal amyloidosis was fourfold higher than that for female patients (OR=4.0; 95% CI=1.5-10.8). This association, particularly marked in patients who were not homozygous for M694V (34.0% vs. 11.6%), was independent of SAA1-allelic variations. Polymorphisms in the SAA2 or APOE gene did not appear to influence susceptibility to renal amyloidosis. Overall, these data, which provide new insights into the pathophysiology of FMF, demonstrate that susceptibility to renal amyloidosis in this Mendelian disorder is influenced by at least two MEFV-independent factors of genetic origin-SAA1 and sex-that act independently of each other.

Author information:

(1)St. Bartholomew's and the Royal London School of Medicine, UK.

Erratum in

Arthritis Rheum. 2000 Oct;43(10):2379.

OBJECTIVE: To investigate genetic susceptibility in the first Indian family

identified as having an autosomal dominantly inherited periodic fever syndrome. The inflammatory disease was characterized chiefly by arthralgia, skin rashes, and AA amyloidosis.

**METHODS:** Markers from known periodic fever susceptibility loci were investigated in 7 affected and 11 healthy members of a north Indian family. These included the TNFRSF1A locus (formerly known as TNFRI), which is involved in autosomal dominant tumor necrosis factor receptor-associated periodic syndrome on chromosome 12p13, the familial Mediterranean fever locus (MEFV) on chromosome 16p13, the hyperimmunoglobulinemia D and periodic fever syndrome (HIDS) locus on chromosome 12q24, and the Muckle-Wells syndrome/familial cold urticaria (MWS/FCU) locus on distal chromosome 1q44.

**RESULTS:** Linkage to both TNFRSF1A and MEFV was definitively excluded, and DNA sequencing of these genes revealed no mutations. Furthermore, there was no evidence of linkage to the HIDS locus. In contrast, significant logarithm of odds scores for 5 markers from the MWS/FCU region were obtained in this family, and the disease segregated with the same haplotype in all affected members.

**CONCLUSION:** We have identified an inherited inflammatory disease in a north Indian family with clinical features overlapping some of those of MWS and FCU. The susceptibility gene maps to distal chromosome 1q44, a region already implicated in both MWS and FCU. Different mutations in the same (or a closely related) gene may be responsible for an inflammatory disease with a broad phenotype among diverse ethnic populations.

Unusual presentation of familial Mediterranean fever: role of genetic diagnosis.

Nir-Paz R(1), Ben-Chetrit E, Pikarsky E, Hassin D, Hasin Y, Chajek-Shaul T.

Author information:

(1)Department of Medicine, Hadassah University Hospital, Jerusalem.

OBJECTIVE: To describe the role of molecular analysis in the diagnosis of an unusual presentation of familial Mediterranean fever (FMF).

CASE REPORT: Two patients presenting with prolonged fever without signs and symptoms of serositis are described. FMF was diagnosed by genetic analysis, which disclosed that both patients were homozygous for the M694V mutation of the Mediterranean fever (MEFV) gene.

CONCLUSION: Molecular analysis of FMF should complement the investigation of patients with fever of unknown origin. This test enables a definite diagnosis of the disease and may promote the diagnosis and treatment of patients with an unusual or incomplete clinical picture of FMF.

Metabolic correlates of oxygen debt predict posttrauma early acute respiratory distress syndrome and the related cytokine response.

Rixen D(1), Siegel JH.

Author information:

(1)Department of Surgery and Anatomy, New Jersey Medical School, University of Medicine and Dentistry of New Jersey, Newark 07103, USA.

**BACKGROUND:** The purpose of this study was to quantify the relationship between negative base excess (base deficit) and lactate as correlates of oxygen debt and the probability of the early acute respiratory distress syndrome (ARDS) response and with regard to the mediator and metabolic response characteristic of this disease.

**METHODS:** Eighty patients with multiple trauma were studied (514 samples) during their intensive care unit courses (Injury Severity Score 27.6+/-8.8, 36% deaths). Simultaneous samples of arterial base excess and lactate as correlates of oxygen debt, and enzyme-linked immunosorbent assay-measured mixed venous cytokines were obtained daily. At each sample period, the patient was categorized as having ARDS or non-ARDS.

**RESULTS:** Twenty-nine patients (36%; 19 deaths) developed ARDS over the period studied: 17 in postinjury days 1 to 4 (EARLY ARDS) and 12 in postinjury days 5 or later (LATE ARDS). Patients subsequently developing ARDS had evidence of ischemic acidosis on or within the first 24 hours after hospital admission (lower base excess -7.1 mmol/L and higher lactate 5.2 mmol/L in ARDS versus base excess -3.8 mmol/L and lactate 3.6 mmol/L in non-ARDS;  $p < 0.05$ ). Patients with EARLY ARDS showed even lower ( $p < 0.05$ ) initial 24 hour mean base excess and higher lactate (base excess -9.1 mmol/L and lactate 6.4 mmol/L) compared with LATE ARDS (base excess -4.3 mmol/L and lactate 3.3 mmol/L). In EARLY ARDS, this degree of ischemic acidosis was followed by a greater mean IL-6 response in the postinjury days 1 to 4 (323 pg/mL) compared with the LATE ARDS response (141 pg/mL) ( $p <$

0.05) or compared with the non-ARDS IL-6 response (67 pg/mL;  $p < 0.001$ ). In addition, in EARLY ARDS, mean IL-8 levels in postinjury days 1 to 4 (264 pg/mL) were higher than in LATE ARDS (168 pg/mL) ( $p < 0.05$ ) and the mean IL-1 response in postinjury days 1 to 4 of EARLY ARDS (65 pg/mL) was greater than non-ARDS (32 pg/mL) ( $p < 0.05$ ). Derivation of probability curves suggests a critical threshold of base excess  $-6.6$  mmol/L or greater for an increased risk of EARLY ARDS. CONCLUSION: These data suggest that the maximum posttrauma oxygen debt (quantified by the ischemia correlates of negative base excess and lactate) is a critical primary determinant of the later fulminant autoinflammatory EARLY ARDS response mediated by the host's endogenous cytokine mediators.

(1)Afd. Klinische Genetica, Leids Universitair Medisch Centrum, RC Leiden.

Familial mediterranean fever (FMF) is an autosomal recessive hereditary disorder associated with mutations in the gene on chromosome 16 encoding the protein pyrine (marenostrine). Marenostrine is thought to stimulate the production of an inactivator of a chemotactic factor (possibly C5a). The mutations result in ongoing inflammation, a hallmark of FMF. DNA diagnosis of FMF is operational in Leiden University, the Netherlands, for one year now.

Familial Mediterranean fever (FMF) is an autosomal recessive disease. Although the possibility of multiple immunologic mechanisms have been studied, the actual mechanism is still unresolved. Forty-one patients with FMF (24 males and 17 females with a mean age and disease duration of 17.8 +/- 4.1 and 4.7 +/- 2.3 years, respectively) and 14 healthy controls (10 males and 4 females with a mean age 23.2 +/- 5.1) were involved in the study. A phagotest was studied in both the patients and control groups with a FACScalibur Flow. All patients were in the acute stages of the disease and had not undergone colchicine treatment for 2 months. The percentage blood phagocytic activity of both granulocytes and monocytes were 84.23 +/- 8.76 and 67.28 +/- 10.15 in the patient group and 94.68 +/- 3.24 and 76.23 +/- 5.7 in the control group, respectively. There was no statistically significant difference in the percentage of phagocytic activity of the granulocytes and monocytes between the FMF patients and healthy controls ( $p > 0.05$  and  $p > 0.05$ , respectively).

Rheumatic disease mimics in childhood.

Ansell BM(1).

Author information:

(1)The Consulting Rooms, Windsor, UK.

Aches and pains in children can arise from multiple problems, varying from a reaction to minor intercurrent infection that rapidly improves to the presence of severe skeletal lesions such as malignancy; they can also be part of a skeletal dysplasia. All cases require a good history (including family history), a full examination, and basic blood tests, which include the erythrocyte sedimentation rate, hemoglobin, white count, platelets, rheumatoid factor, and antinuclear factor. Other tests need be performed only when suspicion has been aroused. Recognition of unusual syndromes is important; no child should be labeled as having juvenile idiopathic arthritis unless there is a clear history with the presence of soft tissue swelling in appropriate sites and other causes for joint pain have been excluded. The conditions that most frequently mimic systemic onset juvenile arthritis are infections, which may have been partially treated, inflammatory bowel disease, malignancy, familial Mediterranean Fever, and the rarer connective tissue diseases, in particular systemic lupus erythematosus. Bacterial infection should be suspected in a child who is feverish and toxic, with a single hot swollen joint that has limited movement and is often rigidly guarded. Should such a child have already received antibiotics, general symptoms may well be minimal, so one is left with the history and a swollen and painful joint. Aspiration for investigation of the synovial fluid as well as blood tests should be undertaken immediately to establish the nature of any underlying infection.

Differential diagnosis of fever of unknown origin in children.

Majeed HA(1).

Author information:

(1)Department of Pediatrics, Faculty of Medicine, University of Jordan, Amman.

Fever of unknown origin in children follows two main clinical patterns, namely fever of unknown origin and chronic episodic fever of unknown origin. Fever of unknown origin is characterized by daily fever persisting for more than 3 weeks. The main causes are infectious, rheumatologic disorders, and malignancy. Chronic episodic fever of unknown origin is characterized by fever lasting for a few days to a few weeks, followed by a fever-free interval and a sense of well-being. The main causes are familial Mediterranean fever, the hyper-immunoglobulin D syndrome, familial Hibernian fever, Behcet disease, the syndrome of periodic fever, aphthous stomatitis, pharyngitis and adenitis, and cyclic neutropenia.

Diagnostic and treatment concerns in familial Mediterranean fever.

Livneh A(1), Langevitz P.

Author information:

(1)The Heller Institute of Medical Research and Department of Medicine F and Rheumatology Unit, Sheba Medical Center, Tel-Hashomer, Israel.

Familial Mediterranean fever (FMF) is an autosomal, recessively inherited disease, affecting people of Jewish, Arabic, Turkish and Armenian ancestry. The disease is the prototype of the periodic febrile syndromes. Its hallmark is short attacks of fever and painful manifestations in the abdomen, joints, chest, scrotum and skin. Chronic and protracted manifestations, particularly nephropathic amyloidosis, chronic arthritis, and protracted myalgia, may also occur in the disease. The diagnosis of FMF should be considered in individuals of an appropriate ethnic background who present with febrile disease of episodic nature. The differential diagnosis in this case is broad and includes a large number of infectious, inflammatory and genetic diseases. However, in most cases, the very specific general and site-restricted features of the FMF attacks on the one hand, and the absence of manifestations typical of other conditions on the other hand, determine the diagnosis of FMF. This chapter presents clues and tips that help in the diagnosis and treatment of FMF.

Familial Mediterranean fever (FMF) and Behçet's disease (BD), both inflammatory

diseases, are highly prevalent in the Middle Eastern and Mediterranean populations. FMF is a Mendelian autosomic recessive disease linked to MEFV, a gene of unknown function. BD in contrast is a polyfactorial disease associated with the major histocompatibility complex. Because FMF and BD have epidemiological similarities, we asked whether the FMF gene was implicated in BD. We screened for the common MEFV mutations a cohort of 114 chromosomes from definite BD patients [meeting the criteria of the International study group] and probable cases [meeting at least two of these criteria]. We screened in parallel an ethnically matched cohort of FMF and control chromosomes. The M694V, V726A and E148Q mutations tended to be more frequent in definite BD (2.6%, 2.6%, and 5.2%, respectively) than in controls (0%, 0%, and 2.2%). The P706 polymorphism was found in 10.5% of the probable BD chromosomes, but in only 1.6% of the controls ( $p=0.01$ ). Because some MEFV mutations were more frequent in BD than in controls, we suggest that they may act as additional susceptibility factors in BD.

The pathophysiological connection between periodic lateralized epileptiform discharges (PLED) and epileptic seizures is still not clear. In the study clinical data and EEG findings were analysed in 22 patients aged 43-90 years with a history of stroke in whom EEG disclosed PLED. Eleven patients were studied in the acute phase of stroke and 11 were studied years after stroke when the

diagnosis was established of poststroke epilepsy. In 2 patients in acute stroke group single epileptic seizures occurred and 5 had partial status epilepticus. In the group with poststroke epilepsy 4 had single seizures and 4 had epileptic status with partial epilepsy seizures. Thus, in 15 out of 22 patients PLEDs were noted after epileptic seizures. In all cases PLED appearance was connected with consciousness disturbances, lasting 1 to 17 days. In 6 cases PLED pattern was interrupted by seizure activity over one hemisphere, in 3 of them partial epileptic seizures were associated with it. In acute phase of stroke neuroimaging demonstrated the presence of fresh ischaemic foci, but in cases of poststroke epilepsy no such fresh foci were observed. These results suggest that PLED frequently can be associated with epilepsy, and in some patients it can be a bioelectrical manifestation of partial status epileptic.

Periodic fever and pharyngitis in young children: a new disease for the otolaryngologist?

Dahn KA(1), Glode MP, Chan KH.

Author information:

(1)Department of Pediatric Otolaryngology, The Children's Hospital, 1056 E 19th Ave, Denver, CO 80218, USA. chan.kenny@tchden.org

**OBJECTIVE:** A clinical entity consisting of periodic fever associated with aphthous stomatitis, pharyngitis and cervical adenitis termed "PFAPA syndrome" in young children (<5 years old) may be unfamiliar to otolaryngologists. We present our 5-year experience of PFAPA syndrome.

**DESIGN:** Case series.

**SETTING:** Tertiary academic.

**PATIENTS:** A 5-year retrospective chart review for children (<5 years old) who have undergone tonsillectomies with and without adenoidectomies was conducted. Medical records from subjects who underwent the procedures for recurrent pharyngitis were reviewed with reference to a history of periodic fever and stomatitis associated with pharyngitis.

INTERVENTIONS: Tonsillectomy with and without adenoidectomy.

MAIN OUTCOME MEASURE: The objective measure was a comparison of the number of visits to the primary care physician for pharyngitis associated with fever in a 3-month period before and after the surgical intervention. The subjective measure was a telephone interview evaluating preoperative and postoperative symptoms.

RESULTS: Of the 117 patients identified, 22 (19%) underwent surgery for recurrent pharyngitis. Five subjects (average age, 2.5 years) were identified as having PFAPA syndrome. The average number of preoperative PFAPA-related complaints was 11.6 compared with 0.2 for the number of postoperative PFAPA-related complaints ( $P=.03$ ).

CONCLUSIONS: Our experience suggests that PFAPA syndrome is an uncommon disease. Most of these children have undergone workup(s) for sepsis performed by their pediatricians because of the associated high fever. The clinical history of this cohort was quite distinctive. This small sample suggests a significant decrease if not cessation of pharyngitis following surgical intervention.

Severe hyperkalemia in two renal transplant recipients treated with standard dose of trimethoprim-sulfamethoxazole.

Koç M(1), Bihorac A, Ozener CI, Kantarci G, Akoglu E.

Author information:

(1)Division of Nephrology, Marmara University Hospital, Istanbul, Turkey.

Hyperkalemia is a serious electrolyte disorder and is a frequent finding in renal transplant recipients. Trimethoprim-induced hyperkalemia has been increasingly reported in recent years. We describe two renal transplant recipients who developed end-stage renal disease secondary to familial Mediterranean fever and presented with severe hyperkalemia secondary to the use of standard dose of trimethoprim. One of the patients had potential underlying adrenal insufficiency, which might be a contributing factor for the development of hyperkalemia. We concluded that renal transplant patients receiving even the standard dose of trimethoprim should be monitored closely for the development of hyperkalemia.

They should be recognized as a group with increased risk in regard to their concurrent renal insufficiency, concomitant use of cyclosporine, and associated tubulointerstitial disease. Patients with secondary amyloidosis are at even greater risk, and subclinical adrenal insufficiency may be an underlying risk factor for the development of severe, life-threatening hyperkalemia among this group of patients.

Mevalonate kinase deficiency and Dutch type periodic fever.

Frenkel J(1), Houten SM, Waterham HR, Wanders RJ, Rijkers GT, Kimpen JL, Duran R, Poll-The BT, Kuis W.

Author information:

(1)Department of General Pediatrics, Wilhelmina Children's Hospital, University Medical Center, Utrecht, The Netherlands. j.frenkel@wkz.azu.nl

Dutch type periodic fever (DPF) is an autosomal recessive hereditary fever syndrome. Cases have been reported worldwide, the majority from France and The

Netherlands. From infancy the patients suffer fever attacks that recur every 2-8 weeks, often precipitated by immunizations, infections or emotional stress. Fever lasts 2-7 days and can be accompanied by malaise, headache, diarrhea, abdominal pain, vomiting, skin rashes, arthralgia, arthritis, tender lymphadenopathy, hepatosplenomegaly, and oral and genital ulcers. Laboratory evaluation during fever shows granulocytosis and elevated acute phase reactants. DPF is caused by a deficiency of the enzyme mevalonate kinase (MK). Besides DPF, the spectrum of MK deficiency includes a severe phenotype, mevalonic aciduria (MA). MA patients have less residual MK activity, leading to substantially higher urinary mevalonic acid excretion than in DPF. Mevalonic aciduria is characterized by mental retardation and dysmorphic features in addition to the clinical features of DPF. At the genomic level, several mutations of varying severity have been identified. The DPF phenotype is caused by one particular mild missense mutation. Most patients are compound heterozygotes for this mutation and a more severe mutation. The mechanism by which MK deficiency leads to fever is not understood. The vast majority of DPF patients have persistently elevated serum IgD and can be classified as having hyperimmunoglobulinemia D and periodic fever syndrome (HIDS). Conversely, most HIDS patients have MK deficiency and hence DPF, but the two disorders do not overlap entirely.

[Marshall syndrome: results of a retrospective national survey].

[Article in French]

Ovetchkine P(1), Bry ML, Reinert P.

Author information:

(1)Service de pédiatrie, centre hospitalier intercommunal de Créteil, France.

Marshall's syndrome or periodic fever syndrome was first described in 1987 in the USA based on observations of 12 children under the age of five with periodic fever (> 38 degrees C) and accompanying aphtous stomatitis, pharyngitis, and cervical adenopathy (PFAPA). In 1998, a national retrospective study was carried

out in France by the pediatric infectious pathology group, and a semeiological analysis was made of 22 cases. The main characteristics of Marshall's syndrome found in this patient population were in agreement with those reported in the literature. The onset of symptoms occurred between the age of 3 months and 12 years, with a mean age of 5 years; no geographical or ethnic predisposing factors were noted. The diagnosis of symptoms was subsequently established at an age ranging from 5 months to 16 years, with a mean age of 6.5 years. It was determined that following an initial phase of generalized clinical manifestations (asthenia, cranial neuritis, dysphagia, anorexia), the symptoms become stereotyped, with the sudden appearance of high fever (> 40 degrees C), shivering, aphtous stomatitis, pharyngitis, and cervical adenopathy. Other symptoms such as cranial neuritis, arthralgia, and abdominal pain may also be present (50% of cases in the present study), but due to their variability of appearance they are of lesser diagnostic value. The main characteristic of Marshall's syndrome is its periodic aspect; with fever occurring every 6 to 9 weeks, with a mean interval of 66 days before recurrence of fever compared to the shorter interval of 21 to 28 days reported in the literature. After excluding the presence of an infection, the differential diagnosis includes the following: familial Mediterranean fever, hyper IgD syndrome, and feverish neutropenia. During the periods of fever, an inflammatory syndrome with hyperleucocytosis and a marked increase in C-reactive protein (CRP) levels and sedimentation rate is observed. The most effective treatment seems to be the early administration of corticoids during the initial phase, prior to the appearance of more specific symptoms. The prognosis is excellent, with a progressive decrease in the incidence of periodic fever and an absence of complications. However, the etiology of Marshall's syndrome has not yet been determined.

Familial Mediterranean fever.

Kubik NJ 3rd(1), Katz JD.

Author information:

(1)Hamot Medical Center, Erie, Pennsylvania, USA.

Familial Mediterranean fever (FMF) is an inherited multisystem disease manifested by painful, febrile attacks affecting the chest, abdomen, joints, and skin. No simple studies confirm the presence of FMF, contributing to the difficulty in diagnosis. A 10-year-old boy initially presented with a diffuse rash and complaints of bilateral joint pain of the hips, knees, and ankles and pain of the right shoulder. The child responded to daily naproxen. One year later, he continued to complain of hip, knee, ankle, and bilateral wrist pain. He also reported mild to moderate recurrent abdominal discomfort. Omeprazole provided intermittent relief. The patient continued to experience episodes of joint and abdominal pain. Two and a half years after he first presented, FMF was considered. In the second case, a 51-year-old man presented to the emergency department with complaints of fever, cough, and abdominal and joint pain. Fever, joint pain, and swelling decreased during the next few days. The patient was maintained on colchicine, with complete resolution of joint pain complaints during the next few days. Colchicine, 1 to 2 mg per day taken continuously during flare and quiescent periods, is the treatment of choice for FMF. Colchicine reduced the severity and frequency of attacks and may also delay or prevent secondary amyloidosis.

Genotype-phenotype assessment of common genotypes among patients with familial Mediterranean fever.

Shinar Y(1), Livneh A, Langevitz P, Zaks N, Aksentijevich I, Koziol DE, Kastner DL, Pras M, Pras E.

Author information:

(1)Heller Institute of Medical Science, Sheba Medical Center, Tel Hashomer, Israel.

OBJECTIVE: To study genotype-phenotype correlation for the 4 most common genotypes found among patients with familial Mediterranean fever (FMF).

METHODS: Thirty patients with the M694V/M694V genotype, 32 with M694V/V726A

genotype, 25 with M694V/E 148Q genotype, and 21 with V726A/V726A genotype were assessed for various clinical manifestations of FMF, and overall disease severity.

**RESULTS:** Patients with the M694V/M694V genotype were found to have an earlier age of onset, higher frequency of joint involvement, higher frequency of erysipelas-like erythema, and required higher doses of colchicine to control the disease compared to the other 3 genotypes.

**CONCLUSION:** The M694V/M694V genotype is associated with more severe disease compared to other common genotypes in patients with FMF.

Author information:

(1)Department of Pediatrics, Ankara University School of Medicine, Turkey.

mtekin@hsc.vcu.edu

Familial Mediterranean fever (FMF) is an autosomal recessive disease. It is characterized by recurrent febrile episodes in association with peritonitis, pleuritis, and arthritis. Progressive systemic amyloidosis is the most important complication of FMF that inevitably leads to chronic renal failure. Recently, the gene for FMF, MEFV, has been cloned and four missense mutations have been described: M694V, M680I, V726A, and M694I. Initial studies have suggested that the presence of the M694V mutation carries a significant risk for the development of amyloidosis. In this study, we present seven families, in which at least two individuals have been diagnosed with FMF and at least one with amyloidosis. Among 18 individuals, in whom molecular testing was performed for the four aforementioned mutations, ten had amyloidosis. None of these ten individuals was found to be homozygous for the M694V mutation. In three families, there were two sibs with amyloidosis. None of the sib-pairs with amyloidosis was found to have the same genotype. There were two or more sibs with the same genotype in four

families. Only one sib from each family developed amyloidosis in these families. These results provide evidence that FMF patients without the M694V mutation are also at risk for the development of amyloidosis. Particular mutations themselves do not appear to be sufficient to explain the occurrence of amyloidosis in all cases with FMF.

The autoinflammatory syndromes are systemic disorders characterized by apparently unprovoked inflammation in the absence of high-titer autoantibodies or antigen-specific T lymphocytes. One such illness, TNF-receptor-associated periodic syndrome (TRAPS), presents with prolonged attacks of fever and severe localized inflammation. TRAPS is caused by dominantly inherited mutations in TNFRSF1A (formerly termed TNFR1), the gene encoding the 55 kDa TNF receptor. All known mutations affect the first two cysteine-rich extracellular subdomains of the receptor, and several mutations are substitutions directly disrupting conserved disulfide bonds. One likely mechanism of inflammation in TRAPS is the impaired cleavage of TNFRSF1A ectodomain upon cellular activation, with diminished shedding of the potentially antagonistic soluble receptor. Preliminary experience with recombinant p75 TNFR-Fc fusion protein in the treatment of TRAPS has been favorable.

Protracted febrile myalgia (PFM) is a rare form of vasculitic disease that affects patients with familial Mediterranean fever (FMF). Mutation analysis performed in 15 patients who suffered from this disorder showed that 9 of the 15 patients were homozygous for M694V. FMF in these 9 patients was associated with more severe symptoms compared to a group of 30 M694V homozygous FMF patients without PFM.

Palindromic rheumatism: effect of dietary manipulation.

Nesher G(1), Mates M.

Author information:

(1)Department of Internal Medicine, Shaare-Zedek Medical Center, Jerusalem, Israel. nesher@inter.net.il

**OBJECTIVE:** Evaluation of the contribution of dietary components in triggering the attacks of palindromic rheumatism (PR), and the effect of dietary manipulation on the frequency and severity of PR attacks.

**METHODS:** Sixteen patients (10 males, 6 females) were diagnosed as having PR during 1994-8 in one center. Their mean age was 45 +/- 6, duration of symptoms prior to diagnosis was 4 +/- 1.4 years, and frequency of PR attacks were 3.1 +/- 1.8/month. All patients were instructed to make a list of the food that was consumed daily and to specify the dates of PR episodes. Data were evaluated after a period of 2-4 months in each patient.

**RESULTS:** In 5 patients (31%) there was an association between episodes of PR and certain foods that were consumed within 36 hours prior to PR episodes. These were fish (2 patients), eggs, canned vegetables and processed cheese (each in one case). Elimination of the relevant food from each patient's diet resulted in complete cessation of the PR attacks in two of the cases, while the other three had milder, infrequent attacks. Four patients were rechallenged with the offending food. In all cases it resulted in recurrence of the PR attacks. No

association between PR episodes and prior consumption of certain foods could be documented in the other 11 patients.

CONCLUSIONS: In some PR patients ingestion of certain foods, specific for each case, can trigger the typical attack. It is suggested that this association should be looked for in any PR patient, as elimination of the offending food from the diet may help in preventing the PR attacks.

An Med Interna. 2001 May;18(5):287.

The hyperimmunoglobulinemia D syndrome is characterized by early onset of attacks of periodic fever and an elevated serum polyclonal Ig D (> 100 U/ml). Symptoms during attacks include joint involvements (arthralgia/arthritis), skin lesions, swollen lymph nodes, headache and abdominal complaints (vomiting, diarrhea and pain). The ethiopathogenia is unknown. It is transmitted by autosomal recessive inheritance. The hyperimmunoglobulinemia D syndrome should be distinguished from other periodic febrile syndroms such as systemic-onset juvenile rheumatoid arthritis, CINCA syndrome, FADA syndrome, familial mediterranean fever and adult-onset Still disease. There is no therapy for the syndrome but the prognosis is good because the frequency and severity of the attacks tends to decrease with age.

Familial Mediterranean fever (FMF) is an inherited disease whose manifestations are acute but reversible attacks of sterile inflammation affecting synovial and serosal spaces. The FMF gene (MEFV) was recently cloned, and it codes for a protein (pyrin/marennosin) homologous to known nuclear factors. We previously reported the deficient activity of a C5a/interleukin (IL)-8 inhibitor, a physiologic regulator of inflammatory processes, in FMF serosal and synovial fluids. We now describe the concomitant expression of MEFV and C5a/IL-8-inhibitor activity in primary cultures of human fibroblasts. Fibroblasts grown from synovial and peritoneal tissues displayed C5a/IL-8-inhibitor activity that could be further induced with phorbol myristate acetate (PMA) and IL-1 beta. Very low levels of chemotactic inhibitor were evident in skin fibroblast cultures or in peritoneal and skin fibroblasts obtained from FMF patients. MEFV was expressed in peritoneal and skin fibroblasts at a lower level than in neutrophils and could be further induced by PMA and IL-1 beta. In the FMF cultures, the MEFV transcript carried the M694V mutation, consistent with the genetic defect found in patients with this disease. MEFV was also expressed in other cell lines that do not produce C5a/IL-8 inhibitor. These findings suggest that human primary fibroblast cultures express MEFV and produce C5a/IL-8-inhibitor activity. The interrelationship between pyrin, the MEFV product, and the C5a/IL-8 inhibitor requires further investigation. (Blood. 2000;96:727-731)

Polyarteritis nodosa (PAN) is a vasculitis of small- and medium-sized muscular arteries with deposition of immune complex in the vessel wall. Although gastrointestinal involvement is common, the symptomatic involvement of the hepatobiliary system is rare. An eight-year old female patient with a previous diagnosis of familial Mediterranean fever (FMF) was hospitalized for right upper quadrant pain and fever. The thickened gall bladder wall by ultrasonography, called for exploration. Histopathological evaluations of the liver biopsy and gall bladder revealed PAN. Corticosteroid therapy was initiated and the patient

recovered fully. This case represents one of the rarest forms of PAN in childhood.

Familial Mediterranean fever (FMF) is an autosomal recessive disease characterised by recurrent attacks of inflammation of serosal membranes. Amyloidosis leading to renal failure is the most severe complication in untreated patients. In Israel FMF is most frequent among Jews of North African origin. Recently the causative gene (MEFV) has been found and the common mutations characterised. The aim of this study was to investigate the carrier rates of the

common MEFV mutations among 400 healthy members of four different ethnic groups (100 in each group) in Israel, and to compare the distribution of the different mutations between FMF carriers and patients. We found a high frequency of carriers among Jews from the various ethnic groups. In North African Jews it was 22%, in Iraqi Jews 39%, in Ashkenazi Jews 21%, and in Iranian Jews 6%. The distribution of the four most common MEFV mutations among healthy individuals (M694V 29%, V726A 16%, M680I 2% and E148Q 53%) was significantly different ( $P < 0.003$ ) from that found in patients (M694V 84.4%, V726A 9.0%, M680I 0% and E148Q 6.6%). Six healthy asymptomatic individuals were found to carry mutations in both alleles: two homozygotes for E148Q and four compound heterozygotes E148Q/other. These results demonstrate a very high carrier rate among all Jewish ethnic groups. They confirm that mutation E148Q is associated with a milder phenotype, which explains the lower prevalence of FMF among the Ashkenazi and Iraqi Jews. This study raises the question of the need for molecular screening for M694V homozygotes in the Israeli North African Jewish community.

Familial Mediterranean fever (FMF) is a hereditary disease commonly found among Jews, Armenians, Turks and Arabs. Recently, FMF was found in the 'Chuetas', a unique community on the island of Mallorca (Spain). To address the question of their possible Jewish origin, we analysed markers known to be linked to the gene responsible for FMF in Jews (MEFV) in this population. We found that 1/3 of the 16p13.3 chromosomes of the 'Chuetas' FMF patients bore the major ancestral haplotypes (S,S2) and their corresponding M694V and E148Q mutations, displayed by Jews from North Africa. Furthermore, we also detected a novel mutation (L110P) in

this community. Yet 2/3 of these patients bore S negative haplotypes and lack the mutations commonly known to cause FMF. These results confirm that at least some of the 'Chuetas' share a common origin with Jews. However, they also provide evidence for the possibility of genetic heterogeneity in this disorder.

Marcel Proust endured severe allergies and bronchial asthma from early childhood. Those who suffer from the frightening and recurrent pangs of asthma often become dependent on their parents particularly mother; Proust was no exception. In his time asthma was poorly understood by physicians who considered the illness to be a type of hysteria. Decades later, we now understand that the severe, poorly controlled, suffocating episodes of asthma were responsible for the complex persona that Marcel Proust had assumed.

Familial Mediterranean fever: high gene frequency and heterogeneous disease among an Israeli-Arab population.

Shinawi M(1), Brik R, Berant M, Kasinetz L, Gershoni-Baruch R.

Author information:

(1)Department of Pediatrics, Rambam Medical Center, Haifa, Israel.

**OBJECTIVE:** Familial Mediterranean fever (FMF) is an autosomal recessive disease that primarily affects non-Ashkenazi Jews, Armenians, Arabs, and Turks. The FMF (MEFV) gene responsible for the disease has been recently identified. Four missense mutations in exon 10 of the FMF gene seem to account for 86% of the DNA variations identified in patients with FMF. We conducted a phenotype/genotype correlation study in a homogenous population of Israeli-Moslem Arab patients with FMF and performed a mutational screening analysis on DNA samples from healthy individuals of this ethnic group.

**METHODS:** Sixty-five patients clinically diagnosed as having FMF underwent molecular genetic studies using polymerase chain reaction and restriction endonuclease digestion methods to detect the presence of the 4 mutations (M694V, V726A, M680I, M694I). We then correlated the presence of each mutation with age of onset, clinical manifestations, and disease severity; patients whose allelic combination included M694V were then excluded from further statistical analysis, since the association of severe disease with the M694V allele has already been shown. In addition, we screened for FMF mutations the DNA samples from 318 healthy Moslem Arab individuals for the presence of these mutations.

**RESULTS:** Among the 65 patients who were clinically diagnosed as having FMF, 78.5% had one or 2 mutation-bearing chromosomes. The most prevalent mutation was V726A, followed by M680I, M694V, and M694I. No significant difference in phenotypic characteristics was found between the patients with the diverse mutations. The total carrier frequency for the 4 mutations was 10.4% (95% confidence interval 0.07 to 0.137).

**CONCLUSION:** A high FMF gene frequency was found among an Israeli-Moslem Arab population. Among the FMF patients from this ethnic group, several mutations were detected, none of which was found to correlate with a severe course of the disease.

[Hyperimmunoglobulinemia D and periodic fever syndrome. A phenotypical analysis of a Spanish family].

[Article in Spanish]

García-Díaz JD(1), Alvarez-Blanco MJ.

Author information:

(1)Servicio de Medicina Interna, Hospital Universitario Príncipe de Asturias, Universidad de Alcalá, Alcalá de Henares, Madrid. jgarciad@hupa.insalud.es

**BACKGROUND:** Hyperimmunoglobulinemia D and periodic fever syndrome (HIDS) is a disorder diagnosed with low frequency, that produces a very prolonged and recurrent fever with other symptoms and analytical markers of inflammation. Its origin seems to be hereditary with a recessive autosomic pattern, but its pathogenic mechanisms are unclear. The aim of this study is to analyse the clinical characteristics and serum levels of immunoglobulins a Spanish family with HIDS.

**METHODS:** We describe a young woman diagnosed with HIDS and investigate the other memberships of her family (parents and 5 brothers) by clinical interview, physical examination, hematological and biochemical analyses and measurements of IgG, IgA, IgM, IgE, IgD and the kappa/lambda ratio of light chains. Moreover, we also determine the IgD in a control group of 35 healthy blood donors.

**RESULTS:** One male brother of the index case also showed a clinical picture of HIDS. The serum IgD levels were increased (above 100 U/ml) in both and in other two sisters without symptoms and were normal in the rest of the family. With only one exception, all individuals of the control group showed a normal IgD level and this was not associated with sex or age. The other immunoglobulins were normal in the family. In spite of the different treatments tested in the index case, only glucocorticoids aborted her fever attacks.

**CONCLUSIONS:** In HIDS the clinical picture and the high IgD levels are both transmitted with a recessive autosomic pattern, but these are not necessarily associated in the same memberships of the family. Its diagnosis is difficult and there is not effective and long-term safe treatment.

Author information:

(1)Pediatric Emergency Unit, Soroka Medical Center, Beer-Sheva, Israel.

PRESS@BUGMAIL.BGU.AC.IL

Familial Mediterranean fever (FMF) is an autosomal recessive disease prevalent among non-Ashkenazi Jews, Armenians, Arabs, and Turks. The Bedouin are nomad Arab tribes residing in desert margins of the Middle East and Arabia. FMF is quite rare in Bedouins, and here we report on two Bedouin families from southern Israel suffering from this disorder. The MEFV mutations found in the Bedouin patients M694I, V726A, and E148Q are consistent with their Arab origin. The disease severity score showed a mild to moderate severity disease in six patients. The Bedouins, leading a unique nomadic life, may prove instrumental in unraveling the role of environmental factors in the course and severity of FMF.

dode@cochin.inserm.fr

Familial Mediterranean fever (FMF) is an autosomal recessively inherited disease affecting patients of the Mediterranean basin. FMF is characterized by recurrent episodes of fever accompanied with topical signs of inflammation. Some patients can develop a renal amyloidosis associated (AA) amyloidosis. The administration of colchicine is an effective preventive treatment of both the attacks and amyloidosis. The FMF gene (MEFV) was cloned and missense mutations were found to

be responsible for the disease. We investigated a large series of 303 unselected and unrelated patients of various ethnic backgrounds with a clinical suspicion of FMF to confirm or invalidate the diagnosis of FMF and to determine the spectrum of MEFV mutations. Molecular analysis focused on all the most frequent mutations identified so far, and an exhaustive analysis of exon 10, containing the mutational hotspot, was performed through DNA sequencing. Sixty-two percent of Sephardic, North African Arabs, Armenian and Turkish patients were either homozygous or compound heterozygous for MEFV mutations. In other populations surrounding the Mediterranean Sea such as Greek, Italian, Portuguese, Kurdish and Lebanese populations, mutations were also found. In general, patients without Mediterranean origin had no mutations in the MEFV gene. Two new mis-sense mutations were identified in exon 10 of the MEFV gene: the S675N in an Italian patient and the M680L in a French patient without any known at-risk ethnic ancestry.

Heart disease is the most prevalent cause of morbidity and mortality in rich countries. Multiple pathogens are epidemiologically linked to human heart disease, and autoinflammatory responses to heart-specific epitopes revealed to the host's immune system (e.g., due to the cytopathic effects of cardiotropic viruses) or attacked by autoaggressive lymphocytes activated by mimicking peptides present in bacteria may be causative in the pathogenesis of chronic inflammatory cardiomyopathy. The experimental system of murine chronic autoimmune myocarditis has been used to analyze aspects of the host immune response. This review presents insights gained by use of this murine model system into molecular

mechanisms governing activation of autoaggressive lymphocytes, target organ susceptibility, and cardiopathogenic epitope mapping and discusses mimicking endogenous epitopes found in pathogens.

Author information:

(1)Department of Radiology, Shaare Zedek Medical Center, Jerusalem, Israel.

**BACKGROUND:** The purpose of this study was to investigate the imaging findings in patients with familial Mediterranean fever (FMF) during and between acute attacks.

**METHODS:** Computerized search of medical records from 1989 to 1998 identified 139 patients with a discharge diagnosis of FMF. Medical records, imaging studies, and pathologic findings were reviewed.

**RESULTS:** Sixty-eight patients had a documented acute attack of FMF, and 71 patients known to have FMF were asymptomatic. Imaging was performed in 68 patients. Radiologic findings included ascites, splenomegaly, hepatomegaly, lymphadenopathy, focal peritonitis, peritoneal cysts, renal changes, and other

incidental findings.

**CONCLUSIONS:** Radiologic findings in symptomatic and asymptomatic FMF patients are not uncommon. Imaging in selected cases may facilitate diagnosis and show complications.

Author information:

(1)Arthritis and Rheumatism Branch, National Institute of Arthritis and Musculoskeletal and Skin Diseases, National Institutes of Health, Building 10, Room 9N-214, Bethesda, Maryland 20892-1820, USA.

Familial Mediterranean fever (FMF) is a recessive disorder characterized by episodes of fever with serositis or synovitis. Recently the FMF gene (MEFV) was cloned; the protein product, pyrin/marenostrin, is thought to regulate inflammation in myeloid cells. In this manuscript we report the mouse and rat homologs of MEFV. The murine gene contains ten exons with a coding sequence of 2304 bp, while the rat homolog has nine exons with a coding sequence of 2253 bp. A considerable amino acid sequence homology was observed between the mouse and human (47.6% identity and 65.5% similarity) and between the mouse and rat genes (73.5% identity and 82.1% similarity). The predicted rodent proteins have several important domains and signals found in human pyrin, including a B-box zinc finger domain, Robbins-Dingwall nuclear localization signal, and coiled-coil domain. However, perhaps because of an ancient frame-shift mutation, neither the mouse nor the rat protein has an intact C-terminal B30.2 domain, in which most FMF-associated mutations have been found in human MEFV. Nevertheless, like the human gene, mouse *Mefv* is expressed in peripheral blood granulocytes but not lymphocytes. Consistent with its expression in granulocytes, *Mefv* was detected at high levels in the primary follicles and marginal zones of the splenic white

pulp. Mefv is localized on mouse Chromosome (Chr) 16, region A3-B1, extending a region of synteny with human Chr 16p13.3. Development of knockout and knockin mouse models may provide further insights into the functional evolution of this gene.

Familial Mediterranean fever (FMF) is a recessive disorder characterized by episodes of fever and neutrophil-mediated serosal inflammation. We recently identified the gene causing FMF, designated MEFV, and found it to be expressed in mature neutrophils, suggesting that it functions as an inflammatory regulator. To facilitate our understanding of the normal function of MEFV, we extended our previous studies. MEFV messenger RNA was detected by reverse transcriptase-polymerase chain reaction in bone marrow leukocytes, with differential expression observed among cells by in situ hybridization. CD34 hematopoietic stem-cell cultures induced toward the granulocytic lineage expressed MEFV at the myelocyte stage, concurrently with lineage commitment. The prepromyelocytic cell line HL60 expressed MEFV only at granulocytic and monocytic differentiation. MEFV was also expressed in the monocytic cell lines U937 and THP-1. Among peripheral blood leukocytes, MEFV expression was detected in neutrophils, eosinophils, and to varying degrees, monocytes. Consistent with the tissue specificity of expression, complete sequencing and analysis of upstream regulatory regions of MEFV revealed homology to myeloid-specific promoters and to

more broadly expressed inflammatory promoter elements. In vitro stimulation of monocytes with the proinflammatory agents interferon (IFN) gamma, tumor necrosis factor, and lipopolysaccharide induced MEFV expression, whereas the antiinflammatory cytokines interleukin (IL) 4, IL-10, and transforming growth factor beta inhibited such expression. Induction by IFN-gamma occurred rapidly and was resistant to cycloheximide. IFN-alpha also induced MEFV expression. In granulocytes, MEFV was up-regulated by IFN-gamma and the combination of IFN-alpha and colchicine. These results refine understanding of MEFV by placing the gene in the myelomonocytic-specific proinflammatory pathway and identifying it as an IFN-gamma immediate early gene.

Behçet's disease in Familial Mediterranean fever: characterization of the association between the two diseases.

Schwartz T(1), Langevitz P, Zemer D, Gazit E, Pras M, Livneh A.

Author information:

(1)Heller Institute of Medical Research, Sheba Medical Center, Tel-Hashomer, Israel.

**OBJECTIVES:** Familial Mediterranean fever (FMF) is a genetic disease, characterized by attacks of fever and painful manifestations. Several vasculitides are more common in FMF than in the general population. The aim of the study was to define and characterize the association between FMF and Behcet's disease (BD), a form of vasculitis not previously related to FMF.

**METHODS:** We conducted a retrospective study in which FMF patients, also suffering from BD (FMF-BD), were recruited from about 4,000 patients registered in our clinic, using a computer survey. Patients identified by the screening process were examined, and those meeting the published criteria for the diagnoses of FMF and BD were classified as FMF-BD cases and compared with unselected FMF and BD controls.

**RESULTS:** The prevalence of BD was higher in FMF than in populations known to be rich in BD (eg, 16 per 4,000 in FMF compared with 1 per 104 in Japan,  $P < .001$ ).

FMF-BD cases and FMF or BD controls were comparable in most demographic, clinical, and laboratory aspects studied. However, more cases than FMF-controls were of Iraqi/Turkish origin and responded less favorably to colchicine. A higher proportion of cases than BD controls had skin, central nervous system, and gastrointestinal manifestations, originated from North Africa, and had family history of BD. In most cases, as in most respective controls, the severity of FMF was of intermediate grade and the extensiveness of BD was limited. The HLA B5 antigen was present in 53% of BD cases and 40% of BD controls.

CONCLUSIONS: BD should be included among the vasculitides complicating FMF. BD and FMF in patients with FMF-BD, and in patients suffering from each of these entities alone, are clinically and demographically comparable.

In a 45-year-old man who from early childhood had been suffering of periodic fever, which did not respond to any therapy attempted, the ultimate diagnosis was hyperimmunoglobulinaemia D syndrome (HIDS). HIDS attacks typically occur every 4-6 weeks and last 3-7 days. The most frequent symptoms are fever, diarrhoea, arthralgias, cold shivers, abdominal pain, vomiting and headache. Physical examination often reveals lymphadenopathy, skin lesions, arthritides, splenomegaly and serositis. Laboratory investigation includes an acute-phase response with granulocytosis and enhanced erythrocyte sedimentation rate. The serum concentration of IgD is increased as is the concentration of IgA. There is no causal therapy. A causative gene mutation was recently identified.

Comment on

Ned Tijdschr Geneeskd. 2000 Apr 22;144(17):809-11.

Hyperimmunoglobulinaemia D and periodic fever syndrome (HIDS) is a rare autosomal recessive disorder. Patients suffer from recurrent attacks (3-6 days) with fever,

abdominal distress, lymphadenopathy, skin lesions and arthralgias. Patients display a constantly elevated serum IgD which serves as a biological marker of the disease. Recently, the gene for HIDS was discovered by two independent groups using positional and functional cloning methods. One group used linkage analysis (positional cloning) and was able to locate the gene for HIDS on the long arm of chromosome 12 (12q24). Mevalonate kinase was an interesting candidate gene because patients with a near complete absence of this enzyme (mevalonic aciduria) do exhibit attacks of fever. Indeed subsequent data showed that there was a decreased enzyme activity due to missense mutations in the mevalonate kinase gene. The other group detected slightly elevated urinary excretion of mevalonic acid during attacks in a HIDS patient (functional cloning). The enzyme activity of mevalonate kinase was lower in cultured cells and sequence analysis identified several missense mutations in cDNA encoding for mevalonate kinase. Mevalonate kinase is a key enzyme in the cholesterol synthesis pathway and it is rather surprising that a defect in the cholesterol metabolism can cause a periodic inflammatory disease such as HIDS.

Familial Mediterranean fever: effects of genotype and ethnicity on inflammatory attacks and amyloidosis.

Mimouni A(1), Magal N, Stoffman N, Shohat T, Minasian A, Krasnov M, Halpern GJ, Rotter JI, Fischel-Ghodsian N, Danon YL, Shohat M.

Author information:

(1)Department of Medical Genetics, FMRC and Beilinson Campus, Rabin Medical Center and Sackler School of Medicine, Tel Aviv University, Tel Aviv, Israel.

**OBJECTIVE:** The gene causing familial Mediterranean fever (FMF)-an autosomal recessive disease characterized by recurrent short episodes of fever associated most commonly with peritonitis, pleuritis, and arthritis-has recently been found and several mutations identified. The most severe complication of the disease is amyloidosis, which can lead to renal failure. The aim of this study was to investigate the role of genetic versus nongenetic factors on the phenotype as

well as on the development of amyloidosis in FMF in a large and heterogeneous group of patients.

**METHODOLOGY:** We studied 382 patients from 4 ethnic origins living in different environments: North African Jews, other Jews, Turks, Armenians living in the United States, and Armenians from Yerevan, Armenia. Information regarding amyloidosis was available for 371 patients. We examined the association between the mutation M694V and the development of amyloidosis, and we also compared the clinical characteristics of the inflammatory attacks in patients from different ethnic origins, while controlling for the type of mutation.

**RESULTS:** A significant association was found between amyloidosis and the most common mutation in exon 10 of the FMF gene (MEFV), M694V (for M694V homozygotes, relative risk = 1.77; 95% CI = 1.16-2.71). Amyloidosis was present in 44 of 171 homozygous FMF patients (25.7%), in 22 of 143 compound heterozygous FMF patients (15.4%), and in 7 of 57 patients carrying other mutations (12.3%). In homozygotes for M694V who had not been treated with colchicine before 20 years of age, the risk of amyloidosis developing before this age was 61.0%. In our series, there were no cases of amyloidosis in 16 patients carrying the common mutation E148Q. We found that the type and severity of the FMF inflammatory symptoms were associated with both the genotype and the country of residence of the patient.

**CONCLUSIONS:** In the light of the high frequency of amyloidosis in homozygotes for the mutation M694V, colchicine treatment should be given to this group irrespective of the severity of the inflammatory attacks to prevent the development of amyloidosis. Our findings also suggest that factors other than genotype, such as environment or genes other than MEFV, play a role in the determination of the severity of the inflammatory attacks in FMF. amyloidosis, specific mutation, phenotype-genotype correlation, ethnicity.

The diagnosis of familial Mediterranean fever (FMF) has until recently been based on clinical signs alone. Discovery of the MEFV gene has enabled a molecular approach to diagnosis, which is already well established for diagnosing typical clinical forms of FMF. We evaluated the utility of this molecular approach in a large series of patients with various clinical presentations and ethnic origins. We looked for mutations in the MEFV gene in 303 unselected consecutive patients with a variable (from high to low) clinical suspicion of FMF. Two mutations were found in 133 patients (44%). In 22 patients (7%), the clinical diagnosis of FMF was unlikely according to the Tel Hashomer clinical criteria. Our results suggest that the spectrum of FMF-associated signs is broader than previously believed. Wider indications for genotyping should lead to more frequent diagnosis of FMF.

Familial Mediterranean fever (FMF) is classically an autosomal recessive periodic inflammatory disease occurring in Mediterranean and Middle Eastern populations. It is caused by mutations affecting both alleles of MEFV, a gene that encodes pyrin (marennostin), an uncharacterized neutrophil protein. Occasional reports of autosomal dominant FMF have often been discounted, on the basis that asymptomatic FMF carriers are common in certain populations, and give rise to pseudo-dominant inheritance. We performed comprehensive MEFV genotyping in five families in whom FMF appeared to be inherited dominantly. Transmission proved to be

pseudo-dominant in two cases, but true dominant inheritance of FMF with variable penetrance was supported by the genotyping results in the other three families. The disease in these cases was associated with heterozygosity for either pyrin DeltaM694 alone or the compound pyrin variant E148Q/M694I, the latter occurring in two unrelated families. Complete MEFV sequencing failed to identify any coding region abnormality in the other allele in any of these cases, and, in the largest kindred, single-allele disease transmission was further supported by analysis of silent single nucleotide polymorphisms, which proved that affected individuals had at least three different complementary alleles. Studies of two further unrelated British patients with FMF associated with simple heterozygosity for pyrin DeltaM694 were also consistent with autosomal dominant inheritance. The clinical features of dominantly inherited FMF were absolutely typical, including AA amyloidosis in a patient with pyrin DeltaM694. These findings extend the spectrum of FMF, and suggest that the methionine residue at position 694 makes a crucial contribution to pyrin's function, and that a 50% complement of normal pyrin activity does not prevent susceptibility to FMF.

The biological function of pyrin, the protein mutated in Familial Mediterranean Fever (FMF), has not been elucidated. Based on sequence homology, a transcription factor activity was proposed for this neutrophil-specific protein. In a yeast two-hybrid assay, neither transcription activation activity nor any self interaction was detected for pyrin. Screening of an expression cDNA library of

peripheral blood leukocytes using as bait the carboxyl portion of pyrin (amino acids 557-781), which contains most of the FMF mutations, led to the identification of P/M-IP1 (pyrin/marenostrin interacting protein 1). A splice variant of P/M-IP1, GTC-90, had previously been described as a component of the 13S hetero-oligomeric protein complex that stimulates in vitro Golgi transport. We have now shown that P/M-IP1 colocalizes with pyrin in the perinuclear cytoplasm of Cos-7 cells and that the interaction between these two proteins is impaired by FMF causing mutations in pyrin. These data suggest that, at some stage of its functional pathway, pyrin resides in the cytoplasm and might be involved in, or impacted by, cellular protein sorting by the Golgi apparatus. The data also imply that P/M-IP1 may be involved in the abnormal inflammatory response that occurs in patients with FMF.

# Erysipelas-like erythema of familial Mediterranean fever: clinicopathologic correlation.

Barzilai A(1), Langevitz P, Goldberg I, Kopolovic J, Livneh A, Pras M, Trau H.

Author information:

(1)Department of Dermatology, Sheba Medical Center, Tel Hashomer, Israel.

**BACKGROUND:** Familial Mediterranean fever (FMF) is an autosomal recessive disease that tends to affect certain ethnic groups. It is characterized by recurrent, self-limited attacks of peritonitis, pleuritis, and synovitis. Erysipelas-like erythema (ELE) is the pathognomonic skin manifestation. Lesions are characterized by tender erythematous plaques, usually located on the lower legs. They may be triggered by physical effort and subside spontaneously within 48 to 72 hours of bed rest. Fever and leukocytosis may accompany this condition.

**OBJECTIVE:** The purpose of this study was to describe the histology and the immunofluorescence findings in ELE and to discuss these observations in relation to the clinical findings in FMF.

**METHODS:** We studied 7 patients with FMF in whom ELE developed. In all patients a biopsy was performed within 18 hours from onset of the lesion. In addition to routine hematoxylin and eosin stains, immunohistochemistry to evaluate the infiltrate and direct immunofluorescence were performed. Patients were followed up for their ELE lesions.

**RESULTS:** Histologic examination revealed edema of the superficial dermis and sparse perivascular infiltrate composed of a few lymphocytes, neutrophils, and nuclear dust. Vasculitis was not observed. Direct immunofluorescence showed, in all cases, deposits of C3 in the wall of the small vessels of the superficial vascular plexus. In some cases fibrinogen and IgM were also observed.

**CONCLUSION:** These findings are in accordance both with those found previously in the erysipelas-like phenomenon and those in the peritoneum of patients with FMF. The sparse infiltrate and the deposition of C3 also are compatible with the clinical picture of self-resolving lesions of short duration. It also suggests that erysipelas-like erythema belongs to the spectrum of neutrophilic dermatoses and supports a pathogenesis that involves abnormal inhibition of the inflammatory cascade.

Sacroiliitis in familial Mediterranean fever: an unusual presentation in childhood.

Beşbaş N(1), Ozdemir S, Saatçi I, Bakkaloğlu A, Ozen S, Saatçi U.

Author information:

(1)Department of Pediatrics, Hacettepe University Faculty of Medicine, Ankara.

Familial Mediterranean fever (FMF) is an autosomal recessively transmitted disease characterized by attacks of fever and serositis. The course of arthritis, which is a common manifestation of FMF, is generally benign. Sacroiliitis due to FMF has been reported by several authors, but all the patients described so far had roentgenographic abnormalities, and most of them were adult cases. Here we report the youngest FMF patient with sacroiliitis without any abnormality on sacroiliac x-ray. She is also the first FMF patient in whom sacroiliac involvement was diagnosed by computed tomography (CT) in childhood. It is concluded that CT is a useful technique for the early diagnosis of destructive arthritis in FMF patients even in early childhood.

[Treatments for amyloidosis beyond symptomatic care].

[Article in French]

Lebrazi H(1), Hachulla E, Saïle R.

Author information:

(1)Laboratoire de biochimie, faculté des sciences Ben M'sik, Casablanca, Maroc.

**INTRODUCTION:** Amyloid syndromes are pathogenetically different, each of the various amyloid diseases requiring specific treatment. Unfortunately, those treatments are often preventive and symptomatic, some efficient therapies being limited to particular types of amyloidosis.

**CURRENT KNOWLEDGE AND KEY POINTS:** Colchicine is effective in the prevention of amyloidosis due to familial Mediterranean fever but is less or not effective in other situations. Cytotoxic agents are useful in the treatment of AL amyloidosis with or without hemopoietic stem cell transplantation. Liver transplantation is indicated for familial polyneuropathy and kidney transplantation for dialysis-related beta 2 microglobulin amyloidosis.

**FUTURE PROSPECTS AND PROJECTS:** In vivo binding of serum amyloid P (SAP) (component shared by all amyloid deposits) to amyloid fibril, is a new avenue in the therapeutic approach. Development of radiolabeled SAP scintigraphy allows assessment of the disease outcome and evaluation of treatment-related effects. The various treatments that were assessed until now with the objective of curing the disease are reviewed.

The E148Q mutation in the MEFV gene: is it a disease-causing mutation or a sequence variant?

Ben-Chetrit E(1), Lerer I, Malamud E, Domingo C, Abeliovich D.

Author information:

(1)Department of Medicine A, Hadassah Hebrew University, Jerusalem, Israel.

Familial Mediterranean fever (FMF) is an autosomal recessive disease characterized by recurrent attacks of serositis. To date more than 18 mutations responsible for the disease were identified in the MEFV gene, one such a mutation is E148Q in exon 2 of the gene. While screening FMF patients for mutations in the MEFV gene, we have identified 2 individuals parents of 2 unrelated FMF patients, who were homozygous for E148Q mutation. Upon clinical examination they were absolutely disease free and therefore raised the possibility that this mutation is a benign polymorphism rather than a mutation causing disease. To further investigate the role of the E148Q in FMF we analyzed 25 parents of FMF patients and a control group of 70 individuals, Jews of Moroccan extraction to match for ethnicity of the patients. The rate of E148Q in the control group was 6.4%, being 7.8% among the patient group. Among the parents group (obligatory carriers), in addition to the 2 parents that were homozygous E148Q, in 2 families one of the parents was heterozygote for E148Q but transmitted the other allele (apparently with unknown FMF mutation) to the affected child. Two healthy sibs of one of the E148Q homozygous were also homozygous E148Q. These observations are not in accordance to the notion that E148Q is a mutation causing disease.

Author information:

(1)Unité de Génétique Médicale, Faculté de Médecine, Université Saint-Joseph, Beirut, Lebanon.

Familial Mediterranean fever is an autosomal recessive disorder characterised by

episodic fever, abdominal and pleuritic pain, serositis and arthritis. The FMF gene (MEFV) has been mapped to chromosome 16p13.3 and generates a protein found exclusively in granulocytes. Seventeen mutations have been reported up to the present in FMF patients. This study involves the screening of 14 mutations in 42 Jordanian patients by two methods: RFLP and ARMS. The most frequent mutations were M694V and V726A (20% and 14% of the alleles respectively), followed by M680I and E148Q (9.5% and 7% of the alleles respectively). The A744S mutation accounts for 2.5% and the M694I, T267I and F479L mutations account each for 1% of the alleles. E167D, R761H, P369S, I692del and M694del mutations were not found in this population. Forty-four percent of the alleles did not have any of the 14 mutations. The results show the diversity and the frequency of the mutations in the Jordanian patients, and open the way for further investigations on patients diagnosed to have FMF and in whom no mutations were found. Author information:

(1)Department of Pediatrics, Hacettepe University Faculty of Medicine, Ankara, Turkey.

Comment in

Turk J Pediatr. 2001 Apr-Jun;43(2):180.

Cyclic neutropenia is a rare disease characterized by regular cyclic fluctuations in the numbers of neutrophils. Patients with the disease suffer from recurrent infections at regular intervals of nearly three weeks. Recently, recombinant human granulocyte colony-stimulating factor (rhG-CSF) was reported to be an effective treatment for this disease. here we describe 17-year-old cyclic

neutropenic female patient with a very rare association of renal amyloidosis of AA type who was under intermittent rhG-CSF treatment for the previous one and a half years. We conclude that although the disorder is usually benign, reactive amyloidosis may rarely develop in cases who remain untreated for a long period of time. However familial Mediterranean fever (FMF) type II should also be born in mind, particularly in predisposed populations.

Living with a child with familial Mediterranean fever: does it affect the quality of life of the parents?

Press J(1), Neumann L, Abu-Shakra M, Bolotin A, Buskila D.

Author information:

(1)Department of Pediatrics, Soroka Medical Center, Ben-Gurion University of the Negev, Beer-Sheva, Israel.

OBJECTIVE: The aim of the present study was to assess the quality of life (QOL) and the psychological status of parents of children with familial Mediterranean

fever (FMF).

**METHODS:** The QOL, anxiety and depression of the parents of 35 children with FMF were evaluated and compared to the parents of 23 healthy children.

**RESULTS:** Mothers of FMF children had lower QOL scores than mothers of healthy children: 5.5 +/- 1.1 versus 6.0 +/- 0.6 ( $p = 0.048$ ). They also expressed higher levels of anxiety and depression. Within each group, mothers were more anxious and depressed than fathers. Parents with several FMF children were not significantly different from parents with only one FMF child.

**CONCLUSION:** The QOL and psychological well being of parents with FMF children were found to be slightly impaired, especially that of the mothers.

Familial Mediterranean Fever (FMF) is an autosomal recessive disease characterized by recurrent self-limited attacks of fever accompanied by peritonitis, pleuritis and arthritis. Approximately 5% of individuals with FMF have been reported to have Henoch-Schönlein purpura (HSP) and about 1% have polyarteritis nodosa (PAN). Protracted febrile myalgia is another vasculitis-associated clinical entity among patients with FMF. Recently, the gene responsible for FMF, MEFV, has been cloned and four missense mutations (M680I, M694V, V726A and M694I) have been described. In this report, we present clinical and laboratory findings and mutation results of 23 children with FMF-associated vasculitis. HSP, PAN and protracted febrile attacks have been diagnosed in 11, 2 and 10 children, respectively. Mutation analysis shows that 3 children are homozygotes for the M694V mutation and 11 are compound heterozygotes for 2 of the studied mutations. M694V/V726A mutations were identified in 8, M694V/M694I in 2

and M680I/M694V in 1 of these children. In six children only one mutation was found and in three none of the studied mutations were identified. This study confirms that most children with FMF-associated vasculitis have identifiable mutations in the MEFV gene. Environmental and/or other genetic factors are possibly involved in the pathogenesis of vasculitis in FMF; elucidation of these mechanisms will help to understand pathogenesis of childhood vasculitides.

[Clinical or biological symptoms leading to the search for amyloidosis].

[Article in French]

Rousset H(1), Sauron C, Barouky R.

Author information:

(1)Service de Médecine Interne, Centre Hospitalier Lyon-Sud, Pierre-Bénite, France.

**INTRODUCTION:** The extracellular, multifocal, disseminated or diffuse localization of amyloidosis accounts for the diversity of clinical presentations and late diagnosis.

**CURRENT KNOWLEDGE AND KEY POINTS:** However, early diagnosis is important, as new drugs have been recently introduced. Both clinical picture and biology help guide diagnosis, including either kidney, heart, skin or neurologic involvement associated with monoclonal gammopathy (primary idiopathic amyloidosis AL); underlying inflammatory or infectious disease, familial Mediterranean fever with proteinuria (secondary amyloidosis AA); cardiac, neurologic or ocular involvement (heredofamilial amyloidosis); carpal tunnel syndrome, joint pain (amyloidosis of hemodialysis). Furthermore, amyloid fibrils are identified on salivary gland biopsy.

**FUTURE PROSPECTS AND PROJECTS:** Due to the introduction of new specific drugs aimed at curing various amyloidoses, early diagnosis is important. Chemotherapy and hematopoietic stem cell transplantation are promising regarding AL amyloidosis, while liver transplantation has proven remarkably successful in

heredofamilial amyloidosis. Progress in molecular biology should allow identification of various forms of familial amyloidosis.

Chloroquine and colchicine, widely used in internal medicine practice for a variety of inflammatory diseases including systemic lupus erythematosus, rheumatoid arthritis, familial Mediterranean fever, and Behçet's disease, may induce neuromuscular complications. Physicians must be familiar with this diagnosis as this iatrogenic neuromuscular pathology may simulate polymyositis, leading thus to inappropriate treatment with prednisone whereas the only effective treatment is to discontinue the drug involved whenever possible. We report three cases of toxic myopathy and/or neuropathy related to chronic chloroquine or colchicine therapy for systemic diseases, and outline the main points to be considered in this situation.

Familial Mediterranean fever (FMF) is a recessively inherited disorder characterized by recurrent, self-limited attacks of fever and serositis and by infiltration of affected tissues by large numbers of neutrophils. A candidate gene for FMF was identified by positional cloning and named "MEFV." The corresponding protein was named "pyrin." To elucidate the currently unknown function of pyrin, we characterized its tissue distribution, regulation of expression during hematopoietic differentiation, and subcellular localization. Reverse transcription-polymerase chain reaction analysis, followed by hybridization with an internal oligonucleotide, demonstrated expression of MEFV in different populations of peripheral blood cells. Among hematopoietic cell lines, MEFV was almost exclusively expressed in cells of the myeloid lineage. Furthermore, MEFV messenger RNA was strongly expressed within 24 hours of dimethyl sulfoxide-induced granulocytic differentiation of HL-60 cells. Analysis of complementary DNA from human solid tumor-derived cell lines revealed expression of MEFV in several cell lines derived from colon and prostate cancers. Expression of MEFV fused to enhanced green fluorescent protein showed that pyrin localized in distinct patches in the cytoplasm, forming a perinuclear cap. Taken together, MEFV is predominantly expressed in myeloid cells and upregulated during myeloid differentiation, and the corresponding protein, pyrin, is expressed in the cytoplasm. Author information:

(1)Department of Pediatrics, Faculty of Medicine, University of Jordan, Amman, Jordan.

Over a period of 7 years, among 175 boys under the age of 16 years with familial Mediterranean fever (FMF), 16 (9%) developed 28 episodes of scrotal swelling that was unilateral in 26 (93%) and bilateral in 2 (7%). Fever and pain were present in 15 (94%) children; fever was characterized by a gradual onset and pain was moderate in intensity. The episodes were self-limiting and lasted from 8 h to 5 days. Scrotal swelling was the presenting feature of FMF in 4 (25%) patients. Six (38%) children underwent surgery; the operative findings, available in 3, showed a normal testis and epididymis and inflammation of the tunica vaginalis. The self-limiting nature of the episodes lasting for a few days was similar to the clinical course of serositis seen in FMF. This strongly suggests that inflammation of the tunica vaginalis, resulting in scrotal swelling, is another feature of FMF serositis. The gradual onset of fever, pain, swelling, and recurrence in a boy of Mediterranean origin, especially in the presence of a relevant family history, strongly points toward the diagnosis of FMF and conservative management. Early diagnosis and prophylactic colchicine therapy are expected to avert recurrences, which may result in ischemic testicular necrosis and FMF nephropathy.

Erratum in

Rheumatology (Oxford) 2000 Oct;39(10):1170.

**OBJECTIVES:** Differences in clinical manifestations of familial Mediterranean fever (FMF) between different ethnic groups have been documented. The FMF gene was recently cloned and four missense mutations (Met694Val, Met680Ile, Val726Ala, and Met694Ile) that account for a large percentage of the patients were identified. The results of initial mutation studies have led to the hypothesis that phenotypic variation of the disease may be attributable to the existence of some of these mutations. The purpose of this study was to evaluate whether this phenotypic variation is associated with the existence of particular mutations in Turkish FMF patients living in Turkey.

**METHODS:** Four missense mutations and genotype-phenotype correlation were investigated in 167 Turkish FMF patients. The patients were grouped according to the presence of the Met694Val and the Met680Ile mutations, and 12 clinical parameters were compared between the groups.

**RESULTS:** The presence of the Met694Val mutation was not found to be associated with a severe form of the disease or the development of amyloidosis. Arthritis frequency was found to be lower in the patients with homozygous Met680Ile mutation.

**CONCLUSIONS:** None of the four missense mutations is associated with a severe disease or the development of amyloidosis in Turkish FMF patients living in Turkey. The influence of unknown environmental factors and/or the presence of other genetic changes are necessary to explain the phenotypic variation of the

disease and the development of amyloidosis.

Familial Mediterranean fever (FMF) is an inherited disorder characterized by recurrent attacks of fever and abdominal, chest, and articular pain. The articular attack of FMF is typically an acute, self-limited, large joint monoarthritis most often affecting the knee or hip. Rarely, a more protracted arthritis may occur. We describe two unusual cases of long-standing FMF arthritis with excellent response to synovectomy.

A 14-year-old girl with familial Mediterranean fever (FMF) had had acute attacks of fever, abdominal pain, and arthritis for 4 years. Her last arthritis attack was protracted, leading to reflex sympathetic dystrophy (RSD) in her right lower extremity. Physical therapy along with sympathetic ganglion block and corticosteroid therapy was used for the treatment. To our knowledge, this is the first reported case of RSD arising in a patient with FMF. Early recognition of RSD in FMF patients is important, and physical therapy should be applied along with medical treatment.

The relation between familial Mediterranean fever and amyloidosis.

Grateau G(1).

Author information:

(1)Service de médecine interne, L'Hôtel-Dieu, Paris, France.

Familial Mediterranean fever (FMF) is the most prevalent type of hereditary recurrent fever. Although the inflammatory attacks that characterize the disease may sometimes be debilitating, reactive amyloidosis remains the most serious manifestation of FMF. Daily treatment with colchicine can prevent both the attacks and amyloid deposition, but FMF-associated amyloidosis has not been eradicated and is still a cause of chronic renal failure in children and adults. The discovery of the gene responsible for FMF, Mediterranean fever gene (MEFV), and of associated mutations represents a major advance that now allows researchers to establish a strong, although nonexclusive association between one specific mutation, M694V, and the amyloid phenotype.

**HISTORY AND CLINICAL PRESENTATION:** Three young Turkish males were admitted because of acute abdominal pain and fever. All 3 patients had recurrent attacks of these symptoms every few weeks since years with each attack lasting 2 to 3 days. One patient developed a renal amyloidosis with an end-stage renal failure.

**DIAGNOSTICS AND CLINICAL COURSE:** All patients presented with local abdominal tenderness and an elevation of inflammatory parameters (WBC, ESR, CRP and fibrinogen). X-ray studies, ultrasound and upper endoscopy were normal. In 1 patient histology yielded amyloid fibrils in the antrum of the stomach. In a molecular genetic analysis 2 patients were compound heterozygous for 2 common mutations of the gene responsible for the familial Mediterranean fever (FMF). In all patients the symptoms vanished spontaneously according to an acute attack of FMF. After symptomatic treatment a prophylaxis with colchicine was started.

**CONCLUSION:** Cloning of the FMF gene and its mutations and identification of the gene product "pyrin" reveals new aspects on genetics and pathophysiology. The improved diagnostic procedure enables an early start of colchicine treatment, especially to prevent renal amyloidosis.

(1)Ankara University School of Medicine, Turkey. mtekin@hsc.vcu.edu

The frequency of acute rheumatic fever (ARF) in patients with familial Mediterranean fever (FMF) was documented and the effects of preceding streptococcal infections on the exacerbation of FMF were determined. In the first part of the study, 162 individuals with FMF were investigated for a history of ARF in a retrospective study. In the second part of the study, antistreptolysin-O (ASO) titres were measured in 130 individuals with FMF. Thirty-six patients had an arthritic attack (group A1), 55 patients had a typical FMF attack without arthritis (group A2) and 39 patients were in the attack-free interval (group B) during the investigation. Nine patients with FMF (5.5%) were considered to have ARF and three of them (1.85%) also had rheumatic heart disease. This prevalence of rheumatic heart disease in FMF is higher than that of the normal population (0.65%) reported in Turkey. Elevated ASO titres were found in 75%, 42% and 38% of

the patients in groups A1, A2 and B, respectively. These percentages were found to be significantly higher in group A1 than in both groups A2 ( $p<0.01$ ) and B ( $p<0.01$ ). We concluded that patients with FMF might be more prone to the late complications of streptococcal infections.

Erratum in

QJM 1999 Sep;92(9):545.

The clinical picture of familial Mediterranean fever (FMF) has been appreciably expanded in the last 10 years. Over 8 years, we studied the expanded clinical profile of FMF in 476 children. Of these, 81% had abdominal pain, 41% chest pain, 42% arthritis, 12% severe myalgia, 12% skin manifestations, 4% scrotal swelling, 3% recurrent episodic fever, and one child (0.2%) developed recurrent hyperbilirubinaemia. Two (0.4%) children developed renal complications which were reversed by colchicine; however of 19 probands, 36 family members suffered from chronic renal failure. Our study indicates a familial predisposition to nephropathy in certain families with FMF. This study is the first to report the expanded clinical profile of FMF in a large group of Arab children, giving an opportunity to compare the findings with those in children with FMF in other ethnic groups, and to help in the study of genotype-phenotype correlation.

Familial Mediterranean fever (FMF) is a recessive inherited disorder affecting Sephardic Jews, Arabs, Armenians and Turks. The gene responsible for FMF was recently cloned and several disease-associated mutations have been described. We have evaluated seven MEFV mutations in 460 chromosomes of 230 unrelated patients with FMF living in Turkey, using PCR methods. The M694V allele accounted for 43.5% of the alleles studied and 19.1% of the patients were homozygous. The M680I, V726A and M694I mutations were responsible for 12.0%, 11.1% and 2.8% of the patients respectively. R761H, K695R and E148Q were rarely encountered. Two thirds of the disease alleles were attributed to three common mutations: M694V, M680V and V726A, but only 54% of the patients carried one or two of the three mutations. Adding the four rarer mutations increased these figures to 72% and 60%, respectively. Altogether, 79.6% of the patients bore at least one of the main mutations, and 84.3% carried at least one of the seven mutations studied. The 28 patients suffering also from amyloidosis carried at least one of five mutations, M694V being the most common. These results suggest that the origin of FMF in Turkey is heterogenous, all common mutations are associated with

amyloidosis. Further, rapid and accurate molecular diagnosis of FMF is feasible in most cases.

New interest in an old disease: familial Mediterranean fever.

Ozen S(1).

Author information:

(1)Department of Pediatrics, Hacettepe University Faculty of Medicine, Ankara, Turkey. sozen@gen.hun.edu.tr

Familial Mediterranean fever (FMF) is characterized by recurrent attacks of fever and serositis. Identifying the mutated gene has shed light on the pathogenesis of the disease. Typical attacks of FMF last 3 to 5 days. Arthritis is present in almost half of all patients and is localized to the ankle, knee or hip. Recently vasculitic features have been increasingly reported in FMF patients, and it may be speculated that vasculitis constitutes a feature of this disease. Genetic

analysis is very important to confirm the diagnosis in patients with a European ancestry. However, at present the yield of genetic testing is not satisfactory; new sequencing techniques permitting more rapid screening and definition of all mutations are necessary. Colchicine is the drug of choice. A trial of colchicine may also help in the differential diagnosis with other periodic fever syndromes.

The Roman Jewish community has been historically continuous in Rome since pre-Christian times and may have been progenitor to the Ashkenazi Jewish community. Despite a history of endogamy over the past 2000 yr, the historical record suggests that there was admixture with Ashkenazi and Sephardic Jews during the Middle Ages. To determine whether Roman and Ashkenazi Jews shared common signature mutations, we tested a group of 107 Roman Jews, representing 176 haploid sets of chromosomes. No mutations were found for Bloom syndrome, BRCA1, BRCA2, Canavan disease, Fanconi anemia complementation group C, or Tay-Sachs disease. Two unrelated individuals were positive for the 3849 + 10C->T cystic fibrosis mutation; one carried the N370S Gaucher disease mutation, and one carried the connexin 26 167delT mutation. Each of these was shown to be associated with the same haplotype of tightly linked microsatellite markers as that found among Ashkenazi Jews. In addition, 14 individuals had mutations in the familial Mediterranean fever gene and three unrelated individuals carried the factor XI type III mutation previously observed exclusively among Ashkenazi Jews. These findings suggest that the Gaucher, connexin 26, and familial Mediterranean fever mutations are over 2000 yr old, that the cystic fibrosis 3849 + 10kb C->T

and factor XI type III mutations had a common origin in Ashkenazi and Roman Jews, and that other mutations prevalent among Ashkenazi Jews are of more recent origin.

To determine the prevalence and characterize demographic, clinical, and genetic features of familial Mediterranean fever (FMF) of late onset, all patients experiencing their first FMF attack at age 40 years or more were identified using the computerized registry of our FMF clinic, and then thoroughly interviewed and examined. The control group consisted of 40 consecutive FMF patients, who arrived at the FMF clinic for their regular follow-up visit and were 40 years of age or older at the time of the examination. The severity of the disease in patients and controls was determined using a modified score, developed previously. Mutational analysis in the FMF gene was performed using a commercial kit. Only 20 of 4000 (0.5%) patients had late-onset FMF. These patients were mostly men, of non-North African origin,  $P < 0.05$  compared to controls. All had abdominal attacks and in most these were the only manifestation of their disease,  $P < 0.001$ . None had chronic or prolonged manifestations of FMF, for example, amyloidosis, chronic arthritis, or protracted myalgia,  $P < 0.001$ . The response to treatment was good despite using low colchicine dose,  $P < 0.05$ . The overall severity score indicated a mild disease,  $P < 0.001$ . Mutational analysis revealed absence of M694V homozygosity,  $P < 0.01$ , compared to our regular FMF population. We conclude that the onset of FMF in a late age defines a milder form of disease with typical clinical, demographic, and molecular genetic characteristics.

Vasculopathy, Behçet's syndrome, and familial Mediterranean fever.

Ozen S(1).

Author information:

(1)Department of Pediatric Rheumatology and Nephrology, Hacettepe University Faculty of Medicine, Ankara, Turkey. sozen@gen.hun.edu.tr

Within the past year information has accumulated on the role of infections in the pathogenesis of vasculitis. Superantigens play an important role in the stimulation of the immune system. Behçet's syndrome is a vasculitis that affects children as well as adults. Recently published childhood studies highlight the importance of family history and geographic differences in this disease. Familial Mediterranean fever is a genetic disease manifesting frequently in children.

Studies on the function of the mutated protein pyrin in this disease are in progress. Some researchers have proposed that pyrin is an anti-inflammatory protein. Understanding its mode of action will help us understand more of the general inflammatory pathway.

Serum soluble intercellular adhesion molecule 1 and interleukin 8 levels in familial Mediterranean fever.

Direskeneli H(1), Ozdogan H, Korkmaz C, Akoglu T, Yazici H.

Author information:

(1)Division of Rheumatology, Faculty of Medicine, Marmara University, Turkey.

**OBJECTIVE:** Familial Mediterranean fever (FMF) is a disease of unknown etiology characterized by recurrent attacks of polyserositis (peritonitis, pleuritis, and arthritis) and fever. We measured levels of soluble intercellular adhesion molecule 1 (sICAM-1) and interleukin 8 (IL-8), which are important mediators in leukocyte-endothelial adhesion and leukocyte accumulation in tissues.

**METHODS:** sICAM-1 and IL-8 levels were studied in 30 patients with FMF during attacks and remission, along with 23 healthy and 26 disease controls. sICAM-1 and IL-8 levels were measured with commercial ELISA systems.

**RESULTS:** Median levels of sICAM-1 were significantly elevated in patients with FMF during attacks (FMF-a) and remission periods (FMF-r) compared to healthy controls (HC) (FMF-a: 600 ng/ml, FMF-r: 520 ng/ml, HC: 353 ng/ml; FMF-a vs. HC:  $p < 0.0001$ , FMF-r vs. HC:  $p = 0.002$ ). IL-8 levels were also significantly elevated in FMF-a compared to HC (37 vs. 25 pg/ml;  $p = 0.009$ ), but not during remission (26 pg/ml;  $p = 0.7$ ). A significant correlation was observed between sICAM-1 and IL-8 levels ( $r = 0.33$ ,  $p = 0.01$ ). sICAM-1 levels also correlated significantly with erythrocyte sedimentation rate, C-reactive protein, and fibrinogen levels of patients with FMF.

**CONCLUSION:** Increased levels of sICAM-1 and IL-8 in FMF suggest that neutrophils are active with increased adhesion in FMF. Since increased levels of sICAM-1 are also observed during remission, subclinical disease activity and inflammation seem to be present in some patients.

Pulmonary associations in familial Mediterranean fever.

Livneh A(1), Langevitz P, Pras M.

Author information:

(1)Heller Institute of Medical Research, Sheba Medical Center, Tel-Hashomer, Israel.

Familial Mediterranean fever (FMF) is a hereditary periodic fever syndrome expressed by acute episodes of fever and painful manifestations. In this report,

the pulmonary manifestations of FMF are reviewed, the most prominent of which are chest attacks due to pleuritis. Nephropathic amyloidosis of the AA type, which complicates FMF in most untreated patients, may progress to affect other organs, including the lungs, but this rarely produces noticeable symptoms. The common association between FMF and vasculitis makes pulmonary hemorrhage, infarction, or infiltrates highly possible. These complications, however, have been reported only rarely. Asthma was found to occur less often than expected in patients with FMF, but methodologic faults make this finding doubtful. Finally, the occurrence of mesothelioma in five patients with FMF who were not exposed to asbestos suggests a role for recurrent FMF serositis in the pathogenesis of this malignancy.

The MEFV gene involved in familial Mediterranean fever was recently cloned and four distinct sequence alterations (M680I, M694V, M694I and V726A) were identified at the 3'-most exon. We genotyped 170 unrelated FMF patients from various ethnic groups in Israel and found that mutation M694V predominates in North African Jews, that mutation V726A is common in Jewish patients other than North African Jews and that all four mutations occur in patients of Arabian origin, namely, Moslems, Christians and Druze. Since these four distinct sequence alterations seem to account for the majority of mutations identified in FMF patients from the middle east, we have devised a simple protocol using PCR mediated site directed mutagenesis or naturally occurring recognition sites to scan for these mutations.

Familial Mediterranean Fever (FMF) is a recessive trait mainly affecting Jews, Turks and Arabs. FMF is characterized by recurrent episodes of painful serositis and fever leaving no sequelae. Involvement of the peritoneum is the most common clinical form. In 1997 the gene that causes FMF (MEFV-gene) was cloned, thus given clinicians an opportunity to diagnose the disease. We have established the method in our laboratory. We describe the first patient diagnosed with FMF in our department by this method.

Familial Mediterranean fever is a hereditary disease prevalent among populations in the Mediterranean area, characterized by sporadic episodes of acute inflammation primarily of the pleural, peritoneal and joint spaces. There is no diagnostic test for routine use. The disease is still uncommon in Norway, but we expect an increased incidence because of immigration. Due to the lack of pathognomonic features many patients undergo unnecessary explorative laparotomy before the diagnosis is established. In this report we present a patient with a

typical history of familial Mediterranean fever. To our knowledge this is the first case ever published in Norway. It is important to keep the disease in mind as a differential diagnosis in patients with recurrent fever and pain, as colchicine represent an efficient treatment in order to prevent both further attacks and secondary amyloidosis.

**OBJECTIVES:** To describe the presentation, clinical course, therapeutic response, and long-term follow-up of patients with a syndrome of periodic fever, aphthous stomatitis, pharyngitis, and cervical adenitis (PFAPA).

**STUDY DESIGN:** Patients with PFAPA (n = 94) referred over a 10-year period completed a registry form and provided medical records. Follow-up telephone calls were made in late 1997 to determine the persistence of episodes and sequelae.

**RESULTS:** PFAPA episodes lasted 4.8 days (95% confidence interval 4.5 to 5.1) and recurred every 28 days (confidence interval 26 to 30), with a maximal temperature of 40.5 degrees C (confidence interval 40. 4 degrees to 40.6 degrees ). Of the 83 children available for follow-up, 34 no longer had episodes. In the remainder the episodes did not differ in character but recurred less frequently over time. The affected children had no long-term sequelae. Glucocorticoids were highly effective in controlling symptoms. Tonsillectomy and cimetidine treatment were associated with remission in a small number of patients.

**CONCLUSIONS:** PFAPA is a not uncommon cause of periodic fever in children. In some children the syndrome resolves, whereas symptoms in others persist. Long-term

sequelae do not develop. The syndrome is easily diagnosed when regularly recurring episodes of fever are associated with aphthous stomatitis, pharyngitis, or cervical adenitis.

We report 28 patients (20 male) with a syndrome characterized by abrupt onset of fever, malaise, aphthous stomatitis, tonsillitis, pharyngitis, and cervical adenopathy (PFAPA syndrome). Episodes of fever occurred at intervals of  $5.1 \pm 1.3$  weeks beginning at the age of  $4.2 \pm 2.7$  years. Fever, malaise, tonsillitis with negative throat cultures, and cervical adenopathy were reported in all 28 patients, aphthae in 19, headache in 5, abdominal pain in 5, and arthralgia in 3. Mild hepatosplenomegaly was observed in 6 patients. Mild leukocytosis, elevation of the erythrocyte sedimentation rate, and fibrinogen were found during attacks. These episodes of illness resolved spontaneously in  $4.3 \pm 1.7$  days. Serum IgD was found elevated ( $>100$  U/mL) in 12 of the 18 patients tested ( $140.2 \pm 62.4$  U/mL). Affected children grow normally, have no associated diseases, and have no long-term sequelae. Attacks were aborted by a single dose of oral prednisone (2 mg/kg) at the beginning of the attack in all 15 patients in whom this medication was prescribed. In 9 patients the syndrome has completely resolved (beginning at

the age of 2.9 +/- 1.3 and lasting 8 +/- 2.5 years). In 3 other patients complete resolution of the attacks occurred after tonsillectomy was performed. PFAPA is sporadic, and no ethnic predilection was found. Increased awareness of the clinical syndrome has resulted in more frequent diagnosis and adequate treatment.

Hyperimmunoglobulinaemia D and periodic fever syndrome (HIDS; MIM 260920) is a rare, apparently monogenic, autosomal recessive disorder characterized by recurrent episodes of fever accompanied with lymphadenopathy, abdominal distress, joint involvement and skin lesions. All patients have high serum IgD values (>100 U/ml) and HIDS 'attacks' are associated with an intense acute phase reaction

whose exact pathophysiology remains obscure. Two other hereditary febrile disorders have been described. Familial Mediterranean fever (MIM 249100) is an autosomal recessive disorder affecting mostly populations from the Mediterranean basin and is caused by mutations in the gene MEFV (refs 5,6). Familial Hibernian fever (MIM 142680), also known as autosomal dominant familial recurrent fever, is caused by missense mutations in the gene encoding type I tumour necrosis factor receptor. Here we perform a genome-wide search to map the HIDS gene. Haplotype analysis placed the gene at 12q24 between D12S330 and D12S79. We identified the gene MVK, encoding mevalonate kinase (MK, ATP:mevalonate 5-phosphotransferase; EC 2.7.1.36), as a candidate gene. We characterized 3 missense mutations, a 92-bp loss stemming from a deletion or from exon skipping, and the absence of expression of one allele. Functional analysis demonstrated diminished MK activity in fibroblasts from HIDS patients. Our data establish MVK as the gene responsible for HIDS.

Author information:

(1)Service de Médecine Interne, Hôpital Cochin, Paris.

An 80-year-old man was admitted with recurrent asphyxiating pleurisy, first attributed to heart failure. During the recurrent episodes, the patient presented fever, signs of inflammation, no signs of heart failure, and subnormal cardiac function, prompting further investigations which disclosed that the patient was a homozygous carrier of the severe type of periodic disease mutation. The patient's age at symptom onset and the clinical features of this case of periodic disease are exceptional. These points emphasize the usefulness of available genetic tests in difficult diagnostic cases. It also reflects current difficulties in trying to establish correlations between genotype and phenotype in periodic disease.

Familial Mediterranean fever (FMF) is a recessively inherited disorder that is common in patients of Armenian ancestry. To date, its diagnosis, which can be made only retrospectively, is one of exclusion, based entirely on nonspecific clinical signs that result from serosal inflammation and that may lead to unnecessary surgery. Renal amyloidosis, prevented by colchicine, is the most severe complication of FMF, a disorder associated with mutations in the MEFV gene. To evaluate the diagnostic and prognostic value of MEFV-gene analysis, we investigated 90 Armenian FMF patients from 77 unrelated families that were not selected through genetic-linkage analysis. Eight mutations, one of which (R408Q) is new, were found to account for 93% of the 163 independent FMF alleles, with both FMF alleles identified in 89% of the patients. In several instances, family studies provided molecular evidence for pseudodominant transmission and incomplete penetrance of the disease phenotype. The M694V homozygous genotype was found to be associated with a higher prevalence of renal amyloidosis and arthritis, compared with other genotypes ( $P=.0002$  and  $P=.006$ , respectively). The demonstration of both the diagnostic and prognostic value of MEFV analysis and particular modes of inheritance should lead to new ways for management of FMF-including genetic counseling and therapeutic decisions in affected families.

Diagnosis of inflammatory non-infectious diseases with a neonatal onset is often retrospective. It may lead to aggressive and iatrogenic procedures. **PATIENT:** A 6-year-old boy was suffering, since birth, from recurrent febrile attacks including rashes, gastrointestinal manifestations and inflammatory joint involvement. This syndrome, partially improved with steroids, could have been of antenatal onset. Since the age of 4 years, the patient is considered as having hyper-IgD syndrome (HIDS).

**DISCUSSION:** HIDS must be distinguished from familial Mediterranean fever. Patients suffer from recurrent fever concomitant to inflammatory joint involvement, abdominal distress, skin lesions, swollen lymph nodes and hepatosplenomegaly (especially seen in children). All patients have high serum IgD (> 100 UI/mL) and IgA levels. Nevertheless, a high IgD level is not specific. Our case could also be part of the CINCA (chronic, infantile, neurological, cutaneous and articular) syndrome, which includes similar early manifestations associated with a constant neurological and frequent ophthalmological involvement and epiphyseal changes; to date, these last three manifestations are not present in our patient.

**CONCLUSION:** HIDS and CINCA syndrome are not known to be modified by any effective therapeutic agent. When presenting at birth, these inflammatory diseases must be considered as entities with a rarely described potential severity.

mshohat@ccsg.tau.ac.il

Familial Mediterranean fever (FMF) is an autosomal recessive disease characterised by recurrent attacks of inflammation of serosal membranes. Amyloidosis is the most severe complication of the disease. The aim of this study was to investigate the genotype-phenotype correlation and specifically the association between amyloidosis and the four common mutations in exon 10 of the gene causing FMF (MEFV) in a total of 83 FMF families from three ethnic groups: North African Jews, Armenians and Turks. A significant association was found between amyloidosis and the specific mutation at the MEFV gene: Met694Val (RR = 1.41, P = 0.02). Amyloidosis was present in 18 out of 87 homozygous FMF patients (20.7%) and in only two out of the 41 compound heterozygous FMF patients (4.9%). No patients carrying other mutations had amyloidosis. There was no significant association between the various mutations and the type or severity of the FMF symptoms. This finding underscores the importance of performing molecular studies on all suspect FMF patients. In addition to providing accurate diagnosis, these tests allow identification of presymptomatic genetically affected individuals, detection of carriers and assessment of the risk for amyloidosis in later life.

Activation of the cytokine network in familial Mediterranean fever.

Gang N(1), Drenth JP, Langevitz P, Zemer D, Brezniak N, Pras M, van der Meer JW, Livneh A.

Author information:

(1)Heller Institute of Medical Research and Department of Medicine, Sheba Medical Center, Tel-Hashomer, Israel.

**OBJECTIVE:** To elucidate the role of cytokines in the pathogenesis of familial Mediterranean fever (FMF), an inherited disease characterized by attacks of serosal membrane inflammation.

**METHODS:** Blood samples were obtained from patients with FMF during attacks and remission. The cytokine concentrations in plasma and in supernatants from whole blood stimulated by bacterial lipopolysaccharide (LPS) were determined.

**RESULTS:** There were 27 patients with FMF, of whom 8 were studied during attacks,

9 during remission and 10 during both attack and remission. FMF attacks did not affect levels of plasma tumor necrosis factor-alpha (TNF-alpha) or interleukin 1beta (IL-1beta). In contrast, compared to remission, FMF attacks were associated with significantly higher mean levels of plasma IL-6 [8.4 pg/ml, 95% confidence interval (CI) 7.8-8.9 in remission vs 59 pg/ml, CI 21.4-96.7 during attacks;  $p=0.0005$ ], sTNFr p55 (1.3 ng/ml, CI 1.2-1.4, vs 1.98 ng/ml, CI 1.6-2.3;  $p=0.005$ ), and sTNFr p75 (2.9 ng/ml, CI 2.5-3.3, vs 4.09 ng/ml, CI 3.2-4.9;  $p=0.0249$ ). The TNF-alpha, IL-1beta, and IL-6 content in supernatants derived from LPS stimulated blood cells was not modified by the attacks of FMF. Significant lower TNF-alpha release in LPS stimulated whole blood was detected in patients who were sampled in a later stage of the attacks ( $r=-0.54$ ,  $p=0.047$ ).

**CONCLUSION:** Our results suggest that the cytokine network is activated during attacks of FMF. IL-6 appears to play an important role in the evolution of FMF attacks. Whether TNF-alpha or IL-1beta has a function in initiating the attacks remains to be established.

(1)Unité de Néphrologie Pédiatrique, Service de Pédiatrie Multidisciplinaire, Hôpital d'Enfants de la Timone, Marseille, France. gpicon@aphml.ap-hm.fr

The hyperimmunoglobulinemia D syndrome (HIDS) is a well-defined entity resembling familial Mediterranean fever. HIDS is a systemic inflammatory disease associated with stimulation of T-cell-mediated immunity. These patients are at low risk for amyloidosis and are not known to develop nephropathy. We report a boy of Mediterranean ancestry who exhibited typical HIDS and end-stage renal failure. Kidney biopsy revealed pauci-immune crescentic glomerulonephritis (cGN). We hypothesized that the glomerular involvement was secondary to the cytokine network activation observed in HIDS. Thus, cGN should be considered as part of the syndrome, and kidney biopsy should be performed early in the course of the

renal disease in patients with HIDS.

Author information:

(1)Department of Pediatrics, Rambam Medical Center and Technion-Israel Institute of Technology Faculty of Medicine, Haifa, Israel. r\_brik@rambam.health.gov.il

**OBJECTIVE:** Familial Mediterranean fever (FMF) is an autosomal recessive hereditary disease which primarily affects non-Ashkenazi Jews, Armenians, Arabs, and Turks. The gene responsible for the disease (MEFV/FMF) has been recently identified. Four common mutations in exon 10 of the MEFV gene seem to account for 86% of the DNA variations identified in patients with FMF. We conducted a phenotype/genotype correlation study in a mixed population of Jewish and Arab children with FMF.

**STUDY DESIGN:** Seventy patients clinically diagnosed as having FMF underwent molecular genetic studies using polymerase chain reaction and restriction endonuclease digestion methods to detect the presence of the four mutations (M694V, M680I, V726A, M694I). We then correlated the presence of each mutation with ethnic origin, age of onset, clinical manifestations, disease severity, and

occurrence of amyloidosis.

**RESULTS:** The M694V mutation, which is predominant in non-Ashkenazi Jews, was found in 92% of our Jewish patients and in only 30% of the Arab patients. All four mutations were identified among 94% of the Arab patients, but with no particular prevalence for any one of them. The presence of a homozygous M694V mutation was significantly associated with a more severe form of the disease: the clinical onset of the disease manifested at an earlier age; the number of attacks per month was higher; the global assessment by the treating physician and the severity of pain scored higher; and arthritis was more frequent. Only patients with the M694V mutation had a family history of amyloidosis. No association was found between the type of mutation and the predominance of fever, abdominal pain, pleuritis, skin eruption, or response to colchicine in the clinical picture.

**CONCLUSIONS:** Homozygosity for the M694V mutation, predominant among North African Jews, is associated with a severe course and prognosis for FMF. This mutation is less common among Arabs and, when present, occurs almost only in heterozygous form. In Arab patients, the disease tends to run a milder course and seems to bear a better prognosis. The phenotype/genotype patterns that are evident from our study of a mixed series of Jewish and Arab children with FMF might provide a rational basis for counseling about the natural history of the disease and for clinical treatment of FMF patients and their families.

Comment in

Amyloid. 1999 Dec;6(4):301-2.

Familial Mediterranean fever (FMF) is a major cause of AA amyloidosis. Recently, the gene (MEFV) causing this disease was cloned and 16 disease associated mutations have been described. We have analyzed 178 FMF patients, 30 of whom also suffered from amyloidosis, for 4 mutations in MEFV. Mutations were identified in 29 of the FMF amyloidosis patients. 27 FMF amyloidosis patients were homozygous for M694V. One patient was found to be homozygous for both V726A and E148Q. In another patient E148Q and V726A were found on one allele, while V726A was found on the second allele. Amyloidosis was far more common among patients homozygous for M694V compared to patients with other mutations ( $P < 0.0001$ ). In 3 patients homozygous for M694V, amyloidosis was the sole manifestation of the disease.

Polyarteritis nodosa: a report from Israel.

Gur H(1), Tchakmakjian L, Eherenfeld M, Sidi Y.

Author information:

(1)Department of Medicine C, The Chaim Sheba Medical Center, Tel Hashomer, Israel.

**BACKGROUND:** The clinical manifestations and outcome of all adult patients with polyarteritis nodosa (PAN), allocated during a 15-year period in the largest medical center in Israel, were examined.

**METHODS:** A retrospective analysis of patients with PAN who fulfilled the American College of Rheumatology (ACR) 1990 Classification Criteria and were either biopsy- or angiography-proven.

**RESULTS:** Nine patients were included in the report. The clinical and laboratory manifestations were similar to those in previous studies. All patients were treated with combinations of cyclophosphamide and corticosteroids. There were two (22%) deaths, 2 and 5 months after initiation of treatment in patients who probably had microscopic polyangiitis (MPA) rather than classical PAN.

Considering the patients with a complete follow-up, 71% had a complete and long-term remission. Moreover, by exclusion of the two patients with probable MPA who died, all of the five patients with classical PAN were alive and well as of

this writing. Two patients (22%) had a long history, since childhood, of familial Mediterranean fever (FMF).

CONCLUSIONS: The clinical presentation and course of PAN in Israeli patients is comparable with reports elsewhere. However, a distinction should be made between PAN and MPA. The present report emphasizes the good long-term prognosis of patients with typical PAN who are treated adequately. In addition, a possible association of PAN with FMF in Israeli patients is suggested.

Familial Mediterranean fever. No role of Mycobacterium tuberculosis in ten patients.

Akcan Y(1), Tuncer S, Unal S, Sökmensuer C, Haznedaroglu CI, Arslan S.

Author information:

(1)Kültür Mah. Namik Kemal Sok. Pestemalci, Apt. No:8/5, 14310 Düzce / BOLU, Turkey. yakcan@hotmail.com.

BACKGROUND: Tuberculosis (TB) and Familial mediterranean fever (FMF) are two common diseases in our region, Turkey. Both share some properties in common: Both cause AA type amyloidosis and have association with some immunological abnormalities. Upon incidentally observing Mycobacterium tuberculosis in bone marrow biopsies of three patients with FMF in a previous study, we intended to elucidate this association prospectively.

MATERIAL AND METHODS: In this study, we examined prospectively 10 FMF patients, 5 male and 5 female, with a median duration of 31 years disease activity. All were under colchicine therapy. They had no sign of renal involvement. The bone marrow biopsies of these patients were examined for the presence of M. tuberculosis by Polymerase chain reaction (PCR), BACTEC culture and pathological stains.

Pathological examination was performed for the existence of granuloma and amyloid deposition by hematoxylin-eosin, Crystal Violet and Congo red stains.

RESULTS: The examination of all bone marrow specimens by the mentioned methods suggest that Mycobacterium tuberculosis has no role in the ethiopathogenesis of FMF. Although the patients had a positive family history of 60% for tuberculosis

and in 80% of them with positive tuberculin skin test.

CONCLUSIONS: We concluded that although there seemed to be a kind of association between both diseases, this relationship is not via the direct existence of bacteria itself. Considering high family history and skin test positivity, one should look for the presence of autoimmune mechanisms under this suspicious relationship between tuberculosis and FMF. Also, this is the first study examined the state of amyloidosis in the bone marrow at an earlier stage of FMF without overt renal findings.

Autosomal dominant periodic fever syndromes are characterized by unexplained episodes of fever and severe localized inflammation. In seven affected families, we found six different missense mutations of the 55 kDa tumor necrosis factor receptor (TNFR1), five of which disrupt conserved extracellular disulfide bonds. Soluble plasma TNFR1 levels in patients were approximately half normal.

Leukocytes bearing a C52F mutation showed increased membrane TNFR1 and reduced receptor cleavage following stimulation. We propose that the autoinflammatory phenotype results from impaired downregulation of membrane TNFR1 and diminished shedding of potentially antagonistic soluble receptor. TNFR1-associated periodic syndromes (TRAPS) establish an important class of mutations in TNF receptors. Detailed analysis of one such mutation suggests impaired cytokine receptor

clearance as a novel mechanism of disease.

Comment in

Am J Hum Genet. 1999 Apr;64(4):939-42.

Familial Mediterranean fever (FMF) is a recessive disorder characterized by episodes of fever with serositis or synovitis. The FMF gene (MEFV) was cloned recently, and four missense mutations were identified. Here we present data from non-Ashkenazi Jewish and Arab patients in whom we had not originally found mutations and from a new, more ethnically diverse panel. Among 90 symptomatic mutation-positive individuals, 11 mutations accounted for 79% of carrier chromosomes. Of the two mutations that are novel, one alters the same residue (680) as a previously known mutation, and the other (P369S) is located in exon 3. Consistent with another recent report, the E148Q mutation was observed in patients of several ethnicities and on multiple microsatellite haplotypes, but haplotype data indicate an ancestral relationships between non-Jewish Italian and Ashkenazi Jewish patients with FMF and other affected populations. Among approximately 200 anonymous Ashkenazi Jewish DNA samples, the MEFV carrier frequency was 21%, with E148Q the most common mutation. Several lines of evidence indicate reduced penetrance among Ashkenazi Jews, especially for E148Q, P369S, and K695R. Nevertheless, E148Q helps account for recessive inheritance in an

Ashkenazi family previously reported as an unusual case of dominantly inherited FMF. The presence of three frequent MEFV mutations in multiple Mediterranean populations strongly suggests a heterozygote advantage in this geographic region.

Familial Mediterranean fever--renal involvement by diseases other than amyloid.

Tekin M(1), Yalçinkaya F, Tümer N, Cakar N, Koçak H, Ozkaya N, Gençgönül H.

Author information:

(1)Ankara University Faculty of Medicine, Turkey.

**BACKGROUND:** In patients with familial Mediterranean fever (FMF) renal involvement is usually in the form of AA amyloidosis. There is increasing evidence that renal involvement may be due to diseases other than amyloid as well.

**METHODS:** Amongst 302 children with FMF we observed and followed 28 with typical clinical and laboratory features of vasculitis. The diagnosis of FMF was established according to the Tel Hashomer criteria.

**RESULTS:** Polyarteritis nodosa, protracted febrile attacks and Henoch-Schönlein purpura were diagnosed in 4, 13, and 11 patients, respectively. The presentation was often difficult to distinguish from FMF attacks, but protracted febrile attacks lasting several weeks, hypertension, thrombocytosis, and dramatic responses to corticosteroid therapy that were observed in many cases were different from what is observed in classical FMF.

**CONCLUSIONS:** We suggest that FMF, perhaps as a consequence of impaired control of inflammatory responses, predisposes to vasculitis with renal involvement.

Pyrin/marenostrin mutations in familial Mediterranean fever.

Booth DR(1), Gillmore JD, Booth SE, Pepys MB, Hawkins PN.

Author information:

(1)Immunological Medicine Unit, Imperial College School of Medicine, Hammersmith Hospital, London, UK.

Familial Mediterranean fever (FMF) is an inherited inflammatory disease that is frequently complicated by reactive systemic (AA) amyloidosis. It is principally recognized in certain Mediterranean populations, and the diagnosis depends on clinical features. Four mutations strongly linked to FMF have lately been identified in a gene encoding a novel protein that has been named pyrin or marenostrin. We studied 27 consecutive patients of varied ethnic origin, including an English man, who had classical, probable or possible FMF. Pyrin/marenostrin genotypes were determined, and AA amyloidosis was sought using serum amyloid P component scintigraphy. Among the 23 patients with classical or probable FMF, 17 were homozygotes or compound heterozygotes for pyrin/marenostrin mutations, and in five, only single allele mutations were identified. Two new mutations, T6811 and delta M694, were discovered in addition to the four described previously. No mutations were identified in three of the four patients with possible FMF. Nine patients had AA amyloidosis, but this association was not restricted to any particular genotype. Most patients with FMF have mutations in both pyrin/marenostrin alleles, and genotyping at this locus is a valuable diagnostic test. Unidentified second mutations are likely to occur in FMF patients who have apparently solitary mutations, and therefore genotype results

must be interpreted in conjunction with the clinical picture.

During our search for the familial Mediterranean fever (FMF) gene, we identified by cDNA selection a 1.2 kb cDNA fragment representing a novel human gene that is expressed in a wide variety of tissues. This gene spans approx. 8.0 kb genomic DNA and has seven exons. Its 3' untranslated region contains a long tandem repeat that gives rise to a polymorphism with two alleles of approx. 1.1 kb and 1.0 kb, with the 1.1 kb allele in strong linkage disequilibrium with FMF in patients of different ethnic backgrounds. However, both genetic and mutational analyses have excluded this gene as the one responsible for FMF. The predicted 424 amino acid protein, designated ZNF213, contains three C2H2 zinc fingers, a Kruppel associated A box and a leucine rich motif (LeR domain/SCAN box), strongly suggestive of a transcription factor.

Hereditary fevers are a group of rare disorders of the inflammatory response. Clinical features include recurrent attacks of fever and organ-localized inflammation. Minimal clinical variations, a unique biochemical-specific abnormality, and the mode of genetic inheritance distinguish the three main diseases: familial Mediterranean fever, hyperimmunoglobulinemia D and periodic fever syndrome, and autosomal dominant recurrent fever. The complete elucidation of pathogenesis of these intriguing disorders will be provided by the genetic studies currently in progress.

B30.2-like domain proteins: update and new insights into a rapidly expanding family of proteins.

Henry J(1), Mather IH, McDermott MF, Pontarotti P.

Author information:

(1)Centre National de la Recherche Scientifique URA 1485, Faculté de Médecine, Limoges, France.

The B30.2 domain is a conserved region of around 170 amino acids associated with several different protein domains, including the immunoglobulin folds of butyrophilin and the RING finger domain of ret finger protein. We recently reported several novel members of this family as well as previously undescribed protein families possessing the B30.2 domain. Many proteins have subsequently been found to possess this domain, including pyrin/marenostrin and the midline 1 (MID1) protein. Mutations in the B30.2 domain of pyrin/marenostrin are implicated in familial Mediterranean fever, and partial loss of the B30.2 domain of MID1 is responsible for Opitz G/BBB syndrome, characterized by developmental midline defects. In this study, we scrutinized the available sequence data bases for the identification of novel B30.2 domain proteins using highly sensitive database-searching tools. In addition, we discuss the chromosomal localization of genes in the B30.2 family, since the encoded proteins are likely to be involved in other forms of periodic fever, autoimmune, and genetic diseases.

J Rheumatol. 1999 Jul;26(7):1638-9.

**OBJECTIVE:** To investigate the prevalence of juvenile chronic arthritis (JCA), familial Mediterranean fever (FMF), and Behçet's disease in Turkish children through a field survey.

**METHODS:** The field survey was based on cluster centering with 2 level strata. A total of 46,813 children were screened. For the diagnosis of chronic arthritis and Behçet's previously suggested criteria were used. We have developed criteria for the diagnosis of probable FMF. Children previously diagnosed to have these diseases were also defined and included.

**RESULTS:** JCA was found in 6.4/10,000. 2.8/10,000 children were previously diagnosed as FMF (minimum phenotype frequency). Together with the probable diagnosis of FMF, the prevalence increased to 9.3/10,000. The findings were also compared with those of our center. None of the 46,813 children had Behçet's disease.

**CONCLUSION:** The prevalence of chronic arthritis is similar to the other childhood populations reported. However, FMF has a very high prevalence.

Familial Mediterranean fever (FMF) is a recessive disease characterized by recurrent attacks of inflammation of serosal membranes, and the gene responsible, MEFV, has been recently identified. Amyloidosis is considered to be the most severe complication. Since colchicine is effective in preventing FMF amyloidosis and since this process can develop even prior to the FMF symptoms, lifelong colchicine treatment is recommended for all FMF patients. Identification of the factor which determines amyloidosis will allow treatment to be directed only to those at risk. In order to investigate the association between amyloidosis and MEFV haplotypes, we studied 56 families from three ethnic groups. We compared the haplotypes of FMF patients with and without amyloidosis in each ethnic group separately and identified 14 different MEFV core haplotypes. A significant association ( $P < 0.004$ ) was found between amyloidosis and a specific core haplotype, 153bp:104bp at markers D16S3370 and D16S2617, respectively. Amyloidosis was present in 20 out of 70 homozygotes for this haplotype and in 6 out of 35 compound heterozygotes for this and other core haplotypes. None of the patients who did not carry this allele had amyloidosis. There was no association between the various haplotypes and severity of the FMF symptoms, age of onset, or age at commencement of colchicine. Further investigation of the MEFV haplotypes in additional patients is recommended as such an association may save many mildly affected or asymptomatic patients with non-amyloidotic genotypes from receiving unnecessary lifelong colchicine treatment.

Does the lack of the P-glycoprotein efflux pump in neutrophils explain the efficacy of colchicine in familial Mediterranean fever and other inflammatory diseases?

Ben-Chetrit E(1), Levy M.

Author information:

(1)Department of Medicine, HadassAh University Hospital, Jerusalem, Israel.

Colchicine is an alkaloid drug commonly used in familial Mediterranean fever (FMF), gout, Behcet's syndrome, psoriasis and Sweet's syndrome. The exact mechanism of its action in these diseases is not entirely known. However, it has been shown that colchicine may inhibit neutrophil chemotaxis, thereby decreasing the inflammatory process. Recently, it was shown that colchicine accumulates in neutrophils in higher concentrations than in lymphomonocytes. Studies dealing

with the multiple drug resistance (MDR) issue disclosed that neutrophils lack the P-glycoprotein (P-gly) membranal pump (encoded by the MDR1 gene). We propose that the preferential accumulation of colchicine in neutrophils compared with lymphomonocytes is due to the absence of the P-gly efflux pump in the former. This may explain the effectiveness of colchicine in diseases where increased chemotaxis is evident. The hypothesis may also provide an explanation for FMF patients who do not respond to the drug.

(1)Arthritis and Rheumatism Branch, National Institute of Arthritis and Musculoskeletal and Skin Diseases, National Institutes of Health (NIH), Bethesda, Maryland 20892-1820, USA.

We used a combination of cDNA selection, exon amplification, and computational prediction from genomic sequence to isolate transcribed sequences from genomic DNA surrounding the familial Mediterranean fever (FMF) locus. Eighty-seven kb of genomic DNA around D16S3370, a marker showing a high degree of linkage disequilibrium with FMF, was sequenced to completion, and the sequence annotated. A transcript map reflecting the minimal number of genes encoded within the approximately 700 kb of genomic DNA surrounding the FMF locus was assembled. This map consists of 27 genes with discreet messages detectable on Northern blots, in addition to three olfactory-receptor genes, a cluster of 18 tRNA genes, and two putative transcriptional units that have typical intron-exon splice junctions yet do not detect messages on Northern blots. Four of the transcripts are identical to genes described previously, seven have been independently identified by the French FMF Consortium, and the others are novel. Six related zinc-finger genes, a cluster of tRNAs, and three olfactory receptors account for the majority of transcribed sequences isolated from a 315-kb FMF central region (between D16S468/D16S3070 and cosmid 377A12). Interspersed among them are several genes that may be important in inflammation. This transcript map not only has permitted the identification of the FMF gene (MEFV), but also has provided us an opportunity to probe the structural and functional features of this region of chromosome 16.

Author information:

(1)Hacettepe University, School of Medicine, Department of Internal Medicine, Ankara, Turkey.

**OBJECTIVE:** To evaluate whether basal levels of circulating cytokines and selectins exhibit a distinct profile in attack-free, non-colchicine taking familial Mediterranean fever (FMF) patients compared to normal healthy controls, and to determine the effect of colchicine treatment on these parameters.

**METHODS:** Serum levels of interleukin (IL)-6, IL-8, tumor necrosis factor (TNF)-alpha, and soluble P-, E-, and L-selectin in attack-free, asymptomatic, non-colchicine using FMF patients (n = 11) and in normal controls (n = 10) were studied. Following 2 months of colchicine treatment the same parameters were evaluated again in the FMF patients.

**RESULTS:** Before colchicine treatment the serum levels of all parameters except soluble P-selectin were significantly higher in FMF patients than in controls. After two months of treatment statistically significant decreases were observed in these parameters ( $p < 0.05$ ).

**CONCLUSION:** A distinct profile of IL-6, IL-8, TNF-alpha, and soluble E- and L-selectin levels was observed in FMF patients, which could reflect the presence of sustained inflammation in attack-free FMF patients. The effect of colchicine on these parameters suggests its therapeutic potential.

Treatment of inflammatory rheumatic disorders in pregnancy: what are the safest treatment options?

Ostensen M(1), Ramsey-Goldman R.

Author information:

(1)Department of Rheumatology, University Hospital of Trondheim, Norway.

The interaction of pregnancy and the rheumatic diseases varies, ranging from life-threatening conditions such as thromboembolic events and progressive renal disease in some autoimmune disorders, to minor flares of peripheral arthritis in inflammatory rheumatic disease. As a consequence, treatment strategy will vary according to the maternal or fetal compromise expected. All nonsteroidal anti-inflammatory drugs (NSAIDs), including high dose aspirin (acetylsalicylic acid), can cause adverse effects during pregnancy related to the inhibition of

prostaglandin synthesis. Prolongation of gestation and labour, constriction of the ductus arteriosus, persistent fetal circulation, impairment of renal function and bleeding are risks of third trimester exposure of pregnant women to all inhibitors of cyclo-oxygenase. Most of these adverse effects can be prevented by discontinuing NSAIDs 8 weeks prior to delivery. Low dose aspirin has not been associated with fetal or neonatal toxicity. Some corticosteroids such as prednisone and prednisolone do not readily cross the placenta and can be safely used during pregnancy as immunosuppressive drugs. Maternal complications related to corticosteroids may occur and close monitoring is therefore mandatory. There is limited information on the safety of disease-modifying antirheumatic drugs including gold, antimalarials, penicillamine (D-penicillamine), sulfasalazine and cyclosporin. Of these agents, sulfasalazine has the best record for tolerability and can be used by pregnant patients. Gold compounds and penicillamine should be discontinued when pregnancy is recognised. Hydroxychloroquine has not been associated with congenital malformations and seems preferable to chloroquine in patients requiring treatment with antimalarials. Use of cyclosporin may be an alternative to other therapy in pregnant patients with severe rheumatic disease. Indications for treatment with colchicine during pregnancy are few, except for familial Mediterranean fever. Azathioprine can be used when the maternal condition requires a cytotoxic drug during the first trimester. Cyclophosphamide, chlorambucil and methotrexate are contraindicated during pregnancy because of their teratogenic potential. Their use may be considered in late pregnancy if the mother has a life-threatening condition.

[The local immune mechanisms of the involvement of the teeth and periodontium in periodic disease].

[Article in Russian]

Akopian GV.

The aim of our investigations was to elucidate some immune aspects of combination of caries and periodontitis with periodic disease (PD), also known as familial

Mediterranean fever. In this regard in patients with active and non-active stage of PD we have studied dynamic changes of concentration of secretory immunoglobulin A (SIgA) in saliva and phagocytic activity of neutrophils derived from gum blood. It has been shown that in patients with PD these indices of local immunity of oral cavity had tendency to a decrease especially in case of PD and periodontitis combination. Disturbances of local immunity was significant in active stage of PD. Based on the obtained data and analysis of latest literature data we suppose that above mentioned changes in local immunity depended on the exhaustion of adaptive properties of patients' local immunity more pronounced in case of chronic inflammation and infection foci formation in oral cavity.

Clinical benefits of diagnosing incipient AA amyloidosis in pediatric rheumatic diseases as estimated from a retrospective study.

Michels H(1), Linke RP.

Author information:

(1)Rheumatic Children's Hospital, Garmisch-Partenkirchen, Germany.  
rheuma-kinderklinik@t-online.de

OBJECTIVE: The diagnosis of AA amyloidosis could not be made in eight patients with pediatric rheumatic diseases as later verified employing the more sensitive

combination of Congo red and additional immunocytochemistry (CRIC). The objective of this paper is to estimate the benefit of CRIC by reevaluating the historical charts with respect to the question as to which of the diagnostic and therapeutic measures would have been altered if the correct diagnosis had been known at the time of the primary biopsy.

**METHODS:** All subsequent biopsies of eight children with historically missed AA amyloidosis in their primary biopsies were retrieved, together with the historical data including the Congo red stains of the biopsies. The biopsies were reexamined blindly for the presence of amyloid and the results were compared with the historical data concerning diagnostic and therapeutic measures.

**RESULTS:** Using CRIC, AA amyloidosis could be identified an average of approximately three years earlier as compared to the historical data. This gain in time would certainly have altered the diagnostic as well as the therapeutic options, i.e. 10 out of 21 biopsies would have been spared and the earlier diagnosis would have initiated more significant antiinflammatory therapy.

**CONCLUSION:** Very early detection of amyloid reduces the diagnostic burden and unveils an option for a consequent antiinflammatory therapy very early in the course of AA amyloidosis.

Colchicine is used in the treatment of gouty arthritis, familial Mediterranean fever, amyloidosis, Behcet disease and dermatoses. Myoneuropathy is a rare side-effect reported either with intoxication or in elderly patients with chronic renal insufficiency causing elevated plasma drug levels. We report the first two cases of myoneuropathy in children, both taking appropriate doses of colchicine, and having normal renal function. The myoneuropathic changes were reversible

after stopping treatment. The cause of colchicine myoneuropathy is unclear. CONCLUSION: In children treated with colchicine, neuromuscular phenomena of unknown aetiology may be related to the drug, even with a lack of intoxication or renal insufficiency.

Familial Mediterranean fever (FMF) and Behçet's disease are relatively rare but may still coexist in the same patient. Sacroiliitis is another feature whose significance is controversial in either of the diseases. We report a case of longstanding FMF with sacroiliitis who later developed typical characteristics of Behçet's disease. Although occurrence by chance cannot be ruled out, this unusual patient may enhance the claims that FMF and Behçet's disease have common aetiopathogenetic mechanisms. It would be appropriate to include this coexistence in the list of differential diagnoses of the two diseases.

Recurrent episodic fever. A presenting feature of familial Mediterranean fever.

Majeed HA(1), Rawashdeh M, Qubain H.

Author information:

(1)Department of Pediatrics, Faculty of Medicine, University of Jordan, Amman, Jordan.

**OBJECTIVES:** To study the natural course and outcome of recurrent episodic fever without serositis as a presenting feature of familial Mediterranean fever (FMF).

**PATIENTS:** Of 309 children with FMF seen over a period of 5 years, 8 presented with recurrent episodes of fever without serositis, imposing a difficult diagnostic problem.

**RESULTS:** The age at onset of fever ranged between 5 months and 8 years with a mean of 2.5 years. Five patients eventually developed serositis. The duration between onset of fever and onset of serositis ranged between 1.5-3 years with a mean of 2 years. Of the 3 patients who did not develop serositis, 2 had a family history of FMF. Therapeutic response to colchicine was dramatic in 7 children (one refused colchicine prophylaxis).

**CONCLUSION:** Episodic fever alone without serositis is a presenting feature of FMF. In patients from Mediterranean ancestors and/or the presence of family history of FMF, a therapeutic diagnostic test with colchicine could be rewarding.

## Transplantation in renal amyloidosis.

Türkmen A(1), Yildiz A, Erkoç R, Ecder T, Görçin B, Türk S, Aydın AE, Eldegez U, Ark E, Sever MS.

Author information:

(1)Istanbul School of Medicine, Department of Nephrology, Turkey.

In this report, the results of renal transplantation in patients with renal amyloidosis were retrospectively analysed and compared with the control group. Fifteen (3.04%) of the 493 renal transplant recipients whom were followed up in Istanbul School of Medicine transplant outpatient clinic, between 1983 and 1997, were included in the study. The etiology of amyloidosis was familial Mediterranean fever in all patients. The mean follow-up period was  $38.3 \pm 31.8$  (range 7-65) months. Twelve of the patients were male and 3 female with the mean age  $34.13 \pm 10.87$  (range 21-60) years. Seven patients had living related, 4 living-unrelated and 4 cadaveric donors. Five patients were lost because of different complications: Three patients died from cardiac amyloidosis all with well functioning grafts, 2, 3 and 36 months after the operation. Sepsis and cardiovascular failure was the probable cause of death in 1 patient who also had chronic rejection. Another one patient with chronic rejection died from hepatic failure. Acute rejection developed in 2 patients. Renal functions of these patients improved by anti-rejection therapies. Chronic rejection developed in 3 patients. In the control group, acute rejection and chronic rejection were diagnosed in 5 and 1 patients, retrospectively. While 1 patients returned to hemodialysis in control group, the others are alive with satisfactory graft function. There was no death in control group. The 5-yr graft and patient survival rates in amyloidosis and the control groups were 75, 77, 95 and 100%, respectively. It was concluded that although transplantation is not a contraindication for the treatment of end stage renal failure in patients with renal amyloidosis, it carries high risk of cardiac complications in the postoperative period. Detailed preoperative cardiovascular evaluations are mandatory in these patients and this intervention should improve the prognosis by excluding the patients who have already been complicated with this problem.

Identification of two Krüppel-related zinc finger genes (ZNF200 and ZNF210) from human chromosome 16p13.3.

Deng Z(1), Centola M, Chen X, Sood R, Vedula A, Fischel-Ghodsian N, Kastner DL.

Author information:

(1)Arthritis and Rheumatism Branch, National Institute of Arthritis and Musculoskeletal and Skin Diseases, Bethesda, Maryland, 20892-1820, USA.

During the course of cloning the gene for familial Mediterranean fever (FMF), we identified a number of transcripts from a 275-kb genomic region on 16p13.3. Two of the transcripts were found to contain multiple C2H2-type zinc finger motifs in tandem arrays, indicating that they are members of the Krüppel-type family. One transcript was found to be an alternatively spliced form of a previously reported zinc finger gene, ZNF200. The other transcript, ZNF210, is 2017 bp and encodes an open reading frame of 504 aa. Northern blot analysis indicates that ZNF210 is expressed in all the tissues tested with the highest expression in heart, skeletal muscle, pancreas, prostate, ovary, and colon. On the other hand, the strongest expression of ZNF200 is in testis, with very low levels in all the other tissues tested. Sequence analysis reveals eight C2H2 zinc finger motifs at the C-terminus of ZNF210 and five in ZNF200. In addition, ZNF210 also possesses a Krüppel-associated box at its N-terminus, indicating that it might function as a transcription repressor. The intron-exon structures of both genes were determined and showed that ZNF210 has seven exons while the coding part of ZNF200 is distributed in four exons. The locations of ZNF200 and ZNF210 are 10 and 120 kb telomeric to the FMF gene, respectively.

Familial Mediterranean Fever is one of the most frequent recessive disease in non-Ashkenazi Jews. The gene responsible for the disease (MEFV) has very recently been identified. The M694V ('MED') mutation was found in about 80% of the FMF Jewish (Iraqi and North African) chromosomes. To see if the presence of this mutation could be correlated with particular traits of the disease, we examined a number of clinical features in a panel of 109 Jewish FMF patients with 0, 1 or 2 MED mutations. We showed that homozygosity for this mutation was significantly associated with a more severe form of the disease. In homozygous patients, the disease started earlier (mean age 6.4 +/- 5 vs 13.6 +/- 8.9) and both arthritis and pleuritis were twice as frequent as in patients with one or no M694V mutation. Moreover, 3/3 patients with amyloidosis displayed two MED mutations. No association was found with fever, peritonitis, response to colchicine and erysipeloid eruption. The present result strongly suggests the potential prognostic value of the presence of this mutation.

**INTRODUCTION:** Periodic disease is a hereditary disorder. Until recently its diagnosis was essentially based on clinical criteria. When the clinical picture was incomplete or atypical, it often required elimination of other diagnoses which sometimes involved extensive and useless investigations. Diagnosis was consequently delayed or irrelevant, with the risk of renal failure when the patient was not treated (or tardily treated).

**CURRENT KNOWLEDGE AND KEY POINTS:** Efforts of molecular geneticists have allowed to track and recently to identify the gene (MEFV) responsible for this disease. Today blood sampling enables identification of the causative mutations, sometimes even before the onset of symptoms.

**FUTURE PROSPECTS AND PROJECTS:** Four mutations clustered on exon 10 already account for 74% of cases in patients originating from the most affected populations and presenting with complete clinical picture. Identification of rare mutations should progressively allow improvement of the test sensitivity, especially in patients with a less typical form of the disease.

(1)Service de médecine interne, Fondation A-de-Rothschild, Paris, France.

**INTRODUCTION:** Peritoneal mesothelioma is a rare malignant neoplasm that might be linked to chronic peritoneal inflammation. As well, the association peritoneal mesothelioma-familial Mediterranean fever is uncommon.

**EXEGESIS:** We report the case of a 60-year-old man who presented for 30 years with standard periodic familial Mediterranean fever accompanied by acute abdominal episodes, sensitive to colchicine. Between 1988 and 1995, acute abdominal episodes were accompanied by more and more profuse recurrent ascites, partially resolving under colchicine treatment. In 1995, the last episode was severe (with loss of weight and inability to tolerate feeding) and conducted to the patient's death due to peritoneal mesothelioma, as confirmed by the biopsy.

**CONCLUSION:** Profuse and recurrent ascites is unusual in standard periodic familial Mediterranean fever. Asbestos exposure at the origin of peritoneal

mesothelioma is not well documented. Furthermore, the disease clinical and paraclinical features are misleading, and the diagnosis is based on histology. The prognosis is severe, and treatment is usually disappointing. Our observation clearly demonstrates the interconnection between an unusual form of profuse and relapsing ascites that occurred in the course of a periodic disease and peritoneal mesothelioma. The potential role of recurrent peritonitis related to familial Mediterranean fever in the pathogenesis of the tumor is discussed.

Familial mediterranean fever and acute myocardial infarction secondary to coronary vasculitis.

Serrano R(1), Martínez MA, Andrés A, Morales JM, Samartin R.

Author information:

(1)Department of Pathology, Hospital 12 de Octubre, Madrid, Spain.

AIMS: We report a case study to elucidate the pathogenesis of polyarteritis nodosa (PAN) type vasculitis, a rare complication of familial mediterranean fever (FMF).

METHODS AND RESULTS: A woman with amyloidosis complicating FMF underwent a cadaveric renal transplantation and 5 years later suffered an acute myocardial infarction secondary to an isolated coronary vasculitis.

CONCLUSIONS: The histopathological findings of the vasculitis were not in keeping with PAN. We postulated that the pathogenesis of vasculitis in FMF is different from that of the classic PAN and might be similar to the mechanism of the serosal inflammation.

Comment in

Ann Intern Med. 1998 Oct 1;129(7):581-2.

**BACKGROUND:** Familial Mediterranean fever is a recessively inherited disorder characterized by episodes of fever with abdominal pain, pleurisy, or arthritis. The familial Mediterranean fever gene, designated MEFV, was recently cloned, and at least three missense mutations (M680I, M694V, and V726A) that account for a large percentage of patients with this disease were identified.

**OBJECTIVE:** To establish a diagnostic test for familial Mediterranean fever.

**DESIGN:** Cross-sectional study of a convenience sample of patients attending familial Mediterranean fever clinics.

**SETTING:** Tertiary referral hospitals.

**PATIENTS:** 107 patients with familial Mediterranean fever, their family members, and controls.

**MEASUREMENTS:** Mutations in the 107 samples were assessed by amplifying genomic DNA with use of primers that selectively amplify the normal or altered DNA sequence of the 3 MEFV mutations (amplification refractory mutation system [ARMS]). Mutations were independently assessed by automated sequencing of genomic DNA amplified by polymerase chain reaction to evaluate the sensitivity and specificity of the ARMS assay.

**RESULTS:** The ARMS assay correctly identified M680I, M694V, and V726A mutations in 82 persons with mutations documented by DNA sequencing (21 homozygotes, 2 compound heterozygotes, and 59 simple heterozygotes). Of 7 persons known from family studies to be noncarriers and 18 unrelated persons who were negative for these mutations by sequencing, none had MEFV mutations according to ARMS.

**CONCLUSION:** The ARMS assay is a rapid, cost-effective, and accurate method for detecting three common mutations in familial Mediterranean fever.

The hereditary periodic fever syndromes: molecular analysis of a new family of inflammatory diseases.

Centola M(1), Aksentijevich I, Kastner DL.

Author information:

(1)Arthritis and Rheumatism Branch, National Institute of Arthritis and Musculoskeletal and Skin Diseases, NIH Building 10, Room 9N210, 9000 Rockville Pike, Bethesda, MD 20892-1820, USA.

The hereditary periodic fever syndromes are a group of Mendelian disorders characterized by episodic fever and serosal or synovial inflammation. Familial Mediterranean fever (FMF) and the hyperimmunoglobulinemia D and periodic fever syndrome are both recessively inherited, while three dominantly inherited syndromes have been described, the best-characterized of which is familial Hibernian fever (FHF). The last year has seen two major developments in this field: the FMF gene was identified on chromosome 16p by positional cloning, and a second major periodic fever locus was mapped to distal chromosome 12p. The FMF gene (MEFV) encodes a novel 781 amino acid protein; to date, eight different missense mutations and a number of polymorphisms have been described. Seven of the eight mutations occur within a region of 82 amino acids near the C-terminus. Computational analysis of the conceptual protein reveals five different domains/motifs compatible with a nuclear effector function. MEFV is expressed preferentially in granulocytes and myeloid bone marrow precursors, giving rise to speculation that the protein may serve as a transcriptional regulator of inflammation in granulocytes. The second periodic fever locus was mapped by two different groups: one studying FHF, the other studying a similar dominantly inherited syndrome designated familial periodic fever. Both genes map to the same 19 cM region on distal chromosome 12p, strongly suggesting a common locus. The molecular characterization of the periodic fever genes should provide important new insights into the regulation of inflammation in general.

Colchicine: 1998 update.

Ben-Chetrit E(1), Levy M.

Author information:

(1)Department of Medicine, Hadassah University Hospital, Jerusalem, Israel.

**OBJECTIVE:** To present an update of the use of colchicine in patients with familial Mediterranean fever (FMF) and other rheumatic and nonrheumatic diseases.

**DATA SOURCES:** Published studies on colchicine retrieved from MEDLINE searches from 1987 to 1997 and reports presented at national and international meetings.

**STUDIES SELECTION AND EXTRACTION:** All studies were reviewed by the authors. Reports addressing the topics of colchicine pharmacokinetics, biological effects, indications for use, and side effects were selected.

**DATA SYNTHESIS:** Colchicine is an alkaloid that may interfere with microtubule formation, thereby affecting mitosis and other microtubule-dependent functions. It has a bioavailability of 25% to 50% when administered orally. Colchicine and its metabolites are excreted through the urinary and biliary tracts. It may be used while breast feeding; however, amniocentesis should be performed when used in pregnancy. The drug may be given to children with FMF. The efficacy of colchicine has been proved in FMF, gout, Behcet's disease, and cirrhosis. Its place in the treatment of scleroderma, sarcoidosis, and skin disorders remains to be determined. Gastrointestinal side effects occur early and are most common manifestations of colchicine toxicity. Severe colchicine toxicity results in

multiple organ failure, convulsions, coma, and death. Potentially, effective treatment with Fab anti-colchicine antibodies unfortunately is unavailable; therefore, treatment is supportive.

CONCLUSIONS: Colchicine is a relatively safe and effective medication for several disorders when used in appropriate dosage in patients with normal kidney and liver function.

Familial Mediterranean fever at the millennium. Clinical spectrum, ancient mutations, and a survey of 100 American referrals to the National Institutes of

Health.

Samuels J(1), Aksentijevich I, Torosyan Y, Centola M, Deng Z, Sood R, Kastner DL.

Author information:

(1)Arthritis and Rheumatism Branch, National Institute of Arthritis and Musculoskeletal and Skin Diseases, National Institutes of Health, Bethesda, Maryland 20892-1820, USA.

Regarded as the most common and best understood of the hereditary periodic fever syndromes, familial Mediterranean fever (FMF) is a recessively inherited disease of episodic fever with some combination of severe abdominal pain, pleurisy, arthritis, and a characteristic ankle rash. The flares typically last for up to 3 days at a time, and most patients are completely asymptomatic between attacks; if untreated with prophylactic colchicine, some patients later develop amyloidosis and renal failure. The recent cloning of the FMF gene on the short arm of chromosome 16p, and the subsequent finding that its tissue expression is limited to granulocytes, has helped to explain the dramatic accumulation of neutrophils at the symptomatic serosal sites; the wild-type gene likely acts as an upregulator of an anti-inflammatory molecule or as a downregulator of a pro-inflammatory molecule. For nearly half a century, FMF was thought to cluster primarily in non-Ashkenazi Jews, Arabs, Armenians, and Turks, although the screening of the 8 known mutations in an American cohort has identified substantial numbers of people from the Ashkenazi Jewish and Italian populations in the United States who also have this disease. Nevertheless, the symptoms often go unrecognized and patients remain undiagnosed for years, not receiving the highly efficacious colchicine therapy; their histories often include multiple laparotomies, laparoscopies, and psychiatric evaluations. The combinations of clinical manifestations among FMF patients are quite heterogeneous, but our American cohort did not establish any connections between individual mutations and specific clinical pictures--as is seen in other diseases like cystic fibrosis, in which distinct genotypes target certain organ systems. Specifically, the data from our American series are insufficient to evaluate the hypothesis that the M694V/M694V genotype confers a more severe phenotype, or increases the risk of amyloidosis; but both our data and the recent literature (160) indicate that amyloidosis can occur in FMF patients with only 1 copy, or no copies, of the M694V mutation. It appears that specific MEFV mutations are probably not the sole determinants of phenotype, and that unknown environmental factors or modifying genes act as accomplices in this disease. Although we hope the discovery of the

FMF gene will allow the diagnosis of FMF to become genetically accurate, the reality is that both clinical and genetic tools must still be used together unless mutations are identified on both of a patient's chromosomes. Physicians should be careful not to rule out the diagnosis in patients of high-risk ethnic backgrounds just because of atypical clinical features, as our data indicate that MEFV mutations are sometimes demonstrable in such patients. At the same time, physicians cannot yet rely solely on a genetic diagnosis because we have not yet identified a sufficient spectrum of mutations, and it is not currently feasible to examine every patient's full DNA sequence for the entire gene; screening an ethnically consistent and clinically positive patient for the 8 known mutations frequently identifies a mutation on only 1 chromosome, and genetic analysis of other classic cases will often reveal none of the 8 mutations. Still, our data suggest that ethnic background is an important predictor of finding 1 of the presently known mutations, and the knowledge of ancestries atypical for FMF can suggest the diagnosis of other hereditary periodic fever syndromes. As the list of FMF-associated MEFV mutations is expanded, and/or new sequencing technologies permit more rapid screening, the value and interpretation of genetic testing for FMF will become more straightforward. Moreover, as the pathophysiology of this disorder becomes less of a hypothesis and more of an understood entity, it is likely that treatment options will broaden beyond the use of daily prophylactic colchicine. Recurrent hyperbilirubinaemia, a feature of familial Mediterranean fever: report of a child and review of the literature.

Majeed HA(1), Halabi I, al-Taleb O.

Author information:

(1)Department of Pediatrics, Faculty of Medicine, University of Jordon, Amman.

Recurrent hyperbilirubinaemia was described as a feature of familial Mediterranean fever in the 1950s and early 1960s. However, over the last 33 years only one case has been published. We present a 12-year-old Arab boy who developed

recurrent hyperbilirubinaemia in the course of familial Mediterranean fever. His response to colchicine was excellent. Review of the literature reveals that hyperbilirubinaemia of familial Mediterranean fever has a distinct clinical picture characterized by concurrent peritonitis, minimal jaundice and short duration. Factors contributing to the paucity of reports in recent literature are discussed.

Familial Mediterranean fever in two Italian brothers.

Breda L(1), Magrí M, Morgese G, Chiarelli F.

Author information:

(1)Department of Pediatrics, University of Chieti, Italy.

Familial Mediterranean fever (FMF) is an autosomal recessive disease of unknown etiology, characterized by recurrent self limited episodes of fever and polyserositis. Some patients develop generalized amyloidosis, which can be fatal. Colchicine therapy modifies the natural history of the disease by decreasing the attack frequency and preventing amyloid deposition. The disease is common among Sephardic Jews, Arabs, Armenians and has also been sporadically found in other ethnic groups of Mediterranean origin. We report two cases of FMF in brothers living in Abruzzo, Italy. They were born from consanguineous parents and complained typical symptoms since childhood. The boy suffered from one febrile attack every week; he presented three episodes of acute scrotum at age 8 and 9. The elder sister showed a spontaneous partial relief during adolescence. Juvenile rheumatoid arthritis was suspected and Aspirin was used for many years without any clinical improvement. Treatment with colchicine 1 mg/day was established at age 13 and 17 respectively, and a sudden reduction of frequency of attacks was obtained. A gingival biopsy did not show amyloid. The three elder brothers are, at present, in good health. Our experience point out the diagnostic difficulties of FMF especially in a country where the disease is uncommon.

Superior vena cava thrombosis and obstructive sleep apnea in a patient with familial Mediterranean fever.

Ustündag Y(1), Bayraktar Y, Emri S.

Author information:

(1)Department of Internal Medicine, Hacettepe University School of Medicine, Ankara, Turkey.

Familial Mediterranean fever (FMF), a paroxysmal, self-limited, inflammatory disease of unknown etiology, may result in thrombotic complications after the development of nephrotic syndrome due to amyloidosis. It has been suggested that there is increased thrombogenic activity in the blood of patients with FMF who did not develop nephrotic syndrome. We describe a patient with FMF who presented with thrombosis in the superior vena cava (SVC) in the absence of nephrotic syndrome, and discuss the contributory role of increased procoagulant activity detected in this disorder. Moreover, the patient was proved to have obstructive sleep apnea (OSA) which we believe was secondary to SVC thrombosis that lead to soft tissue edema in the upper airways. To our knowledge, this is the second reported case in the literature in which OSA occurred secondary to the SVC thrombosis.

Familial Mediterranean fever (FMF) is an autosomal recessive disorder characterized by recurring attacks of fever and serositis. It affects primarily North African Jews, Armenians, Turks and Arabs, in which a founder effect has been demonstrated. The marenostirin-pyrin-encoding gene has been proposed as a candidate gene for the disease (MEFV), on the basis of the identification of putative mutations clustered in exon 10 (M680V, M694I, M694V and V726A), each segregating with one ancestral haplotype. In a search for additional MEFV mutations in 120 apparently non-founder FMF chromosomes, we observed eight novel mutations in exon 2 (E148Q, E167D and T267I), exon 5 (F479L) and exon 10 (I692del K695R, A744S and R761H). Except for E148Q and K695R, all mutations were found in a single chromosome. Mutation E148Q was found in all ethnic groups studied and in association with a novel ancestral haplotype in non-Ashkenazi Jews (S2). Altogether, these new findings definitively establish the marenostirin/pyrin-encoding gene as the MEFV locus.

Familial Mediterranean fever (FMF) is a recessively inherited disorder characterized by attacks of fever and serositis, which affects primarily non-Ashkenazi Jews, Armenians, Turks, and Arabs. We present here a transcriptional map covering the FMF locus that we constructed in the course of

the positional cloning of the gene responsible for this disease. This map was established from a contig constructed with YAC, BAC, and cosmid clones and covers about 500 kb of 16p13.3. It contains nine transcriptional units corresponding to known genes or to genes belonging to known gene families, 23 gene fragments characterized by partial sequences, and an endogenous retrovirus sequence. It thus considerably increases the number of genes in this interval and improves our knowledge concerning some of the genes or gene families present in this region. Data accumulated in this region were also used in a comparative study of different methods of exon detection.

Childhood vasculitis.

Dillon MJ(1).

Author information:

(1)Great Ormond Street Hospital for Children, London, UK.

Vasculitis can and does occur in childhood. Apart from the relatively common vasculitides (Henoch-Schönlein purpura, Kawasaki disease and in world wide terms Takayasu disease) there are a number of important but comparatively rare disorders affecting children. These include macroscopic and microscopic polyarteritis, cutaneous polyarteritis, Wegener's granulomatosis, Churg-Strauss syndrome, primary angiitis of the central nervous system, hypersensitivity angiitis, hypocomplementaemic urticarial vasculitis, vasculitis associated with various connective tissue disorders and vasculitis associated with conditions such as Behçets syndrome, familial Mediterranean fever and Cogan's syndrome. Distinguishing these conditions from other disorders is often difficult and requires clinical acumen and appropriate investigative procedures. With modern therapeutic agents, it is possible to implement appropriate therapy but in spite of this, there remains a not inconsequential morbidity and mortality.

Renal transplantation in secondary systemic amyloidosis.

Heering P(1), Hetzel R, Grabensee B, Opelz G.

Author information:

(1)Department of Nephrology and Rheumatology, Heinrich Heine University, Düsseldorf, Germany.

When renal amyloidosis has progressed to end-stage renal failure, most patients are severely affected by systemic amyloidosis and nephropathy. An alternative to chronic dialysis is renal transplantation. We present a patient with amyloid nephropathy who developed recurrent transplant amyloidosis. Renal transplantation was performed in 1985 with a living related donor. In 1990 the patient developed amyloidosis of the graft with membranous nephropathy and tubular acidosis due to hyporeninemic hypoaldosteronism. Secondary amyloidosis has been reported to involve glandular organs inducing hypothyroidism, hypocortisolism and hypoaldosteronism. Cyclosporine has been reported to induce hyporeninemic hypoaldosteronism and tubular acidosis, but not hypocortisolism and hypothyroidism. Progression of the amyloidosis of the graft was confirmed by a renal biopsy in 1993. Data published in the literature indicate that the survival rate of amyloidotic graft recipients is worse than those of non-amyloidotic graft recipients. This was confirmed in an analysis of the current CTS data which showed an impaired survival rate at 5-yr of  $66 \pm 4\%$  ( $\pm$  SE) for patients with amyloidosis ( $n = 413$ ) as compared with  $86 \pm 1\%$  ( $p < 0.0001$ ) for patients with glomerulonephritis and  $84 \pm 1\%$  ( $p < 0.01$ ) for patients with polycystic kidney disease. Graft survival after 5 years was  $55 \pm 4\%$  in patients with amyloidosis as compared with  $63 \pm 1\%$  ( $p = 0.02$ ) in patients with glomerulonephritis and  $68 \pm 1\%$  in patients with polycystic kidney disease. Graft survival was improved in amyloidotic patients treated with cyclosporine as compared with patients on steroids and azathioprine ( $55 \pm 4\%$  vs.  $38 \pm 8\%$ ,  $p < 0.05$ ). It is concluded that renal transplantation is the renal replacement therapy of choice for patients with AA-type amyloidosis although the overall patient survival is impaired in comparison with patients with other diseases.

Autosomal dominant periodic fevers are characterized by intermittent febrile attacks of unknown etiology and by recurrent abdominal pains. The biochemical and molecular bases of all autosomal dominant periodic fevers are unknown, and only familial Hibernian fever (FHF) has been described as a distinct clinical entity. FHF has been reported in three families-the original Irish-Scottish family and two Irish families with similar clinical features. We have undertaken a genomewide search in these families and report significant multipoint LOD scores between the disease and markers on chromosome 12p13. Cumulative multipoint linkage analyses indicate that an FHF gene is likely to be located in an 8-cM interval between D12S77 and D12S356, with a maximum LOD score (Z max) of 3.79. The two-point Z max was 3.11, for D12S77. There was no evidence of genetic heterogeneity in these three families; it is proposed that these markers should be tested in other families, of different background, that have autosomal dominant periodic fever, as a prelude to identification of the FHF-susceptibility gene.

Urticarial vasculitis is defined by association of an urticaria and/or angio oedema and a vasculitis of the small dermal vessels, leucocytoclastic or mononuclear. Sometimes it is an acute urticaria, of infectious or drug origin. Urticarian vasculitis may also be due to pressure or cold. But usually, it is a chronic urticaria that readily accompanies systemic signs and immunological anomalies, in particular hypocomplementemia. The clinical-biological picture becomes a true entity or is associated with another condition, most often a collagenosis.

Comment in

Circulation. 2000 Feb 8;101(5):E71-2.

**BACKGROUND:** The most troublesome complication of acute pericarditis is recurrent episodes of pericardial inflammation, occurring in 15% to 32% of cases. The cause of the recurrence is usually unknown, although in some cases it may be traced to viral infection or may be a consequence of coronary artery bypass grafting. The optimal method for prevention has not been fully established; accepted modalities include nonsteroidal anti-inflammatory drugs, corticosteroids, immunosuppressive

agents, and pericardiectomy.

**METHODS AND RESULTS:** Based on the proven efficacy of colchicine therapy for familial Mediterranean fever (recurrent polyserositis), several small studies have used colchicine successfully to prevent recurrence of acute pericarditis after failure of conventional treatment. Recently, we reported the results from the largest multicenter international study on 51 patients who were treated with colchicine to prevent further relapses and who were followed up for  $\leq 10$  years.

**CONCLUSIONS:** In light of new trial data that have accumulated in the past decade, we review the evidence for the efficacy and safety of colchicine for the prevention of recurrent episodes of pericarditis. Clinical and personal experience shows that colchicine may be an extremely promising adjunct to conventional treatment and may ultimately serve as the initial mode of treatment, especially in idiopathic cases.

We report gene localization in a family with a benign autosomal dominant familial periodic fever (FPF) syndrome characterized by recurrent fever associated with abdominal pain. The clinical features are similar to the disorder previously described as familial Hibernian fever, and they differ from familial Mediterranean fever (FMF) in that FPF episodes usually do not respond to colchicine and FPF is not associated with amyloidosis. Frequent recombination with the marker D16S2622,  $<1$  Mb from FMF, at 16p13.3, excluded allelism between these clinically similar conditions. Subsequently, a semiautomated genome search

detected linkage of FMF to a cluster of markers at 12p13, with a multipoint LOD score of 6.14 at D12S356. If penetrance of 90% is assumed, the FPF gene maps to a 19-cM interval between D12S314 and D12S364; however, if complete penetrance is assumed, then FPF maps to a 9-cM region between D12S314 and D12S1695. This interval includes the dentatorubropallidoluysian atrophy locus, which, with FPF, gave a maximum two-point LOD score of 3.7 at a recombination fraction of 0. This is the first of the periodic-fever genes, other than FMF, to be mapped.

Positional candidate genes may now be selected for mutation analysis to determine the molecular basis for FPF. Together with the recent identification of the defective gene in FMF, identification of a gene for FPF might provide new insights into the regulation of inflammatory responses.

Autosomal dominant periodic fevers constitute a range of syndromes characterised by recurrent attacks of fever and abdominal pain. Familial Hibernian fever (FHF) has been described in only one United Kingdom based family, but two other Irish families have been found with similar clinical features. FHF resembles familial Mediterranean fever (FMF) in several clinical features, but the mode of inheritance of FHF is dominant whereas FMF is recessive. We have investigated whether autosomal dominant periodic fevers, in particular FHF, map to the FMF susceptibility locus (MEFV) on chromosome 16p13.3. We have used informative microsatellite markers flanking this locus to genotype members of the three families mentioned above. Two point and multipoint lod scores definitively excluded linkage to MEFV in the two larger families. A haplotype study confirmed these findings, indicating that FHF is genotypically as well as phenotypically distinct from FMF.

Author information:

(1)Ahmanson Department of Pediatrics, Steven Spielberg Pediatric Research Center, Cedars-Sinai Medical Center and UCLA School of Medicine, Los Angeles, California 90048, USA.

Familial Mediterranean fever (FMF) is an autosomal recessive disease clinically characterized by recurrent short self-limited attacks of fever accompanied by peritonitis, pleurisy, and arthritis and can lead to amyloidosis and renal failure in the longer term. It is prevalent mainly in non-Ashkenazi Jews, Armenians, Turks, and Arabs. Due to the lack of an accurate diagnostic test, patients often experience years of attacks and invasive diagnostic procedures before the correct diagnosis is made and adequate treatment is begun. Recently, the gene responsible for FMF, denoted pyrin, has been cloned, and three disease mutations have been described (French FMF Consortium, 1997; International FMF Consortium, 1997). In the current study we assessed the spectrum of mutations in this gene in 16 unrelated families of Turkish origin. The three previously reported missense mutations (Met-Ile at codon 680, Met-Val at codon 694, and Val-Ala at codon 726) accounted for 29 of the 34 disease alleles. In one patient in whom no disease mutation was identified, the clinical picture was atypical enough to raise questions regarding the diagnosis. These results imply that the origin of FMF in Turkey is heterogeneous, that molecular diagnosis of FMF is possible in the majority of cases and clinically helpful, and that delineation of the undiscovered disease mutation(s) in the remaining cases remains a high priority.

**OBJECTIVE:** A number of differences have been noted in clinical familial Mediterranean fever (FMF) among ethnic groups. Iraqi Jews and Druzes are characterized by less severe disease. The differences in disease expression raise the possibility of background genes peculiar to specific ethnic groups.

**METHODS:** We analyzed a series of FMF linked microsatellite markers and searched for gene mutations in these 2 populations.

**RESULTS:** We observed a conserved haplotype in 46% of the FMF druze chromosomes that was different from the Mediterranean haplotype but identical to the ARM3 haplotype. In contrast, 56% of the FMF chromosomes in Iraqi Jews displayed the same mutation as that found in Jews from North Africa.

**CONCLUSION:** Variable expression in FMF is probably due to both allelic heterogeneity and/or modifier genes as well as environmental factors.

Familial Mediterranean fever: from the clinical syndrome to the cloning of the pyrin gene.

Pras M.

Familial Mediterranean fever (FMF) is a genetic disorder, restricted to peoples originating in the Middle East. The clinical syndrome is characterized by shortlived febrile episodes, accompanied by inflammation in one of the serous membranes, resulting in peritonitis pleuritis or synovitis. In many untreated FMF patients, systemic amyloidosis developed. The clinical presentation of amyloidosis in FMF is nephropathic, progressing from proteinuria, nephrosis to renal failure and end stage renal disease. Continuous colchicine treatment, which was introduced in 1972, prevents most febrile-inflammatory attacks of FMF, and inhibits the development of amyloidosis in this otherwise fatal disease. Recently, the gene that causes FMF was cloned. It is called the pyrin gene and encodes the pyrin protein. Five missense mutations were found so far in the gene. These give rise to 5 amino acid substitutions, all of them in the carboxyterminal part of the pyrin protein. The pyrin protein is expressed solely in neutrophils white blood cells which are found in large numbers in the inflammatory sites during FMF attacks. It seems that the role of the wild type of the pyrin protein is to inhibit inflammation that can be provoked by a minor insult. The mutated pyrin protein in FMF is probably unable to inhibit these unnecessary inflammatory events. Preliminary studies of phenotype genotype correlation are reported.

Kastner DL(1).

Author information:

(1)National Institutes of Health, Bethesda, Md., USA.

When a patient complains of episodic fever accompanied by unexplained arthritis, peritonitis, pleurisy, or skin rash, this disorder should be considered. The disease-related gene codes for a protein that guides a neutrophil's participation in inflammation; the protein's existence implies an entire regulatory pathway hitherto unknown. At least two other mendelian periodic fever syndromes have also been described.

The effect of colchicine treatment on sperm production and function: a review.

Haimov-Kochman R(1), Ben-Chetrit E.

Author information:

(1)Department of Obstetrics and Gynecology, Hadassah University Hospital, Mount Scopus, Jerusalem, Israel.

Colchicine is used for the treatment of various diseases including gouty arthritis, familial Mediterranean fever (FMF) and Behcet's disease. As a modulator of the microtubules at the cytoskeleton level, it arrests cell division at metaphase and inhibits microtubular-dependent cell motility. Controversy exists as to the adverse effect of colchicine on sperm production and function in healthy subjects as well as in gout, FMF and Behcet's patients. Sperm analysis shows a spectrum of pathology, from oligo- and azoospermia to normospermia with disturbances in sperm motility. These inconsistent sperm pathologies can be explained in part by the variability of the pathophysiology of the underlying disease. Thus, it seems that colchicine by itself may not have a significant direct adverse effect on sperm production and function.

[Can amyloidosis regress?].

[Article in French]

Dray JM(1), Blétry O.

Author information:

(1)Service de médecine interne, Hôpital Foch, Suresnes.

Amyloidosis always worsens in the absence of treatment. Suitable treatments may improve the prognosis, but results depend on the type of amyloidosis. AA amyloidosis can improve according to clinical and biological criteria after the treatment of underlying disease, or after colchicine therapy in familial mediterranean fever. Histological regression is very unusual. A small clinical improvement or at least a stabilisation can be observed in familial amyloidosis with mutation in plasma transthyretin, after liver transplantation. However, the follow-up is short and the mortality is high. In AL amyloidosis, the survival is usually less than 15 months. Some patients have a better survival when they receive chemotherapy similar to that given in multiple myeloma. This could indicate an amyloidosis improvement, or at least a stabilisation.

[Hereditary amyloidosis].

[Article in French]

Grateau G(1).

Author information:

(1)Service de médecine interne, L'Hôtel-Dieu, Paris.

Clinical aspects of hereditary amyloidoses are very diverse, and they pose many diagnostic problems to the physician. Biochemical and genetic aspects are also various. Several proteins are implicated in these hereditary diseases: transthyretin, apolipoprotein A1, gelsolin, fibrinogen alpha chain and lysozyme.

Studies on structural changes induced by the mutations in these proteins should bring new data relevant to our understanding of the amyloidogenic process. Familial mediterranean fever is a hereditary disease of the inflammatory reaction which is associated with AA amyloidosis.

Chronic massive knee effusion in familial Mediterranean fever.

Salai M(1), Zemmer D, Segal E, Corat A, Heyman Z, Davidson B, Langevitz P, Livneh A.

Author information:

(1)Department of Orthopedic Surgery A, Chaim Sheba Medical Center, Tel Hashomer, Israel.

OBJECTIVE: To document the occurrence of chronic massive knee effusions in patients with familial Mediterranean fever (FMF).

PATIENTS: Three cases of chronic massive knee effusion of young FMF patients requiring open synovectomy are presented.

RESULTS: Open synovectomy necessitated protracted rehabilitation, eventually with good results.

CONCLUSIONS: FMF should be considered in the differential diagnosis of chronic massive knee effusion. Early diagnosis and daily colchicine treatment generally result in a good clinical outcome and may eliminate the need for open synovectomy in favor of arthroscopic surgery.

Clinical differences between North African and Iraqi Jews with familial Mediterranean fever.

Pras E(1), Livneh A, Balow JE Jr, Pras E, Kastner DL, Pras M, Langevitz P.

Author information:

(1)Department of Medicine F, Sheba Medical Center, Tel-Hashomer, Israel.

Comment in

Am J Med Genet. 1999 Feb 19;82(5):442.

Familial Mediterranean fever (FMF) is an autosomal recessive disease causing attacks of fever and serositis. The gene causing this disease, designated MEFV, was mapped to the short arm of chromosome 16, but has not yet been cloned. North African and Iraqi Jews constitute the two largest population groups suffering from the disease in Israel. In this report we compared the severity of the disease between these two populations. North African Jews were found to have a more severe disease manifested by an earlier age of onset, an increase in frequency and severity of joint involvement, a higher incidence of erysipelas-like erythema, and a higher dose of colchicine required to control symptoms. The involvement of additional genes, environmental factors, and different mutations in MEFV, may explain the clinical variation in disease severity between these two population groups.

Attacks of pericarditis as a manifestation of familial Mediterranean fever (FMF).

Kees S(1), Langevitz P, Zemer D, Padeh S, Pras M, Livneh A.

Author information:

(1)Heller Institute of Medical Research, Sheba Medical Center, Tel-Hashomer, Israel.

Familial Mediterranean fever (FMF) is characterized by recurrent attacks of febrile serositis. While arthritis, pleuritis and peritonitis are common in FMF, no association of pericarditis with FMF has been described in detail. We

retrospectively studied about 4000 FMF patients, using a computer chart review. Pericarditis was diagnosed when patients sustained attacks of pleuritic retrosternal chest pain and had typical findings in the electrocardiogram, echocardiogram or chest radiogram. The incidence and features of pericarditis in FMF were compared to published data. Over a period of 20 years, one or more episodes of pericarditis were recorded in 27 patients, a significantly higher incidence than in the general population (68 vs. 6 per 10(5) per year,  $p < 0.001$ ). Each patient experienced 1-3 pericarditis attacks, lasting a mean of 4.2 days, accompanied by high temperature and symptoms of FMF attack at another site. The pericarditis attack resolved spontaneously and left no sequelae. FMF patients with pericarditis were comparable to other FMF patients in most demographic and clinical parameters. Pericarditis may be considered another rare manifestation of FMF.

**OBJECTIVE:** To report an uncommon case of familial Mediterranean fever with urological manifestations.

**METHODS/RESULTS:** A case of recurrent hydrocele in a patient with familial Mediterranean fever is described.

**CONCLUSIONS:** Although familial Mediterranean fever is characterized by an acute febrile stage and involvement of the serosa, it may manifest as recurrent hydrocele due to involvement of the urological serosa, as in the case described herein.

Familial Mediterranean fever (FMF) is an inherited disorder characterized by recurrent self-limiting attacks of joint, chest and abdominal pain associated with fever. The most serious complication in FMF is the development of amyloidosis, which usually leads to death from renal failure within a year. The use of colchicine has dramatically reduced this complication. We describe a 56-yr-old female patient with FMF in whom the arthropathy became the dominant clinical feature, resulting in the development of an erosive large and small joint arthritis during the course of the disease. The patient was treated with colchicine, but despite this, later developed amyloidosis confirmed on rectal biopsy, and chlorambucil was added to her treatment. For 10 yr, she also suffered intermittent abdominal pain and had terminal ileal changes suggestive of Crohn's disease. However, she was found to have ischaemic colitis at post mortem secondary to amyloidosis. Ischaemic bowel disease is an extremely unusual event in FMF. Other factors which may have contributed to the terminal ischaemia in

this patient include anaemia secondary to blood loss and a drug-induced myelodysplasia, as well as hypotension during the final septicaemic illness. Clinicians should consider an ischaemic colitis as a possible differential diagnosis of abdominal pain in patients with FMF even in the absence of other clinical evidence of systemic amyloidosis.

Familial Mediterranean fever: clastogenic plasma factors correlated with increased O<sub>2</sub>(-)-production by neutrophils.

Sarkisian T(1), Emerit I, Arutyunyan R, Levy A, Cernjavski L, Filipe P.

Author information:

(1)Department of Genetics, Yerevan State University, Armenia.

Familial Mediterranean fever (FMF) is an autosomal recessive disease predominantly affecting Armenians and non-Ashkenazi Jews. The disease begins in childhood with paroxysmal attacks of pain and fever accompanied by peritonitis, pleuritis, and synovitis. During the acute phase, there is a massive influx of polymorphonuclear leukocytes into the serosal membranes, connected with degranulation of the neutrophils and with secretion of lysosomal enzymes and

pyrogenic substances. An increase in the lipoxygenase product, leukotriene B<sub>4</sub>, a chemotactic agent, and a decrease in the activity of the inhibitor of chemotaxis, C5a, in serosal fluids have been considered responsible. Previous work from our laboratories had shown that the chromosomal instability observed in blood cultures of patients with FMF is secondary to circulating clastogenic factors (CFs), and that the antioxidant enzyme superoxide dismutase, as well as lipoxygenase inhibitors, reduce the chromosome damaging effects. CFs are observed in chronic inflammatory diseases and in various other pathological conditions accompanied by oxidative stress. Similar clastogenic materials were found in supernatants of neutrophils and monocytes after a respiratory burst and were shown to contain lipid peroxidation products and cytokines. In the present study we compared the clastogenic effects exerted by plasma ultrafiltrates from 20 adult patients with FMF to the unstimulated O<sub>2</sub>- production of their neutrophils. In comparison to 20 age- and sex-matched controls, which were studied simultaneously, the O<sub>2</sub>- production by patient's neutrophils was routinely higher than that of controls. The clastogenic effects of patient's plasma, expressed as the number of chromosomal aberrations induced in test cultures of healthy donors, were correlated with the importance of O<sub>2</sub>- production by their neutrophils ( $r = 0.5235$ ). Even if the relative contribution of disturbance in arachidonic acid metabolism, neutrophil activation, and CF formation in the disease process remains unclear, the demonstration of oxidative stress in this genetic disorder suggests the use of antioxidants and free radical scavengers, in particular during acute attacks, when the classical colchicine treatment is without effect.

Seronegative spondyloarthropathy in familial Mediterranean fever.

Langevitz P(1), Livneh A, Zemer D, Shemer J, Pras M.

Author information:

(1)Heller Institute of Medical Research, Sheba Medical Center, Tel-Hashomer, Israel.

To define a possible association between familial Mediterranean fever (FMF) and seronegative spondyloarthropathy (SNSA) and to study features of SNSA in FMF patients, we screened for the presence and manifestations of SNSA in 3,000 FMF patients attending the National Center for FMF in our institution. This population included 160 patients with chronic arthritis, most who suffered from

SNSA. Patients were considered to suffer from SNSA if they had chronic arthritis, inflammatory back/neck pain, and sacroiliitis. Patients who had other diseases associated with SNSA were excluded. Eleven patients, nine men and two women, with chronic monoarthritis or oligoarthritis, grade 2 (four patients) or grades 3 to 4 (seven patients), sacroiliitis, and inflammatory back pain met the criteria for diagnosis of SNSA of FMF. These patients were rheumatoid factor (RF) and HLA-B27 negative. In seven patients, spondyloarthropathy developed while they received colchicine, and in four before colchicine. Most patients responded to treatment with nonsteroidal antiinflammatory drugs, but three required second-line agents. These findings suggest that SNSA is one of the musculoskeletal manifestations of FMF that may occur despite colchicine therapy and requires specific treatment.

Familial Mediterranean fever (FMF) is a recessive disorder of inflammation caused by mutations in a gene (designated MEFV) on chromosome 16p13.3. We have recently constructed a 1-Mb cosmid contig that includes the FMF critical region. Here we show genotype data for 12 markers from our physical map, including 5 newly identified microsatellites, in FMF families. Intrafamilial recombinations placed MEFV in the approximately 285 kb between D16S468/D16S3070 and D16S3376. We observed significant linkage disequilibrium in the North African Jewish population, and historical recombinants in the founder haplotype placed MEFV between D16S3082 and D16S3373 (approximately 200 kb). In smaller panels of Iraqi

Jewish, Arab, and Armenian families, there were significant allelic associations only for D16S3370 and D16S2617 among the Armenians. A sizable minority of Iraqi Jewish and Armenian carrier chromosomes appeared to be derived from the North African Jewish ancestral haplotype. We observed a unique FMF haplotype common to Iraqi Jews, Arabs, and Armenians and two other haplotypes restricted to either the Iraqi Jewish or the Armenian population. These data support the view that a few major mutations account for a large percentage of the cases of FMF and suggest that some of these mutations arose before the affected Middle Eastern populations diverged from one another.

The efficacy of interferon alpha on colchicine-resistant familial Mediterranean fever attacks: a pilot study.

Tunca M(1), Tankurt E, Akbaylar Akpinar H, Akar S, Hizli N, Gönen O.

Author information:

(1)Department of Internal Medicine, Dokuz Eylül University School of Medicine, Balçova, Izmir, Turkey.

About a quarter of familial Mediterranean fever (FMF) patients have recurrent painful attacks of polyserositis despite regular colchicine treatment. There is no known alternative drug for colchicine-resistant cases. We had previously observed a patient with FMF whose painful attacks disappeared during the 6 month period of interferon alpha (IFN) treatment for his chronic hepatitis B. The objective of the present study was to investigate the possible beneficial effect of IFN on these episodes. Twenty-one consecutive attacks in seven adult patients with FMF were treated at early onset with IFN, the dosage being 3-10 million I U s.c. Eighteen of the 21 attacks could be halted in a mean time of 3.05 h, while the intensity of abdominal pain remained very low. Observed side-effects were generally mild and acceptable. IFN may be a useful adjunct for the treatment of colchicine-resistant attacks in FMF patients.

Comment in

Arthritis Rheum. 1998 Aug;41(8):1516-7.

**OBJECTIVE:** To establish a new set of criteria for the diagnosis of familial Mediterranean fever (FMF).

**METHODS:** Twenty-seven features and manifestations typical of FMF were studied to determine their prevalence in 105 patients with FMF and 106 controls. Diagnosis of FMF in the study group was based on clinical judgment. Controls were patients with a variety of other diseases who presented to the emergency room or outpatient clinics with recurrent episodes of pain in body sites usually involved in FMF attacks. Manifestations observed to be significantly more common in FMF patients than in controls were incorporated into the rule proposed for diagnosis of FMF, based on a model of major, minor, and supportive criteria.

**RESULTS:** Two sets of diagnostic criteria were established. A conservative criteria set for diagnosis of FMF was based on the presence of 1 major or 2 minor criteria, or 1 minor plus 5 supportive criteria, and a simple criteria set for diagnosis of FMF required 1 major or 2 minor criteria. The sensitivity and specificity of these 2 criteria sets were >95% and >97%, respectively.

**CONCLUSION:** The proposed new sets of criteria were highly sensitive and specific, and could be used to readily diagnose FMF and to distinguish FMF from other periodic febrile diseases.

(1)Gainesville Veterans Affairs Medical Center, and Department of Medicine, University of Florida College of Medicine, 32610, USA.

Chronic constipation is a common clinical condition that frequently does not respond to routine therapeutic measures. We hypothesized that colchicine would be effective in this condition because we reported that it stimulates intestinal motility in rats and commonly causes diarrhea in patients taking the drug for either gouty arthritis or Familial Mediterranean fever. We prospectively studied seven patients with chronic constipation who were refractory to medical therapy and treated them with oral colchicine 0.6 mg per os three times a day for eight weeks in an open-label pilot study. During the study, the mean number of spontaneous bowel movements significantly increased ( $P < 0.05$ ) from  $1.7 \pm 0.5$  noted during routine therapy of constipation with laxatives and enemas to  $6.4 \pm 0.7$  per week; mean colonic transit time significantly ( $P < 0.05$ ) decreased from  $58.1 \pm 2.5$  to  $47.1 \pm 5.0$  hr; and symptoms of abdominal pain, nausea, and bloating significantly ( $P < 0.05$ ) improved during therapy with colchicine. Oral colchicine (0.6 mg three times a day) therapy appears to be an a promising treatment for chronic constipation and a placebo-controlled trial is indicated to confirm these findings.

Familial Mediterranean fever (FMF) is an autosomal recessive disorder characterized by attacks of fever and serositis. In this paper, we define a minimal co-segregating region of 60 kb containing the FMF gene (MEFV) and identify four different transcript units within this region. One of these transcripts encodes a new protein (marenostrin) related to the ret-finger protein and to butyrophilin. Four conservative missense variations co-segregating with FMF have been found within the MEFV candidate gene in 85% of the carrier chromosomes. These variations, which cluster at the carboxy terminal domain of the protein, were not present in 308 control chromosomes, including 162 validated non-carriers. We therefore propose that the sequence alterations in the marenostrin protein are responsible for the FMF disease.

Ancient missense mutations in a new member of the RoRet gene family are likely to cause familial Mediterranean fever. The International FMF Consortium.

[No authors listed]

Familial Mediterranean fever (FMF) is a recessively inherited disorder characterized by dramatic episodes of fever and serosal inflammation. This report describes the cloning of the gene likely to cause FMF from a 115-kb candidate interval on chromosome 16p. Three different missense mutations were identified in affected individuals, but not in normals. Haplotype and mutational analyses disclosed ancestral relationships among carrier chromosomes in populations that have been separated for centuries. The novel gene encodes a 3.7-kb transcript that is almost exclusively expressed in granulocytes. The predicted protein, pyrin, is a member of a family of nuclear factors homologous to the Ro52 autoantigen. The cloning of the FMF gene promises to shed light on the regulation of acute inflammatory responses.

Familial Mediterranean fever and multiple sclerosis.

Topçuoğlu MA(1), Karabudak R.

Author information:

(1)Department of Neurology, Hacettepe University Hospitals, Ankara, Turkey.  
rk01-k@servis.net.tr

Central nervous system (CNS) manifestations of familial Mediterranean fever (FMF) are extremely rare. These include pseudotumor cerebri, optic neuritis, CNS complications of polyarteritis nodosa type vasculitis, or hypercoagulable states secondary to renal amyloidosis, recurrent aseptic meningitis, and amyloid ophthalmoplegia. We present three patients with FMF whose neurological findings and magnetic resonance imaging (MRI) abnormalities resembled multiple sclerosis (MS). These two conditions in the same patient could arise from either coincidence or an unknown pathophysiological relationship. Both explanations are equally speculative and this matter needs further study, especially to investigate MRI features in FMF patients without CNS symptoms.

Serum prolactin in coeliac disease: a marker for disease activity.

Reifen R(1), Buskila D, Maislos M, Press J, Lerner A.

Author information:

(1)School of Nutritional Sciences, Hebrew University of Jerusalem, Rehovot.

Prolactin, a polypeptide hormone of anterior pituitary origin, has pronounced physiological effects on growth, reproduction, and osmoregulation. Increasing evidence indicates that prolactin also has an immunomodulatory influence on the immune system. The status of prolactin in patients with coeliac disease was investigated by obtaining serum samples from 48 patients with active and non-active coeliac disease. These were compared with samples from 20 children with familial Mediterranean fever and 65 normal controls. Serum prolactin in patients with active coeliac disease was significantly higher than in the other groups studied and reference values. Serum prolactin correlated well with the degree of mucosal atrophy and with the serum concentration of antiendomysial antibodies. Prolactin may play a part in immune modulation in the intestinal damage of coeliac disease and serve as a potential marker for disease activity.

Rheumatology, Ankara, Turkey.

Familial Mediterranean fever (FMF) is a genetically transmitted disease characterized by recurrent attacks of fever and serositis. The most important complication of this disease is the development of amyloidosis. We present our analysis of 425 FMF patients without and 180 with amyloidosis (123 FMF having amyloidosis type I and 57 FMF having amyloidosis type II). The male female ratio was higher in the amyloidosis population (111/69) when compared to the FMF population (225/200) ( $P = 0.048$ ). Consanguinity rate was the same among FMF and amyloidosis groups. However, a family history of amyloidosis was significantly more frequent in the amyloidosis group ( $P = 0.00001$ ). Multivariate analysis has revealed that in FMF patients, the presence of a family history of amyloidosis plus consanguinity has a 6.04 fold increased risk of amyloidosis ( $P < 0.0001$ ). The 5-year chronic renal failure free survival was 43.1% and 18.7% in type I and type II amyloidosis, respectively. The time interval to develop chronic renal failure after the development of amyloidosis was 4.8 in type I and 3.0 years in type II, respectively. We found ten cases of Henoch-Schönlein Purpura and nine of polyarteritis nodosa among our patients. The significance of the association between FMF and vasculitis awaits to be clarified. Among the FMF patients put on colchicine therapy (435), only 10 (2.3%) have developed amyloidosis confirming that this drug protects from amyloidosis. **CONCLUSION:** Since the presence of a familial history of amyloidosis has been defined as the most important risk factor in the development of amyloidosis, we suggest that additional genetic factors may be operative in the development of amyloidosis.

Author information:

(1)Heller Institute of Medical Research, Sheba Medical Center, Tel-Hashomer,

Israel.

**OBJECTIVE:** To determine whether the 2 periodic febrile syndromes familial Mediterranean fever (FMF) and hyperimmunoglobulinemia D syndrome (HIDS) are distinct diseases.

**METHODS:** Clinical manifestations of the diseases were analyzed by physicians experienced with FMF and HIDS. Serum immunoglobulin (Ig) levels were studied in 70 patients with FMF using nephelometry or ELISA and compared with Ig levels in 50 patients with HIDS. Genetic linkage of HIDS with the chromosome 16 polymorphic locus RT70, currently used for refined localization of the FMF susceptibility gene (MEFV), was studied in 9 HIDS families (18 patients) using polymerase chain reaction amplification and gel electrophoresis.

**RESULTS:** The main clinical features distinguishing FMF from HIDS were lymphadenectomy, skin eruption, and symmetrical oligoarthritis in HIDS, and monoarthritis, peritonitis, and pleuritis in FMF. Increased IgG levels were found in 12 patients with FMF (17%), IgA in 16 (23%), IgM in 9 (13%), and IgD in 9 (13%), significantly lower than the prevalence reported for HIDS. We found no evidence for genetic linkage between HIDS and the chromosome 16 marker RT70.

**CONCLUSION:** HIDS and FMF are different entities, clinically, immunologically, and genetically.

Quality of life of patients with familial Mediterranean fever.

Buskila D(1), Zaks N, Neumann L, Livneh A, Greenberg S, Pras M, Langevitz P.

Author information:

(1)Rheumatic Unit, Soroka Medical Center, Ben-Gurion University of the Negev, Beer Sheva, Israel.

**OBJECTIVE:** The aim of the present study was to assess the quality of life (QOL) of patients with Familial Mediterranean Fever (FMF) and to explore its possible contributing factors.

**METHODS:** One hundred and two FMF patients were evaluated using a QOL Scale, and

were compared to 124 healthy controls. The QOL scale includes 16 items, each measured on a 7-point scale (7 indicating maximal satisfaction).

RESULTS: The total QOL score of FMF patients was significantly lower than that of the controls: 81.6 +/- 19.2 vs 88.0 +/- 12.8 ( $p < 0.01$ ). Male and female patients reported similar QOL scores. QOL was inversely correlated with the number of FMF attacks in the last year ( $r = -0.302$ ,  $p = 0.002$ ), and with the number of FMF hospitalizations ( $r = -0.238$ ,  $p = 0.017$ ). Patients with widespread pain, sleep disturbances and headaches had significantly lower QOL scores than patients without them.

CONCLUSIONS: The QOL of FMF patients was found to be impaired compared to healthy controls. Further studies are needed to determine the exact factors affecting the quality of life of FMF patients.

Genetic linkage study of familial Mediterranean fever (FMF) to 16p13.3 and evidence for genetic heterogeneity in the Turkish population.

Akarsu AN(1), Saatci U, Ozen S, Bakkaloglu A, Besbas N, Sarfarazi M.

Author information:

(1)Department of Surgery, University of Connecticut Health Center, Farmington 06030-1110, USA.

Familial Mediterranean fever (FMF) is an autosomal recessive condition that is almost entirely restricted to the non-Askhenazi Jews, Arabs, Armenians, and Turks. Genetic linkage study of a large group of non-Turkish families has previously mapped the FMF locus to the 16p13.3 region and shown that this locus resides 0.305 cM distal to D16S246. Furthermore, allelic association has also been shown with D16S3070 (75%) and D16S3275 (66%). However, no genetic heterogeneity has been described for any of the three major reported groups of FMF families. Here, we describe the genetic linkage relationship of the fourth major group of Turkish families and report the first evidence for genetic heterogeneity of this condition. Two point linkage analysis and haplotype inspection of 15 DNA markers from the reported region of the FMF locus identified

tight linkage in a group of six Turkish FMF families. A maximum lod score of 9.115 at  $\theta = 0.00$  was observed for D16S3024. Nine other DNA markers provided similar evidence of linkage with lod score values of above 5.21. However, two other FMF families were completely unlinked to this region of chromosome 16. Haplotype construction of DNA markers in five consanguineous linked families showed that a segment of homozygosity has been conserved for D16S3070 and D16S2617. No other DNA markers showed any such conservation. Therefore, we suggested that these two markers reside in close proximity to the FMF locus. Furthermore, we observed 80% allelic association with D16S2617 but no association with D16S3070 or any other DNA markers from the FMF critical region. In summary, we conclude that our Turkish families are also linked to the reported FMF locus at 16p13.3, there is a genetic heterogeneity for this condition at least in our group of Turkish families, and D16S2617 is in linkage disequilibrium in the Turkish FMF families. Combination of this study with previously published observations suggests that the FMF locus resides between D16S246 and D16S3070/D16S2617 and within a region of about 250-300 kb.

Author information:

(1)Institute of Internal Medicine and Geriatrics, Catholic University of the Sacred Heart, Rome, Italy.

A 39-year-old man had a 2-year history of fatigue, weight loss, drug-resistant ascites, and decreased intestinal motility. During adolescence he began to suffer frequent episodes of acute benign peritonitis that spontaneously subsided at age 35. The fact that his younger brother was taking colchicine for the same symptoms led us to diagnose familial Mediterranean fever (FMF). The medical workup revealed uniform thickening of the intestinal wall with no signs of amyloidosis.

Exploratory laparotomy revealed diffuse peritoneal mesothelioma that proved to be unresponsive to chemotherapy. There was no history of asbestos exposure. It is probable that the chronic peritoneal inflammation was responsible for the development of this tumor, although in almost all cases of FMF this phenomenon causes only limited peritoneal fibrosis or, less commonly, encapsulating peritonitis. A computerized search of the literature indicates that this is the second report of peritoneal mesothelioma associated with FMF.

Light chain deposition disease complicating familial Mediterranean fever.

Vella JP(1), Doyle GD, Campbell E, Walshe JJ.

Author information:

(1)Division of Nephrology, Beaumont Hospital, Dublin, Ireland.

Familial Mediterranean fever (fMf) is an inherited condition characterized by polyserositis and is sometimes complicated by AA renal amyloidosis leading to nephrotic syndrome and renal failure. We present a case of a man with fMf who presented with rapidly progressive renal failure caused by light chain deposition disease. This disease association has not previously been described in the medical literature.

[Article in Dutch]

Dorhout Mees EJ(1).

Author information:

(1)Ege Universitesi Lojmanlari, Izmit, Turkije.

The stormy development of Turkey in this century resulted in a drastic decrease of illiteracy and in a craving for knowledge among the younger generations. Qualitatively good students are admitted to universities. In the last 25 years, 47 new universities were founded (8 of them private ones), partly for political reasons. Teachers of medicine are underpaid, so that many earn extra money by working in a private practice. The results of medical teaching are adequate, owing in part to quality and motivation of students and interns. Much research is being subsidized by the Turkish Institute for Scientific and Technical Research, Tübitak, but bureaucracy inhibits originality. Research and postgraduate training are increasingly controlled by the pharmaceutical industry. Primary medical care is underdeveloped. The quality of medical treatment is technically adequate; modern diagnostic and surgical methods are available in all major centres. There is much private enterprise in health care (private clinics, private laboratories, research centres, universities and pharmacies). The latest drugs are available and given preference in prescribing. In Southeast Turkey, populated by Kurds, however, the economy has come to a complete standstill and there is an enormous shortage of physicians and hospitals. The prevalence of renal diseases differs from that in the Netherlands: fewer cystic kidneys, less diabetic nephropathy and nephropathy due to analgetics, but more acute glomerulonephritis and amyloidosis due to familial Mediterranean fever. Haemodialysis, is one of the fastest-growing methods of treatment; peritoneal dialysis is rapidly gaining ground. Kidney transplantations have been performed regularly since 1975.

[Follow-up and therapy of acute colchicine poisoning].

[Article in German]

Stern N(1), Kupferschmidt H, Meier-Abt PJ.

Author information:

(1)Schweizerisches Toxikologisches Informationszentrum (STIZ), Zürich.

Colchicine poisoning is a rare event. Its outcome is, compared to other drug intoxications, often serious or even fatal. Intoxications with colchicine may occur by ingestion of tablets as well as by consumption of meadow saffron leaves (*Colchicum autumnale*) that are often mistakenly collected instead of the leaves of ramson herb (*Allium ursinum*). Colchicine poisoning typically shows three phases: initially gastrointestinal symptoms predominate, in the second phase multiorgan failure may occur possibly leading to death. In case the patient survives, the third phase of recovery follows during which the patients often present with hair loss. The fatal dose of acute colchicine poisoning is estimated at about 0.9 mg/kg. Since hemodialysis and hemoperfusion are not effective measures because of the high volume of distribution, an aggressive primary decontamination with gastric lavage and activated charcoal is required as early as possible. A promising new aspect in the treatment of heavy colchicine overdose is the immunotherapy with colchicine-specific fab-fragments. At present this treatment is still in an experimental stage and has been applied so far to one patient with beneficial effects. Unfortunately colchicine-specific antibodies are not yet commercially available.

Author information:

(1)Arthritis and Rheumatism Branch, National Institute of Arthritis and Musculoskeletal and Skin Diseases, National Institute of Health, Bethesda, Maryland 20892, USA. raman@frnf.niams.nih.gov

In this paper we describe the assembly and restriction map of a 1.05-Mb cosmid contig spanning the candidate region for familial Mediterranean fever (FMF), a recessively inherited disorder of inflammation localized to 16p13.3. Using a combination of cosmid walking and screening for P1, PAC, BAC, and YAC clones, we have generated a contig of genomic clones spanning approximately 1050 kb that contains the FMF critical region. The map consists of 179 cosmid, 15 P1, 10 PAC, 3 BAC, and 17 YAC clones, anchored by 27 STS markers. Eight additional STSs have been developed from the approximately 700 kb immediately centromeric to this genomic region. Five of the 35 STSs are microsatellites that have not been previously reported. NotI and EcoRI mapping of the overlapping cosmids, hybridization of restriction fragments from cosmids to one another, and STS analyses have been used to validate the assembly of the contig. Our contig totally subsumes the 250-kb interval recently reported, by founder haplotype analysis, to contain the FMF gene. Thus, our high-resolution clone map provides an ideal resource for transcriptional mapping toward the eventual identification of this disease gene.

Other forms of vasculitis and pseudovasculitis.

Hamuryudan V(1), Ozdoğan H, Yazici H.

Author information:

(1)Department of Internal Medicine, University of Istanbul, Cerrahpaşa Medical Faculty, Cerrahpaşa, Turkey.

Behçet's syndrome can involve all sizes and kinds of blood vessels. There is an association between arterial involvement and venous thrombosis. Pulmonary arterial aneurysms and neurological involvement have a definite influence on mortality. Male sex and young age are indicators of a more severe disease course. Immunosuppressive treatment early in the disease may affect the long term prognosis favourably. Patients with familial Mediterranean fever may develop manifestations of vasculitis. The most common associations are with Schönlein-Henoch purpura and polyarteritis nodosa. In some patients the diagnosis of vasculitis precedes that of familial Mediterranean fever. Kawasaki disease, although rare, can be seen in adults. The coronary sequela of childhood disease can affect the prognosis later in life. Many conditions, like myxoma, cholesterol embolism, calciphylaxis may mimic vasculitic syndromes. These conditions should always be kept in mind because their pathophysiology and treatment are different from true vasculitides.

Comment in

Anaesthesia. 1997 Nov;52(11):1116-7.

Cannabinoids have analgesic and, possibly, anti-inflammatory properties but their clinical use has been restricted by legislation. This is the first United Kingdom report of the controlled use of a standardised pharmaceutical preparation of cannabinoids in capsular form. The therapy was assessed in a patient with

familial Mediterranean fever, who presented with chronic relapsing pain and inflammation of gastrointestinal origin. After determining a suitable analgesic dosage, a double-blind placebo-controlled cross-over trial was conducted using 50 mg tetrahydrocannabinol daily in five doses in the active weeks and measuring effects on parameters of inflammation and pain. Although no anti-inflammatory effects of tetrahydrocannabinol were detected during the trial, a highly significant reduction ( $p < 0.001$ ) in additional analgesic requirements was achieved. Future study designs can now incorporate prescribable forms of cannabinoids but the choice of previous cannabis users only as patients has clinical limitations. Cannabis naive patients would tolerate controlled investigations but may generate medicolegal problems.

Genotypic diagnosis of familial Mediterranean fever (FMF) using new microsatellite markers: example of two extensive non-Ashkenazi Jewish pedigrees.

Dupont M(1), Dross C, Smaoui N, Nedelec B, Grateau G, Clépet C, Gourdier I, Koné-Paut I, Delpech M, Demaille J, Touitou I.

Author information:

(1)Laboratoire de Génétique Moléculaire et Chromosomique, Hôpital A de Villeneuve, Montpellier, France.

Familial Mediterranean fever is an autosomal recessive disease characterised by multiple attacks of serosal inflammation in the absence of treatment. In the absence of timely diagnosis, renal amyloidosis is a life threatening complication. The diagnosis is often missed because no specific test is available. Early colchicine treatment prevents attacks and renal complications. The FMF gene (MEF) has been mapped to chromosome 16p 13.3 but has not yet been identified. We compared the suitability of a series of microsatellite markers (four of them were new) and propose the routine use of seven of these markers, exhibiting alleles in strong linkage disequilibrium with the disease and informative in 100% of diagnosed patients. Moreover, the discovery of a homozygous status for the 3-3-9 (or 3-3-18) haplotype at the core loci (D16S3070,

D16S3082, and D16S3275), which was found in 73% non-Ashkenazi Jewish patients, points to a diagnosis of FMF, even in sporadic cases, with a risk of error of only  $2.10(-5)$ . Two extensive pedigrees covering most indications for genetic counselling are presented, showing that it is now possible both prospectively and retrospectively to identify members likely to have MEF mutations. With the help of this accurate test, colchicine treatment can be better targeted, especially where the symptomatology is mild or atypical.

Rare vasculitic syndromes.

Dillon MJ(1).

Author information:

(1)Great Ormond Street Hospital for Children, London, UK. M.Dillon@ich.ucl.ac.uk

Vasculitis can and does occur in childhood. Apart from the common vasculitides (Henoch-Schönlein purpura, hypersensitivity angiitis and Kawasaki disease) there are a number of important but comparatively rare disorders affecting children. These include macroscopic and microscopic polyarteritis, cutaneous polyarteritis, Wegener's granulomatosis, Churg-Strauss syndrome, primary angiitis of the central nervous system, hypocomplementaemic urticarial vasculitis, vasculitis associated with various connective tissue disorders, Takayasu's disease and vasculitis associated with conditions such as Behcet's syndrome, familial Mediterranean fever and Cogan's syndrome. Distinguishing these conditions from other disorders is often difficult and requires clinical acumen and appropriate investigative procedures. With modern therapeutic agents it is possible to implement appropriate therapy but in spite of this, there remains a not inconsequential morbidity and mortality.

Renal, gastric and thyroidal amyloidosis due to familial Mediterranean fever.

Kavukçu S(1), Türkmen M, Eroğlu Y, Canda T, Yörükoğlu K, Iğci E, Büyükgebiz A.

Author information:

(1)Department of Pediatrics, Faculty of Medicine, Dokuz Eylül University, Izmir, Turkey.

Chronic renal failure developed in a 10-year-old girl due to renal amyloidosis secondary to familial Mediterranean fever (FMF). During management of the chronic renal failure by hemodialysis and of FMF with colchicine, goiter and hypothyroidism were observed. Thyroid fine-needle aspiration and gastric endoscopic biopsies, performed when recurrent abdominal pain could not be controlled, revealed amyloid deposits in both thyroid and gastric tissues. After 6 months' therapy with colchicine and levothyroxine, there was no significant change in the thyroid volume. This is the first case in which gastric amyloidosis secondary to FMF in childhood has been demonstrated. Patients with amyloidosis secondary to FMF who have thyroid enlargement and unexplained gastrointestinal symptoms despite adequate therapy should be evaluated with imaging studies and biopsy examinations.

Colchicine derivatives inhibit neopterin production in human peripheral blood mononuclear cells (PBMC).

Altindag ZZ(1), Werner-Felmayer G, Sahin G, Wachter H, Fuchs D.

Author information:

(1)Institute for Medical Chemistry and Biochemistry, University of Innsbruck, Austria.

Colchicine is a microtubule disrupting agent, mostly used as treatment in various kinds of inflammatory diseases such as acute familial Mediterranean fever and Behcet's disease, as well as gout. In patients with familial Mediterranean fever treatment with colchicine induces a decline of urinary neopterin concentrations which indicates a decrease of cell-mediated immune activation. In this study, we investigated a potential effect of colchicine on the T cell/macrophage system in vitro. The human myelomonocytic cell line THP-1 and PBMC were treated with colchicine or the colchicine derivative, colcemide, in the presence or absence of 250 U/ml interferon-gamma (IFN-gamma) or 10 microg/ml lipopolysaccharide (LPS) for 48 h or 96 h. Colchicine and colcemide increased neopterin/protein production in unstimulated THP-1 cells, but no such effect was apparent in cells stimulated with IFN-gamma. By contrast, when PBMC were treated with colchicine or colcemide a significant reduction in neopterin formation was evident in cells without and with prestimulation by IFN-gamma or LPS. In parallel, reduced production of IFN-gamma was observed in PBMC. These data suggest that colchicine and colcemide are able to inhibit T cell activation within the cellular immune response.

**OBJECTIVE:** To evaluate the frequency of vasculitis, mainly in the forms of Henoch-Schönlein purpura and polyarteritis nodosa (PAN), and to investigate the presence of occult blood in the first stool specimens after an abdominal attack in Turkish patients with familial Mediterranean fever (FMF).

**METHODS:** Review of the charts of 207 patients with FMF seen between 1983 and 1993 with respect to clinical vasculitis. A prospective study designed to test the

presence of occult blood in the first stool specimens obtained after abdominal attack and at least one week later in 36 patients with FMF compared with healthy and diseased controls.

RESULTS: There were 15 patients with Henoch-Schönlein purpura (7%), 2 with definite and one with probable PAN (1%), one of whom developed perirenal hematoma. The diagnosis of FMF was made after the onset of Henoch-Schönlein purpura in 9 and subsequent to the development of PAN in one patient. Occult blood was positive in the first stool specimens obtained after an attack in 17 of the 36 patients with FMF (47%), a finding not reported previously.

CONCLUSION: Vasculitis seems to be an important but not a widely recognized feature of FMF.

Periodic syndromes of childhood.

Arav-Boger R(1), Spier Z.

Author information:

(1) Dana Children Hospital, Tel-Aviv Sourasky Medical Center, Sackler Faculty of Medicine, Tel Aviv University, Israel.

Periodic syndromes of childhood comprise a large group of disorders that require long-term follow-up to be diagnosed. Several disorders have fixed rhythmicity and are therefore identified more easily. Other disorders are usually diagnosed after a prolonged follow-up and exclusion of other more common childhood diseases. In general, most of the periodic fever syndromes have a benign prognosis, and their symptomatology tends to improve in the long term. Periodic syndromes without fever or chronic pain syndromes constitute not only a diagnostic dilemma but also a therapeutic challenge. A general diagnostic approach to the periodic syndromes is outlined in Figure 1.

[Hyper-IgD-syndrome].

[Article in German]

Suschke J(1), Walther JU.

Author information:

(1) Kinderpoliklinik der Universität München.

We report on a 6-year-old Romanian girl with recently diagnosed hyper-IgD-syndrome. The leading symptom of this rare disease are periodic pyrexia, joint involvements (arthralgias/arthritis) and swollen lymph nodes. A permanent increase of alpha 1-acid glycoprotein fucosylation indicates persisting inflammation. Most important in differential diagnosis is familial Mediterranean fever. Therapy is merely supportive as yet, the long-term outlook seems good despite duration of the illness. CONCLUSION: the hyper-IgD-syndrome must be considered in cases of otherwise unexplained periodic fever.

Chronic colchicine treatment does not impair glucose tolerance in familial Mediterranean fever patients.

Burstein R(1), Seidman DS, Zemer D, Shpilberg O, Arnon R, Epstein Y, Pras M.

Author information:

(1)Heller Institute of Medical Research, Sheba Medical Center, Tel Hashomer, Israel.

**OBJECTIVE:** To investigate a long-term colchicine treatment in inhibiting normal release of insulin, in response to a glucose load.

**SETTING:** The Heller Institute of Medical Research, Sheba Medical Center, Tel-Hashomer.

**PATIENTS:** Thirty-one familial Mediterranean fever (FMF) patients, treated continuously with colchicine (1.0-2.0 mg.day<sup>-1</sup>) for 2-13 years.

**METHODS:** A standard oral glucose tolerance test (OGTT) was performed to study the effect of long-term colchicine treatment on glucose-induced insulin response. An intravenous glucose tolerance test (IVGTT) was then performed on randomly chosen FMF patients (n = 9) and age-matched controls (n = 5). Glucose was administered 30 min after intravenous colchicine (2 mg) infusion. The sum of 1st- and 3rd-min insulin levels served as an index of early-phase insulin release.

**RESULTS:** Based on the Office Guide to Diagnosis of Glucose Intolerance [13], one subject exhibited impaired glucose tolerance and two others had abnormal dynamics of glucose during the test but normal values at 120 min. Insulin values were normal in all participants. No significant differences were found in maximal glucose and insulin concentration, nor in the insulin release index between FMF colchicine-treated and healthy controls.

**CONCLUSIONS:** Based on these findings, no impairment in glucose dynamics could be demonstrated in chronically colchicine treated patients, compared to untreated controls.

The clinical patterns of arthritis in children with familial Mediterranean fever.

Majeed HA(1), Rawashdeh M.

Author information:

(1)Department of Pediatrics, Faculty of Medicine, University of Jordan, Jordan.

We studied the clinical patterns of arthritis in 133 children with familial Mediterranean fever (FMF) over 5.5 years. Six clinical patterns were noted. The commonest was recurrent monoarticular arthritis as seen in 95 children (71%), mainly affecting the knee and ankle joints. This type followed two different courses: acute (< 1 month) and chronic (> 1 month). In 18 (14%) children, both knee or ankle joints were simultaneously and symmetrically involved: here too the course was either acute or chronic. Five (4%) children developed symmetric polyarthritis similar to juvenile rheumatoid arthritis (JRA). Six (4%) children developed asymmetric oligoarticular arthritis similar to acute rheumatic fever (ARF). The small joints of the hands (SJH) were involved in seven (5%) children, and the small joints of the feet in one. One child developed sacroiliitis similar to ankylosing spondylitis (AS). Between attacks, the joints were normal. Overall, outcome was good: residual damage of the hip joint occurred in one patient and of the shoulder in another. Although the clinical presentation and course of FMF arthritis are diverse, delineating these clinical patterns may help with earlier recognition and treatment. The low incidence of residual articular damage in this study may be related to the use of colchicine prophylaxis.

The changing face of familial Mediterranean fever.

Livneh A(1), Langevitz P, Zemer D, Padeh S, Migdal A, Sohar E, Pras M.

Author information:

(1)Heller Institute of Medical Research, Sheba Medical Center, Tel-Hashomer, Israel.

Familial Mediterranean fever (FMF) is a genetic disease characterized by painful febrile "attacks" of serositis and the development of amyloidosis. Although FMF has been extensively studied and described, new data have accumulated during the last decade. This report gives an update, focusing specifically on (1) newly characterized manifestations, such as acute scrotal "attacks," protracted febrile myalgia, and spondyloarthropathy; (2) progress made in the diagnosis and treatment of FMF-amyloidosis; (3) experience acquired with colchicine, establishing its safety in common practice, childhood, conception, and pregnancy; (4) colchicine's role in the prevention and treatment of FMF-amyloidosis; (5) new laboratory findings; and (6) new considerations in the differential diagnosis. The most important achievement in recent years, however, is the mapping of the FMF susceptibility gene to chromosome 16p, a finding that raises hopes for prompt cloning of the gene and elucidation of the mechanisms involved in FMF expression.

Serum soluble interleukin-2 receptor levels in familial Mediterranean fever.

Erken E(1), Güneşçar R, Ozbek S, Konca K.

Author information:

(1)Department of Rheumatology, Faculty of Medicine, Cukurova University, Balcal, Adana, Turkey.

**OBJECTIVE:** To investigate serum soluble interleukin-2 receptor (sIL-2R) in familial Mediterranean fever (FMF) and assess its role in acute FMF crisis.

**METHODS:** Serum sIL-2R concentrations were measured in patients with FMF during acute crises and during inactive periods of the disease, using an immunoenzymatic assay kit. Twenty four FMF patients during acute crisis (active FMF), 17 patients with inactive FMF, 24 healthy controls, and 20 active patients with rheumatoid arthritis (as a disease control group) were studied.

**RESULTS:** Serum sIL-2R concentrations were increased during an acute FMF crisis compared with the values in inactive FMF patients and healthy controls ( $P = 0.0105$  and  $P = 0.0012$  respectively), while there was no significant difference between the mean values in active FMF and rheumatoid arthritis patients ( $P = 0.7325$ ). In 14 of the FMF group whose blood samples were available in both active and inactive phases, sIL-2R concentrations were significantly higher in an acute attack than in an attack-free period ( $P = 0.027$ ).

**CONCLUSIONS:** An increase in sIL-2R may be a result of hyperreactivity of IL-2R-expressing cells during an acute inflammatory attack of FMF.

Oral absorption characteristics and pharmacokinetics of colchicine in healthy volunteers after single and multiple doses.

Ferron GM(1), Rochdi M, Jusko WJ, Scherrmann JM.

Author information:

(1)Department of Pharmaceutics, State University of New York at Buffalo, USA.

Colchicine is an antimitotic drug used to treat gout and familial Mediterranean fever. Absolute bioavailability, pharmacokinetics, and absorption characteristics of colchicine after single 1.0-mg doses in oral solution or tablet form or 0.5-mg intravenous doses were compared in 6 subjects. This study was combined with 14 days of multiple-dose administration of 1.0-mg colchicine tablets in 6 subjects. Serial blood samples were collected for 48 hours after administration of single doses and for 120 hours after the last dose in the multiple-dose regimen. Plasma colchicine profiles as measured by radioimmunoassay were analyzed using

deconvolution and compartmental methods. After intravenous bolus injection of colchicine, the area under the concentration-time curve (AUC) was  $61.2 \pm 12.7$  ng.hr/mL, steady-state volume of distribution ( $V_{ss}$ ) was  $419 \pm 95$  L, systemic clearance (Cl) was  $8.5 \pm 1.8$  L/hr, and the terminal half-life ( $t_{1/2}$ ) was  $57.8 \pm 10.7$  hours. After oral administration in solution form, peak plasma concentrations ( $C_{max}$ ) of  $6.50 \pm 1.03$  ng/mL were reached at time ( $t_{max}$ )  $1.07 \pm 0.55$  hours, with a rate of  $0.109 \pm 0.024$  hr<sup>-1</sup> ( $C_{max}/AUC$ ); bioavailability was  $47 \pm 14\%$ . Oral tablets yielded similar  $C_{max}$ ,  $t_{max}$ , and  $C_{max}/AUC$  values, but AUC was significantly lower. Most participants exhibited a secondary peak within 6 hours of administration, possibly in relation to a second absorption site or enterohepatic recirculation. This second absorption process was significantly longer than the first one, and accounted for a similar amount of colchicine absorbed. From the multiple-dose study, a model including an alteration of colchicine absorption due to possible drug-induced gastrointestinal modifications allowed better determination of steady-state plasma concentrations of colchicine.

The coexistence of familial Mediterranean fever and polyarteritis nodosa; report of a case.

Koçak H(1), Cakar N, Hekimoglu B, Atakan C, Akkök N, Unal S.

Author information:

(1)Department of Pediatric Nephrology, Social Security Hospital, Ankara, Turkey.

We describe a 14-year-old boy with a 5-year history of familial Mediterranean fever (FMF), treated with colchicine, who developed polyarteritis nodosa (PAN). He was admitted to our hospital with fever, general weakness, arthritis, and purpura. Five weeks after admission, hypertension was noted. Skin biopsy showed perivascular leukocyte infiltration in the epidermis. An aortography revealed multiple aneurysms of the renal, common hepatic, and intercostal arteries. He was treated with intravenous methylprednisolone, oral cyclophosphamide, and azathioprine. The known rare association of FMF and PAN is discussed.

We conclude that untreated women with FMF have up to a 30% incidence of infertility due to ovulatory dysfunction and peritoneal adhesions. Some of these women conceive during ovulation induction with or without insemination. We have described the first case of a successful and normal pregnancy in a patient with FMF following in vitro fertilization (IVF) while on prophylaxis colchicine therapy after other treatments for infertility were unsuccessful.

Autosomal dominant familial Mediterranean fever--like syndrome.

Mache CJ(1), Goriup U, Fischel-Ghodsian N, Chen X, Schwingshandl J.

Author information:

(1)University Children's Hospital, Graz, Austria.

We report a syndrome characterized by recurrent episodes of fever and serositis in an Austrian family. Three family members over two successive generations were affected. The febrile episodes had their onset at the age of 11-12 years, lasted 1-5 weeks, and occurred in intervals of 6-24 months. While the disorder resembles familial Mediterranean fever (FMF) clinically, ethnic distribution and other features suggest a distinct entity. Clinically, the attacks last longer than the usual FMF attacks, and in the male patients are associated with scrotal inflammation. Genetically, the disorder appears to be inherited as an autosomal dominant syndrome, whereas FMF is autosomal recessive. Molecular analysis made the involvement of a gene in the FMF region of chromosome 16p13.3 highly unlikely. CONCLUSION: An Austrian family with recurrent fever syndrome is reported. Ethnicity, clinical features, and molecular studies point to a distinct clinical entity.

Localization of the familial Mediterranean fever gene (FMF) to a 250-kb interval in non-Ashkenazi Jewish founder haplotypes. The French FMF Consortium.

[No authors listed]

Chromosome 16p13.3 harbors a gene (MEF) associated with familial Mediterranean fever (FMF), a recessive disease very common in populations of Mediterranean ancestry. In the course of positional cloning of MEF, we genotyped 26 non-Ashkenazi Jewish FMF pedigrees (310 meioses) with 15 microsatellite markers, most of which were recently developed by Généthon. Identification of recombination events in the haplotypes allowed narrowing of the MEF interval to a region between D16S3124 (telomeric) and D16S475 (centromeric). Two markers, D16S3070 and D16S3275, a microsatellite marker isolated from a YAC that also contains D16S3070, showed no recombination with the disease. Linkage disequilibrium and haplotype analysis highlighted the existence of a founder haplotype in our population. The core ancestral alleles were present in 71% of MEF-bearing chromosomes at loci D16S3070 and D16S3275. Furthermore, identification of historical crossing-over events in these pedigrees indicated that MEF is located between these two loci, which are both contained in a 250-kb genomic fragment.

Recurrent aphthous ulcers: a review of diagnosis and treatment.

Woo SB(1), Sonis ST.

Author information:

(1)Harvard School of Dental Medicine, Boston, USA.

Recurrent aphthous ulcers, or RAU--also called canker sores--are among the oral mucosal conditions that dentists and physicians see most commonly in their patients. Several systemic conditions are associated with oral aphthouslike ulcers, and aphthae themselves often are mistaken for recrudescant oral herpes simplex virus, or HSV, infections. This article will review RAU, describe systemic conditions associated with aphthous-like ulcerations and discuss the differences between RAU and recrudescant oral HSV infections.

Clin Exp Rheumatol. 1996 Jul-Aug;14(4):355-8.

Clin Exp Rheumatol. 1997 Jan-Feb;15(1):118-9.

**OBJECTIVE:** To characterize the systemic manifestations and joint disease in patients with recurrent aphthous stomatitis (RAS).

**METHODS:** The presence and features of extra-oral manifestations were determined by a rheumatologist, who examined and interviewed 64 patients, referred during 1993 to the oral medicine clinic for treatment of RAS. Controls were 65 medical staff members of a military clinic associated with the hospital.

**RESULTS:** Based on the rheumatologist's findings and published criteria, the patients were diagnosed as suffering from RAS alone (24 patients), Reiter's syndrome (8), Behçet disease (8), familial Mediterranean fever (1), or RAS with undiagnosable extra oral manifestations (23). Thirteen patients in the last group had joint disease ( $p < 0.01$  compared to the controls), characterized by recurrent mono- or oligoarthritis/arthritis of short duration, affecting mostly the large joints. Conjunctivitis, pustular rash, lower back pain and urethritis/cervicitis

were also common in RAS patients, but only the latter was significantly more frequent in RAS patients than in controls ( $p < 0.02$ ).

CONCLUSION: These findings suggest that patients with RAS have an increased frequency of a palindromic type joint disease.

Familial Mediterranean fever in Arab children: the high prevalence and gene frequency.

Rawashdeh MO(1), Majeed HA.

Author information:

(1)Department of Paediatrics, Faculty of Medicine, Jordan University of Science and Technology, Irbid, Jordan.

Over a period of 3 years, 192 children with familial Mediterranean fever were prospectively studied. Of these, 106 (55%) were girls and 86 (45%) were boys. The prevalence was 1:2600 children with a gene frequency of 1:50. The age at onset ranged between 4 months and 16 years. Of these patients 24% started their illness below the age of 2 years and 88% were symptomatic before the age of 10 years: 82% had recurrent abdominal pain, 43% had pleurisy, 37% had arthritis, 15% had cutaneous manifestations, 12% had splenomegaly and 4% had hepatomegaly. The presenting symptoms were abdominal pain in 51%, unilateral chest pain in 23% and arthritis in 26%. The family history was positive in 62%. Of 12 affected families 19 members had/have renal failure and amyloidosis was confirmed in 7 patients. CONCLUSIONS: Our data show a high prevalence of familial Mediterranean fever and a high gene frequency in Arab children similar to that reported in Jews and Americans.

Unstimulated peripheral blood mononuclear cells from patients with the hyper-IgD syndrome produce cytokines capable of potent induction of C-reactive protein and serum amyloid A in Hep3B cells.

Drenth JP(1), van der Meer JW, Kushner I.

Author information:

(1)Department of Medicine, MetroHealth Medical Center, Cleveland, OH 44109, USA.

The hyper-IgD and periodic fever syndrome (HIDS) and familial Mediterranean fever (FMF) are both characterized by attacks of periodic fever accompanied by acute phase responses that are substantially higher in HIDS than in FMF. To determine whether this difference could be due to differences in production of acute phase protein-inducing mediators, we studied PBMC from HIDS and FMF patients in the inactive phase of disease. Unstimulated PBMC from patients with inactive HIDS released significantly more IL-1 beta, IL-6, and TNF-alpha than did PBMC from patients with FMF, but unstimulated PBMC from the latter group released significantly more IL-1 beta and IL-6 compared with controls. Conditioned medium (CM) derived from PBMC of patients with inactive HIDS induced significantly greater CRP production and significantly higher mRNAs for CRP and SAA in Hep3B cells than did CM derived from the PBMC of patients with inactive FMF. Stimulation of PBMC with LPS led to further increases in cytokine production and in acute phase protein-inducing ability in both patient groups and in controls. These findings suggest that the greater acute phase response seen in HIDS compared with FMF reflects greater production of acute phase protein-inducing cytokines in the former patients and indicates that PBMC from inactive HIDS patients are already activated in vivo. Finally, the finding of both quantitative and qualitative differences in cytokine production by unstimulated PBMC from HIDS and FMF patients supports the likelihood of different pathogeneses of these diseases.

Colchicine in breast milk of patients with familial Mediterranean fever.

Ben-Chetrit E(1), Scherrmann JM, Levy M.

Author information:

(1)Hadassah University Hospital, Jerusalem, Israel.

**OBJECTIVE:** To clarify whether colchicine is excreted in breast milk, and to compare its concentrations in the serum and breast milk of lactating women who have familial Mediterranean fever (FMF).

**METHODS:** Using a specific radioimmunoassay, we determined colchicine concentrations in the serum and breast milk of 4 patients at various time points, following oral administration of the drug. The study evaluated 4 patients with FMF who had been taking colchicine on a long-term basis.

**RESULTS:** Colchicine was found to be excreted in breast milk. Its levels ranged between 1.9 and 8.6 ng/ml, which were similar to those found in the serum (parallel concentration time curves). However, there appeared to be a considerable variation in colchicine milk concentration among the different patients, which might be related to individual breast milk composition and, possibly, to other nutritional or metabolic factors.

**CONCLUSION:** The extensive peripheral tissue binding and relatively low concentration of colchicine in breast milk suggests that the amount ingested by the infant is small. Furthermore, based on our clinical experience, nursing appears to be safe for lactating women with FMF who continue to take colchicine.

**BACKGROUND:** Familial Mediterranean fever (FMF) is a genetically linked disorder common amongst races of the Eastern Mediterranean region. Typical symptoms include episodic pain syndrome extending throughout the chest or abdomen associated with histopathological signs of amyloidosis of the kidney.

**AIM:** To investigate possible connections between the aseptic inflammation that occurs during pain crises and cell membrane structural and functional integrity in patients with FMF.

**METHODS:** Oxidative stress parameters in 42 patients in remission and during a pain crisis were compared with 21 normal subjects.

**RESULTS:** The patient group had significantly greater concentrations of chemiluminescent and thiobarbituric acid-reactive substances in the blood plasma and lower concentrations of alpha-tocopherol than the control group while in remission; these changes were exacerbated during pain crises. Analyses of the phospholipid composition of erythrocyte membranes showed significant increases in amounts of acidic phospholipids (phosphatidic acid, monophosphatidylinositol and cardiolipin) and lysophosphatidylcholine compared with healthy subjects.

**CONCLUSIONS:** The pattern of differences in membrane phospholipid composition was consistent with increased oxidative stress in patients with FMF.

Atypical PFAPA syndrome (periodic fever, aphthous stomatitis, pharyngitis, adenitis) in a young girl with Fanconi anemia.

Scimeca PG(1), James-Herry AG, Weinblatt ME.

Author information:

(1)Division of Pediatric Hematology/Oncology, North Shore University Hospital-Cornell University Medical College, Manhasset, New York 11030, USA.

**PURPOSE:** To describe a case of atypical, severe, periodic fever, aphthous stomatitis, pharyngitis and adenitis syndrome (PFAPA syndrome) in a patient with Fanconi anemia. Important aspects about the PFAPA syndrome and Fanconi anemia are reviewed.

**PATIENTS AND METHODS:** An 8-year-old girl with Fanconi anemia was noted to have a pattern of periodic fever, stomatitis, and pharyngitis consistent with the diagnosis of PFAPA syndrome, a generally benign disorder. After prednisone treatment for the syndrome, life-threatening intestinal ulceration and perforation developed, which was successfully treated.

**CONCLUSION:** In patients with underlying hematologic disease such as Fanconi anemia, PFAPA syndrome may be associated with severe clinical problems in contrast to otherwise normal children with the disorder.

The effect of desmopressin on platelet aggregation defect in systemic amyloidosis: a preliminary report.

Demiroğlu H(1), Barişta I, Gürsoy M, Oymak O, Dündar S.

Author information:

(1)Department of Hematology, Hacettepe University Medical School, Ankara, Turkey.

Systemic amyloidosis may often be complicated with haemorrhagic tendency. The causes of this manifestation are factor deficiencies, hyperfibrinolysis and vasculopathy. In order to investigate the role of platelets, if any, we performed platelet aggregation tests with different aggregants in 10 patients with systemic amyloidosis due to familial Mediterranean fever and 10 healthy controls. Platelet aggregation was defective with different aggregants (ADP, epinephrine, collagen) in patients compared with controls. Platelet aggregation tests repeated after desmopressin (DDAVP) administration were normalized. These findings may suggest a role of a platelet aggregation defect in haemorrhagic diathesis complicating systemic amyloidosis. DDAVP may benefit patients with this disease in case of bleeding and before surgical interventions.

Induced TNF production in vitro as a test for familial Mediterranean fever.

Schattner A(1), Gurevitz A, Zemer D, Hahn T.

Author information:

(1)Department of Medicine 'A', Hebrew University, Jerusalem.

We have previously demonstrated an altered pattern of tumor necrosis factor (TNF) secretion in patients with familial Mediterranean fever (FMF). To examine whether TNF determination could assist in diagnosing FMF, we stimulated heparinized blood of 51 asymptomatic FMF patients with lipopolysaccharide (LPS) and then measured TNF production in response to inducers, compared to unstimulated blood cells and to cells from a control group of 12 matched healthy subjects. Following LPS pretreatment, which induced TNF release, FMF patients produced significantly less TNF than controls, whether production was 'spontaneous' or induced by either LPS or phytohaemagglutinin ( $p < \text{or} = 0.003$ ). Such 'exhaustion' did not occur in untreated cells. We then used these results to classify a further group of 29 FMF patients and 10 matched healthy controls ('validation' group) who underwent the same studies. The test correctly identified 25/29 patients as having FMF and 7/10 controls as not having FMF; a sensitivity of 86% and a specificity of 70% (likelihood ratios 2.9 (positive test) and 0.2 (negative)). Identification of a blunted TNF response following previous stimulation by a simple assay, may help the diagnosis of FMF in asymptomatic patients, provided it is interpreted in conjunction with supportive clinical data.

Author information:

(1)Department of Medicine, Cerrahpasa Medical Faculty, University of Istanbul, Turkey.

**OBJECTIVE:** To make a retrospective and prospective analysis of the frequency of symptomatic inflammatory bowel disease in patients with Behçet's syndrome (BS).

**METHODS:** The medical records of the first 1000 patients with BS were reviewed

retrospectively for past or present history of diarrhoea. The past and present history of diarrhoea was also elicited prospectively among 147 consecutive patients with BS and 78 diseased controls (42 with rheumatoid arthritis, 17 with systemic lupus erythematosus, seven with seronegative spondylarthropathy, and 12 with miscellaneous rheumatic diseases). Inflammatory mucosal changes were sought in rectal biopsy specimens from 75 patients with BS, 47 diseased controls (29 with nephrotic syndrome, eight with rheumatoid arthritis, six with familial Mediterranean fever, and four with ankylosing spondylitis), and 14 patients with ulcerative colitis.

**RESULTS:** In chart review there were only seven Behçet's patients with diarrhoea; none of them had inflammatory bowel disease. In the prospective survey there were no significant differences between the BS and control groups in the past and present history of diarrhoea. There were no significant differences in the rectal mucosal histology between patients with BS and controls, while patients with ulcerative colitis showed pronounced differences.

**CONCLUSION:** Symptomatic inflammatory bowel disease is not common in BS patients from Turkey.

This report presents refined genetic mapping data for the gene causing familial Mediterranean fever (FMF), a recessively inherited disorder of inflammation. We sampled 65 Jewish, Armenian, and Arab families and typed them for eight markers

from chromosome 16p. Using a new algorithm that permits multipoint calculations for a dense map of markers in consanguineous families, we obtained a maximal LOD score of 49.2 at a location 1.6 cM centromeric to D16S246. A specific haplotype at D16S283-D16S94-D16S246 was found in 76% of Moroccan and 32% of non-Moroccan Jewish carrier chromosomes, but this haplotype was not overrepresented in Armenian or Arab FMF carriers. Moreover, the 2.5-kb allele at D16S246 was significantly associated with FMF in Moroccan and non-Moroccan Jews but not in Armenians or Arabs. Since the Moroccan Jewish community represents a relatively recently established and genetically isolated founder population, we analyzed the Moroccan linkage-disequilibrium data by using Luria-Delbrück formulas and simulations based on a Poisson branching process. These methods place the FMF susceptibility gene within 0.305 cM of D16S246 (2-LOD-unit range 0.02-0.64 cM).

The requirements for amyloidogenesis, as it is currently understood, include an adequate amyloid precursor pool, a nidus for fibrillogenesis, interactions with a set of common components (most of which are involved in basement membrane structure) and amyloid turnover. These factors serve as the basis for therapeutic attack. General strategies focusing on each of these factors are presented with examples from the experimental and clinical literature. These include reducing the amyloid precursor protein pool in familial amyloid polyneuropathy by liver transplantation, inhibiting nidus formation in familial Mediterranean fever by the use of colchicine, inhibiting amyloid precursor protein/heparan sulphate interaction in experimental inflammation-associated amyloidosis by the use of novel small molecule anionic sulphates and sulphonates, and the use of new analogues of doxorubicin in light chain amyloidosis to accelerate amyloid

removal. The potential significance of local and systemic amyloid deposits is discussed in the light of new information on the genetics of Alzheimer's disease, observations made in patients receiving long term dialysis for renal failure, and the potential involvement of amyloid deposits in the pathogenesis of non-insulin-dependent diabetes mellitus.

Colchicine enhances intestinal permeability in patients with familial Mediterranean fever.

Fradkin A(1), Yahav J, Diver-Haber A, Zemer D, Jonas A.

Author information:

(1)Pediatric Gastrointestinal Unit, Chaim Sheba Medical Center, Tel Hashomer, Israel.

OBJECTIVE: Colchicine therapy is complicated by frequent gastrointestinal adverse effects.

METHODS: We compared intestinal permeability in 21 patients with familial

Mediterranean fever on long-standing colchicine therapy (mean 5.8 years) and significant gastrointestinal complaints and 12 untreated patients and 14 healthy volunteers. The double probe (lactulose/mannitol) permeability test was performed using a hyperosmolar test solution (1580 mosmol) and the differential urinary recovery ratios were calculated.

**RESULTS:** Familial Mediterranean fever patients on colchicine therapy had significantly higher lactulose/mannitol urinary excretion ratios (0.073) compared to untreated patients (0.035) and to healthy controls (0.021). Untreated familial Mediterranean fever patients had significantly greater urinary lactulose/mannitol recovery ratios than controls ( $P < 0.02$ ). No correlation was found between the degree of enhanced permeability and the length of exposure to the drug or the severity of clinical symptoms.

**CONCLUSIONS:** Intestinal permeability was significantly enhanced in patients with familial Mediterranean fever treated with colchicine.

Amyloidosis.

Friman C(1), Pettersson T.

Author information:

(1)Department of Medicine, Helsinki University Central Hospital, Finland.

Developments concerning amyloidosis associated with rheumatic diseases or often causing musculoskeletal symptoms are reviewed. The pathogenesis, clinical manifestations, diagnosis, and therapy of amyloid A, amyloid light-chain, and amyloid beta 2-microglobulin amyloidosis are discussed from the standpoint of a clinical rheumatologist. The biology of the precursor protein serum amyloid A (SAA) has been extensively studied, and a new assay for SAA has been developed. In amyloid beta 2-microglobulin amyloidosis, modified beta 2-microglobulin may function as a pathogenic factor that initiates an inflammatory reaction in which macrophages produce cytokines that induce osteoclastogenesis and bone resorption. Further experience with serum amyloid P component scintigraphy in the diagnosis and monitoring of amyloidosis has accumulated. Guidelines for the dosage of

colchicine in the treatment of amyloidosis associated with familial Mediterranean fever have been published. In amyloid light-chain amyloidosis, intensive chemotherapy in combination with bone marrow transplantation or autologous stem-cell infusion has potential therapeutic significance.

Comment in

Clin Infect Dis. 1996 Jan;22(1):28-9.

A 15-year-old boy with a 13-year history of periodic fevers, lymphadenopathy, and leukocytosis showed virological, serological, immunohistologic, and molecular evidence of persistent, active, Epstein-Barr virus (EBV) infection. Acyclovir and several other agents failed to alter his clinical course. Comprehensive immunological studies could not identify a defined immune deficiency syndrome to explain the persistent infection, although he does continue to have circulating polymeric EBV-specific immunoglobulin type A, as is seen in individuals during acute EBV infections. In vitro work suggests that this polymeric antibody prevents B cell infection by EBV. Cumulative data suggest that this patient suffers from a novel form of EBV infection.

INTRODUCTION: We describe 3 cases of hyperimmunoglobulinemia D syndrome (hyper-IgD syndrome).

CASES REPORT: As the 2 first cases are conventional with an onset in childhood, the third one appeared later suggesting possibility of acquired syndrome. The 3 cases presented with one or several skin eruptions during febrile attacks.

COMMENTS: Up to now, 64 cases of this syndrome have been described. Skin lesions are observed in 80 p. 100 of patients. In this particular clinical context, they must lead to the diagnosis. This 3 cases and the review of literature show that skin manifestations are polymorphic, transient, not very symptomatic and not correlated to IgD rates. Histological examination may reveal urticarial reaction with leucocytoclastic vasculitis, where IgD could directly or not interact.

Brucellosis is an endemic disease in Portugal. There was an increase in incidence in 1994. Neurobrucellosis (NB), although only occurring in 5 to 10% of cases of cases of chronic infection, has heterogeneous forms of presentation which makes differential diagnosis difficult. By reviewing four years of in-patient clinical files in the neurology Ward of St. António dos Capuchos Hospital, the authors study the clinical features, complementary tests, therapy and evolution of differential diagnosis of eight patients with neurobrucellosis.

Renal amyloidosis in childhood. An overview of the topic with 25 years experience.

Tinaztepe K(1).

Author information:

(1)Department of Pediatrics, Hacettepe University Faculty of Medicine, Ankara, Turkey.

Amyloidosis is a heterogeneous group of diseases characterized by extracellular accumulation of an eosinophilic, hyalin and proteinaceous material containing mucopolysaccharide substance in various tissues and organs. Knowledge about the chemical structure of amyloid fibril proteins has led to the recognition of various forms of amyloidosis including Amyloid-A (AA), Amyloid-L (AL), hereditary, senile, dialysis-related, localized and cerebral amyloidosis. It is now recognized that all types of amyloid contain amyloid P (AP) component which is derived from the serum amyloid P component, a normal circulating glycoprotein and a member of the pentraxin family. A recent classification proposed by WHO-IUIS (Nomenclature Subcommittee) is based on the chemical nature of amyloid fibrils rather than their clinical and pathologic features. The kidneys are frequently involved, and renal failure is the major cause of death. Childhood renal amyloidosis is almost always secondary (reactive, AA type) and usually associated with chronic inflammatory, infectious and hereditary diseases. In developed countries, rheumatoid arthritis is the most common cause of renal amyloidosis, while in developing countries patients with familial Mediterranean fever (FMF) (untreated) and chronic suppurative infections constitute a large proportion of renal amyloidosis cases. No specific therapy is currently available for amyloidosis. Once renal amyloidosis develops, progress to end-stage renal failure is almost inevitable within 2-13 years. The aim of treatment is to give effective supportive therapy and to control the underlying diseases by colchicine, alkylating agents and appropriate antibiotics. The prognosis of patients with end-stage renal failure can be improved by maintenance dialysis and renal transplantation. The growing knowledge about the pathogenesis and chemical nature of amyloid fibrils may open up further avenues for the discovery of

specific therapeutic modalities against amyloidosis.

Colchicine-induced lactose malabsorption in patients with familial Mediterranean fever.

Fradkin A(1), Yahav J, Zemer D, Jonas A.

Author information:

(1)Pediatric Gastrointestinal Unit, Chaim Sheba Medical Center, Tel-Hashomer, Israel.

Abdominal pain and diarrhea are frequent side effects of chronic colchicine therapy. Drug-induced lactose deficiency has been demonstrated in the experimental animal. Lactose malabsorption was assessed by the lactose breath test in 23 patients with familial Mediterranean fever (FMF) receiving colchicine for 0.25-15 years (mean 3.16). Twenty FMF patients not receiving colchicine and 38 non-FMF lactose malabsorbers served as controls. Patients receiving colchicine had a significantly higher percentage of lactose malabsorption (20/23, 87%) versus nontreated FMF patients (13/20, 65%;  $P < 0.05$ ). Lactose intolerance was also more prevalent in colchicine-treated patients (17/23, 74%) versus nontreated FMF (5/20, 25%;  $P < 0.0005$ ) and control lactose malabsorbers (16/38, 42%;  $P < 0.01$ ). Of the 12 patients investigated before and 3 months after colchicine administration, 7 showed induction or aggravation of lactose malabsorption. The lactose-free diet resulted in partial improvement of symptoms. Colchicine induces significant lactose malabsorption in FMF patients and this is partially responsible for the gastrointestinal side effects of the drug.

[Hyperimmunoglobulin D syndrome].

[Article in French]

Drenth JP(1), Denecker NE, Prieur AM, Van der Meer JW.

Author information:

(1)Département de Médecine interne, Hôpital Universitaire St Radboud, Nimègue, Pays-Bas.

The hyper-IgD syndrome is a rare entity characterized by early onset of attacks of periodic fever. All patients have an elevated serum IgD (> 100 U/ml). Symptoms during attacks include joint involvements (arthralgias/arthritis), abdominal complaints (vomiting, pain, diarrhoea), skin lesions, swollen lymph nodes, and headache. In 1992 an International hyper-IgD study group was established, and to date the diagnosis has been made in 60, mainly European patients; 14 come from France. The disorder occurs in families and is transmitted by autosomal recessive inheritance. Linkage studies indicate that the gene encoding for familial Mediterranean fever is different from the gene for the hyper-IgD syndrome. In children the hyper-IgD syndrome should be distinguished from two other periodic febrile disorders. CINCA (chronic inflammatory, neurological, cutaneous and articular syndrome) and FAPA (periodic fever, adenopathies, pharyngitis, and aphthous stomatitis) share some symptoms with the hyper-IgD syndrome but in these syndromes serum IgD is normal. The pathogenesis remains to be elucidated but during attacks all patients have an acute-phase response with elevated C-reactive protein concentrations. During the febrile episodes, the inflammatory cytokines such as IL-6 TNF alpha, IFN gamma are increased together with natural occurring inhibitors such as IL-1ra and sTNFr. There is no therapy for the syndrome and patients will experience attacks during their entire life although frequency and severity tend to diminish with age.

Apolipoprotein E increases the fibrillogenic potential of synthetic peptides derived from Alzheimer's, gelsolin and AA amyloids.

Soto C(1), Castaño EM, Prelli F, Kumar RA, Baumann M.

Author information:

(1)Department of Neurology, New York University Medical Center, NY 10016, USA.

Apolipoprotein E (apoE) has been found in association with several different types of systemic and cerebral amyloid deposits and the presence of the epsilon 4 allele constitutes a risk factor for Alzheimer's disease. It has been shown that apoE binds and promotes the fibrillogenesis in vitro of Alzheimer's amyloid beta-peptide, suggesting an important role for apoE in the modulation of amyloidogenesis. Due to the co-localization of apoE with several biochemically distinct amyloid deposits, it has been proposed that apoE plays a general role modulating and/or participating in amyloidosis. In the present study, we show for the first time that apoE, isolated from human plasma, increases fibril formation of synthetic peptides comprising the amyloidogenic sequences of gelsolin amyloid related to familial amyloidosis Finnish type, and amyloid A found in secondary amyloidosis and familial Mediterranean fever. Our results suggest that apoE acts as a general pathological chaperone in various amyloidoses by enhancing the transition from soluble peptides into amyloid-forming, pathological molecules.

Author information:

(1)Department of Medical Chemistry, Faculty of Medicine, Vrije Universiteit, Amsterdam, The Netherlands.

Crossed affinoimmunoelectrophoresis using concanavalin A and Aleuria aurantia lectin as diantennary glycan- and fucose-specific affinocomponents, respectively, was applied to study changes in the concentration and glycosylation of the acute phase protein alpha 1-acid glycoprotein (AGP) in sera obtained from patients with hyperimmunoglobulinemia D and periodic fever syndrome. Increases in concentration of AGP compared to control values were found not only during attacks, but also during remissions. Compared to healthy controls, the presence of diantennary glycan-containing glycoforms of AGP also increased during febrile attacks, while no changes were found during remissions. A continuous high degree of alpha 1-->3 fucosylation was accompanied by a continuous high expression of sialyl Lewisx on AGP. Despite the clinical picture of recurrent febrile attacks with asymptomatic intervals, these studies indicate that hyperimmunoglobulinemia D should be considered a condition of persistent inflammation.

Familial Mediterranean fever in the "Chuetas" of Mallorca--origin in inquisition?

Buades J(1), Ben-Chetrit E, Levy M.

Author information:

(1)Division of Medicine, Hospital Joan March, Mallorca, Spain.

Comment in

Isr J Med Sci. 1995 Aug;31(8):503-4.

The aim of our study was to compare the features of familial Mediterranean fever (FMF) in Mallorcan "Chuetas" with those in non-Ashkenazi Jews in Israel. The clinical and laboratory data of FMF were evaluated in a recently identified cluster of 50 FMF patients from Mallorca (the Chuetas) and 45 patients from Israel. We found that the prevalence and clinical manifestations of FMF were similar among the Chuetas and the Israeli group. Furthermore, in contrast to other ethnic groups with FMF, joint involvement was quite common in both the Chuetas (70%) and the Israeli group (75%). The Chuetas are descendants of Mallorcan Jews who emigrated from Spain to the island in the 12th century. The non-Ashkenazi Jews originated mainly in North Africa and are descendants of refugees who escaped from Spain as a result of the Inquisition in the 15th century. We suggest that the non-Ashkenazi Jews and the Chuetas may have a common gene defect for FMF.

Apolipoprotein E carboxyl-terminal fragments are complexed to amyloids A and L. Implications for amyloidogenesis and Alzheimer's disease.

Castaño EM(1), Prelli F, Pras M, Frangione B.

Author information:

(1)Department of Pathology, New York University Medical Center, New York 10016, USA.

Apolipoprotein E (ApoE) immunoreactivity is consistently present in the senile plaques and neurofibrillary tangles of Alzheimer's disease (AD) brain. In vitro, apoE, and in particular its apoE4 isoform, can bind to and promote fibrillogenesis of the amyloid A beta peptide, the main constituent of senile plaques. These findings, together with the strong genetic association between late onset AD and the E4 allele of apoE, have strengthened the hypothesis that apoE may have a central role in the pathogenesis of AD by modulating A beta cerebral accumulation. However, apoE immunoreactivity is present in all cerebral and systemic amyloidoses tested, and tryptic apoE fragments have been identified in association with amyloid A (AA). In order to further elucidate the interaction between apoE and amyloids, we purified AA and amyloid L (AL) fibrils from patients with familial Mediterranean fever and primary amyloidosis, respectively, and studied the association of apoE with AA and AL proteins. In each case, apoE fragments, detected by Western blot, co-purified with the amyloid fibrils. Microsequencing analysis identified COOH-terminal fragments of apoE, similar to the 10-kDa fragment produced by thrombin digestion that contains the purported

binding region to A beta. In vitro co-incubation of AA with purified human apoE resulted in the formation of an SDS-resistant AA.apoE complex and a higher degree of polymerization of the AA peptide. These findings and similar results obtained from AD senile plaques suggest that 1) the carboxyl-terminal fragment of apoE is complexed to amyloid fibrils and resists proteolysis in vivo and 2) apoE may promote amyloidogenesis through a conformation-dependent interaction regardless of the primary structure of the amyloid precursors.

[Nephrotic syndrome in familial Mediterranean fever--effect of colchicine therapy].

[Article in Danish]

Højberg AS(1), Mertz H.

Author information:

(1)Børneafdelingen og patologisk institut, Aalborg Sygehus.

Familial Mediterranean fever (FMF) is a genetic disorder virtually restricted to people originating from the Middle East. It is characterized by short, self-limiting, febrile attacks of peritonitis, synovitis, pleuritis or an erysipelas-like erythema. Without treatment systemic amyloidosis often develops and causes death in renal failure, usually at an early age. Two siblings with FMF and renal amyloidosis are presented. One had nephrotic syndrome, the other severe proteinuria. Continuous colchicine treatment reverse the nephrotic syndrome and in both patients the proteinuria was reduced. It is concluded, that even though colchicine can improve severe renal amyloidosis, early diagnosis of FMF is crucial because continuous colchicine treatment prevents both the febrile attacks and the amyloidosis.

Dominant inheritance in two families with familial Mediterranean fever (FMF).

Yuval Y(1), Hemo-Zisser M, Zemer D, Sohar E, Pras M.

Author information:

(1)Heller Institute of Medical Research, Sheba Medical Center, Tel-Aviv  
University Medical School, Tel-Hashomer, Israel.

Familial Mediterranean fever (FMF) is an autosomal-recessive disease which affects almost exclusively people of Mediterranean and Middle Eastern origin. We examined the possibility of a dominant inheritance of FMF among our 3,000 patients in Israel. Two hundred forty FMF patients were members of 77 families in which the disease affected more than one generation. In 75 of these families the occurrence of FMF in more than one generation was found to be consistent with a recessive mode of inheritance due to a high gene frequency (q) and consanguinity among parents of the patients. In 2 families, one of Ashkenazi and the other of Georgian Iraqi origin, in which FMF occurred in 4 consecutive generations, the mode of inheritance could be explained only by autosomal-dominant inheritance.

Cytokine activation during attacks of the hyperimmunoglobulinemia D and periodic fever syndrome.

Drenth JP(1), van Deuren M, van der Ven-Jongekrijg J, Schalkwijk CG, van der Meer JW.

Author information:

(1)Department of Medicine, University Hospital St. Radboud, Nijmegen, The Netherlands.

The hyperimmunoglobulinemia D and periodic fever (hyper-IgD) syndrome is typified by recurrent febrile attacks with abdominal distress, joint involvement (arthralgias/arthritis), headache, skin lesions, and an elevated serum IgD level (> 100 U/mL). This familial disorder has been diagnosed in 59 patients, mainly from Europe. The pathogenesis of this febrile disorder is unknown, but attacks are joined by an acute-phase response. Because this response is considered to be mediated by cytokines, we measured the acute-phase proteins C-reactive protein (CRP) and soluble type-II phospholipase A2 (PLA2) together with circulating concentrations and ex vivo production of the proinflammatory cytokines interleukin-1 alpha (IL-1 alpha), IL-1 beta, IL-6, and tumor necrosis factor alpha (TNF alpha) and the inhibitory compounds IL-1 receptor antagonist (IL-1ra), IL-10, and the soluble TNF receptors p55 (sTNFr p55) and p75 (sTNFr p75) in 22 patients with the hyper-IgD syndrome during attacks and remission. Serum CRP and PLA2 concentrations were elevated during attacks (mean, 213 mg/L and 1,452 ng/mL, respectively) and decreased between attacks. Plasma concentrations of IL-1 alpha, IL-1 beta, or IL-10 were not increased during attacks. TNF alpha concentrations were slightly, but significantly, higher with attacks (104 v 117 pg/mL). Circulating IL-6 values increased with attacks (19.7 v 147.9 pg/mL) and correlated with CRP and PLA2 values during the febrile attacks. The values of the antiinflammatory compounds IL-1ra, sTNFr p55, and sTNFr p75 were significantly higher with attacks than between attacks, and there was a significant positive correlation between each. The ex-vivo production of TNF alpha, IL-1 beta, and IL-1ra was significantly higher with attacks, suggesting that the monocytes/macrophages were already primed in vivo to produce increased amounts of these cytokines. These findings point to an activation of the cytokine network, and this suggests that these inflammatory mediators may contribute to the symptoms of the hyper-IgD syndrome.

Purification and characterization of a C5a-inactivating enzyme from human peritoneal fluid.

Ayesh SK(1), Azar Y, Barghouti II, Ruedi JM, Babior BM, Matzner Y.

Author information:

(1)Hematology Unit, Hadassah University Hospital, Mount Scopus, Jerusalem, Israel.

Earlier work has suggested that familial Mediterranean fever, an inherited disorder characterized by sporadic episodes of inflammation involving the pleural and peritoneal cavities and the joints, is caused by the lack of a C5a inactivator normally found in serosal fluid. We have purified this inactivator from ascites fluid and obtained a protein of molecular weight 53 to 56 kD with a specific activity 10,000-fold greater than the crude material. On Western blot, an inhibitory antibody recognized a single antigenic species at the same molecular weight. The enzyme had no activity against denatured bovine serum albumin. With recombinant C5a as substrate, the  $K_m$  and  $V_m$  were 3.4  $\mu\text{mol/L}$  and 52 nmol C5a/min/mg protein, respectively.

[Hyper-IgD syndrome (HIDS)].

[Article in Italian]

Scolozzi R.

In 1984, Van der Meer first reported six patients with a long history of

recurrent attacks of fever of unknown cause and a constantly elevated polyclonal IgD (> 100 U/mL); he suggested the acronym of "hyper-IgD syndrome" (HIDS). A recent literature review identified 60 cases (59 from Europe and 1 from Japan). The mean age was 27 years (range: 3-69 years). The family studies have shown a positive family history for periodic fever (40% out of the patients) but not for hyper-IgD. The median age at onset was 0.5 years (range from the first weeks of life to 53 years). The length of the febrile attacks, though variable, lasted from 3 to 7 days. The frequency of the attacks varied among the individual patients, but in general it was once a month or bimonthly. The fever was sustained in all 60 patients (from 38 degrees C to 41 degrees C), with a rapid rise, a plateau and a slow decline to normal values over 5 days. The associated clinical findings involve abdominal symptoms (pain, vomiting, diarrhea), recurrent peritonitis, lymphadenopathy, splenomegaly, articular manifestations (non-destructive recurrent arthritis) and skin lesions (vasculitis). The prognosis is benign. The aetiopathogenesis of HIDS is unknown. The role of IgD in the pathogenesis remains to be elucidated. The therapy is only supportive.

[Recurrent pericarditis in familial Mediterranean fever].

[Article in Hebrew]

Tauber T(1), Zimand S, Kotzer E.

Author information:

(1)Pediatrics Dept., Assaf Harofeh Medical Center, Z'rifin.

The diagnosis of familial Mediterranean fever (FMF) is based on clinical evidence, since there is no specific diagnostic test. Manifestations are recurrent attacks of fever accompanied by serositis, mainly involving the peritoneum, pleura and joints. Although pericardial inflammation has been considered rare, when echocardiography is used to detect it, an incidence of 27% has been reported. We describe a boy of 11 and a girl of 15 years who developed recurrent pericarditis despite treatment with steroids, nonsteroidal anti-inflammatory drugs and pericardiocentesis. A few months after the first episode, both patients were admitted with typical bouts of FMF. Continuous prophylaxis with colchicine was initiated, and there were no further attacks during 18 and 10 month follow-ups, respectively. We conclude that acute or recurrent pericarditis in children or young adults of Mediterranean origin may be due to FMF.

Comment in

Presse Med. 1995 Nov 18;24(35):1666.

Acute orchitis or a mass in testis usually evokes a neoplasm, a torsion or

infectious disease for the clinician. Rarely, a systemic disease is involved. Nevertheless, testicular involvement occurs during vasculitis, Behçet or granulomatous diseases, but is uncommonly the first manifestation. Histologic changes after biopsy or orchiectomy usually give the diagnosis. Testicular localization of systemic disease does not change the general treatment.

Adhesive small bowel obstruction caused by familial Mediterranean fever: the incidence and outcome.

Ciftci AO(1), Tanyel FC, Büyükpamukçu N, Hiçsönmez A.

Author information:

(1)Department of Pediatric Surgery, Hacettepe University, Ankara, Turkey.

Familial Mediterranean fever (FMF) is a disease characterized by recurring and self-limiting attacks of febrile serosal inflammation involving the peritoneal, synovial, and pleural membranes. Peritonitis is the most common clinical picture of FMF, and repeated acute abdominal episodes may result in formation of peritoneal adhesions that may cause adhesive small bowel obstruction (ASBO) requiring surgical intervention. This subject has neither been clarified nor thoroughly evaluated in the literature. The records of 355 pediatric patients diagnosed to have FMF were reviewed in order to clarify the incidence and outcome of ASBO without prior laparotomy during the course of FMF. The incidence rate has been found as 3% with no mortality. This figure shows ASBO to be the most frequent complication of FMF. Therefore this life-threatening surgical emergency should be kept in mind in the differential diagnosis of acute abdominal attacks during the course of FMF.

Rapid multipoint linkage analysis of recessive traits in nuclear families, including homozygosity mapping.

Kruglyak L(1), Daly MJ, Lander ES.

Author information:

(1)Whitehead Institute for Biomedical Research, Massachusetts Institute of Technology, Cambridge 02142.

Homozygosity mapping is a powerful strategy for mapping rare recessive traits in children of consanguineous marriages. Practical applications of this strategy are currently limited by the inability of conventional linkage analysis software to compute, in reasonable time, multipoint LOD scores for pedigrees with inbreeding loops. We have developed a new algorithm for rapid multipoint likelihood calculations in small pedigrees, including those with inbreeding loops. The running time of the algorithm grows, at most, linearly with the number of loci considered simultaneously. The running time is not sensitive to the presence of inbreeding loops, missing genotype information, and highly polymorphic loci. We have incorporated this algorithm into a software package, MAPMAKER/HOMOZ, that allows very rapid multipoint mapping of disease genes in nuclear families, including homozygosity mapping. Multipoint analysis with dozens of markers can be carried out in minutes on a personal workstation.

Familial Mediterranean fever: high gene frequency among the non-Ashkenazic and Ashkenazic Jewish populations in Israel.

Daniels M(1), Shohat T, Brenner-Ullman A, Shohat M.

Author information:

(1)Institute of Medical Genetics, FMRC, Beilinson Medical Center, Sackler Faculty of Medicine, Tel Aviv University, Petah Tiqva, Israel.

Familial Mediterranean fever (FMF) is an autosomal recessive recurrent episodic inflammatory disorder that occurs with high frequency in certain populations in the Mediterranean area. Using extended pedigree data of 90 FMF probands, we calculated the FMF gene frequency in various ethnic groups in Israel by analyzing the frequency in a total of 2,312 first cousins. The heterozygote frequencies were as follows: 1:4.9 (0.2 +/- 0.06) for the Libyan subgroup, 1:6.4 (0.16 +/- 0.03) for the other North African countries subgroup, 1:13.3 (0.07 +/- 0.04) for the Iraqi subgroup, 1:11.4 (0.09 +/- 0.06) for the Ashkenazic subgroup, and 1:29.4 (0.03 +/- 0.03) for the remaining ethnic groups. The observed number of affected parents and offspring of the probands was in agreement with the estimated gene frequency. Thus, the FMF gene frequency is very high in all Jewish ethnic groups in Israel, especially those originating in North African countries. This also explains the parent-to-off-spring transmission of FMF reported in

North-African Jews.

Author information:

(1)Department of Pediatrics B, Chaim Sheba Medical Center, Tel Hashomer, Israel.

Behçet's disease, a multisystem disease is, by its nature, difficult to diagnose. The first manifestation of the disease may precede the appearance of other symptoms and signs essential for diagnosis by many years. In patients of Mediterranean origin, the early manifestations of the disease, may be confused with those of familial Mediterranean fever (FMF). Determination of HLA-B5 may, however, contribute to the diagnosis in children with partial manifestations of Behçet syndrome.

[Colchicine: recent data on pharmacokinetics and clinical pharmacology].

[Article in French]

Chappey O(1), Scherrmann JM.

Author information:

(1)Laboratoire de pharmacocinétique, faculté de pharmacie, université Paris V, France.

Colchicine is widely used in the treatment of acute gouty arthritis. Recently, colchicine was shown to be effective in inflammatory diseases such as familial Mediterranean fever. Two proteins can modulate its pharmacokinetics: tubulin, the specific intracellular receptor for colchicine which determines the plasma half-life, and P-glycoprotein, an active efflux pump towards some anticancer drugs which regulates colchicine absorption, distribution, and elimination. Therapeutic dosage is monitored empirically, by the control of the balance between the occurrence of side effects and the clinical efficacy. Recently, using a specific and sensitive radioimmunoassay, the investigation of plasma concentrations during single and multiple dose studies has allowed to define the colchicine pharmacokinetic parameters. Following oral route, colchicine bioavailability is extremely variable (from 24 to 88% of the administered dose), the distribution volume is elevated (7 l/kg) but the binding to albumin is moderate. Colchicine elimination occurred mainly via hepatic pathways and the elimination half-life ranged from 20 to 40 hours. In multiple dose study (1 mg/d), the steady-state is reached 8 days after the first oral administration and plasma concentrations ranged from 0.3 to 2.5 ng/ml. Pharmacokinetic/pharmacodynamic studies show that the biological effects of colchicine were not related to plasma concentrations but with intraleukocyte concentrations. Drug interactions may occur when colchicine is associated to drugs which interact with cytochrome P450 and/or P-glycoprotein and modify renal and/or hepatic clearances. The therapeutic drug monitoring of colchicine during these circumstances could allow to prevent the observation of side effects.

Cryoglobulinemia and other dysproteinemias, familial Mediterranean fever, and POEMS syndrome.

Cuéllar ML(1), García C, Molina JF.

Author information:

(1)Louisiana State University School of Medicine, Department of Medicine, New Orleans 70112, USA.

The introduction of newer technology in the past few years, especially the use of second-generation enzyme-linked immunosorbent assays, recombinant immunoblot assays, reverse transcriptase, and DNA amplification, have clearly defined the role of hepatitis C virus as the most important etiologic factor in the development of mixed cryoglobulinemia. This has led to a better understanding of the pathogenic mechanisms involved in disease expression, particularly vasculitis, and also has provided a rationale for the use of interferon alfa and other antiviral drugs in the therapy of these disorders. The clinical manifestations of the syndrome also have been well characterized, as well as some of the risk factors. There also has been an improvement in our understanding of the pathogenic mechanisms involved in multiple myeloma and related monoclonal gammopathies, as well as several attempts to improve early recognition of bone disease with magnetic resonance imaging. The susceptibility gene for familial Mediterranean fever has been better characterized, as have risk factors for colchicine toxicity. The role of cytokines has been better delineated for both monoclonal gammopathies and POEMS (polyneuropathy, organomegaly, endocrinopathy,

M protein, and skin changes) syndrome.

[Article in Japanese]

Takenaka K(1), Yanase T, Nagatomo H, Tanaka A, Nawata H.

Author information:

(1)Third Department of Internal Medicine, Faculty of Medicine, Kyusyu University.

A 26-year-old female was admitted to our hospital on December 4, 1992, because of recurrent fever. She had experienced recurrent fever of over 38 degrees C, occurring at irregular intervals 4-6 times a year with chest or abdominal pain, since the age of 19. After delivery of a baby at the age of 25, her symptoms had increased to once a week. In the febrile phase, leukocytosis, an increased erythrocyte sedimentation rate and positive CRP were recognized. These symptoms and laboratory findings spontaneously disappeared within a few days. Despite systemic and careful examinations, no evidence of infectious diseases, collagen diseases or malignant diseases were found. There were no significant differences of serum and urine catecholamines, and urine etiocholanolone between the febrile phase and the afebrile phase. An intravenous infusion of metaraminol induced symptoms similar to a spontaneous attack, and the metaraminol rechallenge test became negative after she was treated with oral colchicine. Based on these findings, she was diagnosed as having familial Mediterranean fever. Since she was treated with colchicine, the febrile attacks have decreased. Significantly, her elder brother has had similar recurrent fever with abdominal pain. He was diagnosed as having familial Mediterranean fever due to a positive metaraminol provocative test, and his febrile attacks have also been suppressed by colchicine. This is the first case of familial Mediterranean fever with obvious family history in Japan.

Location of the gene causing hyperimmunoglobulinemia D and periodic fever syndrome differs from that for familial Mediterranean fever. International Hyper-IgD Study Group.

Drenth JP(1), Mariman EC, Van der Velde-Visser SD, Ropers HH, Van der Meer JW.

Author information:

(1)Department of Medicine, University Hospital St Radboud, Nijmegen, The

Netherlands.

The hyperimmunoglobulinemia D and periodic fever (hyper-IgD) syndrome is typified by recurrent febrile attacks with abdominal distress, joint involvement (arthralgias/arthritis), headache, skin lesions, and an elevated serum IgD level ( $> 100$  U/ml). This familial disorder has been diagnosed in 56 subjects worldwide. As the hyper-IgD syndrome resembles familial Mediterranean fever, one could speculate that both result from mutations in the same gene. The gene causing familial Mediterranean fever (MEF) has been located on chromosome 16p. We have studied 10 families with 19 affected and 28 non-affected subjects. The clinical findings and IgD determinations from these families are compatible with autosomal recessive inheritance. Using highly polymorphic markers surrounding the MEF gene, only negative Lod scores were obtained, whereas haplotype analysis excluded this locus as the cause of the hyper-IgD syndrome. In addition, no indication for linkage was obtained with markers from other candidate gene regions on chromosomes 17q and 14q.

Colchicine treatment of AA amyloidosis of familial Mediterranean fever. An analysis of factors affecting outcome.

Livneh A(1), Zemer D, Langevitz P, Laor A, Sohar E, Pras M.

Author information:

(1)Sheba Medical Center, Tel-Hashomer, Israel.

**OBJECTIVE:** To elucidate factors possibly influencing the outcome of colchicine therapy in patients with amyloidosis of familial Mediterranean fever (FMF).

**METHODS:** Retrospective analysis of data abstracted from the charts of all 68 FMF patients with amyloidosis who presented during the study period (1974-1992) with proteinuria ( $\geq 0.5$  gm/24 hours) and creatinine values  $\leq 2.5$  mg/dl, received colchicine, and were followed up for  $\geq 5$  years.

**RESULTS:** At the end of the study period, kidney disease had worsened in 31 patients and remained stable in 22. Proteinuria had regressed in 15 patients.

Deterioration was related to initial serum creatinine values  $\geq 1.5$  mg/dl ( $P < 0.01$ ) and to mean colchicine dosage  $\leq 1.5$  mg/day ( $P < 0.001$ ). The 3 groups were comparable in terms of initial urinary protein levels, duration of proteinuria, presence of hypertension, occurrence of febrile attacks, sex distribution, and proportion of non-compliant patients.

**CONCLUSION:** The therapeutic dosage of colchicine for amyloidosis of FMF is  $> 1.5$  mg/day. This dosage is effective only in patients with initial serum creatinine levels  $< 1.5$  mg/dl.

Risk factors of aseptic intracranial venous occlusive disease.

Najim al-Din AS(1), Mubaidin A, Wriekat AL, Alqam M.

Author information:

(1)Jordan University Hospital, Medical Centre, Amman.

**INTRODUCTION:** Risk factors for aseptic intracranial venous occlusive disease are varied but only few epidemiologic studies were performed to verify the relative importance of particular factors.

**PATIENTS AND METHODS:** A 2-year hospital-based prospective study was conducted in two hospitals to identify the clinical characteristics and risk factors of patients with confirmed aseptic intracranial venous occlusive disease.

**RESULTS:** 21 patients were identified, representing 0.9% of the total neurological admissions. Men were more commonly affected than women; 81% of the patients presented in a clinical picture indistinguishable from idiopathic intracranial hypertension. Risk factors included Behçet's disease in 4, the puerperium in 3, thrombophilia in 3, familial Mediterranean fever in 2, malignancies in 1, lupus anticoagulant in 1, and the contraceptive pill in 1.

**CONCLUSION:** Aseptic intracranial venous occlusive disease proved to be not rare in Arabs. It should be considered seriously in the differential diagnosis of idiopathic intracranial hypertension, particularly in males. Several risk factors were incriminated.

Possible protection against asthma in heterozygotes for familial Mediterranean fever.

Brenner-Ullman A(1), Melzer-Ofir H, Daniels M, Shohat M.

Author information:

(1)Department of Medical Genetics, FMRC, Beilinson Medical Center, Petah Tiqva, Israel.

To identify a specific heterozygote advantage in familial Mediterranean fever (FMF), responsible for the high carrier rate of 1/6 in North African Jews, we studied the morbidity and mortality of 148 parents of affected patients and of 148 ethnically matched control persons. Our data demonstrate an apparently reduced prevalence of asthma in the heterozygotes compared with the control persons (3 vs. 6). There were no significant differences between the 2 groups in fertility rate, number of pregnancies and deliveries, or the prevalence of common

diseases. Our data are in agreement with previous studies which demonstrated decreased asthma prevalence in FMF patients. It further confirmed, these findings suggest that identification of the FMF gene on 16p may provide an insight into asthma.

Amyloidosis: prognosis and treatment.

Gertz MA(1), Kyle RA.

Author information:

(1)Division of Hematology and Internal Medicine, Mayo Clinic, Rochester, MN 55905.

The objective of this study was to review (1) the factors that have been linked to prediction of clinical outcome and survival in amyloidosis and (2) the available studies on the therapy for localized and systemic forms of amyloidosis. We made a retrospective review of the relevant literature on treatment and prognosis in localized and systemic amyloidosis dating back to 1975. The most important prognostic factors in amyloidosis are the presence of congestive heart failure, beta 2-microglobulin, and whether peripheral neuropathy dominates the presentation. The presence of a monoclonal light chain in serum or urine, multiple myeloma, and hepatic involvement are also important adverse factors. Colchicine is beneficial in treating familial Mediterranean fever and may play a role in managing secondary amyloidosis in inflammatory bowel disease. Chlorambucil is particularly useful in juvenile rheumatoid arthritis with amyloidosis. Dimethyl sulfoxide provides benefit in bladder and lichen amyloidosis. A trial of alkylating agent-based chemotherapy is reasonable in symptomatic primary systemic amyloidosis. Advances have been made in the treatment of amyloidosis and include chemotherapy, dialysis, transplantation, and improved supportive care. Definite disease regressions with long-term survival (> 10 years) are seen. Unfortunately, alternatives still need to be developed: Of 859 patients with primary systemic amyloidosis seen at the Mayo Clinic from 1982 to 1992, the median survival was 2.1 years.

**OBJECTIVE:** We describe a newly defined syndrome of protracted febrile myalgia in patients with familial Mediterranean fever (FMF).

**METHODS:** Fourteen patients with FMF were admitted with an attack of severe disabling myalgia accompanied by fever, high erythrocyte sedimentation rate, and hyperglobulinemia, lasting up to 6 weeks.

**RESULTS:** Unlike in the classical manifestations of FMF response to corticosteroids therapy was prompt.

**CONCLUSION:** Protracted febrile myalgia is an uncommon dramatic manifestation of FMF that may occur despite colchicine therapy and requires treatment with corticosteroids.

[Acute abdomen].

[Article in German]

Schmid PA(1), Suter S, Greminger P.

Author information:

(1)Departement für Innere Medizin, Universitätsspital Zürich.

A 28-year-old turkish patient was admitted to hospital several times within the last years because of acute abdominal and thoracic pain. On each admission laboratory parameters indicative of an acute inflammatory process were initially found to be slightly increased; however, the cause for the complaints remained undetected. During a recent episode of acute abdominal pain a short increase of these laboratory parameters (particularly of CRP) could be documented, and since no other diagnostic sign indicative of an other disease was found, familial mediterranean fever was diagnosed. A basic therapy with colchicine was initiated, and since five months the patient remained mostly free of symptoms.

Fibromyalgia in familial Mediterranean fever.

Langevitz P(1), Buskila D, Finkelstein R, Zaks N, Neuman L, Sukenik S, Smythe HA, Pras M.

Author information:

(1)Heller Institute of Medical Research, Chaim Sheba Medical Center, Tel Hashomer, Israel.

**OBJECTIVE:** To determine whether chronic lower body pain in a subpopulation of patients with familial Mediterranean fever (FMF) is due directly to the musculoskeletal manifestations of FMF or whether they are connected to mechanical problems in the low back and leg/foot or to other factors operative in fibromyalgia (FM).

**METHODS:** In 93 consecutive patients with FMF a point count of 14 tender points (TP) was conducted by thumb palpation. Tenderness thresholds were assessed in

some of the TP and of control point sites by Chatillon dolorimeter.

RESULTS: In female patients with FMF dolorimeter thresholds of fibrositic and control point sites were significantly lower than in male patients with FMF ( $p < 0.004$ ). Also patients with FMF with back pain and foot/leg pain are more tender than patients with FMF without this characteristic ( $p < 0.001$ ).

CONCLUSION: The detection of FM and definition of tenderness thresholds is relevant to this disease, since musculoskeletal complaints are common in this group of patients but not always explained by objective findings.

(1)Laboratoire de Biologie Vasculaire et Cellulaire, Université Paris 7, Hôpital Lariboisière, France.

Free and total plasma, granulocyte and mononuclear cell colchicine concentrations

were measured by radioimmunoassay in 30 patients with familial Mediterranean fever treated with colchicine 0.5 to 2 mg day<sup>-1</sup>. Colchicine concentrations showed a large intersubject variability in plasma (0.13-1.75 ng ml<sup>-1</sup>), granulocytes (4 to 64 ng/10<sup>9</sup> cells), and mononuclear cells (11.4 to 57.6 ng/10<sup>9</sup> cells). Whereas unbound and total plasma colchicine concentrations were well correlated, no correlation was found between total or free plasma and granulocyte or mononuclear cell colchicine concentrations and dose of administered colchicine. In contrast, total or free plasma and granulocyte or mononuclear cell colchicine concentrations were correlated using a hyperbolic function indicating saturable colchicine distribution in both leukocyte populations.

Polyarteritis nodosa type vasculitis in a patient with familial Mediterranean fever treated with cyclosporin A.

Henckes M(1), Roskams T, Vanneste S, Van Damme B, Vanrenterghem Y.

Author information:

(1)Department of Nephrology, University Hospital, U.Z. Gasthuisberg, Leuven, Belgium.

Patients with amyloidosis secondary to familial Mediterranean fever (FMF) are known to tolerate cyclosporin A poorly. We report a case of severe cyclosporin toxicity in a patient with FMF amyloidosis who underwent kidney transplantation. The clinical syndrome consisted of severe gastrointestinal, neuromuscular, and psychiatric disturbances. Histological examination of the transplanted kidney revealed vasculitis of the polyarteritis nodosa type. We hypothesize that FMF patients are more vulnerable to the acute vascular toxicity of cyclosporin due to defective inhibition of complement activation, leading to a widespread vasculitis of the polyarteritis nodosa type.

Acute scrotal pain complicating familial Mediterranean fever in children.

Eshel G(1), Vinograd I, Barr J, Zemer D.

Author information:

(1)Paediatric Intensive Care Unit, Assaf Harofeh Medical Centre, Zerifin, Israel.

Twenty-nine children with familial Mediterranean fever presented with 39 attacks of acute scrotal pain. Of these, 25 patients had an acute scrotum complicating familial Mediterranean fever and only four had testicular torsion. Scrotal pain was the only manifestation of a familial Mediterranean fever crisis in 36 episodes and in 15 boys scrotal involvement was the first manifestation of the condition. Fourteen patients were treated medically. Of 15 patients who underwent scrotal exploration there were no definite diagnostic findings in 11 and four had testicular torsion. Three cardinal features strongly suggest the diagnosis of acute scrotum in familial Mediterranean fever in a boy of Mediterranean origin with a relevant family history: recurrent scrotal pain or swelling; body temperature above 37.5 degrees C; and gradual onset of pain, usually of more than 12 h duration. Conservative management can safely be undertaken in these boys without fear of losing a salvageable testis.

(1)Department of Medicine, University Hospital St Radboud, Nijmegen, The Netherlands.

We studied 50 patients (28 male and 22 female) with the hyper-IgD and periodic fever syndrome. Most patients originated from Europe, namely The Netherlands (28 cases; 56%), France (10 cases, 20%), and Italy (3 cases, 6%), but 1 patient was from Japan. A hereditary component is suggested by 18 patients coming from 8 families. The syndrome is typified by a very early age at onset (median, 0.5

years) and life-long persistence of periodic fever. Characteristically, attacks occur every 4-8 weeks and continue for 3-7 days, but the individual variation is large. Attacks feature high spiking fever, preceded by chills in 76% of patients. Lymphadenopathy is commonly present (94% of patients). During attacks, 72% of patients complained of abdominal pains, 56% of vomiting, 82% of diarrhea, and 52% of headache. Joint involvement is common in the hyper-IgD syndrome with poly-arthralgia in 80% and a non-destructive arthritis, mainly of the large joints (knee and ankle), in 68% of patients. Eighty-two percent of patients reported skin lesions with some attacks; these demonstrated vasculitis histologically. Serositis has been seen in only 3 patients (6%), while amyloidosis has not been recorded in any of the patients with this syndrome. Immunizations precipitated attacks in 54% of patients. All patients had a persistently elevated serum IgD level ( $> 100$  U/mL), and in 82% of cases the serum IgA was likewise elevated. During attacks there is an acute-phase response adjudged by leukocytosis, neutrophilia, and increased ESR. The etiology remains to be elucidated, and treatment is supportive. The hyper-IgD syndrome is distinct from other periodic fever syndromes like systemic-onset juvenile rheumatoid arthritis, adult-onset Still disease, and familial Mediterranean fever.

Colchicine disposition in patients with familial Mediterranean fever with renal impairment.

Ben-Chetrit E(1), Scherrmann JM, Zylber-Katz E, Levy M.

Author information:

(1)Division of Medicine, Hadassah University Hospital, Jerusalem, Israel.

**OBJECTIVE:** To assess the pharmacokinetics of serum colchicine in patients with familial Mediterranean fever (FMF) with renal impairment.

**METHODS:** Using a specific radioimmunoassay we determined serum colchicine concentration at various time points following oral administration of a single dose of the drug.

**RESULTS:** Patients with renal insufficiency had a mean  $\pm$  SD apparent total colchicine clearance of  $0.168 \pm 0.063$  l/h/kg, apparent volume of distribution of  $4.56 \pm 1.64$  l/kg and elimination half-life ( $t_{1/2}$ ) of  $18.8 \pm 1.2$  h.

Patients with FMF with normal kidney function had a mean clearance of  $0.726 \pm 0.110$  l/h/kg, volume of distribution of  $4.87 \pm 2.05$  l/kg and terminal  $t_{1/2}$  of  $4.4 \pm 1.0$  h.

**CONCLUSION:** The kidneys have an important role in the clearance of colchicine. Caution should be exercised in the use of colchicine in patients with renal insufficiency.

Comment in

Histopathology. 1994 Dec;25(6):597-8.

Although amyloid deposition in relation to blood vessels is a well-recognized feature of generalized amyloidosis, lymphatic vessel amyloidosis is not mentioned in the literature. Systematic investigation of tissue removed at autopsy from patients with generalized amyloidosis and biopsy specimens from cases of localized amyloidosis and familial Mediterranean fever showed that amyloid deposition around lymphatics is by no means uncommon. The material investigated was mainly large and small bowel, lung, heart and kidney. Amyloid was identified by green birefringence with the Congo red stain on cross-polarization and lymphatics by their lack of immunostaining for CD34. Involvement of lymphatics was noted in 20 of the 42 organs from which specimens were examined, and was always accompanied by involvement of blood vessels and/or the interstitium. In the intestine, lymphatic amyloidosis was found mainly in the submucosa and subserosa, and was also demonstrated by electronmicroscopy in one case. Although lymphatic amyloidosis was equally common in the heart, lung and kidney, it was usually less prominent here than in the intestine. No lymphatic involvement was seen in localized amyloidosis. As the lymphatics play a central role in the resorption of interstitial proteins, they are probably also involved in the resorption of amyloid proteins. Amyloid deposition in the vicinity of lymphatics is probably the result of decompensation of this process.

Autosomal recessive disorders among Arabs: an overview from Kuwait.

Teebi AS(1).

Author information:

(1)Department of Genetics, Yale University School of Medicine, New Haven, Connecticut.

Kuwait has a cosmopolitan population of 1.7 million, mostly Arabs. This population is a mosaic of large and small minorities representing most Arab communities. In general, Kuwait's population is characterized by a rapid rate of growth, large family size, high rates of consanguineous marriages within the Arab communities with low frequency of intermarriage between them, and the presence of genetic isolates and semi-isolates in some extended families and Bedouin tribes. Genetic services have been available in Kuwait for over a decade. During this time it has become clear that Arabs have a high frequency of genetic disorders, and in particular autosomal recessive traits. Their pattern is unique and some disorders are relatively common. Examples are Bardet-Biedl and Meckel syndromes, phenylketonuria, and familial Mediterranean fever. A relatively large number of new syndromes and variants have been delineated in Kuwait's population, many being the result of homozygosity for autosomal recessive genes that occurred because of inbreeding. Some of these syndromes have subsequently been found in other parts of the world, negating the concept of the private syndrome. This paper provides an overview of autosomal recessive disorders among the Arabs in Kuwait from a personal perspective and published studies, and highlights the need for genetic services in Arab countries with the goal of prevention and treatment of genetic disorders.

Author information:

(1)Heller Institute of Medical Research, Sheba Medical Center, Tel-Hashomer, Israel.

The tunica vaginalis is 1 of the sites involved in the recurrent febrile attacks of serositis, which are the hallmark of familial Mediterranean fever. The attacks present clinically as "orchitis." We report on a patient with familial Mediterranean fever in whom recurrent episodes of scrotal attacks were complicated by testicular necrosis requiring orchiectomy. The case emphasizes the challenge of recognizing and differentiating these attacks from other causes of acute scrotum.

Elective laparoscopic appendectomy in patients with familial Mediterranean fever.

Reissman P(1), Durst AL, Rivkind A, Szold A, Ben-Chetrit E.

Author information:

(1)Department of General Surgery, Hadassah University Hospital, Jerusalem, Israel.

Familial Mediterranean fever (FMF) also known as hereditary polyserositis, is an inherited disorder commonly found in Armenians, Turks, Arabs, Balkans, and Jews originating from North African countries. The diagnosis of FMF is based on clinical findings and family history, as no specific diagnostic test is yet available. One of its main clinical features is recurrent acute episodes of peritonitis. During such an episode, physical examination and laboratory findings may be similar to those for acute appendicitis. Therefore up to two-thirds of FMF patients undergo emergency appendectomy, with the appendix being normal in most cases. As laparoscopic appendectomy has proved to be safe and advantageous, and to prevent misdiagnosis and unnecessary emergency surgery, we performed elective laparoscopic appendectomy in 13 FMF patients ranging in age from 8 to 32 years. They had been suffering from the disease for 1 to 12 years (mean 3.8) and had had an average of 3.5 yearly episodes of FMF peritonitis. All procedures were concluded by laparoscopy without conversion to open surgery. The average postoperative hospital stay was 3.07 days. The only complication was superficial wound infection in one patient (7.6%), and the mean time to regain full normal activity was 8.5 days. We conclude that elective laparoscopic appendectomy in FMF patients is safe. It helps to exclude appendicitis as a cause for peritonitis in these patients and may prevent unnecessary emergency surgery.

Serum concentration and urinary excretion of beta 2-microglobulin and microalbuminuria in familial Mediterranean fever.

Saatci U(1), Ozdemir S, Ozen S, Bakkaloglu A.

Author information:

(1)Department of Paediatric Nephrology, Hacettepe University, Faculty of Medicine, Ankara, Turkey.

Familial Mediterranean fever is characterised by recurrent and self limited attacks of fever and polyserositis and its devastating complication is the development of renal amyloidosis. In order to detect the presence of early glomerular and tubular damage in patients with familial Mediterranean fever and to assess the possible role of beta 2-microglobulin in the inflammatory attacks of this disease, serum and urine beta 2-microglobulin concentrations and microalbuminuria were evaluated in these patients. A total of 20 patients with familial Mediterranean fever were studied on and off colchicine treatment; seven of these patients developed a familial Mediterranean fever attack when they were off treatment. During the familial Mediterranean fever attacks serum beta 2-microglobulin concentrations decreased, whereas fractional excretion of beta 2-microglobulin, urine beta 2-microglobulin creatinine, and urine albumin/creatinine ratios increased. We conclude that glomerular and tubular functions deteriorate during the attacks. Further studies are needed to discover the effector(s) causing these transient glomerular and tubular disorders.

Author information:

(1)Urology and Nephrology Center, University of Mansoura, Egypt.

We studied the results of renal transplantation in 16 patients with renal amyloidosis and in 46 controls with primary glomerulonephritis. Amyloidosis was primary in five and secondary to familial Mediterranean fever (FMF) in 11. All patients received live related donor kidneys and the majority had one-haplotype HLA match. One- and 5-year graft and patient survival rates were comparable in both groups. Moreover, the frequency of acute rejection episodes and the mean serum creatinine values were not significantly different between members of the two groups. Significant gastrointestinal symptoms in the form of nausea, vomiting, abdominal pains, and diarrhoea occurred in seven of the patients with amyloidosis (43.7%) and in only one of the controls (2%) ( $P = 0.001$ ). All seven recipients with amyloidosis who developed the gastrointestinal manifestations were receiving cyclosporin and six had FMF. Maintenance colchicine treatment prevented recurrence of FMF symptoms. In one patient discontinuation of colchicine was followed by recurrence of FMF symptoms. Recurrence of renal amyloidosis was not observed in five patients subjected to Trucut graft biopsies 1, 2, 3, 18 and 72 months post-transplantation. It is concluded that live-related donor kidney transplantation is a safe procedure in patients with amyloidosis and follows a course similar to glomerulonephritis patients.

Colchicine in the treatment of AA and AL amyloidosis.

Livneh A(1), Zemer D, Langevitz P, Shemer J, Sohar E, Pras M.

Author information:

(1)Heller Institute of Medical Research, Sheba Medical Center, Tel Hashomer, Israel.

Colchicine is an effective medication in the prevention and treatment of amyloidosis of familial Mediterranean fever. Its therapeutic effect depends on the stage of renal disease and the drug dose. To evaluate colchicine effect in AA amyloidosis of other diseases and in primary AL amyloidosis, the literature was reviewed. Findings were that (1) the effect of colchicine in reactive amyloidosis has not been methodically studied, but anecdotal reports suggest it may be beneficial; and (2) the results of studies and case reports on the effect of colchicine in primary amyloidosis are conflicting. Because a therapeutic effect of colchicine in primary and reactive amyloidosis has been shown in sporadic cases, a prospective, controlled, multicenter study assessing the effect of colchicine in all types of amyloidosis appears to be justified. Until such a study is available, the addition of colchicine in an appropriate dose to any therapeutic regimen of patients with AA or AL amyloidosis should be considered.

(1)Department of Radiology and Radiological Science, Johns Hopkins Hospital, Baltimore, MD 21287.

Amyloidosis is a rare systemic disease caused by extracellular deposition of an insoluble protein. Although it is usually seen in a systemic form, 10%-20% of cases can be localized. Systemic amyloidosis is subclassified into an idiopathic primary form and a secondary or reactive form. Patients with primary amyloidosis have no underlying condition or disease. Men are affected more than women, and the mean age at presentation is 55-60 years. Some causes of secondary amyloidosis are multiple myeloma (10%-15%), rheumatoid arthritis (20%-25%), tuberculosis (50%), or familial Mediterranean fever (26%-40%). Radiographic studies of 90 patients with biopsy-proved primary or secondary amyloidosis were reviewed. Computed tomographic (CT) scans demonstrated a wide spectrum of disease in the cardiothoracic, gastrointestinal, genitourinary, and musculoskeletal systems. Amyloid deposition simulated both inflammatory and neoplastic conditions. Amorphous or irregular calcifications were occasionally identified within the amyloid deposit. Definitive diagnosis requires biopsy confirmation, as CT findings are nonspecific.

Inheritance of renal amyloidosis in Chinese Shar-pei dogs.

Rivas AL(1), Tintle L, Meyers-Wallen V, Scarlett JM, van Tassell CP, Quimby FW.

Author information:

(1)New York State College of Veterinary Medicine, Department of Pathology, Ithaca.

Renal amyloidosis (RA) and recurrent fever of unknown origin (RFUO) are characteristics of familial Mediterranean fever (FMF), a human disorder inherited as an autosomal-recessive trait. Although no animal model has been established for FMF, a similar syndrome of RFUO and RA has been reported in Chinese Shar-pei (CSP) dogs. This report addresses two questions: (1) Is RA inherited in CSP dogs? (2) If it is, is it possible to hypothesize the type of inheritance involved? Two studies were conducted to answer these questions: a historical cross-sectional comparison, which included CSP and non-CSP dogs with RA; and a prospective study

that included CSP dogs with RA, RFUO, or both. The cross-sectional comparison resulted in an odds ratio of 10 for RA in CSP dogs under 7 years of age. The prospective study of 28 dogs with RA or RFUO identified 20 that had RFUO and RA, three with RA alone, and five with RFUO alone. RFUO preceded RA in all cases with both conditions. The RFUO/RA combination was observed in both sexes. Four dogs with RFUO with or without RA were born to parents that either were alive at age 7 or had died because of conditions other than kidney failure/RA. When one parent was known to express one of these conditions, the prevalence of RA was between 25% and 50% among littermates.(ABSTRACT TRUNCATED AT 250 WORDS)

Effect of long-term colchicine therapy on jejunal mucosa.

Hart J(1), Lewin KJ, Peters RS, Schwabe AD.

Author information:

(1)Department of Pathology, UCLA School of Medicine.

Colchicine is recommended as daily prophylactic therapy in patients with familial Mediterranean fever (FMF) to prevent febrile paroxysms. The drug is known to be a potent inhibitor of mitotic activity and might therefore be expected to have a significant adverse effect on tissues that undergo rapid turnover. We studied small bowel biopsies from nine patients with FMF who were receiving daily low-dose oral colchicine therapy. In each patient the lengths of 20 crypts and villi were measured and the number of mitotic figures in 20 crypts were counted. The data were compared with similar measurements from histologically normal-appearing biopsies obtained from 14 patients with a variety of mild gastrointestinal complaints. The mean crypt length was found to be significantly greater (0.197 mm vs 0.186 mm,  $P < 0.0001$ ) and the mean villous length significantly smaller (0.369 mm vs. 0.442 mm,  $P < 0.0001$ ) in the FMF patients than in the control population. In addition, the mean number of mitotic figures per crypt was significantly higher in the FMF patients (2.58 vs 1.00,  $P < 0.001$ ). The data reveal a pattern of mucosal injury in the colchicine-treated FMF patients characterized by a hyperplastic crypt-villous atrophy pattern with

increased mitotic rate, which is indicative of an increase in cell turnover and opposite to what we anticipated based on colchicine's known effect on mitotic activity.

Taiwanese patient with recurrent polyserositis: report of a case.

Lee WY(1), Tsai S, Kao JH, Lai MY.

Author information:

(1)Department of Internal Medicine and Emergency Medicine, National Taiwan University Hospital, Taipei, R.O.C.

A 26-year-old man had suffered from recurrent abdominal pain, ascites and arthralgia since childhood. The symptoms occurred usually during the winter, and each attack lasted for two to three days. Initially, the frequency was about once a year, but it had increased to once every one to four months after an exploratory laparotomy carried out four years ago. Leukocytosis accompanied each episode. Many laboratory examinations and imaging studies failed to show pathologic lesions. Laparoscopic examination revealed only yellowish ascites with a hyperemic mesentery and omentum. There were never any sequelae after the attacks. After prophylaxis with colchicine 0.6 mg three times a day, no more attacks occurred. Familial Mediterranean fever (familial paroxysmal polyserositis) was the most likely diagnosis. Recognizing this disease entity in Taiwanese patients may help to avoid unnecessary operations.

[Monosymptomatic familial Mediterranean fever as the cause of fever of unknown origin].

[Article in German]

Böck A(1), Simbruner G.

Author information:

(1)Universitätsklinik für Kinderheilkunde, Wien.

A previously healthy 2 year old female child developed fever of unknown origin recurring in monthly cycles. The periodic fever attacks, family history and ethnologic criteria were in agreement with familial mediterranean fever, although further more major symptoms were missing. It was highly unusual to find repeatedly raised levels of angiotensin I converting enzyme, a finding previously not described in literature. Excluding any other differential diagnosis by intensive investigations, together with a positive metaraminol provocation test, the diagnosis of a rare, monosymptomatic variant of familial mediterranean fever was proposed. Amyloidosis was excluded by rectal biopsy. Monosymptomatic familial mediterranean fever is very seldom. We suggest to measure routinely angiotensin I converting enzyme for further evaluation of our findings.

The association between Henoch-Schönlein syndrome and renal amyloidosis: a proposal of a pathogenic mechanism.

Tinaztepe K(1), Güçer S, Bakkaloğlu A, Tinaztepe B.

Author information:

(1)Department of Pediatrics, Hacettepe University Faculty of Medicine, Ankara.

The clinicopathological analysis of 250 pediatric cases that had been tissue-diagnosed with renal amyloidosis revealed three patients associated with Henoch-Schönlein syndrome (HSS). The renal biopsies revealed AA-type amyloidosis in all three cases. Case 2 displayed focal and segmental proliferative glomerulonephritis in the same renal biopsy. No evidence of well-known diseases and/or conditions for the development of AA-type amyloidosis except for familial Mediterranean fever (FMF) existed in these particular cases. On the other hand, the frequency of the association between FMF and HSS has been reported extensively in the literature; thus, common etiological factors can be considered. The mechanism involved in amyloid deposition in these cases may be related to HSS-associated chronic antigenemia and/or FMF through a mechanism that is, to date, unknown. Further studies are needed to clarify this causal relationship.

Diagnostic value of bone marrow biopsy in patients with renal disease secondary to familial Mediterranean fever.

Sungur C(1), Sungur A, Ruacan S, Arik N, Yasavul U, Turgan C, Caglar S.

Author information:

(1)Department of Nephrology, Hacettepe University, School of Medicine, Ankara, Turkey.

Systemic AA type amyloidosis with renal involvement is the major cause of morbidity and mortality in patients with familial Mediterranean fever (FMF). A histopathological examination is essential to achieve a definite diagnosis in systemic amyloidosis. The diagnostic yield of the procedure varies according to the biopsy site and renal biopsy has the highest yield. On the other hand this

procedure has its own complications and requires hospitalization of the patient. Alternative biopsy sites have been proposed with varying degrees of sensitivity and morbidity to reduce the morbidity and mortality of solid organ biopsies. We performed bone marrow biopsies in 39 patients with FMF who had different stages of renal disease. Thirty-one (79.5%) of the 39 specimens showed significant perivascular amyloid infiltration when stained with crystal violet and Congo red. An immunoperoxidase stain with a monoclonal antibody proved that these deposits were AA type amyloid. We suggest that bone marrow biopsy can be utilized for a safe and quick diagnosis of systemic amyloidosis in patients with FMF and renal disease.

Increased chromosome breakage is observed in patients with familial mediterranean fever (FMF). Their plasma contains clastogenic material inducing chromosome damage in cells from healthy persons. It is proposed that increased oxyradical generation by activated polymorphonuclear cells in blood and serosal fluids of these patients leads to the formation of a clastogenic factor (CF), as it is observed in other chronic inflammatory diseases. Also similar to these diseases, the clastogenic effects are prevented by superoxide dismutase and partially by inhibitors of arachidonic acid metabolism.

Author information:

(1)Laboratoire d'Immunologie, Hôpital de Sainte-Marguerite, Marseille, France.

OBJECTIVE: The etiopathogenesis of Behçet's disease (BD) has not yet been

clarified but might involve immune dysfunction. As cytokines are involved in the regulation of immune responses and inflammatory reactions, we investigated whether they may play a role in the pathogenesis of BD.

**METHODS:** We investigated spontaneous and lipopolysaccharide (LPS) stimulated production of tumor necrosis factor alpha (TNF alpha), interleukin (IL) 1, IL-6, IL-8 and granulocyte monocyte macrophage colony stimulating factor (GM-CSF) by peripheral blood monocytes from 21 patients with BD, 10 healthy controls and 10 patients with familial Mediterranean fever (FMF), another chronic inflammatory disease. We also studied superoxide generation and surface antigen expression by polymorphonuclear neutrophils (PMN).

**RESULTS:** The spontaneous secretion of TNF alpha, IL-6 and IL-8 by monocytes was significantly increased in patients with active BD. The secretion of TNF alpha, IL-1, IL-6 and IL-8 was found to be in normal range in asymptomatic patients with FMF. The LPS stimulated production of TNF alpha, IL-6, IL-1 and IL-8 was significantly increased in patients with BD, without any correlation with BD activity. In vitro, PMN spontaneously generated significant amounts of superoxide in patients with active BD.

**CONCLUSION:** Taken together, our results suggest that monocyte and PMN dysfunctions may play a role in the pathogenesis of BD.

Effect of pregnancy on renal function in amyloidosis of familial Mediterranean fever.

Livneh A(1), Cabili S, Zemer D, Rabinovitch O, Pras M.

Author information:

(1)Heller Institute of Medical Research, Sheba Medical Center, Tel-Hashomer, Israel.

**OBJECTIVE:** To study the effect of pregnancy on kidney function in patients with familial Mediterranean fever (FMF) with amyloidosis.

**METHODS:** A retrospective analysis relating kidney function at term to kidney function at conception and to blood pressure and colchicine treatment before and

during pregnancy in 17 patients with 29 pregnancies found among more than 3000 patient files in our FMF clinic.

RESULTS: Following pregnancy, 7 patients (24% of pregnancies) experienced a decline in renal function. Urine protein  $\geq 2$  g/24 h at conception was present in all pregnancies which sustained deterioration in contrast to 6 of 22 which did not ( $p < 0.001$ ). Serum creatinine  $\geq 1.5$  mg/dl at conception was present in 3 patients, all of whom experienced deterioration of renal function during pregnancy ( $p < 0.01$ ). Neither colchicine dose nor elevated blood pressure correlated with status of renal function at term.

CONCLUSION: Our findings suggest a possible deleterious effect of pregnancy on amyloid nephropathy and that this effect may be associated with more advanced renal disease at conception.

Familial Mediterranean fever (FMF) is an autosomal recessive disease causing attacks of fever and serositis. The FMF gene (designated "MEF") is on 16p, with the gene order 16cen-D16S80-MEF-D16S94-D16S283-D16S291-++ +16pter. Here we report the association of FMF susceptibility with alleles as D16S94, D16S283, and D16S291 among 31 non-Ashkenazi Jewish families (14 Moroccan, 17 non-Moroccan). We observed highly significant associations at D16S283 and D16S291 among the Moroccan families. For the non-Moroccans, only the allelic association at D16S94 approached statistical significance. Haplotype analysis showed that 18/25 Moroccan FMF chromosomes, versus 0/21 noncarrier chromosomes, bore a specific haplotype for D16S94-D16S283-D16S291. Among non-Moroccans this haplotype was present in 6/26 FMF chromosomes versus 1/28 controls. Both groups of families are largely descended from Jews who fled the Spanish Inquisition. The strong haplotype association seen among the Moroccans is most likely a founder effect, given the recent origin and genetic isolation of the Moroccan Jewish community. The lower haplotype frequency among non-Moroccan carriers may reflect differences both in history and in population genetics.

Familial Mediterranean fever (FMF) is an autosomal recessive disease characterized by attacks of fever and serosal inflammation; the biochemical basis is unknown. We recently reported linkage of the gene causing FMF (designated "MEF") to two markers on chromosome 16p. To map MEF more precisely, we have now tested nine 16p markers. Two-point and multipoint linkage analysis, as well as a study of recombinant haplotypes, placed MEF between D16S94 and D16S80, a genetic interval of about 9 cM. We also examined rates of homozygosity for markers in this region, among offspring of consanguineous marriages. For eight of nine markers, the rate of homozygosity among 26 affected inbred individuals was higher than that among their 20 unaffected sibs. Localizing MEF more precisely on the basis of homozygosity rates alone would be difficult, for two reasons: First, the high FMF carrier frequency increases the chance that inbred offspring could have the disease without being homozygous by descent at MEF. Second, several of the markers in this region are relatively nonpolymorphic, with a high rate of homozygosity, regardless of their chromosomal location.

Familial mediterranean fever (or recurrent hereditary polyserositis) is a genetic disorder with an autosomal recessive pattern of inheritance which occurs mostly in patients with eastern Mediterranean origin. Two Dutch patients are described, a 25-year-old women and her 58-year-old father, who suffered from recurring abdominal complaints, fever, and increased erythrocyte sedimentation rate, without evidence of Middle Eastern ancestry or hyperimmunoglobulinemia D.

Familial Mediterranean fever (FMF) is an autosomal recessively inherited inflammatory disorder characterized by recurrent short episodes of fever, peritonitis, arthritis, and pleuritis. Recently, linkage was demonstrated between FMF and the VNTR probes 3'HVR and 5'HVR of the alpha-globin complex at 16p13.3

(theta = 0.06-0.10, Lodmax = 9.76-14.47) and the insertion/deletion polymorphism detected by the probe CMM65 of D16S84 (theta = 0.04, Lodmax = 9.17). We have now mapped the FMF gene between the two flanking markers D16S283/D16S291 (theta = 0.038) and D16S80 (theta = 0.159). The proximity of the microsatellite markers in D16S283 and D16S291 to the FMF gene allows preclinical diagnosis in most pedigrees with affected individuals.

Evidence for linkage of the gene causing familial Mediterranean fever to chromosome 17q in non-Ashkenazi Jewish families: second locus or type I error?

Aksentijevich I(1), Gruberg L, Pras E, Balow JE Jr, Kovo M, Gazit E, Dean M, Pras M, Kastner DL.

Author information:

(1)Arthritis and Rheumatism Branch, National Institute of Arthritis and Musculoskeletal and Skin Diseases, National Institutes of Health, Bethesda, MD 20892.

Familial Mediterranean fever (FMF) is an autosomal recessive disorder of unknown pathogenesis, characterized by recurrent, self-limited attacks of fever with synovitis, peritonitis, or pleurisy. Using DNAs from affected Israeli families, we have recently mapped the gene causing FMF (designated MEF) to the short arm of chromosome 16, with two-point lod scores in excess of 20. In this report we consider the possibility of a second FMF susceptibility locus. Before discovering linkage to markers on chromosome 16, we had found suggestive evidence for linkage to chromosome 17q, with the following maximal two-point lod scores: D17S74 (pCMM86),  $Z = 2.47$ , (theta = 0.20); D17S40 (pLEW101),  $Z = 2.15$  (theta = 0.15); D17S35 (CRI-pP3-1),  $Z = 1.78$  (theta = 0.15); D17S46 (pLEW108),  $Z = 1.69$  (theta = 0.18), D17S254,  $Z = 2.30$  (theta = 0.20). Moreover, multipoint linkage analysis using D17S74 and D17S40 as fixed loci gave  $Z = 3.27$  approximately 10 centimorgans (cM) telomeric to D17S40. Data with the chromosome 17 markers alone in our families suggested locus heterogeneity. Nevertheless, our families were not separable into complementary subsets showing linkage either to chromosome 16 or

to chromosome 17. We also examined the possibility that the positive lod scores for chromosome 17 might reflect a secondary, modifying locus. By several measures of disease severity, families with positive lod scores for chromosome 17 loci had no worse disease than those with negative lod scores for these loci. We conclude that chromosome 17 does not encode a major FMF susceptibility gene for some of the families, nor does it encode a disease-modifying gene. Rather, it would appear that linkage to chromosome 17 is a "false positive" (type I) error. These results reemphasize the fact that a lod score of 3.0 corresponds to a posterior probability of linkage of 95%, with an attendant 1 in 20 chance of observing a false positive.

[Autonomic neural functioning in children with the periodic syndrome].

[Article in Italian]

Meossi C(1), Domenici R, Saponati G, Castelli S.

Author information:

(1)U.O. Pediatria, U.S.L. n. 6, Presidio Ospedaliero di Lucca.

The pathogenesis of periodic syndrome (recurrent abdominal pain, cyclic vomiting, headache and other equivalents of childhood migraine) is often related in the literature to a "neuro-vegetative dysfunction", by which occasional stimuli (environmental, metabolic, emotional) should find a particular somatic expression. The homeostatic role of the autonomic nervous system could be deficient in these cases, but systematic research has never been done to explore this hypothesis. We have evaluated the autonomic nervous function in 38 children (12 M, 26 F) with periodic syndrome, by cardiovascular autonomic function tests. They consist of ortho- and parasympathetic parameters obtained by ECG registration and pressure monitoring during deep breathing, Valsalva manoeuvre, lying to standing postural change, sustained handgrip. In the absence of adequate pediatric references values, we have previously standardized these tests in a population of 198 healthy children (94 M, 104 F), aged 8.3-15.7 years. Results

have been compared with our standard reference values, matching them by t-test for independent data: in both sexes, significant differences have been found out in only one of 11 parameters ( $p < 0.05$ ) of the autonomic tests performed.

Children affected by periodic syndrome reveal a reduced heart rate variation in transition from the early orthosympathetic phase to the late parasympathetic one after lying to standing passage, showing a smaller fluctuation of autonomic feedback systems. The physiological meaning of this result is unclear. However, in children with periodic syndrome no prevalence of ortho- or parasympathetic systems is evident.

Neurologic manifestations in familial Mediterranean fever.

Gedalia A(1), Zamir S.

Author information:

(1)Pediatric Rheumatology Unit, Soroka Medical Center, Ben Gurion University of the Negev Beer Sheva, Israel.

Neurologic involvement in children with familial Mediterranean fever is relatively uncommon and rarely described in the pediatric literature. Although headaches occur frequently, meningitis and convulsions are rare. Thirteen of 101 children with familial Mediterranean fever developed neurologic manifestations. Of these 13 patients, 10 had headaches during acute episodes of the fever. Two patients had convulsions with fever before the age of 5 years; the convulsions and acute episodes recurred at ages 9 and 10 years. Another patient had two episodes of aseptic meningitis followed by convulsive disorder before the diagnosis of familial Mediterranean fever was made; his convulsions were resistant to antiepileptic drugs alone and subsided only when colchicine was added. The possibility of neurologic involvement should be considered in patients with familial Mediterranean fever.

The recently published, detailed cytogenetic-based physical map of chromosome 16 has the highest resolution of any autosomal cytogenetic map thus far constructed. The genetic map has been integrated with the cytogenetic map to facilitate the regional localization of disease genes by linkage. Disease genes for tuberous sclerosis, familial Mediterranean fever, Rubinstein-Taybi syndrome and Morquio A syndrome have now been assigned to chromosome 16. The search for the adult polycystic kidney disease gene has recently been narrowed to the analysis of candidate loci on chromosome 16, and localization of the gene determining juvenile Batten disease has been further refined by disequilibrium mapping.

Author information:

(1)Hematology Unit, Hadassah University Hospital, Mount Scopus, Jerusalem, Israel.

The complement fragment C5a and the cytokine interleukin-8 (IL-8) are proinflammatory peptides with potent chemotactic activity toward neutrophils. We have previously shown that C5a can be inactivated by a protease that is found in normal synovial and peritoneal fluids but is absent from serosal fluids obtained from patients with familial Mediterranean fever (FMF). We report here that serosal fluids can also eliminate the chemotactic activity of IL-8. The agent responsible for IL-8 elimination appears to be the C5a-inactivating protease, because the pure protease can inactivate IL-8, inactivation of IL-8 by normal peritoneal fluid is partly prevented by an antibody raised against the purified C5a-inactivating protease, and IL-8 is not inactivated by peritoneal fluids from patients with FMF. The ability of this protease to inactivate both, early (C5a) and late (IL-8) inflammatory mediators identifies it as a potentially significant regulator of inflammation.

In order to demonstrate the effect of prophylactic colchicine treatment on the natural history of familial Mediterranean fever (FMF), a family is presented with 6 out of 9 siblings affected by FMF. Each patient represents a different stage of the amyloidotic kidney disease of FMF and the effect of continuous colchicine treatment on its course. Considered together, the members of this family present an almost complete clinical, genetic, and behavioral picture of the disease.

Author information:

(1)Department of Orthopaedic Surgery, Chaim Sheba Medical Center, Tel-Hashomer Hospital, Tel Aviv, Israel.

Familial Mediterranean fever (FMF) is a hereditary disorder affecting people of Mediterranean stock, mainly Sephardic Jews and Armenians. It is characterized by attacks of arthritis, either short, self-limited episodes typically lasting 72 hours or protracted attacks lasting from two weeks to one year. The latter form affects mainly the large joints of the lower limb. The hip joint is the most vulnerable and likely to be affected by the protracted attacks, which may result in destruction of the articular cartilage and, in some cases, aseptic necrosis of the femoral head. Eighteen FMF patients (19-52 years) underwent 22 total hip replacements between 1971 and 1985 at our hospital. Six of the 18 initial prostheses experienced aseptic loosening. This relatively high incidence led us to recommend implantation of cementless hip prostheses following meticulous synovectomy as the treatment of choice. The results of these surgeries and the uniqueness of total hip replacement in FMF patients are presented here and discussed.

Transplantation for renal amyloidosis.

Kiliçturgay S(1), Haberal M.

Author information:

(1)Turkish Transplantation and Burn Foundation Hospital, Ankara.

Renal transplantation therapy performed for amyloid nephropathy is controversial because of the fatal effects of the disease. Amyloidosis is a relatively frequent disease and is generally associated with familial Mediterranean fever (FMF) in Turkey. Renal transplantation in the treatment of amyloid nephropathy started in January 1985. Till now, 18 (3.2%) renal transplantations have been performed on

patients who had amyloid nephropathy. The mean follow-up period was 34.6 months. Fourteen renal grafts still function well (creatinine: 1-3.2 mg/dL). The overall 1-year patient and graft survival rates were 88.9% and 83.0%, respectively. These rates are not statistically different from renal transplantations done for other cases of renal failure. Therefore, patients with end-stage renal failure due to amyloidosis can be considered as appropriate candidates for renal transplantation.

Srinivas KV, Neverov NI, Kolonduk NV, Tambovtseva EV, Kozlova RI.

Serum lipids were estimated in patients with renal amyloidosis (RA): 21 with familial Mediterranean fever (FMF) and 24 with secondary renal amyloidosis versus FMF patients without renal dysfunction or having chronic glomerular nephritis. All the RA patients had dyslipidemia of atherogenic nature the severity of which correlated with that of renal disorder. Our results showed the presence of dyslipidemia early during RA course. It is renal involvement that results in dyslipidemia observed in FMF patients.

A preliminary and retrospective review--with a southern perspective--of some traveller's pathologies, mostly imported, and leading to hospital admission in Guadeloupe (FWI). End stage patients (cancer, AIDS...) frequently travel for a last, "compassional" trip. Ischemic heart disease is the leading pathology imported from the mother country (France). As well as in diabetes or psychiatric illness, destabilization frequently occurs as a consequence of travel (jet lag). Compulsive tennis plus dehydration cause the very common stone passage of nephrolithiasis. Concern is growing for heroin withdrawal syndrome or cocaine (crack)-abuse, and for supply for rare and expensive anticancer, antigraft rejection or antinfective (AIDS) agents. Much more familiar to us are photodermatitis, larva migrans, dengue, or ciguatera, locally acquired. On the other hand some pathologies are quite "exotic" to us: Kaposi sarcoma, Lyme, or Behçet disease, familial mediterranean fever, brucellosis.

Author information:

(1)Department of Medical Genetics, Beilinson Medical Center, Petah Tikva, Israel.

Familial Mediterranean fever (FMF) is a recurrent inflammatory disorder characterized by short episodes of fever, peritonitis, pleuritis, and arthritis. While FMF has been shown to be inherited in an autosomal recessive fashion in both non-Ashkenazi Jews and Armenian families, clinical differences have raised the possibility of genetic heterogeneity. As its pathogenesis is unknown, mapping of the gene for FMF may provide the first objective method for early and accurate diagnosis of this disease. After excluding 45% of the entire human genome, we studied 14 Armenian and 9 non-Ashkenazi Jewish families with FMF and tested linkage with the alpha-globin locus on chromosome 16. Analysis of the PvuII length polymorphism of the 3' HVR (hypervariable region) probe showed significant linkage with the FMF gene (maximum lod score [lodmax] = 9.76 at maximum recombination fraction [theta] = .076). In the Armenians, the lodmax = 3.61 at theta = .10; and for the non-Ashkenazi Jews, lodmax = 6.28 at theta = .06. There was no evidence for genetic heterogeneity between the Armenians and the non-Ashkenazi Jews (chi 2 = 1.28; P = .26) or within either ethnic group (chi 2 = .00; P = .50). Thus, the gene for FMF is linked to the alpha-globin complex on chromosome 16p in both non-Ashkenazi Jews and Armenians.

The arthritis of familial Mediterranean fever.

Garcia-Gonzalez A(1), Weisman MH.

Author information:

(1)Department of Medicine, University of California, San Diego 92103.

Familial Mediterranean fever (FMF) is a disease of unknown etiology and pathogenesis. In addition to fever, arthritis is among its most frequent manifestations. The arthritis of FMF is typically an acute, episodic, self-limited process with no sequelae. The radiographic features of FMF arthritis are usually limited to transient, often severe osteoporosis. Synovial fluid analysis may mimic septic arthritis with very high white blood cell counts; cultures are uniformly negative. The course of FMF is almost always benign, with no residual articular incapacity. Some patients, limited to certain ethnic groups, develop renal amyloidosis. Colchicine therapy modifies the natural history of the disease by decreasing the attack frequency and preventing amyloid deposition. At present, a lipocortin deficiency appears to be the likely candidate for a pathogenic mechanism. An unusual case with dramatic periarticular features (periostitis) and a protracted course with an excellent response to synovectomies is reported here. There is no explanation for the exuberant periarticular bone formation noted in this case, but a variety of recently discovered growth factors may be implicated.

[Familial amyloidosis].

[Article in French]

Grateau G(1), Roux ME.

Author information:

(1)Département de Médecine interne, Hôpital Cochin, Paris.

Familial amyloidosis is characterized by its great clinical and genetic heterogeneity. The most frequent form is amyloidotic neuropathy which may be due to deposits of several amyloid proteins, such as transthyretin, apolipoprotein A1 and gelsolin. Other varieties include predominant lesions of another organ, such as kidney, heart, eye or skin. In most of these lesions, a punctual mutation affects the amyloid protein itself. In other varieties, the amyloid protein is not affected by mutation and, rarely, unknown. The advances achieved in our understanding of transthyretin deposition should improve our knowledge of amyloidosis in general.

Temporomandibular arthritis in familial Mediterranean fever.

Tovi F(1), Gatot A, Fliss D.

Author information:

(1)Department of Otolaryngology, Head and Neck Surgery, Soroka Medical Center, Beer-Sheva, Israel.

Temporomandibular joint arthritis is a rare manifestation of familial Mediterranean fever and should be considered in patients of Mediterranean origin. Recently we treated four patients suffering from this condition, and intra-articular corticosteroid injection resulted in rapid resolution of the pain and disability in two. Computed tomography confirmed the usefulness of this therapeutic modality.

Autosomal dominant 'Mediterranean fever' in a Finnish family.

Karenko L(1), Pettersson T, Roberts P.

Author information:

(1)Fourth Department of Surgery, Helsinki University Central Hospital, Finland.

Erratum in

J Intern Med 1993 Jan;233(1):101.

A 23-year-old Finnish man was examined because of an 8-year history of recurrent bouts of fever and abdominal pain. His father had been repeatedly investigated because of similar episodes since he was 24 years old, and one of the father's sisters was reported to have had recurrent periods of fever. The clinical features closely resembled those of familial Mediterranean fever (FMF), a syndrome rarely described in families of European descent. Unlike typical FMF, which is inherited as an autosomal recessive trait, the mode of inheritance of the syndrome in our family may be regarded as dominant. During a recent attack, serum concentrations of interleukin-1-beta, interleukin-6 and acute phase reactants, including serum amyloid A protein, were high. No signs of amyloidosis were detected in our patients.

The effect of maternal use of colchicine on fetuses is unknown. The children of 116 women with Familial Mediterranean Fever (225 completed pregnancies) were studied. There was no unusual frequency of fetal abnormality among women taking colchicine before or during pregnancy. Colchicine treatment does not apparently harm mother or child.

The effect of pregnancy on renal function in amyloidosis of familial Mediterranean fever.

Cabili S(1), Livneh A, Zemer D, Rabinovitch O, Pras M.

Author information:

(1)Heller Institute of Medical Research, Sheba Medical Center, Tel-Hashomer, Israel.

The effect of pregnancy on kidney function was studied in 29 pregnancies of 17 patients with familial Mediterranean fever (FMF) and amyloidosis. Pregnancy associated deterioration of renal function occurred in seven patients who had advanced renal disease at conception, marked by serum creatinine  $\geq 1.5$  mg/dl or urine protein  $\geq 2$  g/24 h. This finding suggests that the severity of

renal disease at conception may predict the fate of kidney function during pregnancy and puerperium.

Mapping of the familial Mediterranean fever gene to chromosome 16.

Gruberg L(1), Aksentijevich I, Pras E, Kastner DL, Pras M.

Author information:

(1)Department of Medicine F, Sheba Medical Center, Tel Hashomer, Israel.

Familial Mediterranean fever (FMF) is an autosomal recessive disease characterized by recurrent attacks of fever, synovitis, peritonitis, or pleurisy. Some patients eventually develop systemic amyloidosis. The biochemical cause of the disease is unknown. We have conducted a genome-wide search for the FMF locus using 125 different DNA markers and mapped the FMF gene to the short arm of chromosome 16. The study was performed on 35 Israeli families primarily of North African and Iraqi origin. For the five markers D16S82 (p41-1 SacI), D16S80 (24-1 TaqI), D16S84 (pCMM65 TaqI), D16S83 (pEKMDA2-1 RsaI), and HBA (5'HVR RsaI) we obtained maximum lod scores of 2.72 (theta = 0.08), 10.34 (theta = 0.04), 9.66 (theta = 0.050), 9.35 (theta = 0.03), and 14.31 (theta = 0.08), respectively. Multipoint analysis with HBA and D16S84 defined as a fixed loci gave a maximum lod score of 19.86 centromeric to D16S84. Crossovers defined by these markers place the FMF gene in an area of approximately 5 cM between D16S80 and D16S84. Other genes mapped to this area (16p13.3) include phosphodiesterase IB (PDE1B), hydroxyacyl-glutathione hydrolase (HAGH), phosphoglycolate phosphatase (PGP), and the gene that causes adult polycystic kidney disease (PKD1). None of these genes bear an obvious pathophysiological relationship to FMF. Using additional markers from this region we hope to localize more precisely the FMF gene and to offer the possibility of prenatal diagnosis in selected cases. Our ultimate goal is to isolate and characterize the FMF gene.

Familial Mediterranean fever: analysis of inheritance and current linkage data.

Shohat M(1), Danon YL, Rotter JL.

Author information:

(1)Department of Pediatrics, Children Hospital, Beilinson Medical Center, Petah Tikva, Israel.

Familial Mediterranean fever (FMF) is a genetic disorder characterized by recurrent attacks of fever and inflammation of serosal surfaces. Unlike many mendelian disorders, the mode of transmission has been subject to some controversy as segregation analysis studies have always demonstrated fewer "observed" than "expected" affected individuals. Despite efforts to map the gene causing FMF, no definite linkage has been yet identified. This review analyses

the epidemiologic and genetic characteristics in order to evaluate critically the inheritance of the disease and provide a perspective on the current biochemical and molecular genetic studies whose aim is to locate the gene for this disease.

Twin studies in familial Mediterranean fever.

Shohat M(1), Livneh A, Zemer D, Pras M, Sohar E.

Author information:

(1)Heller Institute of Medical Research, Sheba Medical Center, Tel Hashomer, Israel.

Familial Mediterranean fever (FMF) is a genetic disease characterized by recurrent short episodes of fever, accompanied by peritonitis, pleuritis, or arthritis. The disease is almost completely ethnically restricted to patients of Mediterranean descent--Sephardic Jews, Armenians, Anatolian Turks, and Arabs. Although many family studies have been performed, no twin study has been reported as yet. We studied 21 di- and monozygotic twin sets, identified among the 1,943 FMF patients in our registry. Full concordance was observed in all the 10 monozygotic twin sets. In the 11 dizygotic twins, concordance for FMF disease was found in only 3 pairs. Variability in the clinical manifestations and degree of severity have been noted within twins. These findings provide definitive evidence for the genetic cause of FMF. They also support the single gene autosomal recessive model, and provide support for the contention that the lower observed than expected incidence found in FMF is due to genetically affected but clinically undiagnosed patients.

Colchicine analogues: effect on amyloidogenesis in a murine model and, in vitro, on polymorphonuclear leukocytes.

Wolach B(1), Gotfried M, Jedeikin A, Lishner M, Brossi A, Ravid M.

Author information:

(1)Department of Pediatrics, Sackler Faculty of Medicine Tel-Aviv University, Israel.

Colchicine has been used in diverse clinical settings such as gout, familial Mediterranean fever, liver cirrhosis, Behcet's disease and pericarditis. It also has an antimitotic potential hitherto unexplored due to its narrow therapeutic toxic ratio. The aim of the present study was to compare the effectiveness and the toxicity of colchicine and three analogues: thiocolchicine, 2,3 dimethyl-colchicine and 3-dimethylthiocolchicine in the blockage of amyloid synthesis in a murine model. 3-demethylthiocolchicine was equipotent to colchicine in the blockage of casein induced amyloidogenesis. However, it was markedly less toxic (LD50 11.3 mg kg<sup>-1</sup> vs. 1.6 mg kg<sup>-1</sup>). Thiocolchicine was toxic (LD50 1.0 mg kg<sup>-1</sup>) and 2,3 didemethyl-colchicine was far less effective. The effect of 3-dimethylthiocolchicine on polymorphonuclear leukocytes was then compared to colchicine. The effect of this analogue on inhibition of chemotaxis was equivalent to that of colchicine whereas the latter was superior to the analogue in the suppression of phagocytosis (by a ratio of 2:1) and in the inhibition of bactericidal activity (by a ratio of 10:1). Since in therapeutic concentrations the only detectable effect of colchicine on PMNs is inhibition of chemotaxis, our data may point to 3-demethylthiocolchicine as an optional, perhaps superior alternative to colchicine for some of its therapeutic indications.

[Toxic myopathy with kidney failure as a colchicine side effect ifn familial Mediterranean fever].

[Article in German]

Stefanidis I(1), Böhm R, Hägel J, Maurin N.

Author information:

(1)Medizinische Klinik II, Technische Hochschule Aachen.

A 24-year-old woman with familial Mediterranean fever (FMF) had for one year been treated with colchicine, 1 mg daily, for repeated bouts of fever, abdominal pain and arthritis. She was also known to have renal amyloidosis. Lately she had developed gastrointestinal symptoms, muscle pain and obvious, predominantly proximal muscular weakness in both legs. The cause of the symptoms was rhabdomyolysis with an increased creatinine activity of 1000 U/l and marked myoglobinuria (1600 micrograms/l), as well as renal failure with normal uric acid and a creatinine clearance of 3 ml/min per 1.73 m<sup>2</sup>. Serum creatinine concentration was 970 µmol/l, urea 34 mmol/l. Muscle biopsy corresponded to a subacute necrotizing myopathy with vacuole formation, signs typical of toxic damage. Renal biopsy confirmed advanced amyloidosis. The colchicine dose was reduced to 0.5 mg/d. The renal failure responded to conservative treatment. The myopathy symptoms receded within 4 weeks, creatinine clearance rising to 25 ml/min per 1.73 m<sup>2</sup>. 12 months after reduction of the colchicine dose the patient was without any FMF-related symptoms.

Whipple's disease, familial Mediterranean fever, adult-onset Still's disease, and enteropathic arthritis.

McMenemy A(1).

Author information:

(1)University of Texas Medical School, Houston.

Whipple's disease is a rare multisystem disorder of infectious etiology. Efforts to culture the responsible organism have been unsuccessful. Nucleotide sequencing and amplification of bacterial 16S ribosomal DNA revealed the organism to be most

similar to bacteria of the *Rhodococcus*, *Streptomyces*, and *Arthrobacter* genera. Several clinical studies of the long-term use of colchicine for the treatment of familial Mediterranean fever demonstrate its utility for symptom control and prevention of complications by amyloidosis in both adults and children. Normal growth, development, and subsequent fertility were seen in children treated with colchicine. Adult-onset Still's disease has previously been thought to have a generally good outcome, although some patients develop chronic arthritis and disability. No markers have been available for prognosis. A study of 62 patients revealed the presence of polyarthritis, root joint involvement, and rash at initial presentation to be associated with a poorer outcome. Enteropathic arthritis may be seen as a complication of both Crohn's disease and ulcerative colitis. The onset of peripheral arthritis coincides with or follows the onset of bowel symptoms in most cases, whereas spondylitis may precede the onset of inflammatory bowel disease by years. HLA-B27 is present in 50% to 75% of cases of spondylitis. No HLA association with inflammatory bowel disease or peripheral arthritis has been consistently found.

Case report: severe pyoderma associated with familial Mediterranean fever--favorable response to colchicine in three patients.

Lugassy G(1), Ronnen M.

Author information:

(1)Institute of Hematology, Barzilai Medical Center, Ashkelon, Israel.

Familial Mediterranean fever (FMF) is an autosomal recessive disorder that occurs most frequently among Sephardic Jews and Armenians. It is characterized by recurrent episodes of fever, peritonitis, pleuritis, and arthritis. Skin lesions are seen in some patients. Diagnosis of FMF usually is made on clinical grounds only, typically when recurrent attacks of abdominal pain, fever, and arthritis are observed in a patient with an appropriate ethnic background and family history. To date, there are no specific diagnostic laboratory tests for FMF. Three patients with severe recurrent Pyoderma are covered in this report. In all

three cases, the cutaneous lesions were associated with clinical manifestations of FMF and responded to colchicine therapy favorably. The importance of such an association and its therapeutic consequences are emphasized.

A canine febrile disorder associated with elevated interleukin-6.

Rivas AL(1), Tintle L, Kimball ES, Scarlett J, Quimby FW.

Author information:

(1)Department of Pathology, New York State College of Veterinary Medicine, Cornell University, Ithaca 14853.

Familial Mediterranean Fever (FMF) is a human disorder characterized by recurrent fever of unknown origin (RFUO), renal amyloidosis, and evidence of peritonitis, pleuritis, and/or synovitis. This report suggests that Chinese Shar-pei (CSP) dogs suffer from a similar syndrome. CSP dogs with RFUO (n = 15) showed greater levels of IL-6 in serum than normal controls, hypergammaglobulinemia, and normal or supranormal in vitro lymphocyte blastogenesis in response to mitogen stimulation, when compared to healthy afebrile dogs. In patients 2 years old or older, RFUO was associated with renal failure, renal amyloidosis, and swollen joints. An epidemiological survey of privately owned dogs indicated a RFUO prevalence of 23% in CSP dogs (n = 132) and 1% in dogs of all breeds (n = 98). Increased levels of circulating cytokines, such as IL-6, have been shown to influence such processes as the febrile response, antibody production, and the synthesis of amyloid precursors. We propose that CSP dogs with RFUO, renal amyloidosis, and joint inflammation may serve as an animal model of FMF and that the clinical syndrome is associated with elevated levels of circulating IL-6.

A 55-year-old male presented with a recurrent fever of over 38 degrees C, occurring at irregular intervals 1-6 times a month with chest, back or abdominal pain. After admission to our hospital, we found the following characteristics: 1) the febrile attacks were accompanied by obvious inflammatory findings and pleuritis or peritonitis; 2) the patient's elder sister had a similar periodic fever; and 3) there were no apparent causative factors responsible for his symptoms. Therefore, we diagnosed this as a case compatible with familial Mediterranean fever. The febrile attacks have been completely suppressed by daily colchicine. This is the seventh case of familial Mediterranean fever reported in Japan.

**BACKGROUND:** Familial Mediterranean fever is an autosomal-recessive disease characterized by acute attacks of fever with sterile peritonitis, pleurisy, or synovitis. The biochemical basis of the disease is unknown, but determining the chromosomal location of the gene for the disorder should be a first step toward defining the biochemical events.

**METHODS AND RESULTS:** As part of a systematic genome-wide search, we sought evidence of linkage between familial Mediterranean fever and chromosome 16 DNA markers in 27 affected non-Ashkenazi Jewish families from Israel. Two loci from the subtelomeric region of the short arm of chromosome 16 (16p) had lod scores sufficient to establish linkage (a score greater than or equal to 3). One DNA marker (D16S84) gave a maximal lod score of 9.17 (odds of 10(9.17) to 1 in favor of linkage) at a recombination frequency (theta) of 0.04. A probe associated with the hemoglobin alpha complex (5'HVR) gave a maximal lod score of 14.47 at a theta of 0.06. Multipoint linkage analysis indicated that the following was the most likely gene order: the centromere, the gene for familial Mediterranean fever, D16S84, hemoglobin alpha, and the telomere. The maximal multipoint lod score was 19.86. There was a striking degree of homozygosity at chromosome 16p loci in the affected offspring of eight consanguineous couples.

**CONCLUSIONS:** The gene that causes familial Mediterranean fever in non-Ashkenazi Jews maps to the short arm of chromosome 16.

Treatment of gout and crystal arthropathies and uses and mechanisms of action of nonsteroidal anti-inflammatory drugs.

Abramson SB(1).

Author information:

(1)New York University Medical Center, New York.

Nonsteroidal anti-inflammatory agents have anti-inflammatory, analgesic, and antipyretic actions. Nonsteroidal anti-inflammatory drugs are the preferred class of agents for the treatment of gout and other crystal-induced arthropathies. The use of colchicine for other than the prophylaxis of acute attacks is discouraged owing to side effects, which include death. The inhibition of the enzyme prostaglandin H synthase by most nonsteroidal anti-inflammatory drugs explains many of their effects and toxicities. However, it is likely that additional biologic actions are important. These include the inhibition of the transcription of the gene for prostaglandin H synthase, a direct central effect on peripheral inflammation, and the modulation of the functions of a variety of cells (eg, neutrophils, lymphocytes, and chondrocytes). This review focuses on the current controversy in the treatment of gout and discusses the recent literature on the actions of nonsteroidal anti-inflammatory drugs.

The Authors describe the case of a non-Hebrew Italian girl suffering from short-lasting fever episodes, associated with abdominal colic, since the age of 3. The occurrence of acute arthrosynovitis during the last episode, at 12 years of age, clinically confirms the diagnosis of familial mediterranean fever, as previously supposed. The increase in urinary coproporphyrins, with normal values of delta-aminolevulinic acid and porphobilinogen poses the problem of the differential diagnosis between hereditary coproporphyria and secondary coproporphinuria. The importance of this case lies in the presence of electroencephalographic alteration since the first years of life, suggesting a temporal epilepsy for which the patient was at length submitted to anti-epileptic treatment. Electroencephalographic alterations, of different type and uneasy

interpretation, are described in the literature with a frequency which does not seem accidental. Renal biopsy does not show amyloid, nor the RMN reveals cerebral abnormalities. The anti-epileptic therapy being withdrawn, the patient was treated with daily administrations of colchicine (1 mg/die); 18 months after, she is disease free.

Familial Mediterranean fever is an inherited disease, occurring almost exclusively in Arabs, Jews and Turks. Cases are very rarely described in the USA, USSR, France, and patients are all natives to the Mediterranean area. This paper describes two cases of familial Mediterranean fever in brothers native to Campania, Italy. Both had complained of repeated episodes of fever, with acute abdomen, thoracalgia and arthralgia since the age of about 20. One of them had had pleuritis when he was 6 years old. In the period preceding our first observation, both underwent laparotomy to evaluate abdominal symptoms, with negative results. After ruling out other diseases with similar signs and symptoms, we raised the hypothesis of familial Mediterranean fever, despite the fact that the literature has described very few Italian natives affected by this disease. The diagnostic hypothesis was confirmed by the positivity of the metaraminol provocation test. At the same time we evaluated the presence of amyloidosis by rectal biopsy, with negative results. Treatment with colchicine 1 mg/day per os was established. Dramatic improvement of the symptoms was observed in both patients. The present paper stresses the importance of familial

Mediterranean fever, its correct diagnosis in Italy and the fundamental role played by the metaraminol provocation test as a determinant diagnostic tool. It allows establishment of appropriate treatment as soon as possible, so that renal amyloidosis, the most severe complication and major prognostic determinant of familial Mediterranean fever, can be prevented. Inappropriate, useless and potentially harmful surgical diagnostic procedures are also avoided.

Acute colchicine intoxication--possible role of erythromycin administration.

Caraco Y(1), Putterman C, Rahamimov R, Ben-Chetrit E.

Author information:

(1)Division of Medicine, Hadassah University Hospital, Ein Kerem, Jerusalem, Israel.

A 29-year-old patient with familial Mediterranean fever and amyloidosis involving the kidney, liver, and gastrointestinal tract received longterm colchicine, 1 mg daily. In the last year she developed diarrhea and abdominal pain, that coincided with toxic colchicine blood levels. After 2 weeks of oral erythromycin therapy

she was hospitalized for acute, life threatening colchicine toxicity, with fever, diarrhea, abdominal pain, myalgia and lower extremity parasthesias and later convulsions and alopecia. Pancytopenia evolved into rebound leukocytosis, disturbed liver function and hypoglycemia. After a long stormy course she improved. Colchicine toxicity with combined liver and renal impairment and the role of erythromycin in her colchicine toxicity are discussed.

Decreased interleukin 1 activity released from circulating monocytes of patients with familial Mediterranean fever during in vitro stimulation by lipopolysaccharide.

Rozenbaum M(1), Katz R, Rozner I, Pollack S.

Author information:

(1)Department of Rheumatology, Bnai Zion Medical Center, Haifa, Israel.

Familial Mediterranean fever (FMF) is an inherited disorder of unknown etiology characterized by recurrent episodes of serous membrane inflammation. Interleukin 1 (IL-1) is a mediator of inflammatory processes. We hypothesized that IL-1 may play a role in acute attacks of FMF. Thus we tested IL-1 production by monocytes derived from patients with FMF. Nine patients were tested during acute attacks and 9 were asymptomatic when tested. Monocytes derived from peripheral blood of patients and controls were stimulated with lipopolysaccharide (LPS) and IL-1 activity in the supernatant was tested using a T helper cell line (D10-4G.1). IL-1 secretion during acute attacks was decreased whereas IL-1 production in asymptomatic patients was comparable to healthy controls. Followup of symptomatic patients during the recovery period revealed normalization of IL-1 secretion. Addition of indomethacin (prostaglandin E2 inhibitor) to LPS stimulated monocytes did not change IL-1 activity in patients or healthy controls. We conclude that in vitro IL-1 activity in patients with FMF is associated with the intensity of the inflammatory process.

Author information:

(1)INSERM U26, Hôpital Fernand Widal, Paris, France.

Thanks to the development of a sensitive and specific radioimmunoassay for colchicine, the pharmacokinetics of colchicine is now well-established after single oral doses. Absorption is characterized by a zero-order rate constant while disposition appears biexponential with a rapid distribution phase ( $t_{1/2} = 1.8$  h) and a long elimination phase ( $t_{1/2} = 20$  h). All studies confirm the large total body clearance (35 l/h) predominantly by the extrarenal route and the large distribution volume (700 l). Further studies need to be performed to investigate colchicine absorption and to describe the metabolic pathway of the drug. To date, relationships between colchicine plasma levels and pharmacological effects have not been defined. Monitoring of plasma levels in patients with familial Mediterranean fever should improve treatment with colchicine. However, the therapeutic range has not been precisely determined. The use of colchicine in the treatment of liver cirrhosis and primary biliary cirrhosis is a recent development; so, assuming that a large part of total body clearance depends on hepatic function, the influence of hepatic diseases on colchicine disposition needs to be investigated in order to define the most appropriate therapeutic dosing.

Spectrum of renal involvement in familial Mediterranean fever.

Said R(1), Hamzeh Y, Said S, Tarawneh M, al-Khateeb M.

Author information:

(1)Department of Medicine, Jordan University, Amman.

Kidney biopsies were performed on fifteen patients with a long-standing history of familial Mediterranean fever (FMF) and evidence of renal involvement. On light microscopy, seven patients were found to have amyloidosis, six mesangial proliferative glomerulonephritis (MsPGN) and two patients rapid progressive glomerulonephritis (RPGN). Immunofluorescent studies of the six biopsies with MsPGN were positive for mesangial IgA deposits (IgA nephropathy) in three patients and IgM mesangial deposits in three (IgM nephropathy). We conclude that in patients with FMF and renal involvement, non-amyloid renal lesions (IgA nephropathy, IgM nephropathy and RPGN) should be considered in the differential diagnosis in addition to amyloidosis.

[Familial Mediterranean fever and myeloma: an undescribed association].

[Article in Spanish]

Esquinas Blanco G(1), Jiménez Rojas C, Macías Montero MC, Rodríguez Heredia JM, Gallegos Cid A, García-Arroba J.

Author information:

(1)Hospital Universitario, Getafe, Madrid.

An atypical case of familial mediterranean fever is presented in a 55 year old male with neither family antecedents nor ethnic determinants. The patient presented isolated articular involvement and positive response in the metaraminol provocation and colchicine suppression test. It was associated with monoclonal type IgG kappa gammopathy which evolved over one year until obtaining criteria, although asymptomatic, for myeloma. The increase of the monoclonal component and the infiltration of the bone medulla by plasmatic cells were considered as signs of progression inducing the initiation of treatment despite the lack of symptoms. Both entities are discussed and a mechanism justifying their association is proposed: interleukin-6 produced by macrophages in the inflammatory articular foci due to the deficiency of the C5a inhibitor existing in familial mediterranean fever, may act on a plasmatic cell clone in which receptors for IL-6 exist as a paracrine growth factor.

Colchicine prevents kidney transplant amyloidosis in familial Mediterranean fever.

Livneh A(1), Zemer D, Siegal B, Laor A, Sohar E, Pras M.

Author information:

(1)Heller Institute of Medical Research, Sheba Medical Center, Tel-Hashomer, Israel.

Twenty-one familial Mediterranean fever (FMF) patients who received a kidney transplant for terminal renal failure due to amyloidosis were studied retrospectively to evaluate the prophylactic effect of colchicine on graft amyloidosis. Proteinuria, highly suggestive of kidney transplant amyloidosis, developed in 11 patients within a median of 3 years after transplantation (range 0.5-10 years). In 10 patients, repeated urinalyses for protein were negative during a median of 5 years after transplantation (range 1-13). Patients who developed proteinuria or transplant amyloidosis received smaller colchicine doses

than patients without proteinuria--mean 0.69 (range 0-1) versus 1.53 (range 1-2) milligrams per day ( $p = 0.0002$ ), suggesting that colchicine prevents or delays development of transplant amyloidosis. This prophylactic effect of colchicine was complete at a dose of 1.5 mg/day or more and absent at a daily dose of 0.5 mg or less. In patients who received 1 mg/day, individual variability in the response to colchicine was observed. We conclude that the development of amyloidosis of the kidney transplant in FMF is inevitable at a colchicine dose lower than 1 mg/day, unpredictable at 1 mg/day and usually preventable with 1.5 mg/day or more.

Colchicine myopathy in a case of familial Mediterranean fever: immunohistochemical and ultrastructural study of accumulated tubulin-immunoreactive material.

Himmelmann F(1), Schröder JM.

Author information:

(1)Institut für Neuropathologie, Klinikum der Rheinisch-Westfälischen Technischen Hochschule, Aachen, Federal Republic of Germany.

Severe colchicine myopathy occurred in a 24-year-old patient treated with colchicine because of familial mediterranean fever complicated by renal amyloidosis. In addition to prominent autophagic vacuoles containing heterogeneous osmiophilic material and pleomorphous bodies, cytoplasmic deposits of finely granular material were detected that have not been noted in previous cases of colchicine myopathy. This granular material was immunoreactive for antibodies to tubulin, alpha-tubulin, and beta-tubulin. These observations substantiate the suggestion that alterations of the microtubular network represent the initial step in the pathogenesis of colchicine myopathy.

Immunofluorescence study of childhood renal amyloidosis.

Tinaztepe K(1), Güçer KS.

Author information:

(1)Department of Pediatrics, Hacettepe University Faculty of Medicine, Ankara.

In this paper, the findings of immunofluorescence (IF) studies of 57 patients with childhood biopsy-proven renal amyloidosis are presented. All specimens were investigated by the direct IF technique and the simultaneous use of antisera to human IgG, IgM, IgA, fibrinogen and C3. Antisera to C1q, C4, HbsAg, IgE (in each of ten cases), kappa and lambda light chains of immunoglobulins (Igs) and albumin (in each of five cases) were also used. AA type amyloidosis was determined in all patients by Wright's potassium permanganate reaction. In thirty-four of these patients (60%), Familial Mediterranean Fever (FMF) was found to be the underlying disease for renal amyloidosis. In 39 cases (68.5%), renal biopsy showed positive fluorescence staining while in 18 cases (31.5%), fluorescence staining was negative. The immunofluorescence pattern of glomerular deposits was neither granular nor linear but large isolated or confluent masses which were located in the mesangium and in the capillary walls, and were similar in all cases whatever the antisera used. The areas showing immunofluorescence staining almost corresponded to the locations of amyloid deposits. Immunoreactants showed various combinations of deposition with the exception of IgE, HbsAg and albumin antisera which yielded continuously negative reactions. C3 was the immunoreactant most commonly encountered. Kappa and lambda light chains of Igs were demonstrated in one of five biopsy specimens tested. Although it was not diagnostic, this IF pattern was found to be rather characteristic. Demonstration of immunoglobulins and other components of the humoral immune system is not a rare occurrence in renal amyloidosis, and passive absorption of plasma proteins does not simply explain these immunohistologic findings.

Evaluation of the hypercoagulable state by measuring protein C and antithrombin III levels in nephrotic syndrome and in familial Mediterranean fever-related amyloidosis.

Topaloğlu R(1), Saatçi U, Bakkaloğlu A, Beşbaş N, Başsoy Y.

Author information:

(1)Department of Pediatrics, Hacettepe University Faculty of Medicine, Ankara.

The levels of protein C (PC) and antithrombin III (AT III) antigens (ag) were measured in the plasma of 39 patients with various histologic types of primary nephrotic syndrome (NS) and in 12 patients with amyloidosis secondary to familial Mediterranean fever (FMF). The controls comprised 15 healthy children. Normal or elevated PC levels were observed in primary NS patients (mean 64%, range 36-98%) and in amyloidosis patients (mean 58%, range 48-70%). There was no difference found between PC ag levels in primary NS and in amyloidosis patients. In addition, no correlation existed between protein selectivity and the PC ag levels in the primary NS patients. Normal and decreased levels of AT III were observed (mean 29 mg/dl, range 11.1-39 mg/dl) in the patients with primary NS and amyloidosis (mean 31 mg/dl range, 21-39 mg/dl). The AT III ag levels of these two groups did not differ and no correlation was found between protein selectivity and AT III levels in primary NS patients. These results suggest that in patients with primary NS, or amyloidosis secondary to FMF, hypercoagulability is not related to a deficiency in PC ag levels due to a dynamic balance between urinary losses, increased rate of hepatic synthesis, catabolism and the distribution of PC in the body compartments. Patients with low AT III levels may be more susceptible to thromboembolic complications than patients with normal levels.

Normal renin-aldosterone-insulin and potassium interrelationship in FMF patients and amyloid nephropathy.

Shemer J(1), Royburt M, Cabili S, Iaina A, Pras M, Eliahou H.

Author information:

(1)Department of Internal Medicine, Sheba Medical Center, Tel-Hashomer, Israel.

The renin-aldosterone system and plasma insulin were studied in 19 patients with familial Mediterranean fever (FMF). Their relationships to serum potassium level at rest and before and after oral glucose loading are described. An interesting finding is the occurrence of hyperkalemia in the absence of oliguria, in the advanced stages of renal failure. No differences were found in the activity of the renin-angiotensin-aldosterone system to explain these variations in serum potassium found in some of the patients. The response of the renin-aldosterone system to glucose loading showed no abnormality, and the regular relationship between serum potassium, plasma renin activity (PRA), aldosterone, insulin, and plasma pH is maintained. Levels of insulin, potassium, and bicarbonate in serum or plasma pH were found similar in FMF patients with normal renal function with and without proteinuria. Further decrease in renal function due to the progression of the underlying disease is manifested by an increase in FENa<sup>+</sup> and FEK<sup>+</sup> and a hyperchloremic metabolic acidosis, as is the case in other patients with chronic renal failure.

[Familial Mediterranean fever--a case report].

[Article in German]

Unsinn KM(1), Fischer H.

Author information:

(1)Universitäts-Kinderklinik Innsbruck, Österreich.

A case of a ten years old boy with recurrent fever and abdominal pain starting at the age of five years is reported. Later the attacks were accompanied by chest pain. There were only indifferent changes in laboratory examination. Neither a wide range of antibiotics, nor appendectomy and tonsillectomy prevented the boys symptoms. The diagnose was established after five years by a positive Metaraminol test, that precipitated a disease-like attack. The therapeutic use of colchicine-salicylate reduced the severity and frequency of attacks in out patient. In agreement with other authors it should be emphasized, that in general the benefit of colchicine outweighs possible side effects of a long term therapy also in children.

A 48 year-old male patient from Turkey underwent laparotomy 13 years before admission to one unit because of persistent pain in the upper abdomen and fever. Subsequently, he was repeatedly admitted to surgical departments with recurrent upper abdominal pain and fever. The patient was admitted for medical

investigation to our department with fever and left pleuritic pain. During this observation period he repeatedly had attacks of fever lasting for one day with leucocytosis. The diagnosis of familial Mediterranean fever was made. Therapy with colchicine (1.5 mg/day) led to complete remission, maintained over the follow-up period of 2 years to date.

Familial mediterranean fever is a childhood disease which usually starts around the age of 4 years. Its onset is insidious with common and misleading symptoms such as fever and abdominal pain. Accordingly, this disease is often recognized

belatedly from evocative data from previous history such as the recurrence of attacks, familial descent from certain ethnic groups and the lack of other obvious etiology. The clinical picture within this age group is similar to that observed in adults and does not present any clinical or biological originality. Colchicine remains the only efficient treatment to prevent both acute manifestations and amyloidosis. The former is geared toward its current use among children (growth retardation and gonadic disturbances) and is not really relevant, at least in this particular disease.

[Article in German]

Connemann BJ(1), Steinhoff J, Benstein R, Sack K.

Author information:

(1)Klinik für Innere Medizin, Medizinische Universität Lübeck.

A 15-year-old girl of Turkish descent had for one year complained of severe recurrent fever-associated deep back pains. Since she was three years of age she had suffered from repeated attacks of fever and severe abdominal pain which ceased spontaneously in 1-3 days. On physical examination the sacrum and iliosacral joints were very painful to percussion, and she limped. Radiography revealed symmetric destructive sacroiliitis. Despite the unusual location of the arthritis, the triad of fever, abdominal pain and arthritis, as well as her belonging to an ethnic "at risk" group, pointed to the diagnosis of familial mediterranean fever (FML) or recurrent hereditary polyserositis. This diagnosis was confirmed by a positive metaraminol provocation test in that infusion of metaraminol reproduced the typical pains. Collagen diseases, rheumatic disease, acute porphyria and chronic infectious processes were excluded. The sacroiliitis quickly responded to long-term administration of colchicine, 0.5 mg twice daily. The patient also has Hageman factor deficiency whose significance remains unclear.

Familial Mediterranean Fever is a genetically determined disease occurring predominantly in Arabs, Armenians, Jews and very rarely in Turks. It is characterized by moderately elevated body temperature and by abdominal, pulmonary or arthritic complaints. These symptoms are recurrent appearing at short intervals and persisting for not more than two days. Renal amyloidosis may be a complication. Thus, treatment should be continued for life. The pathomechanism of the disease is not clear. Colchicine has been shown to give good symptomatic relief. Surprisingly, the prolonged use of this mitotic poison is virtually devoid of untoward side effects, even in pregnancy and childhood.

Recurrent hereditary polyserositis or familial Mediterranean fever: An overview.

Cook GC(1).

Author information:

(1)Department of Clinical Sciences, Hospital for Tropical Diseases, London.

The etiology and pathogenesis of recurrent hereditary polyserositis (RHP) remain undetermined. There is a good evidence for a genetic basis (transmission being by a recessive Mendelian mode of inheritance), but not all cases have a family history and an infective (or other environmental) components has not been excluded. The marked variation in presentation and complications (in particular the prevalence of amyloid deposition) in different series suggests that this might not be a homogeneous entity. Vascular involvement is a basic prerequisite for the periodic attacks, and evidence for transient immunological abnormalities is incontrovertible. There are no reliable diagnostic techniques. Colchicine is of value in treatment, but its mode of action is unclear. More macro- and microepidemiological studies are required and will be of paramount importance. Clinical observations and molecular genetic studies should address the possibility that two or more immunological or metabolic defects might be interwoven; why for example do only some affected groups develop AA amyloidosis? Simple, non-invasive diagnostic tests are required for the uncomplicated disease and also for the presence of amyloid deposition. Preventive strategies might eventually involve genetic engineering techniques, but in the immediate future, education of doctors and other health care workers - to raise the "index of awareness" of RHP, in order that colchicine treatment can be commenced early in the disease - forms an important strategy. Colchicine therapy is not without complications and an alternative chemotherapeutic agent should be sought.

Pulmonary hypertension and familial Mediterranean fever: a previously unrecognized association.

Johnson WJ(1), Lie JT.

Author information:

(1)Division of Nephrology and Internal Medicine, Mayo Clinic, Rochester, MN 55905.

Familial Mediterranean fever is an autosomal recessive inherited disorder characterized by recurrent episodes of fever accompanied by inflammation of the peritoneum, pleura, synovial membranes, and skin. The disorder predominantly affects persons of Mediterranean origin. The most serious complication of the disease is amyloidosis, which is the cause of death in a substantial proportion of adult patients with the disorder. Only one previous report has described pulmonary hypertension in a patient with systemic amyloidosis associated with multiple myeloma. Herein we describe the first known occurrence of pulmonary hypertension due to pulmonary amyloidosis in a 48-year-old woman with familial Mediterranean fever. Postmortem examination showed extensive deposits of amyloid in the pulmonary vessels, alveolar capillary walls, and myocardium, which explained the hypoxia, hypotension, and terminal cardiac arrhythmias that were the immediate cause of death in this patient.

[Periodic disease and periarteritis nodosa in the same patient: coincidence?].

[Article in French]

Pechère M(1), Helfer C, Laurencet FL.

Author information:

(1)Clinique médicale thérapeutique, Hôpital cantonal universitaire, Genève.

Familial Mediterranean fever (FMF) chiefly affects patients of Arabic, Jewish, Armenian or Turkish origin and takes the form of recurrent episodes of peritonitis, arthritis or pleurisy. Periarteritis nodosa (PAN) is a vasculitis affecting elderly people and manifested by a general deterioration, unexplained fever and peripheral neuropathy or muscular weakness. We describe a patient presenting both diseases. Ours is the seventh reported case associating these two affections. This association was suspected by SACHS and co-workers who discovered an increased frequency of PAN in patients with FMF compared to the expected rate for the whole population (7). These observations warrant a search for PAN in young patients affected by FMF and showing signs of vasculitis.

Exclusion of linkage between familial Mediterranean fever and the human serum amyloid A (SAA) gene cluster.

Sack GH Jr(1), Talbot CC Jr, McCarthy BG, Harris EL, Kastner D, Gruberg L, Pras M.

Author information:

(1)Department of Medicine, Johns Hopkins University School of Medicine, Baltimore, Maryland.

We studied the relationship between the autosomal recessive trait familial Mediterranean fever (FMF) and the serum amyloid A (SAA) genes by comparing alleles of a highly polymorphic dinucleotide repeat and a conventional restriction fragment length polymorphism (RFLP) in the SAA gene cluster in Israeli FMF kindreds. By haplotype analysis, our data indicate a minimum crossover frequency of 22% between the SAA gene marker and FMF. By conventional linkage analysis this eliminates a minimum of 10.4 cM including and surrounding the SAA gene cluster as the site of the FMF mutation although SAA proteins are prominent physiologic markers of the acute attacks.

Long-term colchicine treatment in children with familial Mediterranean fever.

Zemer D(1), Livneh A, Danon YL, Pras M, Sohar E.

Author information:

(1)Department of Medicine, Heller Institute of Medical Research, Sheba Medical Center, Tel-Hashomer, Israel.

Three hundred fifty children (younger than age 16) who had familial Mediterranean fever (FMF) were given continuous prophylactic treatment with colchicine (1-2 mg/day) for 6-13 years. Complete remission of febrile attacks was achieved in 64%

of the patients, and partial remission in 31%. Protracted attacks of arthritis virtually disappeared. None of the children developed amyloidosis while on the colchicine regimen. Side effects of colchicine were insignificant, and did not prompt permanent discontinuation of treatment in any of the children. Their growth, development, and subsequent fertility were normal. The efficacy of long-term colchicine treatment of children with FMF makes early diagnosis life saving.

Whipple's disease, familial Mediterranean fever, and adult-onset Still's disease.

McMenemy A(1).

Author information:

(1)University of Texas Medical School, Houston.

Whipple's disease is a multisystem disorder thought to be caused by infection by rod-shaped bacilli. Early diagnosis remains difficult, because initial clinical features are nonspecific. Ultrasonography and computed tomographic scanning were used to demonstrate distinctive lymphadenopathy in Whipple's disease. Magnetic resonance imaging showed central nervous system lesions that were reversible with antibiotic therapy. Familial Mediterranean fever, or recurrent polyserositis, is an autosomal recessive disorder common among patients of Mediterranean heritage. Erysipelas-like skin lesions are commonly described. Other skin lesions, including Schönlein-Henoch purpura, nonspecific purpura, diffuse erythema, and angioneurotic edema are now reported. Renal complications, thought previously to be due primarily to amyloid, are also caused by immunoglobulin deposition resulting in mesangial proliferative glomerulonephritis. Adult-onset Still's disease is a systemic illness characterized by quotidian fever and a fleeting, salmon-colored rash. The long-term evolutions of juvenile-onset and adult-onset Still's disease were compared and found to be similar, except for the occurrence of amyloidosis in the latter group of patients. Prognosis of patients with articular features was worse than that of patients with extra-articular features. A multicenter survey of Japanese patients found few significant differences

between Japanese and non-Japanese cases. Less well-recognized features of adult-onset Still's disease, including neurologic complications, uveitis, and peritonitis, are reported.

Secondary systemic amyloidosis: response and survival in 64 patients.

Gertz MA(1), Kyle RA.

Author information:

(1)Dysproteinemia Clinic, Mayo Clinic, Rochester, Minnesota 55905.

From 1956 through 1989, 38 men and 26 women were seen at the Mayo Clinic with biopsy-proven AA. The underlying disorder was rheumatic disease in 42, infectious disease in 11, inflammatory bowel disease in 6, and other causes in 5. All patients were symptomatic at the time of diagnosis. Fifty-eight of the 64 patients had proteinuria or renal insufficiency. Fourteen also had significant symptoms of gastrointestinal amyloid, and 6 had amyloid goiter. None of the patients had symptomatic cardiac involvement, and only 3 had palpable hepatomegaly. Renal, gastric, rectal, fat, and marrow biopsies were positive for amyloid in 100%, 94%, 82%, 58%, and 46% of tested patients, respectively. The median survival of the entire group was 24.5 months. Thirty-five of the 47 deceased patients died as a direct result of their amyloidosis, primarily from complications of renal failure. Nine were successfully treated and had regression of the disease. Two with bronchiectasis responded to long-term cyclic antibiotic therapy, as did 1 patient with osteomyelitis. One patient with inflammatory bowel disease responded to surgical resection, and 1 with familial Mediterranean fever responded to colchicine. Four patients with rheumatic disease were treated with cyclophosphamide (in 2) and methotrexate (in 2), with complete resolution of their renal disease. All 9 successfully treated patients are alive, with a median follow-up of 58 months. Statistical analysis revealed that creatinine values greater than or equal to 2.0 mg/dl (P less than 0.003) and a serum albumin value less than 2.5 g/dl (P less than 0.02) were associated with a poorer survival. The single strongest variable associated with poor survival was a serum creatinine

level greater than 2 mg/dl at presentation, with a median survival of 11.2 months compared to patients with a creatinine level less than 2.0 mg/dl, with a median survival of 56.9 months.

[A diagnostic controversy: the significance of 14-6/sec positive spikes in clinical electroencephalography].

[Article in Italian]

Domenici R(1), Meossi C, Stefani G, Castelli S.

Author information:

(1)U.O. Pediatria, Ospedale di Lucca, Italia.

There has been a great deal of discussion as to the clinical significance of E.E.G. 14-6 per second positive spikes (14-6 PS), a short burst lasting one second or less which occurs during light sleep in monopolar recordings, mainly in the posterior temporal regions and usually involving the parietal and occipital regions as well, for the most part in unsymmetrical fashion. Early interpretations stress the epileptic nature of vegetative attacks in patients

with an inter-critical E.E.G. reading characterized by 14-6 P.S. Subsequently, however, this hypothesis has been refuted, mainly because E.E.G. intra-critical recordings have never shown evidence of any sort of paroxysmal activity. At present time experts think that the presence of 14-6 PS may be merely an indication of an electrical alteration associated with disorders in the neurovegetative area. In order to evaluate the possibility of using them as a diagnostic marker of migraine equivalents and periodic syndromes, we reviewed wake and sleep E.E.G. recordings, carried out consecutively and hence not selectively, in 617 children aged 5-16 years. 14-6 PS were present in 109 children (17.6%), 63 of whom showed evident symptoms of periodic syndrome (headache, recurrent abdominal pain, cyclic vomiting, kinesis, etc.); hence 46 E.E.G. recordings were false positive. 510 children were lacking in 14-6 PS, 91 of these presented symptoms of periodic syndromes (false negative). 14-6 PS are hence a marker 40.9% sensitive, 90.1% specific, with a predictable value of 57.7%. The search for 14-6 PS in children with periodic syndrome is not particularly sensitive as a test, but it is fairly specific: it may well constitute an useful element in diagnosis.

Characterization of high molecular weight amyloid A proteins.

Prelli F(1), Pras M, Shtrasburg S, Frangione B.

Author information:

(1)Department of Pathology, New York University Medical Center, New York 10016.

Human amyloid A protein (AA) is usually composed of the NH<sub>2</sub>-terminal 76 amino acid residue of serum amyloid A protein (SAA), although lower and higher molecular weight fragments have been reported. We studied the primary structure of six AA proteins with molecular weights of 11 kDA-15kDA, as determined by SDS-PAGE. Automated Edman degradation of the intact purified proteins and sequence analysis of enzymatic peptides revealed that the AA proteins were composed of only 74 to 87 residues. Moreover, fragments of apolipoprotein E or histones 2a, 3 and 4 were associated with these AA molecules. Thus, AA

heterogeneity may reflect diverse processing of the SAA precursor and a very close association with other proteins.

Urinary albumin excretion in patients with familial Mediterranean fever: a pilot study.

Oren S(1), Viskoper JR, Ilan S, Schlesinger M.

Author information:

(1)Department of Internal Medicine B, Barzilai Medical Center, Ashkelon, Israel.

Amyloidosis of the kidney is the most threatening complication in familial Mediterranean fever (FMF), and colchicine has been shown to reduce its occurrence. In the preclinical stage of kidney amyloidosis, no proteinuria is observed by the standard Albustix method. However, whether these patients have normal or increased urinary albumin excretion is not known. The purpose of this study was to evaluate albumin excretion in FMF patients treated with colchicine and to compare these values to those of a normal control group. Twenty-two subjects with FMF were compared with 16 normal subjects matched with regard to age and body surface area. The two groups did not differ with regard to female/male ratio and arterial pressure. Urine samples were collected overnight while patients were recumbent and in the daytime while they were ambulant. After measuring albumin concentration (Ua) by radio-immunoassay and creatinine concentration through the standard method, the urinary albumin excretion rate (UaV) and urinary albumin creatinine ratio (Ua/c) were calculated. In the FMF group, three patients had microalbuminuria--defined as an albumin excretion rate higher than 20 micrograms/min. Two of them had this condition only in the early morning collection. These three patients were characterized by a longer duration of symptoms (18 vs. 9 years). No patient in the control group had microalbuminuria. The mean UaV in the FMF group did not differ significantly from that of the control group.(ABSTRACT TRUNCATED AT 250 WORDS)

Familial Mediterranean fever in a fraternal twin: a laboratory evaluation.

Topouzian NB(1), Bowie LJ.

Author information:

(1)Department of Pathology and Laboratory Medicine, Evanston Hospital, IL 60201.

Familial Mediterranean fever (FMF) is an autosomal recessive disease of unknown etiology and has no known diagnostic markers. Periodic attacks of pain and fever can be precipitated by dietary fat or dairy products and by the same factors that

are known to elevate serum free fatty acids (FFA). Several tests related to lipid metabolism were made on the serum and urine of a fraternal twin with FMF during attacks and remission. The results were compared with those of the unaffected, asymptomatic twin and healthy adults. Low density lipoprotein-cholesterol was elevated in both twins. Gas chromatography revealed many urinary FFA during attacks and fewer during remission. Urinary organic acids determined by gas chromatography/mass spectrometry (GC/MS) revealed slight elevations of glycollic, oxalic, and methylmalonic acids during an attack. Serum gamma-glutamyl transferase (GGT) levels were at or below the low limits of normal for both twins. Hematological studies revealed low values for erythrocyte parameters for the affected twin. Both twins had low serum iron and an increased iron binding capacity. These findings may represent a defect in fatty acid metabolism which is being compensated by alternate pathways which may generate oxidants. Both FFA and oxidants are injurious to cell membranes and may be the cause of the polyserositis which occurs during an attack.

Determination of autoantibodies in patients with familial Mediterranean fever and their first degree relatives.

Swissa M(1), Schul V, Korish S, Livneh A, Pras M, Shoenfeld Y.

Author information:

(1)Research Unit of Autoimmune Diseases, Heller Institute, Israel.

Sera samples of 168 patients with familial Mediterranean fever (FMF) and their 184 first degree relatives were analyzed for the presence of autoantibodies to ssDNA, dsDNA, poly (I), poly (G), cardiolipin, histones, RNP and Ro(SSA), using an enzyme linked immunosorbent assay (ELISA). A similar analysis was employed on culture fluids of Epstein-Barr virus (EBV) transformed B lymphocytes derived from patients with FMF and healthy controls. No increased incidence of these antibodies was observed among patients with FMF and their relatives compared to healthy controls. It is possible that autoimmune features observed in FMF are the result of nonspecific changes occurring in inflammation and not due to autoimmune mechanisms.

Comment in

Am J Med. 1992 Nov;93(5):587.

Am J Med. 1992 May;92(5):579-80.

**PURPOSE:** The pleiotropic inflammatory effects of tumor necrosis factor (TNF) prompted a study of this cytokine in familial Mediterranean fever (FMF), a recurrent polyserositis of unknown etiology.

**PATIENTS AND METHODS:** Thirty-six asymptomatic and 24 patients with acute FMF were studied and compared with 20 matched healthy subjects. TNF levels were measured by bioassay in the plasma and in supernatants of peripheral blood mononuclear cells (PBMC) incubated alone or with an inducer (lipopolysaccharide, phytohemagglutinin [PHA], or Sendai virus). Cytotoxicity could be abolished in all cases by preincubation with monoclonal anti-TNF-alpha antibodies.

**RESULTS:** No TNF was found in plasma and non-induced PBMC supernatants. Induced TNF production was markedly decreased in patients with acute FMF and increased in asymptomatic FMF patients to levels over those of control subjects (p less than 0.05). Thus, PHA-induced TNF levels were 4 U/mL in patients with acute FMF, 25 U/mL in asymptomatic patients, and 14 U/mL in healthy control subjects (median values), and the other inducers gave similar results. Retesting of patients first studied during an acute episode when their disease was quiescent also revealed a fivefold increase in TNF production. These results were independent of the use of colchicine, which also had no effect on TNF levels when taken by volunteers (1 mg/day) or when added to the PBMC cultures ( $10^{-7}$  M).

**CONCLUSIONS:** Since TNF has a very short half-life in plasma, the capacity of PBMC to respond to TNF inducers may more accurately reflect its synthesis. A marked decrease in this response in acute FMF suggests "exhaustion" of cells that are already highly activated to produce TNF and the possible participation of TNF in the pathogenesis of FMF.

The authors report a case of Familial Mediterranean Fever (FMF) in a Turkish patient. FMF is characterised by paroxysmal attacks of fever, peritonitis and/or pleuritis or arthritis. FMF is almost exclusively confined to populations of Mediterranean origin and it is often familial. The diagnosis is mainly clinical. Recently an enhanced dopamine beta-hydroxylase (DBH) activity was described as a diagnostic test. We confirmed this in our patient. FMF was successfully treated by chronic colchicine therapy: 1-2 mg daily, which reduced DBH activity to normal levels.

Colchicine prophylaxis in familial Mediterranean fever: reappraisal after 15 years.

Ben-Chetrit E(1), Levy M.

Author information:

(1)Department of Medicine A, Hadassah University Hospital, Jerusalem, Israel.

As determined in this study of 45 patients, the prolonged use of colchicine

therapy in familial Mediterranean fever (FMF) is safe and effective in preventing flares of FMF and amyloidosis. It has acceptable adverse effect profile and can be used in children and pregnant women. Its discontinuation predisposes patients to acute FMF attacks and the development of amyloidosis. Articular involvement is less responsive to colchicine and may require therapy with nonsteroidal antiinflammatory drugs.

The authors report a case of familial Mediterranean fever in a pregnant woman treated with Colchicine. She delivered normally at term. A review of the literature shows that colchicine does not have a teratogenic effect which it was long thought to have. All the same it is best to carry out fetal karyotype examination using early amniocentesis. Furthermore, colchicine improves fertility which is disturbed in these patients and pregnancy has a good effect on the disease.

Colchicine: a state-of-the-art review.

Levy M(1), Spino M, Read SE.

Author information:

(1)Division of General Pediatrics, Hospital for Sick Children, Toronto, Ontario, Canada.

Colchicine is an ancient drug that is attracting renewed interest because of its actions at a subcellular level. Specifically, it interferes with microtubule growth and therefore affects mitosis and other microtubule-dependent functions. Various mechanisms have been proposed to account for the action of colchicine in acute gouty arthritis, its interaction with cellular membrane and cyclic 3',5'-adenosine monophosphate, and its action in amyloidosis. Pharmacokinetic studies have been relatively limited and their results somewhat contradictory, with mean terminal elimination half-lives of 19 minutes to 9 hours being reported. Some of these differences may be attributed to assay difficulties. Colchicine can cause gastrointestinal side effects and should be used with care to protect patients from toxic doses. Colchicine-induced myopathy and neuropathy may be more frequent than previously recognized, and therefore patients receiving long-term therapy should be monitored carefully. Bone marrow depression has been reported, primarily in cases of acute colchicine intoxication, and intravenous administration of the drug has been associated with severe pancytopenia and death. Colchicine intoxication causes multiple organ failure. Because of its cytogenic effects and reported association with Down's syndrome, the agent should not be used by pregnant women.

[Recurrent aseptic meningitis in periodic disease or Mollaret's meningitis?].

[Article in French]

Collard M(1), Sellal F, Hirsch E, Mutschler V, Marescaux C.

Author information:

(1)Clinique Neurologique, Strasbourg.

A 33 year-old Sephardic Jewish man with familial mediterranean fever (FMF), presented during a 7 year period, 6 episodes of aseptic meningitis, improving within less than 24 h after spinal tap. Cerebrospinal fluid analysis showed a mixed leucocytic pleocytosis ranging from 100 to 1,000 cell/mm<sup>3</sup>. Spinal fluid cultures for bacteria, viruses and viral antibodies were always negative. Our case supports other reports showing that recurrent aseptic meningitis, although rare, may occur in FMF. It usually responds to treatment with colchicine, like other manifestations of the disease. FMF meningitis has been compared to Mollaret's meningitis whose cause is undetermined. However, Mollaret's meningitis, unlike FMF, is sporadic and ubiquitous, is not transmitted genetically and affects men and women equally. Moreover, in Mollaret's meningitis transient neurological abnormalities, such as signs of encephalitis have often been reported: polyserositis or associated amylosis are absent, there is no biological inflammatory syndrome, and in 65% of the patients the CSF contains specific large mononuclear-derived cells called endothelial cells. Such abnormalities have not been described in FMF.

[Selective involvement of the gastrointestinal tract in amyloidosis in a female patient with periodic disease and intact kidneys].

[Article in Russian]

Arutiunian VM, Eganian GA, Khachatrian VA.

The authors describe a rare case of amyloidosis in a female patient suffering from periodic disease (PD) for 18 years without any clinico-laboratory signs of renal impairment but with marked clinical, (malabsorption, cachexia), endoscopic, x-ray and other manifestations of gastrointestinal amyloidosis. This case is of interest since patients suffering from amyloidosis due to PB develop malabsorption very rarely, namely in 2-3% of cases. As a rule, it develops in patients with pronounced chronic renal failure on hemodialysis or with a history of kidney transplantation. In this particular case, the patient demonstrated selective marked damage to the gastrointestinal tract, with the kidneys remaining practically intact. A possibility of the indicated variety of amyloidosis should be considered in specification of the genesis of persistent diarrhea in PB patients.

Amyloidosis: clinical picture, immunological and biomolecular features, treatment prospects.

Dammacco F(1).

Author information:

(1)Istituto di Patologia Speciale Medica, Università degli Studi di Bari, Italy.

Amyloidosis is the name given to a group of clinically protean diseases whose common feature is the tissue accumulation of amyloid fibrils which have specific optical and staining properties, and are both insoluble in physiological solvents and resistant to proteolytic enzymes. Fibril deposition and progressive extracellular infiltration eventually result in atrophy due to compression. The structure of these fibrils embraces a wide range: immunoglobulin light chain or their fragments, acute phase proteins, hormones, protease inhibitors, beta

2-microglobulin, natriuretic peptides, and proteins whose function is still unknown. Despite this heterogeneity, however, they share a common crystallographic beta-pleated sheet structure. The clinical spectrum includes apparently primary forms, amyloidosis of myeloma, forms secondary to familial Mediterranean fever, Alzheimer's disease, forms associated with type 2 diabetes or medullary carcinoma of the thyroid, inherited-familial amyloidosis, and other less common conditions. Two pathogenetic phases are involved: enhanced production of precursor proteins and their abnormal enzyme cleavage, resulting in the formation of intermediate products corresponding to the amyloid fibrils. The results of treatment are still disappointing: alkylating agents and/or cortico-steroids are used in primary forms and for amyloidosis of myeloma; colchicine in familial Mediterranean fever; DMSO in renal amyloidosis; plasmapheresis in inherited-familial forms, together with the supportive management obviously dictated by clinical manifestations.

Autoantibodies in familial Mediterranean fever (recurrent polyserositis).

Ben-Chetrit E(1), Levy M.

Author information:

(1)Hadassah University Hospital, Department of Medicine, Jerusalem, Israel.

The presence of autoantibodies in our familial Mediterranean fever (FMF) patients was investigated using various immunological techniques. Immunofluorescence screening of 50 FMF sera revealed only one positive for antinuclear antibodies. ELISA assay and nitrocellulose filter assay revealed no difference between FMF sera and healthy controls with regard to the presence of anti-dsDNA antibodies. In Western blotting using HeLa cell extract, FMF patients' sera neither detected anti-Sm, RNP, SSA/Ro, SSB/La antibodies nor any new common band. These findings suggest that it is unlikely that FMF belongs to the family of the autoimmune 'collagen' diseases.

IgD immune complex vasculitis in a patient with hyperimmunoglobulinemia D and periodic fever.

Boom BW(1), Daha MR, Vermeer BJ, van der Meer JW.

Author information:

(1)Department of Dermatology, University Hospital, Leiden, The Netherlands.

We describe a 27-year-old Dutch woman with the hyperimmunoglobulinemia D and periodic fever syndrome. During febrile attacks she occasionally presented with skin lesions on the distal parts of her upper and lower extremities, with the histologic picture of a leukocytoclastic vasculitis. Clear perivascular deposits of IgD and C3 were presented in early lesional skin on immunofluorescence investigation. Circulating IgD immune complexes were demonstrated on several occasions, both during and in between clinical attacks. These findings are consistent with an IgD immune complex-mediated pathogenesis for the skin lesions. In 10 patients with other forms of immune complex vasculitis of the skin, minimal perivascular deposits of IgD were found in four cases. In these cases, however, IgD was never found as the solitary immunoglobulin class.

Author information:

(1)Department of Medicine, Cedars-Sinai Medical Center, UCLA School of Medicine.

Familial Mediterranean fever is an autosomal recessive disease manifested by recurrent short episodes of fever associated with polyserositis. It is common in a variety of Mediterranean and near Eastern populations. The biochemical defect is unknown, and there have been few studies of genetic marker associations or linkage with the disease. We have screened blood samples from members of 14 nuclear Armenian families, the population with the highest known gene frequency, for 19 different polymorphic phenotypic genetic markers. These 14 families included 31 affected and 43 unaffected family members. No association was found with any of the markers studied. Linkage could be excluded at the distance of 0-15% recombination with 14 markers. Linkage could not be excluded with 5 other markers. These results exclude the FMF gene from those portions of the human gene map that are at least 0.5% recombination distance from these 14 genetic markers, and represent the first comprehensive step in the eventual localization and isolation of the FMF gene.

Familial Mediterranean Fever (FMF) is an inherited disease, closely following the pattern of autosomal recessive inheritance. Amyloidosis is the most severe complication of the disease. The prevalence of pregnancy loss in women with FMF is considered to be high. There is no information to support the possibility of increase risk of late pregnancy complications or change in the natural course of the disease. Two cases are presented with complicated FMF. One case with proved amyloidosis and the second patient with ascites. Pregnancy and neonatal outcome were uneventful in both. No further deterioration in the systemic disease occurred.

Author information:

(1)Department of Medicine, Cedars-Sinai Medical Center, Los Angeles, CA.

Familial Mediterranean Fever (FMF) is an autosomal recessive disease manifested

by recurrent short episodes of fever associated with polyserositis. Although the biochemical defect is unknown, there are several immunologic abnormalities which have been described in this disease. To examine critically whether there is linkage between FMF and the immunogenetic region (major histocompatibility complex-MHC) on chromosome 6, including the HLA, BF, and GLO1 loci, blood samples from members of 13 nuclear Armenian families were tested for these genetic markers. These 13 families included 28 affected and 42 unaffected family members. Linkage could be excluded at 7.5% recombination with the HLA ABC and D loci. Linkage could be excluded at 2.5% recombination for GLO1. Linkage could not be excluded with BF individually, but can be rejected based on the haplotype data. No association was found with either BF, GLO1, and HLA DQ alleles. HLA DR4 was found more often in affected cases than in controls; however, after adjusting for the number of antigens tested this was not significant. Our results would appear to exclude the immunogenetic region on chromosome 6 from linkage with FMF in the Armenian population.

[Level of leukotrienes B4 and C4 in the blood of patients with periodic disease].

[Article in Russian]

Gabrielian ES, Grigorian SV, Davtian DG, Mkhitarian GS, Panosian AG.

The level of LTB4 and LTC4 in blood plasma of patients with familial mediterranean fever is significantly higher than in healthy donors:  $53 \pm 10$  pg/ml for LTB4 (normal -  $25 \pm 5$  pg/ml) and  $175 \pm 22$  pg/ml for LTC4 (normal  $67 \pm 19$  pg/ml). The more increase of the LTB4 and LTC4 content in plasma is observed during attacks of fever -  $107 \pm 21$  pg/ml (LTB4) and  $249 \pm 34$  pg/ml (LTC4). Hyperbaric oxygenation of patients, used to relieve pain and fever, reduces the level of leukotrienes.

Serum amyloid A and P protein genes in familial Mediterranean fever.

Shohat M(1), Shohat T, Rotter JI, Schlesinger M, Petersen GM, Pribyl T, Sack G, Schwabe AD, Korenberg JR.

Author information:

(1)Department of Pediatrics, Cedars-Sinai Medical Center, Los Angeles, CA 90048.

Two recent studies have suggested the involvement of serum amyloid A (SAA) and P (APCS) genes in familial Mediterranean fever (MEF). To test the role of SAA and APCS in MEF and MEF-amyloidosis, we studied 17 informative families (15 Armenians, 2 non-Ashkenazi Jews) and 8 MEF patients with amyloidosis using a candidate gene approach. No evidence for any MEF-associated polymorphism was found in any of the 41 Armenian and Jewish MEF patients tested. Our family studies allowed us to rule out tight linkage between SAA and MEF (lod score = -2.16, theta less than or equal to 0.06). For APCS we found that the allele frequency in the MEF-amyloidosis patients was similar to that in 18 unrelated MEF patients without amyloidosis and their 33 healthy parents. Finally, we excluded close genetic linkage between APCS and MEF at 8.5 cM or less (lod score = -2.2).

Colchicine is a substance derived from the Colchicum Autumnale plant, its pharmacological uses have been demonstrated over the years. Initially used for the treatment of acute gout, it has been utilized for a wide variety of diseases, including mediterranean familial fever, alcoholic, posthepatitic and primary biliary liver cirrhosis. We have demonstrated in different studies that colchicine reduces markedly mortality rates in cirrhotics and the levels of interleukin-1 in patients with primary biliary cirrhosis.

We describe a 54-year-old man who suffered from familial Mediterranean fever, but the fever has been the only symptom during a 10-year period. During this period, results of laboratory tests and roentgenographic studies were negative. On the basis of these findings we propose that familial Mediterranean fever can be included in the causes of persistent fever in patients with long periods of fever.

Peritoneal and synovial fluids of patients with familial Mediterranean fever lack a protein that inhibits neutrophil chemotaxis by antagonizing the complement-derived inflammatory mediator C5a. The C5a inhibitor activity was studied with the use of a C5a binding assay where peritoneal fluids were tested for their ability to inhibit recombinant C5a binding to dibutyryl cyclic adenosine monophosphate-induced U937 cells. In contrast to normal peritoneal fluids, those from patients with familial Mediterranean fever contained less than 1% C5a inhibitor activity. Gel filtration and ion exchange chromatography of peritoneal fluids from those patients did not yield any fraction that inhibited C5a binding. We suggest that the serosal tissue of patients with familial Mediterranean fever is devoid of C5a inhibitor activity and that this deficiency may explain in part the local inflammatory episodes characteristic of this disease.

The cutaneous manifestations in children with familial Mediterranean fever (recurrent hereditary polyserositis). A six-year study.

Majeed HA(1), Quabazard Z, Hijazi Z, Farwana S, Harshani F.

Author information:

(1)Department of Pediatrics, Faculty of Medicine, University of Kuwait.

In a six-year study of 46 children with familial Mediterranean fever (recurrent hereditary polyserositis), 20 children (43 per cent) developed cutaneous manifestations. Ten children had 18 episodes of erysipelas-like erythema which proved to be specific for the disease. Twelve children (26 per cent) had 31 episodes of non-specific purpuric rash and six children (13 per cent) had nine episodes of Henoch-Schönlein purpura. Other manifestations included diffuse erythema of the face, and/or trunk, angioneurotic oedema, diffuse erythema of the palms and soles followed by mild desquamation of the skin, Raynaud's phenomenon and a subcutaneous nodule. The mean frequency of the cutaneous lesions was 1.6/patient/year before colchicine therapy and 0.4/patient/year after colchicine therapy ( $p = 0.0005$ ). The high incidence of cutaneous manifestations and their response to colchicine strongly suggest that skin involvement is an integral part of familial Mediterranean fever.

Partial characterization of a C5a-inhibitor in peritoneal fluid.

Ayesh SK(1), Ferne M, Flechner I, Babior BM, Matzner Y.

Author information:

(1)Hematology Unit, Hadassah University Hospital Mount Scopus, Jerusalem, Israel.

We have recently described a 40-kDa protein in peritoneal fluid that neutralized the chemotactic activity of the C fraction C5a. It was deficient in peritoneal fluids of patients suffering from familial Mediterranean fever. Further characterization of the inhibitor with the use of <sup>125</sup>I-rC5a binding to dibutyryl cAMP-induced U937 cells revealed dependence on the peritoneal fluid concentration, on the time of incubation and on temperature and pH. Fractionation of <sup>125</sup>I-C5a on Sephadex G-50 column, before and after incubation with peritoneal fluid, revealed similar fractionation patterns despite loss of biologic activity of the treated C5a (but not its binding to polyclonal anti-C5a antibody). Analysis of rC5a by SDS-PAGE before and after treatment with partially purified C5a inhibitor, revealed slight modification of the inhibitor-treated C5a. Using various protease inhibitors (i.e., PMSF) suggested that the C5a inhibitor is a serine protease. It neutralized C5a by means of limited proteolysis which did not change C5a immunologic properties and changed only slightly its m.w. but abolished its receptor binding and chemotactic functions. It is suggested that the C5a inhibitor plays a role in the regulation of inflammation in serosal tissues and that its deficiency in familial Mediterranean fever may explain the attacks of sterile inflammation characteristic of this disease.

(1)Birmingham and Midland Eye Hospital, UK.

Comment in

Lancet. 1990 Feb 24;335(8687):480.

The visual evoked responses (VERs) to both flash and pattern stimulation were recorded in 44 children with migraine, with or without aura, and 8 with periodic syndrome. The controls were 50 age and sex matched children. VERs of 50 sex matched adults with migraine were also recorded. The fast wave amplitude in children with migraine was higher than that in controls. The amplitude was higher in younger children with migraine (under 13 years) than that in older children or adults with migraine. Children with periodic syndrome had VERs similar to those of children with migraine. The VER, especially in children, may prove to be a useful test in the diagnosis of migraine.

[Clinico-immunological parallels in children with periodic disease].

[Article in Russian]

Astvatsatryan VA, Eridzhanian AKh, Tevosian VK.

Children aged 3 to 15 years afflicted with periodic disease were subjected to clinical and immunological examinations. The role played by derangements of certain components of the immune system in the development and course of periodic disease was outlined. Assay of T lymphocytes and immunoglobulins of the main classes in the blood serum and saliva of children with periodic disease was found to be of the diagnostic and prognostic value. To assess the gravity of periodic disease and to predict it, it is necessary to carry out a comprehensive estimation of the clinical findings and of the data pertaining to humoral, cellular and local immunity.

Epidemiology of juvenile chronic arthritis and other connective tissue diseases among children in Kuwait.

Khuffash FA(1), Majeed HA, Lubani MM, Najdi KN, Gunawardana SS, Bushnaq R.

Author information:

(1)Department of Paediatrics, Faculty of Medicine, Kuwait University, Safat.

An 8-year hospital-based retrospective study on the epidemiology of juvenile chronic arthritis (JCA), systemic lupus erythematosus (SLE) and other connective tissue diseases among children in Kuwait is described. There were 108 children with JCA, 20 children with SLE, 23 children with other connective tissue diseases and 24 children with arthritis of familial Mediterranean fever (FMF). The average annual incidence of JCA was 2.84 cases/10(5) children under the age of 12 years and the 1988 prevalence was 18.7/10(5). The polyarticular, systemic and

oligoarticular onset types were observed in 42, 29 and 29%, respectively. The incidence and prevalence of SLE were 0.53 and 3.37/10(5), respectively. The findings are compared with those from other countries.

Palindromic rheumatism in Israel--a disease entity? A survey of 34 patients.

Eliakim A(1), Neumann L, Horowitz J, Buskila D, Kleiner-Baumgarten A, Sukenik S.

Author information:

(1)Rheumatology Unit, Soroka Medical Center, Beer-Sheva, Israel.

Over a period of 10 years 34 patients were diagnosed as suffering from palindromic rheumatism. Eighty-one percent of the patients were of North African origin. This is significantly higher ( $p = 0.01$ ) than the age-adjusted origin of the general population in the region. Attacks were usually monoarthritic or oligoarthritic in nature. The joint most often involved was the knee.

Prophylactic therapy with colchicine was ineffective. Gold salts brought about partial remission in three of six patients. Despite a relatively long average follow-up period of 9.3 years and the finding of a positive rheumatoid factor in 12% of the patients, not one of the patients developed rheumatoid arthritis. In 50% of the patients we detected an unexplained elevation in serum globulins and immunoglobulins. The possible association between this syndrome and Familial Mediterranean Fever is discussed.

Amyloid goiter and arthritides after kidney transplantation in a patient with systemic amyloidosis and Muckle-Wells syndrome.

Schwarz RE(1), Dralle H, Linke RP, Nathrath WB, Neumann KH.

Author information:

(1)Department für Addominal und Transplantationschirurgie, Medizinische Hochschule Hannover, F.R. Germany.

A case of hereditary AA amyloidosis with Muckle-Wells syndrome is described. After a successful kidney transplantation for chronic renal failure due to renal amyloid deposits at age 21, the patient, a white female now 26 years of age, developed a large amyloid goiter as a manifestation of the systemic amyloidosis and recurrent monarthritides. Both observations are novel for this disease. Subtotal thyroidectomy and oral colchicine administration, known to be effective in preventing complications of familial Mediterranean fever, another hereditary type of AA amyloidosis, proved highly effective in the management of this unusual case.

Author information:

(1)Department of Medicine, School of Medicine, Jordan University, Amman.

Two patients with a long-standing history of familial Mediterranean fever (FMF) presented with gross hematuria, oliguria, and acute renal failure; both required dialysis support. Kidney biopsies from both patients revealed crescentic rapid progressive glomerulonephritis (RPGN) without amyloidosis. One patient recovered renal function with methylprednisolone pulse therapy and cyclophosphamide. The second patient did not improve and required regular hemodialysis. He is asymptomatic on colchicine therapy. To our knowledge, these are the first cases documenting the presence of RPGN in patients with FMF.

Familial Mediterranean fever in Armenians: autosomal recessive inheritance with high gene frequency.

Rogers DB(1), Shohat M, Petersen GM, Bickal J, Congleton J, Schwabe AD, Rotter JL.

Author information:

(1)Department of Pediatrics, Harbor-UCLA Medical Center, Torrance.

Familial Mediterranean fever (FMF) is a recurrent episodic inflammatory disorder

of unknown pathogenesis that occurs with high frequency in non-Ashkenazi Jews and Armenians. However, there are some differences in the clinical manifestations of FMF in these ethnic groups. FMF has been reported to be an autosomal recessive disease in non-Ashkenazi Jews, with a male/female ratio of 1.7, indicating reduced penetrance in females. However, the inheritance is less clear for Armenians. To resolve this problem, we studied prospectively families of 64 Armenian index cases randomly ascertained at the UCLA FMF clinic. Fifty-three families containing 176 sibs in addition to the probands were analyzed by genetic segregation analysis (exclusions included: six single-child families, four families in which one of the parents was also affected, and a family with incomplete information). Upper and lower bounds of the segregation ratio were estimated, and ranged from .10 +/- .03 to .18 +/- .05 when only definitely affected sibs were classified as affected; .17 +/- .04 to .27 +/- .05 when considering "possibly affected" sibs as affected; and .19 +/- .04 to .30 +/- .05 when incomplete penetrance in females was corrected. A value of .25 is the expected segregation ratio for autosomal recessive inheritance, and our data are consistent with this mode of inheritance. We can reject autosomal dominant inheritance, where the expected segregation ratio is .5. Using extended pedigree data, we calculated an FMF gene frequency of 0.073 and a carrier rate of 1/7, which is about four times the frequency in non-Ashkenazi Jews.(ABSTRACT TRUNCATED AT 250 WORDS)

Determination by ELISA of anti-DNA antibodies in patients with familial Mediterranean fever.

Flatau E(1), Shneyour A, Hadad N, Shimoni Z.

Author information:

(1)Department of Internal Medicine B, Central Emek Hospital, Afula, Israel.

Positive titers of antibodies against double-stranded (ds) and single-stranded (ss) DNA were found in the sera of 4 and 6 patients, respectively, of 18 who had familial Mediterranean fever (FMF). While anti-dsDNA antibodies were found only

in patients with active disease, there was no correlation between the presence of anti-ssDNA antibodies and disease activity. The antibody titers were lower than those found in patients with active systemic lupus erythematosus. This may be due in part to the fact that all the FMF patients were treated with colchicine.

Retroperitoneal lymphadenopathy in familial Mediterranean fever.

Rimon D(1), Meir Y, Cohen L.

Author information:

(1)Department of Internal Medicine B, Faculty of Medicine, Technion-Israel Institute of Technology, Lady Davis Carmel Hospital, Haifa, Israel.

Peripheral lymphadenopathy is rarely observed, whereas mesenteric lymphadenopathy is found occasionally on laparotomies in patients with familial Mediterranean fever (FMF). Retroperitoneal lymphadenopathy was reported only once in an autopsy of a patient with FMF. Our case is the second one, and the first one to be diagnosed during life, by means of abdominal ultrasonography and computerized tomography. In patients with FMF, where lymph node biopsy was done, the

pathological finding was non-specific lymphoid hyperplasia.

Hypothesis: familial Mediterranean fever--a genetic disorder of the lipocortin family?

Shohat M(1), Korenberg JR, Schwabe AD, Rotter JL.

Author information:

(1)Medical Genetics Birth Defects Center, Ahmanson Pediatric Center, Los Angeles, CA.

Familial Mediterranean fever is an autosomal recessively inherited disorder of unknown cause characterized by recurrent attacks of inflammation, involving mainly the peritoneum, pleura, synovia, and skin. Based on a phenotype analysis, we propose that its manifestations may be related to a genetic defect in one of the family of lipocortin proteins. Evidence is presented supporting an abnormality in the first step of prostaglandin/leukotriene synthesis.

Amyloidosis in children with familial Mediterranean fever.

Koçak H(1), Beşbaş N, Saatçi U, Bakkaloğlu A.

Author information:

(1)Department of Pediatrics, Ondokuz Mayıs University Faculty of Medicine, Samsun.

In this survey 113 children with secondary amyloidosis due to familial Mediterranean fever are reviewed in regard to their respective histories, and physical and laboratory findings. The beneficial effects of colchicine in the treatment of this condition are evaluated. The number of children presented with amyloidosis secondary to familial Mediterranean fever was considerable. The male-female ratio was 4/3. It was observed that the number of patients with amyloidosis increased through the adolescent period, and that most of the cases demonstrated phenotype I (74.33%). Another important finding was the increase of partial thromboplastin time in 96 out of 113 cases (84.95%). All the symptoms of the periodic attacks were relieved by colchicine. A significant difference was found between the serum total protein and albumin values before and after colchicine therapy.

Author information:

(1)Endocrinology Unit, Children's Hospital, Winnipeg, Manitoba, Canada.

Comment in

Med J Aust. 1989 Oct 2;151(7):422.

Six Australian children fulfilled the diagnostic criteria for familial Mediterranean fever. None had a family history of the disease, but five children came from ethnic groups that typically were associated with the disease. The symptoms commenced before five years of age in all the children, and three children underwent unnecessary operations because of the symptoms of recurrent fever and abdominal pain. All six children benefited from colchicine prophylaxis by mouth. More cases can be expected to be recognized in Australia because of the large number of Australian children with a Mediterranean heritage.

[Fever of unknown origin and colchicine-sensitive amyloidosis: familial Mediterranean fever?].

[Article in German]

Schneider W(1), Wehmeier A.

Author information:

(1)Medizinische Klinik und Poliklinik der Universität Düsseldorf.

A 39-year-old man who had for 20 years suffered from recurrent fever, abdominal pain and joint pains was diagnosed to have generalized amyloidosis type AA. Suspected of having familial mediterranean fever (FMF) he was treated with colchicine, 2 mg daily. Within four years the fever bouts became milder and the amyloidosis no longer progressed. Since the patient was a foundling it was impossible to prove FMF, despite the typical signs and the successful treatment.

Familial Mediterranean fever (recurrent hereditary polyserositis) in children: analysis of 88 cases.

Majeed HA(1), Barakat M.

Author information:

(1)Department of Paediatrics, Kuwait University, Safat.

The clinical profile, course and complications of familial Mediterranean fever (recurrent hereditary polyserositis) seen in 88 children over a period of 11 years are presented. Forty eight children (55%) started their illness below the age of 5 years, and the mean age of onset was 4.9 years. Peritonitis occurred in 85% of children, arthritis in 50%, pleuritis in 33% and erysipelas-like lesions in 16%. Two children developed renal amyloidosis, and one third of the children were subjected to unnecessary operative surgery, reflecting the diagnostic difficulties. The arthritis was mono-articular in 80% and polyarticular in 20% of children with arthritis, and was seronegative (rheumatoid factor and antinuclear antibodies). Human leucocyte antigen (HLA) typing for the B-27 antigen carried out in ten children with arthritis was negative. The synovial attack showed a wide variation in the clinical presentation, course and duration of arthritis,

causing diagnostic difficulties. The difficulties in the differentiation of recurrent hereditary polyserositis (familial Mediterranean fever) arthritis from the common causes of acute and chronic juvenile arthritis and the seronegative spondyloarthropathies are discussed. Of 45 children treated with colchicine, 42 children (93%) achieved a therapeutic response.

[Familial Mediterranean fever--an important differential diagnosis in systemic juvenile chronic arthritis].

[Article in German]

Michels H(1), Häfner R, Vogel P.

Author information:

(1)Rheuma-Kinderklinik Garmisch-Partenkirchen.

Familial Mediterranean Fever (FMF), characterized by recurring episodes of fever, serositis, arthritis, skin changes and complicated by amyloidosis in 30%-60% of cases frequently begins in childhood. Systemic juvenile rheumatoid arthritis (systemic JRA, Still's disease) is the most important differential diagnosis. In

our series of 10 patients the mean age of onset was 4.9 +/- 2.2 years (range 2-9 years). The mean time period elapsed before the diagnosis was established was 4.1 +/- 2.7 years (range 1.5-10 years). Three of our 10 patients already had developed renal amyloidosis at the time of diagnosis. Essential criteria for differential diagnosis against systemic JRA were positive family history for FMF (4/10), ethnic background (9/10 of Turkish decent), typical erysipeloid skin rashes (4/10), attacks of abdominal pain accompanied by fever (10/10) and the characteristic pattern of recurrent episodes lasting only a few days each (a patient's diary monitoring the attacks may be helpful). In problematic cases the metaraminol provocative test can be helpful. If an elevated plasma dopamine beta-hydroxylase activity appears to be a specific finding in FMF patients, this may well open up new avenues in the early diagnosis of the disease. Since amyloidosis can be prevented by prophylactic long lasting treatment with colchicine, a timely diagnosis of FMF is the physician's challenge.

[Familial Mediterranean fever in a German family].

[Article in German]

Hawle H(1), Winckelmann G, Kortsik CS.

Author information:

(1)Deutsche Klinik für Diagnostik, Wiesbaden.

A 14-year-old German boy had the characteristic signs and symptoms of familial mediterranean fever with recurrent attacks of fever which ran a uniform course and were self-limiting. Laparoscopy revealed sterile peritonitis and marked humoral inflammatory signs. Each acute phase was confined to three days, alternating with symptom-free intervals which lasted for as long as several months. The boy's father and three other members of the paternal family have had similar disease symptoms. Even in patients who are not members of a predisposed ethnic group familial mediterranean fever should be included in the differential diagnosis as a rare cause of recurrent episodes of fever of unknown aetiology.

Polyarteritis nodosa and familial Mediterranean fever: a report of 2 cases and review of the literature.

Glikson M(1), Galun E, Schlesinger M, Cohen D, Haskell L, Rubinow A, Eliakim M.

Author information:

(1)Department of Medicine A, Hadassah University Hospital, Jerusalem, Israel.

Two cases of polyarteritis nodosa (PAN) in patients with familial Mediterranean fever (FMF) are reported. These and another 11 cases found in the literature suggest that PAN occurs more commonly in patients with FMF than would be expected in the general population. Perirenal hematoma, which is surprisingly high in patients with FMF, is a life threatening complication of PAN. The diagnosis of PAN in patients with FMF may be delayed due to the similarity of the clinical manifestations of both diseases.

[Article in French]

Bellin MF, Deutsch JP, Bletry O, Langlois P, Bousquet JC, Cortez A, Godeau P, Grellet J.

A case of encapsulating peritonitis complicating the course of familial Mediterranean fever is reported. This encapsulating peritonitis was responsible for abdominal pain and had a "pseudocystic" appearance on ultrasonography and computed tomography. Ultrasound guided aspiration produced a yellowish fluid rich in proteins and poor in cells. Surgical operation revealed a congested appearance of the peritoneum associated with a richly fibrinous appearance of the external

wall of the mass. The differential diagnosis is discussed.

Renal transplantation in amyloid nephropathy.

Heering P(1), Kutkuhn B, Frenzel H, Linke RP, Grabensee B.

Author information:

(1)Department of Nephrology, University of Medicine, Düsseldorf, FRG.

Renal transplantation was performed in 2 patients with end-stage renal disease due to AA-type amyloidosis. One patient with amyloidosis of rheumatoid arthritis (RA) origin died twelve months after renal transplantation in cardiogenic shock. AA-amyloid deposits were demonstrated in the graft even though there were excellent function and no proteinuria. The second patient with amyloid nephropathy due to familial Mediterranean fever (FMF) showed no impairment of graft function 24 months after transplantation. These 2 cases are compared to an additional 31 cases of renal transplantation for amyloid nephropathy described in the literature. Proteinuria was reported in 32.3% and amyloid was detected in the functioning graft in 41.4%. The function was excellent even when small amyloid deposits were present in the graft. Renal transplantation is indicated in cases of amyloid nephropathy of the AA-type, provided life threatening amyloid involvement of other organs is not present.

Amyloid proteins and amyloidoses: complexity updated.

Goffin YA.

Amyloid is a beta-pleated fibrillar protein principally constituted of light chains of immunoglobulins (kappa or lambda) in primary or myeloma-associated amyloidosis, of AA proteins in secondary amyloidosis and familial Mediterranean fever, and of variants of prealbumin - now called transthyretin - in senile amyloidosis and in familial polyneuropathies. Other identified amyloidogenic proteins involve APUD protein derivatives (calcitonin), beta 2 microglobulin in chronic hemodialysis-related amyloidosis and beta protein in Alzheimer disease. After a short review of experimental findings and theories concerning the pathogenesis of amyloid deposition, the clinical aspects of amyloidosis are discussed stressing their great diversity. The diagnostic approach is also examined, with particular emphasis on rectal and kidney biopsy and subcutaneous

adipose tissue aspirates. Finally, some comments on the treatment of amyloidosis (role of colchicine and DMSO) are made.

The biochemical genetics of amyloid fibril proteins.

Carbonara AO(1), Bottaro A.

Author information:

(1)Dipartimento di Genetica, Università degli Studi di Torino.

Amyloidoses are a very heterogeneous set of diseases, characterized by extracellular deposition of fibrillar proteins in different tissues. It is still a matter of debate whether the different forms of amyloidosis can share some common etiological mechanisms, or they are completely unrelated. The biochemical characterization of the protein component of the deposits provides a powerful system of classification for the different amyloidotic disorders and shades light on the molecular mechanisms of selective precipitation from soluble precursors and of tissue-specific deposition. Furthermore, identification and analysis of the genes coding for the precursors, and clarification of the kind of inheritance in some familial forms of amyloidosis, make prevention through genetic counselling and predictive diagnosis possible.

Catecholamine metabolism in recurrent hereditary polyserositis. Pathogenesis of acute inflammation: the retention-leakage hypothesis.

Barakat MH(1), Malhas LN, Gumaa KK.

Author information:

(1)Department of Internal Medicine, Kuwait University.

Recurrent hereditary polyserositis (RHP), also known as familial Mediterranean fever, is a genetically-determined disease characterized by paroxysmal attacks of peritonitis, pleuritis, arthritis or inflammation of other serous membranes. We have previously suggested that the pathogenesis of this disease seems to be related to abnormal catecholamine metabolism. This study compares the plasma and urine catecholamine profile in patients with RHP during different clinical states to that in controls. In RHP there were lower plasma and higher urine dopamine levels in the asymptomatic state and during attacks, while norepinephrine levels remain unchanged. However, plasma epinephrine was significantly lower in the asymptomatic state but markedly higher during attacks. The urine epinephrine values in both situations were similar but significantly lower than in controls, suggesting abnormal renal excretion of epinephrine. The urine metanephrine was markedly elevated in the asymptomatic state compared to controls, but remained unchanged during the attacks, again suggesting defective renal clearance of metanephrine. Metaraminol infusion, which induces attacks in RHP patients, was associated with an increase in plasma dopamine and epinephrine (but not norepinephrine); yet the urinary levels of dopamine, epinephrine and metanephrine remained the same, confirming the dissociation between the plasma and urinary levels of these catecholamines, probably due to abnormalities in the renal clearance mechanism. We postulate that this dissociation leads to retention of these amines in the plasma which may subsequently leak through the serous membranes (the target organs) and incite an acute inflammatory process. Colchicine, the only known drug that protects against disease attacks, reduces the plasma levels of these amines, and thus may act by preventing retention that leads to leakage and subsequent inflammation.

The association of nephrotic syndrome and renal vein thrombosis: a clinicopathological analysis of eight pediatric patients.

Tinaztepe K, Buyan N, Tinaztepe B, Akkök N.

Cases with a pathological diagnosis of renal venous thrombosis (RVT) associated with nephrotic syndrome (NS) were studied retrospectively for clinicopathological evaluation. The material consisted of 21 RVT cases which were diagnosed in 2000 consecutive pediatric necropsies, with an overall incidence of about one percent. Eight of the 21 RVT cases were associated with nephrotic syndrome (34%), and this group formed 0.4 percent of the total necropsies in our pediatric center. The glomerulopathies of these nephrotic patients consisted of three cases of Finnish-type congenital NS (FCNS), three cases of renal amyloidosis secondary to familial Mediterranean fever, and two cases of membranoproliferative glomerulonephritis (MPGN). The presence of sepsis associated with disseminated intravascular coagulation, and the morphological age of the thrombi suggested that the RVT was secondary to sepsis in the FCNS cases. In the MPGN and secondary renal amyloidosis cases, the long duration of both the nephrotic state and the administration of diuretics along with glucocorticoid treatment and also the newly formed thrombi without infarction are strong evidences, although not definite, that the RVT developed as a complication of the glomerulopathy. Even though there were no definite clinical criteria for the diagnosis of most of the RVT cases, we would like to emphasize the importance of flank pain, the rapid deterioration of renal functions in a stable nephrotic patient, as well as the hypercoagulable state in the consideration of the development of RVT which indicate the need for appropriate radiological studies for confirmation of this condition during life.

Plasma dopamine beta-hydroxylase: rapid diagnostic test for recurrent hereditary polyserositis.

Barakat MH(1), Gumaa KA, Malhas LN, el-Sobki NI, Moussa MA, Fenech FF.

Author information:

(1)Department of Internal Medicine, Faculty of Medicine, Kuwait University.

The diagnosis of recurrent hereditary polyserositis (RHP; also known as familial Mediterranean fever) remains one of exclusion since there has been no specific diagnostic laboratory test. A previous study suggested that the disorder is related to abnormal catecholamine metabolism. Plasma dopamine beta-hydroxylase (DBH) activity was assayed spectrophotometrically in 91 RHP patients and 162 controls. The activity was significantly higher in untreated symptom-free patients and in patients with acute attacks, than in controls (mean [SEM] 155.8 [14.1] vs 43.3 [1.9] mumol/min/1 p less than 0.0001). Colchicine treatment reduced DBH activity to control levels. The test showed a high diagnostic accuracy and specificity for RHP, whether the patient was symptom-free or having an acute attack. Moreover, it is easy to carry out.

Abdominal fat tissue aspirate in amyloidosis of familial Mediterranean fever.

Tishler M(1), Pras M, Yaron M.

Author information:

(1)Department of Rheumatology, Ichilov Hospital, Tel Aviv Medical Center, Israel.

Abdominal fat tissue aspirates from 20 patients with biopsy-proved amyloidosis were investigated by polarized microscopy after staining with Congo-red. Positive results were obtained in 4 of 5 patients with primary amyloidosis (AL) and in none of 15 with amyloidosis (AA) of Familial Mediterranean Fever (FMF). We suggest that although this technique is simple, safe and effective in other forms of amyloidosis, it cannot be used as a diagnostic tool in FMF patients suffering from amyloidosis.

Mollaret's meningitis. A variant of recurrent hereditary polyserositis, both provoked by metaraminol.

Barakat MH(1), Mustafa HT, Shakir RA.

Author information:

(1)Department of Medicine, Faculty of Medicine, Kuwait University.

Mollaret's meningitis is a rare condition with a characteristic clinical and cerebrospinal fluid picture. In many ways it resembles recurrent hereditary polyserositis (familial Mediterranean fever) in its natural history, pattern of attacks, and response to colchicine. Association of the two conditions has been reported, so far, in two patients only. In our patient the symptoms of both conditions were induced by a metaraminol provocative infusion. We have previously introduced this as a specific diagnostic and confirmatory test for recurrent hereditary polyserositis. The possibility that the two conditions represent different manifestations of a single disease is therefore strengthened.

The clinical and biochemical spectrum of hereditary amyloidosis.

Varga J(1), Wohlgethan JR.

Author information:

(1)Division of Rheumatology, Thomas Jefferson University, Philadelphia, PA 19107.

Familial amyloidosis, once described as a puzzling and highly unusual form of polyneuropathy, is now recognized to be a collection of familial diseases with usually autosomal-dominant inheritance and widespread ethnic distribution. Familial amyloidosis occurs throughout the world and encompasses an extremely broad spectrum of clinical manifestations. In some families, progressive peripheral neuropathy dominates the illness, while in others, renal failure, ocular amyloid deposits, cardiac decompensation, or intracranial hemorrhage is the most significant clinical feature. The Portuguese (type I) and the Iowa (type III) neuropathies characteristically begin with lower limb involvement, while in the Indiana (type II) form, upper limb neuropathy is seen first; in the Japanese families with familial amyloid polyneuropathy, symptoms first become evident around age 40, whereas in the Texas family, onset is in the seventh decade. The prognosis for the different families is highly variable. Current classification of the familial amyloid polyneuropathy syndromes is based on their characteristic clinical presentations, but ongoing biochemical identification of the protein composition of amyloid substance in each form will make a more rational nosology

feasible in the near future. To date, no therapy has been shown to arrest or reverse the progressive accumulation of amyloid deposits in most forms of familial amyloidosis. Familial Mediterranean fever is a major exception, and the incidence of amyloidosis associated with this disease has been dramatically reduced by the widespread prophylactic use of colchicine. Technology currently available permits the reliable identification of asymptomatic relatives at risk for developing amyloid neuropathy as well as the prenatal identification of carriers of the mutant transthyretin gene. These strategies can be used in genetic counseling aimed at reducing the continued propagation of the mutant gene.

Colchicine in therapy. State of the art and new perspectives for an old drug.

Famaey JP(1).

Author information:

(1)Department of Rheumatology, Hôpital Universitaire Saint-Pierre, University of Brussels, Belgium.

Colchicine is the most specific treatment in acute gouty attacks. In several European countries, oral colchicine is still used for routine treatment of acute gout. Its selectivity is used as a diagnostic tool. It is also active in the treatment of acute crises of chondrocalcinosis and more occasionally of other arthritic crises (e.g. sarcoidosis). Colchicine appears to be the necessary adjuvant prophylactic drug when starting a hypouricemic treatment with uricosuric or uricolytic drugs for avoiding acute gouty crisis due to sudden mobilisation of the uric acid pool. Besides gout, colchicine is the drug of choice for treating familial mediterranean fever. It appears to be helpful in the treatment of Behçet's disease. It seems also useful for treating fibrosing conditions such as liver cirrhosis and scleroderma. As an adjuvant therapy, it helps treating dermatological disorders which are associated with leucocyte migration as an essential pathogenic factor (e.g. psoriasis, dermatitis herpetiformis, necrotising vasculitis ...). It has been advocated as an adjuvant therapy in malignant diseases as a support in radiotherapy and as an useful drug in various other diseases where it has been tried occasionally (e.g. Paget's disease of the bone, idiopathic thrombocytopenic purpura, disc syndrome). This very old drug remains a modern therapeutic agent.

The immune regulation in familial Mediterranean fever (FMF).

Melamed A(1), Cabili S, Zakuth V, Spirer Z.

Author information:

(1)Pediatric Department, Rokach Hospital, Tel Aviv Medical Center, Israel.

In order to investigate a possible immune regulation imbalance in familial Mediterranean fever (FMF), the T-cell subsets and interleukin (IL)-1 and -2 production were examined in 39 patients (32 consecutive; 7 previous) and 14 controls. Results in the FMF group indicated no change in total T-cells and B-cells. The number of suppressor T-cells and helper cells were significantly decreased, as compared to the controls ( $14 \pm 5.2$ ,  $19 \pm 4.6$  vs.  $31 \pm 4.6$ ,  $41 \pm 5.3$ , respectively), and the NK cells were significantly increased ( $16 \pm 4.8$ ,  $36 \pm 2.1$ ). Peripheral blood monocytes from the patients with FMF produced higher amounts of IL-1 and lower amounts of IL-2 than those from the control subjects. The latter results were enhanced when the FMF group was subdivided on the basis of pretreatment with colchicine and presence of amyloidosis. This study, although preliminary, indicates an immune regulation imbalance in FMF patients. Further research is necessary to understand the interrelation of amyloidosis and colchicine treatment.

Pericardial involvement in familial Mediterranean fever.

Erol C(1), Sonel A, Candan I, Omürlü K, Akyol T.

Author information:

(1)Cardiac Research Center, Faculty of Medicine, University of Ankara, Cebeci-Ankara, Turkey.

Two patients with familial Mediterranean fever showed the classic features of pericardial involvement and one of them (Case 2) had pericardial effusion detected by echocardiography. These and previously published cases show that familial Mediterranean fever should be considered as a cause of pericarditis

and/or pericardial effusion.

[The metaraminol provocation test in the diagnosis of familial Mediterranean  
fever].

[Article in German]

Huppertz H(1), Michels H.

Author information:

(1)Universitäts-Kinderklinik, Würzburg.

Familial Mediterranean Fever (FMF) is a cyclic inflammatory disease of unknown pathogenesis and autosomal recessive inheritance. Diagnosis is notoriously difficult by the lack of specific signs or laboratory tests although early diagnosis is mandatory to avoid developmental delay or possibly fatal amyloidosis by treatment with colchicine. In adults, Metaraminol Provocative Test (MPT) has been described as specific and highly sensitive in the diagnoses of FMF. We tested 18 children, 9 of whom suffered from FMF. They were ill for 5 years and had been treated as in-patients for 3 months without improvement (median values). 5 of the children with FMF had a positive test results. 4 children with FMF were

negative. All 9 children with other disorders were negative, too. During the course of diagnosis, they had been suspected of suffering from FMF. So, in childhood, MPT is specific for FMF but does not identify all children with FMF. However, a positive MPT may be a great help in diagnosing FMF.

Serum amyloid A (SAA) gene variations in familial Mediterranean fever.

Sack GH Jr(1).

Author information:

(1)Department of Medicine, Johns Hopkins University School of Medicine, Baltimore, MD.

Novel structural changes in members of the serum amyloid A (SAA) gene family have been found in four patients of varied ethnic backgrounds with familial Mediterranean fever. Since the genes for these small acute phase proteins are generally well conserved, these observations suggest that alterations of serum amyloid A genes, their protein products and/or their regulation may be responsible for familial Mediterranean fever.

Between 1976 and 1983, the authors studied 50 new patients affected with periodic disease. 16 of them-mean age: 29-presented muscular manifestations. They may be grouped into two clinical aspects: muscular pain and contractures. The authors consider that these symptoms, first described in 1945, are an inherent part of the clinical picture of the disease. They discuss their relationship with periarteritis nodosa and remind the fact that their pathogenesis remains unknown.

Enhanced neutrophil chemiluminescence in familial Mediterranean fever.

Anton PA(1), Targan SR, Vigna SR, Durham M, Schwabe AD, Shanahan F.

Author information:

(1)Department of Medicine, UCLA 90024.

Familial Mediterranean Fever is a disorder of unknown cause characterized by recurrent, self-limited paroxysms of serosal inflammation. Although the neutrophil is the predominant cell involved, no cellular abnormalities are known.

Chemiluminescence was studied in neutrophils from 20 asymptomatic patients with this disease and 21 healthy controls to evaluate the oxidative response to formyl-methionyl-leucyl-phenylalanine (f-met-leu-phe). In a subset of patients with familial Mediterranean fever, neutrophils but not monocytes were shown to have significantly enhanced chemiluminescence compared to controls. The enhanced responsiveness of neutrophils to f-met-leu-phe in this disease was found to occur at a postreceptor level. Receptor binding assays demonstrated no differences in binding affinity and receptor number between patients and controls. In addition, a similar enhancement in chemiluminescence was observed with an alternative stimulus (zymosan). In contrast to chemiluminescence, chemotaxis induced by f-met-leu-phe was not enhanced in patients with familial Mediterranean fever. The enhanced neutrophil chemiluminescence may identify a subclinical inflammatory state in attack-free patients with familial Mediterranean fever, as enhanced chemiluminescence is also observed in chronic inflammatory diseases with active inflammation.

Severe myalgia in familial Mediterranean fever: clinical and ultrastructural aspects.

Schapira D(1), Ludatscher R, Nahir M, Lorber M, Scharf Y.

Author information:

(1)Department of Rheumatology, Rambam Medical Center, Haifa, Israel.

Severe myalgia is an uncommon feature of familial Mediterranean fever (FMF). A patient is presented in whom acute myalgia and high fever were the sole clinical findings during an FMF attack. The ultrastructural picture of the muscle tissue during the acute stage was characterised by a large deposition of collagen fibrils. The myalgia subsided during colchicine treatment. The clinical and ultrastructural features of myalgia in FMF are discussed in the light of the relevant literature.

Amyloid and amyloidosis.

Breathnach SM(1).

Author information:

(1)Department of Medicine (Dermatology), Charing Cross and Westminster Medical School, London, U.K.

Cutaneous lesions are present in up to 40% of patients with primary and myeloma-associated systemic amyloidosis and occur as a result of tissue deposition of immunoglobulin light chain material derived from a circulating paraprotein. The occurrence of waxy, purpuric mucocutaneous lesions provides a crucial early pointer to underlying occult plasma cell dyscrasia; the combination of the symptoms of the carpal tunnel syndrome, macroglossia, and specific mucocutaneous lesions is highly characteristic. Although secondary systemic (reactive) amyloidosis rarely gives rise to clinically evident cutaneous lesions, it may be etiologically related to a number of chronic dermatoses. Lesions of nodular primary localized cutaneous amyloidosis are indistinguishable from those of primary and myeloma-associated systemic amyloidosis, and they result from local plasma cell infiltration. Macular and papular (lichen amyloidosis) variants

of primary localized cutaneous amyloidosis may have a familial or racial basis and are characterized by a tendency for keratinocytes to undergo filamentous degeneration and apoptosis. The prognosis of patients with plasma cell dyscrasia-related systemic amyloidosis remains poor, since there is little response to therapy with cytotoxic agents, colchicine, or dimethylsulfoxide. Colchicine is the drug of choice in the prevention and treatment of the renal amyloidosis associated with familial Mediterranean fever, and dimethylsulfoxide may be useful in the management of patients with secondary systemic amyloidosis. Macular amyloid and lichen amyloidosis generally follow a chronic course with intractable pruritus; there have been isolated reports of the beneficial effect of dermabrasion, topical dimethylsulfoxide, and therapy with the aromatic retinoid, etretinate.

IgA nephropathy in patients with familial Mediterranean fever.

Said R(1), Nasrallah N, Hamzah Y, Tarawneh M, al-Khatib M.

Author information:

(1)Department of Medicine, School of Medicine, Jordan University, Amman.

Two patients with a long-standing history of familial Mediterranean fever were found to have both microscopic hematuria and proteinuria during the acute attacks. Kidney biopsies from both patients revealed diffuse mesangial proliferative glomerulonephritis with intense mesangial IgA and C3 deposits and no evidence of amyloidosis. To our knowledge these are the first 2 cases documenting the presence of mesangial IgA nephropathy in patients with familial Mediterranean fever.

[Acetylation phenotype in patients with periodic disease].

[Article in Russian]

Podymov VK, Vinogradova OM, Kovaleva VL, Kochubei LN, Galstian SM.

Acetylation phenotype distribution (activity of N-acetyltransferase enzyme) was studied in 29 patients with periodical disease (PD), 73 healthy persons (Armenians), and 20 patients (also Armenians) suffering from epithelial coccygeal cysts. The results obtained indicated the prevalence of slow acetylation phenotype (67%) in the entire Armenian population. PD was characterized by slow acetylation type (28 of 29 patients had slow acetylation with a high frequency of very slow inactivators). The other hereditary pathology, also specific for Armenians (epithelial coccygeal cysts), was characterized by another type of acetylation--a rapid one. The role of slow acetylation as a genetic marker of PD was discussed.

Degradation and deposition of amyloid AA fibrils are tissue specific.

Prelli F(1), Pras M, Frangione B.

Author information:

(1)Department of Pathology, New York University Medical Center, New York 10016.

The complete amino acid sequences of two related AA proteins (Mr 9700 and 5300) derived from thyroid tissue from a patient, NOR, with the autosomal recessive disease familial Mediterranean fever were determined. Heterogeneity found at position 52 indicates these proteins are fragments of two allelic or isotypic SAA precursor molecules similarly degraded at unusual sites and deposited in the thyroid. Degradation appears to be tissue and/or enzyme(s) specific since the carboxy terminus of both fragments is Ala-Ala and is different from other AA amyloid fibrils extracted from various tissues in different patients. Electron micrographic studies reveal these fragments retain the characteristics of native amyloid fibrils under physiological conditions even after exposure to dissociating agents.

Autosomal dominant familial Mediterranean fever-like syndrome with amyloidosis.

Gertz MA(1), Petitt RM, Perrault J, Kyle RA.

Author information:

(1)Division of Hematology, Mayo Clinic, Rochester, MN 55905.

We report a pedigree in which a syndrome that resembled familial Mediterranean fever occurred in four family members over three successive generations. All four patients had systemic amyloidosis. Typically, patients with familial Mediterranean fever show an autosomal recessive inheritance pattern. The disorder commonly afflicts Sephardic Jews, Arabs, and persons of Turkish descent. Colchicine therapy dramatically reduces the attack rate of serositis. The family described herein is unique because of their European ethnicity and the autosomal dominant inheritance pattern. Unlike typical familial Mediterranean fever, colchicine had no influence on the attacks and did not prevent amyloidosis in the three patients who received this treatment.

Fertility and obstetric history in patients with familial Mediterranean fever on long-term colchicine therapy.

Ehrenfeld M(1), Brzezinski A, Levy M, Eliakim M.

Author information:

(1)Department of Medicine A, Hadassah University Hospital, Jerusalem, Israel.

The obstetric histories were examined for 36 women with familial Mediterranean fever (FMF) on long-term colchicine treatment followed for periods ranging between 3 and 12 years. Seven of 28 pregnancies (25%) associated with colchicine

therapy ended in miscarriage. Thirteen women (36%) had periods of infertility; these were due to ovulatory dysfunction in six women, to peritoneal adhesions in four and remained unexplained in three women. The rates for miscarriage and infertility are high but are similar to those reported for women with FMF before colchicine therapy was introduced. All 16 infants born to mothers who had taken colchicine during pregnancy were healthy. Currently, we do not advise discontinuation of colchicine before planned pregnancy but recommend amniocentesis for karyotyping and reassurance.

PIP: The obstetric histories of 36 women with familial Mediterranean fever (FMF) on longterm colchicine treatment were followed for periods ranging from 3-12 years and examined. 7 of 28 pregnancies (25%) associated with colchicine therapy ended in miscarriage. 13 women (36%) had periods of infertility; these were due to ovulatory dysfunction in 6 women, to peritoneal adhesions in 4, and were unexplained in 3 women. Primary amyloidosis A. Immunohistochemical and biochemical characterization.

Picken MM(1), Pelton K, Frangione B, Gallo G.

Author information:

(1)Department of Pathology, New York University Medical Center, New York 10016.

Primary "idiopathic" amyloidosis is usually related to immunoglobulin light chain (AL) associated with immunocytic dyscrasias, while secondary "reactive" amyloidosis (AA) is related to serum amyloid A protein (SAA) and typically occurs with chronic inflammation, malignancy, or familial Mediterranean fever. In the present study, amyloid fibril protein extracted from frozen and paraffin-embedded tissue from a patient (CAR) with primary systemic amyloidosis proved to be AA

protein by immunohistochemical, immunochemical, and amino terminal sequence. Extracts from both frozen and formalin-fixed paraffin-embedded kidney and spleen yielded similar monomers and dimers of the AA protein. The additional high-molecular-weight bands and a distinct 12,000-dalton fragment in the amyloid protein extracted from the formalin-fixed paraffin-embedded lung suggest that different processing of proteins, ie, by polymerization and/or degradation, may occur in different organs.

Neutrophil function studies in clinical medicine.

Matzner Y(1).

Author information:

(1)Hematology Unit, Hadassah University Hospital, Jerusalem, Israel.

A complete evaluation of neutrophil function including: chemotaxis; adhesion; aggregation; phagocytosis; granule content and degranulation; respiratory burst activity; and bacterial killing; is expensive and requires the services of a specialized laboratory. However, preliminary screening of a patient with a predisposition toward infection, can be carried out using simple and inexpensive methods. These include examination of blood films, which may prove helpful in the diagnosis of Chediak-Higashi syndrome and specific granule deficiency; the Rebut skin window test, which estimates chemotactic defects; the NBT test, which screens for chronic granulomatous disease patients; and peroxidase staining of the blood film in order to estimate the content of myeloperoxidase, when myeloperoxidase deficiency is suspected. For final diagnosis and determination of genetic transmission and radical treatment, ie, bone marrow transplantation, specific tests are indicated. Neutrophil function studies have also proved useful in detecting diseases in which defects in neutrophil function are secondary to the primary disorder. Indeed, increased neutrophil chemotaxis has been reported in the active phase of diseases such as: familial Mediterranean fever; psoriasis vulgaris, Behcet's syndrome and Sweet's syndrome. In these disorders the

neutrophil chemotaxis assay has aided in the diagnosis and follow-up, particularly in evaluating the response to antiinflammatory agents, such as colchicine.

Structure of a human serum amyloid A gene and modulation of its expression in transfected L cells.

Woo P(1), Sipe J, Dinarello CA, Colten HR.

Author information:

(1)Medical Research Council Clinical Research Centre, Harrow, Middlesex, United Kingdom.

The structure of a human serum amyloid A (SAA) genomic clone (SAAg9) has been analyzed and the nucleotide sequence of the coding regions is compared with that of the cDNA for apoSAA1. The leader and coding sequences of exons 2 and 3 are identical to SAA1. However, there are 10 nucleotide and 7 derived amino acid substitutions in exon 4. These changes are identical to the amino acid sequence of the amyloid protein associated with familial Mediterranean fever. In particular, the amino acid substitution (Thr to Phe) at residue 69 of SAA1 may have an important role in this type of hereditary amyloidosis. The genomic clone SAAg9 has been transfected into mouse L cells, and constitutive expression of human specific mRNA and protein were observed in stable transfected clones. The expression of both SAA mRNA and protein were increased by incubation of the transfected cells with purified human interleukin-1 (IL-1), both human and mouse recombinant IL-1, and recombinant human tumor necrosis factor alpha. The induction of SAA is pretranslational and is likely to be mediated by protein factor(s) since incubation with cycloheximide diminished IL-1-dependent increase in SAA mRNA.

Recurrent polyserositis (familial Mediterranean fever) in a Japanese.

Schwabe AD(1), Nishizawa A.

Author information:

(1)Department of Medicine, University of California, Los Angeles 90024.

A 36-year-old male of pure Japanese ancestry presented with a classical 20-year history of Recurrent Polyserositis manifested by self-limited attacks of fever plus pleuritis, peritonitis or arthritis. These attacks were completely suppressed by daily prophylactic colchicine, but recurred when the drug was briefly discontinued. For the past 10 years he has been on 1.2 mg of colchicine daily and has had no further febrile attacks. Although several cases of periodic or cyclic febrile disorders in patients of Japanese ancestry have been cited in the literature, the patient described here appears to satisfy the required criteria for a diagnosis of Recurrent Polyserositis in a Japanese.

Skin and nail changes in the arthritic foot.

Gilkes JJ.

The arthritic process is unlikely to be confined to the foot; similarly the cutaneous lesions associated with the arthritic foot are often widespread. Careful examination of the skin and nails, particularly the finger nails, may be helpful in the differential diagnosis when the patient presents with a painful foot joint. Conversely, certain cutaneous lesions may alert the physician to the possibility of joint disorders presenting at some later date. In this chapter, it is not possible to mention every skin lesion associated with an arthropathy. Some skin lesions are specific but many are non-specific and occur in several rheumatic diseases. The rheumatologist and dermatologist work in closest co-operation when managing patients with lupus erythematosus and psoriatic arthritis and it is for this reason there is particular emphasis on these two diseases. Patients with rheumatoid arthritis and gout usually come within the province of the rheumatologist, but there are often many characteristic dermatological features to these diseases. This chapter also includes some more esoteric diseases such as Familial Mediterranean fever, Behçet's syndrome, disseminated gonococcal infection and Lyme disease which may present a diagnostic problem to the general physician, rheumatologist or dermatologist.

Panniculitis in familial Mediterranean fever. Case report with histopathologic findings.

Danar DA, Kwan TH, Stern RS, Kasdon EJ, Birnbaum PS, Brown RS.

A 79-year-old Armenian-born woman with stable, long-term familial Mediterranean fever had progression of chronic renal failure concurrently with two types of skin lesions. One lesion resembled erysipelas, which is quite common in familial

Mediterranean fever, whereas the other was panniculitis, only occasionally described in familial Mediterranean fever. The unique histopathologic features of the latter are presented. The onset of acute cutaneous disease in this patient coincided with worsening renal disease and preceded a flare of disease activity in other sites after a 14-year period of quiescence. The severe and unremitting pain from the skin lesions and their tendency to form nonhealing ulcers were substantial causes of morbidity in this patient with familial Mediterranean fever.

Preparative fractionation of amyloid proteins on a microgram scale by high-performance liquid chromatography and polyacrylamide gel electrophoresis.

Kaplan B, Pras M.

Preparative separation of amyloid proteins on a microgram scale is presented. Amyloid fibrils solubilized in aqueous 50% acetonitrile containing 0.1% trifluoroacetic acid, are fractionated by reverse-phase high-performance liquid chromatography. Fractionation of amyloids obtained from patients with familial Mediterranean fever allowed isolation of a protein identical with a conventionally isolated AA-protein. Sodium dodecyl sulfate-polyacrylamide gel electrophoresis is used for preparative separation of AL-proteins. Two protein extraction procedures from Coomassie Blue stained gels are applied using elution in 0.1% sodium dodecyl sulfate containing buffer and 6 mol/l guanidine-HCl solution. The eluted proteins are concentrated and sodium dodecyl sulfate and dye are removed by acetonitrile precipitation of sample.

Observer variation in grading sacroiliac radiographs might be a cause of 'sacroiliitis' reported in certain disease states.

Yazici H, Turunç M, Ozdoğan H, Yurdakul S, Akinci A, Barnes CG.

Radiological sacroiliitis in Behçet's syndrome (BS) has been a subject of controversy. We have examined pelvic radiographs of 38 patients with BS and 28 age and sex matched controls which we reported previously, and also 17 with

ankylosing spondylitis (AS), 27 with non-renal familial Mediterranean fever (FMF), and 33 with primary osteoarthritis (OA). Initially, five observers assessed radiographs on two different occasions according to the New York criteria for sacroiliitis in a blind protocol. Later, three of them examined the various possible abnormalities of the sacroiliac (SI) joints after training sessions. Although the inter- and intraobserver variation was quite high, all observers found the expected changes in patients with AS. The abnormalities detected in the other diseases were either mild, inconsistent, or both. Erosions were confined to patients with AS, and osteophytes and glenoid sulci to patients with OA. We conclude that high observer variation in interpreting a film of the anteroposterior (AP) view of the pelvis for sacroiliitis may be a major cause of reported 'sacroiliitis' in BS and FMF.

Recurrent pulmonary atelectasis as a manifestation of familial Mediterranean fever.

Brauman A, Gilboa Y.

Comment in

Arch Intern Med. 1989 Jul;149(7):1698.

Recurrent attacks of pulmonary atelectasis were the leading sign of familial Mediterranean fever in a young man of Jewish-Georgian extraction. His mother suffered from the more common manifestations of the disease. Treatment with colchicine caused a complete disappearance of his attacks. However, when challenged by discontinuing colchicine therapy for eight days, another, documented attack of pulmonary atelectasis occurred. To our knowledge, this is the first case of familial Mediterranean fever presenting with recurrent pulmonary atelectasis.

[Muckle-Wells syndrome or association of joint pain attacks, urticarial outbreaks and sensory deafness?].

[Article in French]

Serratrice G, Pouget J.

The Muckle and Well's syndrome corresponding to a transmission of the autosomic dominant type, combines bouts of urticaria, episodes of arthralgias to a shrinking of the ear and a sensory deafness. Sometimes, it evolves into a renal amylosis. Sometimes, as the case presented here, it combines multiple malformations. Its place in nosology is imprecise. It is, at the same time, close to systemic urticaria, sensory deafness, amylosis and specially amylosis of the periodic disease. But the common link between the various elements of the syndrome remains undetermined, for the time being.

[Familial Mediterranean fever. Study of a Swiss child].

[Article in German]

Federspiel B, Tönz O.

Familial Mediterranean fever (FMF) has been observed in a Swiss child without ethnic predisposition. The case is analyzed and the current literature briefly reviewed. Recurrent attacks of fever, accompanied by abdominal pain, colic and arthritic symptoms, and often by pleuritic pain and a transitory skin rash, are the hallmarks of FMF, which is predominantly seen in ethnic groups of the Mediterranean area, notably Sephardic Jews, Turks and Armenians. However, it rarely occurs among individuals without an ethnic predisposition. Its most ominous manifestation is amyloidosis, which leads to chronic renal failure within a matter of years. Thanks to colchicine treatment, which is now widely accepted, patients often lead normal lives, and it appears that amyloidosis can be prevented.

[Comparative aspects of the course of periodic disease without and with amyloidosis (analysis of 437 case studies)].

[Article in Russian]

Vinogradova OM, Kochubei LN, Vasil'eva NA.

The paper is concerned with an analysis of a course of periodic disease (PD) without and with amyloidosis using also a method of the determination of survival rates in 437 patients followed up for 20 yrs. A course of PD without amyloidosis was benign and did not affect the patients' survival. In the development of amyloidosis the prognosis was unfavorable and determined by a degree of generalization of amyloidosis.

[Successful therapeutic effect on periodic disease with the intermittent use of colchicine].

[Article in Bulgarian]

Maleev A, Naumov N.

The continuous application of colchicine reduces considerably the incidence of the paroxysms in patients with periodic disease. A patient is described, a Bulgarian, with periodic disease with a duration of 40 years (family Mediterranean fever), successfully treated with intermittent application of colchicine according to a schedule for the last 3 years. The evolution of the clinical manifestations was followed up as well as the absence of effect by the corticosteroid therapy applied before. The intermittent application of colchicine, in this case, prevents totally the paroxysms with high temperature and pain in abdomen, chest and joints with a considerable smaller amount of the drug applied. The intermittent application of colchicine should first be tried in the treatment of patients with periodic diseases.

[Metabolism of arachidonic acid in the thrombocytes of patients with periodic disease].

[Article in Russian]

Panosian AG, Grigorian SV, Davtian DG, Gevorgian GA, Gabrielian ES.

Washed platelets of patients with familial Mediterranean fever (FMF) were incubated with I-14C arachidonic acid (AA). Only 10% of AA were transformed into thromboxane A<sub>2</sub>, 12(S)-12-hydroxy-5Z,8Z,10E,14Z-eicosatetraenoic acid (12-HETE) and 12(S)-12-hydroxy-5Z,8Z,10E-heptadecatrienoic acid (HHT), which strongly indicates the suppression of platelet lipooxygenase and cyclooxygenase or the

deficit in these enzymes in FMF. However, there were no noticeable alterations in AA platelet metabolism during attacks of fever and immediately after hyperbaric oxygenation used to relieve pain and fever. The data obtained suggest that arachidonic acid metabolism plays an important role in the pathogenesis of FMF.

Increased procoagulant response of monocytes from patients with familial Mediterranean fever.

Courillon-Mallet A, Bevilacqua M, Wautier JL, Dervichian M, Cattani D, Caen J.

Familial Mediterranean Fever (FMF) is an inherited disease of unknown etiology characterized by recurrent inflammatory episodes. Circulating fibrin was found in patients with FMF in absence of clinical manifestation of thrombosis and was statistically less frequently observed in patients treated with colchicine. These results suggest a cellular dysfunction. Therefore, we examined the procoagulant activity (PCA) of isolated mononuclear leukocytes and purified monocytes from FMF patients (n = 20). No PCA was detectable on freshly-isolated monocytes. After several hours of culture, FMF monocytes contained more PCA than control cells and the difference was more marked after endotoxin stimulation. Data obtained with coagulation factor-deficient plasma and anti-human apoprotein III antiserum indicated that the enhanced PCA in FMF monocytes is thromboplastin-like. Lysozyme and interleukin 1 production by monocytes were similar in patients and controls. The increased monocyte PCA appears to be due to an intrinsic and selective higher responsiveness of monocytes.

Familial Mediterranean fever (recurrent hereditary polyserositis) in Arabs--a study of 175 patients and review of the literature.

Barakat MH, Karnik AM, Majeed HW, el-Sobki NI, Fenech FF.

Recurrent hereditary polyserositis (RHP) or familial Mediterranean fever (FMF) is a chronic inherited illness of obscure aetiology. The disease is characterised by paroxysmal attacks of fever, peritonitis, pleuritis or arthritis, and predominantly affects Sephardic Jews, Arabs, Turks and Armenians. In this study, we report our 11-year experience of 175 Arab patients with this disease. As with other ethnic groups, the most common manifestation (93.7 per cent) was peritonitis. Arthritis (33.7 per cent) and pleurisy (32 per cent) were next in frequency. Adult patients in this series unlike those in other ethnic groups, rarely presented with arthritis. Similarly rare were amyloidosis, rashes, splenomegaly, hepatomegaly or lymphadenopathy. The aetiology of this disease is not clear but we suspect that abnormalities in catecholamine metabolism may be a factor in the pathogenesis.

The effects of long-term colchicine therapy on male fertility in patients with familial Mediterranean fever.

Ehrenfeld M, Levy M, Margalioth EJ, Eliakim M.

Four out of 19 male patients suffering from familial Mediterranean fever (FMF) had fertility problems while on colchicine therapy (0.5-2.0 mg daily for as long as 11 years). Three of the patients had had children while off therapy but their wives could not conceive while they were on therapy. In one patient primary

sterility remained one year after cessation of colchicine. In this and two other patients the spermogram was normal but the sperm penetration test was pathological. The fourth patient had azoospermia. Patients should be informed about this possible risk of colchicine therapy. The need for continued follow-up and the value of the sperm penetration test in the detection of fertility problems in male patients on long-term colchicine therapy are stressed. It is concluded however, that overall the benefits outweigh the danger of long-term colchicine treatment in male patients with FMF.

Tissue distribution of amyloid deposits in Abyssinian cats with familial amyloidosis.

DiBartola SP, Tarr MJ, Benson MD.

The tissue distribution of amyloid deposits was studied in 15 related Abyssinian cats with familial amyloidosis. There was interstitial medullary amyloidosis in the kidneys of all 15 cats but only 11 had detectable glomerular involvement. The thyroid glands, stomach and colon were affected in all cats examined. Most of the cats also had amyloid deposits in the small intestine, spleen, heart, adrenals, pancreas, liver, lymph nodes and bladder. In 50 per cent or fewer of the cats examined, there was involvement of the parathyroids, lung and gonads. The central nervous system was not involved in any of the 3 cats evaluated. In 8 of the cats, no concurrent inflammatory disease could be detected. The tissue distribution of amyloid deposits resembled that found in other breeds of domestic cats with systemic amyloidosis. Despite the wide tissue distribution of amyloid deposits, clinical signs were related to renal amyloidosis. Familial amyloidosis in the Abyssinian cat may represent a valuable spontaneous animal model for the study of Familial Mediterranean Fever in man and the pathogenesis of reactive amyloidosis in general.

[Destructive arthropathy in familial Mediterranean fever].

[Article in German]

Kissling R, Brandenberg J, Papandreou A, Käppeli R.

Mediterranean fever, an autosomal recessive hereditary disease usually affecting closely circumscribed populations, is already characterized in early life by recurrent bouts of fever accompanied by polyserositis. One feared complication is amyloidosis, while the other, which is less frequent and almost unknown in Central Europe, is chronic destructive arthropathy. This partial aspect of familial Mediterranean fever is illustrated by the case of an Armenian born in 1960. The value of a theoretically conceivable basic therapy with colchicine is considered. Colchicine has apparently produced good results in the early stages of destructive arthropathy, although the mechanism by which this occurs is not yet understood. The positive effect described is likewise not evident in all cases.

Cardiac amyloid deposits in endomyocardial biopsies. Light microscopic, ultrastructural, and immunohistochemical studies.

Frenzel H, Schwartzkopff B, Kuhn H, Lösse B, Thormann J, Hort W, Linke RP.

In four patients with unexplained, abnormal thickening of the interventricular septum as demonstrated by echocardiography, right ventricular endomyocardial biopsy revealed unexpected cardiac amyloid deposits that resulted in increased myocardial thickness and rapidly progressive heart failure. Light microscopically, amyloid was observed in the subendocardial layer, interstitium, and walls of the intramural arterioles. Electron-microscopically, the amyloid fibrils were adjacent to the basement membranes of the heart muscle cells and the vascular smooth muscle cells. Immunohistochemical typing with specific antibodies against different amyloid fibril proteins on glutaraldehyde-fixed paraffin sections revealed different amyloid types. In two patients with generalized idiopathic amyloidosis and in two others with amyloidosis in multiple myeloma, the A-lambda form was diagnosed. In a fifth patient, AA-amyloidosis was found in familial Mediterranean fever with cardiac manifestation without thickening of the interventricular septum. The amyloid deposits were located almost exclusively

within the walls of the myocardial arterioles. The amount of amyloid as observed in the myocardial biopsies correlates with the rapidly progressive cardiac failure. It is suggested that in patients with abnormal thickening of the interventricular septum of unknown origin the diagnosis should be clarified by endomyocardial biopsy.

Colchicine in the prevention and treatment of the amyloidosis of familial Mediterranean fever.

Zemer D, Pras M, Sohar E, Modan M, Cabili S, Gafni J.

To determine whether colchicine prevents or ameliorates amyloidosis in patients with familial Mediterranean fever, we followed 1070 patients with the latter disease for 4 to 11 years after they were advised to take colchicine to prevent febrile attacks. Overall, at the end of the study, the prevalence of nephropathy was one third of that in a study conducted before colchicine was used to treat familial Mediterranean fever. Among 960 patients who initially had no evidence of amyloidosis, proteinuria appeared in 4 who adhered to the prophylactic schedule and in 16 of 54 who admitted non-compliance. Life-table analysis showed that the cumulative rate of proteinuria was 1.7 percent (90 percent confidence limits, 0.0 and 11.3 percent) after 11 years in the compliant patients and 48.9 percent (18.8

and 79.0 percent) after 9 years in the noncompliant patients (P less than 0.0001). A total of 110 patients had overt nephropathy when they started to take colchicine. Among 86 patients who had proteinuria but not the nephrotic syndrome, proteinuria resolved in 5 and stabilized in 68 (for more than eight years in 40). Renal function deteriorated in 13 of the patients with proteinuria and in all of the 24 patients with the nephrotic syndrome or uremia. We conclude that colchicine prevented amyloidosis in our high-risk population and that it can prevent additional deterioration of renal function in patients with amyloidosis who have proteinuria but not the nephrotic syndrome.

Medical examination of Israeli 17-year-olds before military service as a national resource for health information.

Kark JD, Kedem R, Revach M.

At age 17 years Israelis undergo medical examination for the purpose of health classification for military service. The potential use of this extensive data

collection system for epidemiologic studies is illustrated for selected conditions. Trends in diagnosed disorders over a 25-year period are exemplified in the changing prevalence of tuberculosis, bronchial asthma, diabetes, epilepsy and heart defects. Within birth cohorts, cross-sectional analyses of height, body mass, blood pressure and disorders--such as bronchial asthma, allergic rhinitis, diabetes, psychiatric diagnoses and such genetic conditions as familial Mediterranean fever--point to clear ethnic differences. Educational level is strongly associated with measures of health status. Potential uses of this resource include: detecting groups in need of preventive, curative and rehabilitative care, assessing changing needs and priorities of health care, evaluation of intervention programs and health services provided in childhood, a wide spectrum of etiologic studies including assessment of health effects of social change, follow-up studies including the natural history of disorders, and developing data systems such as national registries of rare or important conditions. Issues relating to data reliability and validity, changing disease classification and nonexamination of groups exempted from military service limit interpretation of findings and restrict uses of this resource. Emphasis on standardization of data collection and diagnostic criteria, quality assurance and improved data management will be necessary.

[Familial Mediterranean fever. Immunogenetic and rheumatologic aspects of the disease in a Turkish sibship].

[Article in German]

Langer HE, Robin-Winn M, Stangel W, Zeidler H.

A family study was performed in 24 members of a Turkish sibship with familial Mediterranean fever (FMF) with 5 patients affected in 3 generations. The

well-known autosomal-recessive inheritance of the disease was masked by a pseudodominant appearance, reflecting the striking frequency of congenial marriages. The immunogenetic investigation excluded a linkage between the expression of the disease and the HLA system. The arthritis of FMF was characterized typically by monarticular attacks in large joints of the lower limb. Frequently this manifestation led to diagnostic problems, particularly at the onset of the disease. No patient presented the clinical or radiological signs of sacroileitis. An observation of the disease process up to 3 years showed a benign prognosis of FMF-arthritis in 3 of 4 patients. Neither long-lasting functional impairment nor radiological signs of erosion had to be recognized. One patient suffered from a necrosis of the femoral head, possibly caused by the recurrent inflammation of the hip joint. Laboratory findings reflected the clinical picture of relapsing acute inflammation in an uncharacteristic manner. Their diagnostic significance exists mainly for the exclusion of other diseases.

[Kidney transplantation in a case of amyloidosis].

[Article in French]

Cuvelier R, Pirson Y, Cosyns JP, Squifflet JP, Alexandre GP, van Ypersele de Strihou C.

Renal transplantation was performed in five patients with various forms of amyloidosis (familial amyloidosis, Mediterranean fever and Crohn's disease). All grafts were functioning one year after the operation. Only one patient died of cardiac shock more than 10 years after transplantation; the other recipients are alive with a functioning graft from 12 to 67 (mean, 41) months after transplantation. No early severe infection was observed in any patient. Graft biopsy obtained in three patients disclosed amyloid deposits in only one: deposits initially (72 months post-transplantation) mild and perivascular, became more prominent in the vessels and extended into the mesangium 4 1/2 years later. Extrarenal amyloid involvement observed in four cases did not lead to serious clinical consequences during the follow-up period. Renal transplantation thus provides an effective treatment of terminal renal failure due to amyloidosis whatever its cause.

[Amyloidosis and familial Mediterranean fever].

[Article in French]

Pras M.

Familial Mediterranean Fever (F. M. F.) is an autosomal recessive disorder occurring most commonly in Sephardi Jews and Armenians. Two phenotypic features characterize the disease: brief episodic febrile attacks of peritonitis, pleuritis or synovitis recurring from childhood or adolescence and the development of systemic amyloidosis. Attacks are accompanied by striking elevations of acute phase proteins, including serum amyloid A protein. The amyloidosis of Familial Mediterranean Fever is of the AA type, and manifest clinically as a nephropathy that passes through proteinuria, nephrotic and uremic stages to renal death. Although there is ethnic variation in the incidence of amyloidosis of F. M. F. in our patient population--predominantly Sephardi Jews of North African extraction--an amyloidotic death at an early age is their genetic destiny. Since the introduction in 1972 of colchicine to prevent the febrile attacks, the drug has been proven and become the main stay of therapy. Today, colchicine has been shown to be effective in preventing amyloidosis as well as the febrile attacks in Familial Mediterranean Fever. End stage renal disease is not the end of the road for patients with F.M.F. because of improving outlook for dialysis and renal transplantation in these patients.

[Synovitis in familial Mediterranean fever].

[Article in German]

Langer HE, Huth F, Behfar S, Zeidler H.

Arthroscopy done on a 24-year-old turkish male with familial Mediterranean fever (FMF) and arthritis of the knee joint provided morphological data during the acute stage of FMF-arthritis. Main finding is a heavy granulocytic infiltration of the subsynovial stratum, similar to that seen in non-specific purulent inflammation, accompanied by marked ectasis and hyperaemia of the synovial vessels. In the microbiologically sterile synovial fluid cell counts and lactate values are found as in bacterial arthritis. The typical history and the characteristic course of the disease are indicators for the diagnosis. Serological, immunological and radiological findings are non-specific. The efficacy of prophylactic colchicine in symptomatic therapy could be verified but it is essential that the drug is taken regularly and that the patient is instructed accordingly. Investigation of other members of the family showed a high frequency of intermarriages and the presence of this autosomal-recessive inherited disease in three generations.

Clinically benign fever of unknown origin: a personal retrospective.

Weinstein L.

The purpose of this discussion has been to bring to the attention of physicians the fact that all instances of etiologically undefined persistent fever are not associated with potentially serious or life-threatening organic disease, regardless of the height of the temperature. As has been pointed out, many patients with FUO clearly have disorders that are clinically benign, and the cause of these disorders is defined much more frequently on the basis of information obtained from a detailed historic inquiry than on the basis of findings made during the most meticulous physical examination and extensive laboratory studies. These individuals are usually seen first in an outpatient setting and seldom, if ever, require hospitalization because the cause of their FUO can, with uncommon exceptions, be identified as a physiologic or emotional dysfunction, a reaction to a drug or a chemical, or a disorder that is genetically determined. Failure to recognize that even a high elevation of the temperature can represent a clinically benign situation may lead to unnecessary hospitalization, during which the many investigations that are usually carried out may serve only to reinforce the patient's concern about a serious disease. It is most important for both patients and physicians to be aware that temperature, like all other physiologic and chemical measurements in humans, is expressed by a range of values and that a temperature of 98.6 degrees F is not normal for all persons. It must also be appreciated that "normal" temperature varies with age. The newborn infant may develop high-grade fever in the absence of disease because of marked instability of the vasomotor system.(ABSTRACT TRUNCATED AT 250 WORDS)

Crohn's ileitis complicated by amyloidosis: observations and therapeutic considerations.

Becker SA, Bass D, Nissim F.

We present a patient with clinically asymptomatic amyloidosis associated with Crohn's ileitis. A distinction should be made between immunocytic dyscrasia associated with amyloidosis (formerly primary or myeloma-associated amyloidosis) and acquired systemic amyloidosis (formerly secondary amyloidosis). We compare the natural course of amyloidosis complicating Crohn's disease with these complicating familial Mediterranean fever (FMF), and discuss the role of resection and the rationale behind colchicine therapy. Our patient is the first reported case in which colchicine therapy alone has been successful in the prophylactic treatment of amyloidosis complicating Crohn's ileitis.

Cervical spine involvement in familial Mediterranean fever.

Sukenik S, Horowitz J, Boehm R, Bar-Ziv J.

We report a case of familial Mediterranean fever (FMF) complicated by nephrotic syndrome and renal failure due to amyloidosis. This case is unique in that the severity of joint involvement necessitated bilateral hip replacement and later caused cervical apophyseal joint fusion, the latter being a lesion not previously

described in the course of FMF.

Renal amyloidosis in Jordan.

Amr SS, Hamzeh YS.

Twenty cases of renal amyloidosis were observed among 182 patients who underwent kidney biopsy at Jordan University Hospital (JUH) during the period 1979-1983. Eight cases were classified as primary amyloidosis while the remaining 12 were secondary to various underlying diseases, the most significant one was familial Mediterranean fever (FMF). Comparison of incidence of renal amyloidosis in kidney biopsy series from neighbouring countries is presented.

Isolation and characterization of amyloid protein AA in the Abyssinian cat.

DiBartola SP, Benson MD, Dwulet FE, Cornacoff JB.

Amyloid fibrils were isolated by extraction in deionized water from the kidneys of an Abyssinian cat with familial renal amyloidosis. The fibrils were suspended in a buffer containing 6 M guanidine hydrochloride and reduced and alkylated using dithiothreitol and iodoacetic acid. The resulting amyloid fibril subunit protein was isolated by chromatography on a column of Sepharose CL6B. It was fragmented using cyanogen bromide, and the resultant peptides were separated by reverse phase high performance liquid chromatography. The protein was characterized by determination of the amino acid sequence of the cyanogen bromide fragments using a Beckman 890C sequencer. The primary structure of this amyloid

fibril subunit protein showed strong homology with amyloid protein AA found in man and animals with spontaneous and experimentally induced reactive systemic amyloidosis. This study confirms the reactive nature of familial renal amyloidosis in the Abyssinian cat and suggests that this disease may be a valuable spontaneous animal model for the study of familial Mediterranean fever in man.

[Article in French]

Bitar E, Rizk A, Nasr W, Gédéon EM, Tabbara W.

A young unmarried Lebanese woman presenting with periodic disease (familial paroxysmal polyserositis) since she was 3 months old developed recurrent abundant ascites at the age of 21 years. Several hundred millilitres of strongly eosinophilic fluid were evacuated. Exploratory laparotomy unexpectedly disclosed an encapsulating peritonitis with adhesions involving the small bowel and the ascending colon; there were masses of lipid-laden cells, clusters of cholesterol/crystals and marked mesoepithelial reaction. In view of the patient's dramatic response to colchicine 2 mg/day, these findings were regarded as being related to the periodic disease.

Circulating hydroxy fatty acids in familial Mediterranean fever.

Aisen PS, Haines KA, Given W, Abramson SB, Pras M, Serhan C, Hamberg M, Samuelsson B, Weissmann G.

Episodes of fever, serositis, and arthritis in familial Mediterranean fever (FMF) suggested circulating mediators of acute inflammation (e.g., neutrophil activation). The mean serum neutrophil-aggregating activity of 51 FMF patients was  $2.5 \pm 0.2$  cm<sup>2</sup>/min, compared to  $1.0 \pm 0.1$  cm<sup>2</sup>/min in 20 normal controls ( $P$  less than 0.0002). Lipid extracts of FMF sera retained neutrophil-aggregating activity and had UV absorbance peaks at 269 and 279 nm, indicating the presence of lipids with a conjugated triene structure. Chromatography of extracts yielded peaks that were coeluted with reference dihydroxycosatetraenoic acids, had UV

absorbance peaks at 259, 269, and 279 nm, and possessed neutrophil-aggregating activity. The presence of leukotriene B<sub>4</sub> was excluded by chromatography following methyl-esterification. Monohydroxy compounds identified in FMF extracts by gas chromatography/mass spectrometry included 5-hydroxyicosatetraenoic acid, and 9- and 13-hydroxyoctadecadienoic acids. Hydroxy acids were present in 19 of 31 FMF sera and absent in extracts of sera from 8 patients with active systemic lupus erythematosus, 7 with fever from infection, and 12 normal controls. The finding of circulating mono- and dihydroxy fatty acids in FMF suggests that defects in the formation or elimination of these compounds might play a role in the pathogenesis of FMF.

[Patient with familial Mediterranean fever and amyloidosis].

[Article in Bulgarian]

Atanasova P.

A patient is described, with genetic form of amyloidosis with family Mediterranean fever. The secondary amyloidosis, that developed as a complication,

has been preceded by attacks of acute articular and abdominal pains of several years. Elevated level of ethicholanolon in urine was established as well as extremely high values of serum fibrinogen, admitted to be pathognomonic signs of family Mediterranean fever. The eposition of amyloidosis is confirmed via rectal and renal punch biopsy. In spite of the diffuse character of the deposited amyloid in the renal tissue, there were still no signs of glomerular sclerosis and clinical--normal depuration renal function was observed, with normal creatinine clearance and normal nitrogenous bodies in serum. A favourable effect of colchicine therapy was observed in the patients both as regards the acute attacks of the disease and as regards the renal involvement.

The prevention of amyloidosis in familial Mediterranean fever with colchicine.

Cabili S, Zemer D, Pras M, Aviram A, Sohar E, Gafni J.

Colchicine has been used since 1972 to prevent the acute attacks of familial Mediterranean fever. The present study shows that colchicine is also effective in the prevention of amyloidosis. If initiated in patients without evidence of renal disease there is no appearance of proteinuria and no progression to renal insufficiency over long follow-up periods. Moreover, it ameliorates the course of the disease in patients with amyloid nephropathy and normal renal function. It does not alter the course of the disease if initiated after renal function is even mildly impaired. These findings suggest that colchicine prevents the new deposition of amyloid.

Degradation of amyloid A and serum amyloid A by red blood cell haemolysate in patients with familial mediterranean fever.

Shainkin-Kestenbaum R, Winikoff Y, Zimlichman S, Gorodischer R, Pras M.

Enzymatic activity for the degradation of serum amyloid A (SAA) and amyloid A (AA) was detected in erythrolysates of normal subjects and patients with familial mediterranean fever. A significant difference between the activity of normal subjects and patients was not found. Serum inhibited the SAA (but not the AA) haemolysate proteolytic activity. Interindividual variation in the susceptibility of SAA to degradation by RBC haemolysates was shown. The original digestible

fraction of SAA became gradually resistant to proteolytic cleavage over a 9 month period while the susceptibility of AA to degradation remained unchanged in this time period. These findings suggest that enzymatic degradation of SAA depends on the source of SAA, as well as inhibitory activity in serum.

C5a-inhibitor deficiency in peritoneal fluids from patients with familial Mediterranean fever.

Matzner Y, Brzezinski A.

Normal peritoneal fluid contains an inhibitor of neutrophil chemotaxis that acts by antagonizing the complement-derived chemotactic anaphylatoxin C5a. The inhibitor resembles a substance previously described in synovial fluids and is a protein with a molecular weight of approximately 40,000 as determined by gel filtration. In contrast, levels of inhibitory activity in peritoneal fluids from five patients with familial Mediterranean fever were decreased to less than 10 per cent of those found in normal subjects. Gel filtration of peritoneal and synovial fluids from these patients did not yield any fraction with inhibitory activity. We suggest that C5a-inhibitor deficiency in joint and peritoneal fluids from patients with familial Mediterranean fever may have a role in the pathogenesis of the inflammatory attacks characteristic of this disease.

[Familial Mediterranean fever. Description of a case observed by us].

[Article in Italian]

Passiu G, Perpignano G, La Nasa G, Carcassi U.

Familial mediterranean fever (FMF) is an hereditary disorder characterized by attacks of febrile serosal inflammation involving pleura or peritoneum and synovium, followed usually by insidious onset of amyloidosis. In other patients amyloidosis of AA-type is the only finding of the disease. This disorder is common in Jews of Sephardi and Ashkenazi ancestry, Arabs, Armenians and Turks. In this work the clinico-biological features and the therapeutical aspects of a patient, suffering from FMF, of Italian ancestry are presented.

Adrenal insufficiency in a general hospital over a 14-year period.

Shapiro M, Zalewski S, Steiner Z, Bernheim J, Nabriski D, Taragan R, Bruderman I, Shinkman L.

Over a 14-year period, 26 patients with adrenal insufficiency of multiple etiology were evaluated. Eight were diagnosed at autopsy, six of whom had acute

bilateral adrenal hemorrhage. Nine had chronic adrenal insufficiency. Of these, five were idiopathic and three had polyglandular disorders. Four others had tuberculosis. Six of nine patients with chronic adrenal insufficiency were hyperpigmented. Unusual manifestations of adrenal hypocorticism included hypercalcemia, flaccid paralysis, and joint contractures. The presence of multiple hormonal deficiencies focused the diagnosis on hypopituitarism. Two cases of isolated ACTH deficiency were detected. Patients with familial Mediterranean fever with amyloidosis commonly presented with reduced adrenal reserve rather than overt insufficiency. Metastatic cancer of the adrenal glands was a rare cause of reduced adrenal reserve.

Metaraminol provocative test: a specific diagnostic test for familial Mediterranean fever.

Barakat MH, El-Khawad AO, Gumaa KA, El-Sobki NI, Fenech FF.

The diagnosis of familial Mediterranean fever has been one of exclusion. In a placebo-controlled, double-blind, cross-over study a challenge with a 10 mg dose of metaraminol infusion was followed within 48 h by a typical disease-like attack in all of 21 patients with familial Mediterranean fever but in none of 21 control subjects. The induced attacks were milder and of shorter duration than the spontaneous ones. The metaraminol-induced symptoms were similar to the natural disease attacks and could be prevented with prophylactic colchicine therapy. No

significant side-effects were observed.

Diminished activity of a chemotactic inhibitor in synovial fluids from patients with familial Mediterranean fever.

Matzner Y, Partridge RE, Levy M, Babior BM.

Synovial fluids from patients with osteoarthritis contain a chemotactic inhibitor that acts by antagonizing the complement-derived chemotactic anaphylotoxin, C5a.

The activity of this inhibitor in synovial fluids from patients with several forms of inflammatory arthritis (rheumatoid arthritis, systemic lupus erythematosus, ankylosing spondylitis, and gout) were comparable to the activity present in osteoarthritic synovial fluids. In contrast, levels of inhibitory activity in synovial fluids from 9 patients with familial Mediterranean fever were decreased to less than 20% of those found in osteoarthritis fluids. The possibility was considered that the diminished inhibitory activity in fluids from patients with familial Mediterranean fever plays a part in the pathogenesis of the inflammatory attacks characteristic of this disease.

[Immunomorphological evaluation of intestinal function in periodic disease patients].

[Article in Russian]

Mamikonian RS, Arutiunian VM, Eganian GA.

Based on clinico-endoscopic, x-ray, immunological and immunohistochemical studies the authors demonstrate the role of disorders in the components of humoral and cellular immunity in the development of intestinal inflammation and amyloidosis in patients with periodical disease. Circulatory disorders, congestive hyperemia, edema of the intestinal mucosa, and spasmodic intestinal dyskinesia that develop during an attack of periodical disease are the initial components in the pathogenesis of inflammatory intestinal lesions seen during periodical disease.

[Familial Mediterranean fever].

[Article in German]

Brunner U, Streit H, Münch U.

The diagnosis of familial Mediterranean fever is often difficult. The typical symptoms of this disease have been observed in two Turkish patients. The diagnostic criteria are short attacks of fever recurring in varying intervals, and painful symptoms in the abdomen, chest, joints or skin. Since no specific test for familial Mediterranean fever is available, the diagnosis must be based on precise clinical criteria and a genetic disorder with autosomal recessive inheritance and predilection for people of Mediterranean stock, particularly sephardic Jews and Armenians. The therapeutic response to colchicine may confirm diagnostic accuracy. Amyloidosis is a major symptom of the disease and dominates the further clinical picture. Treatment with dimethyl sulfoxide (DMSO) may inhibit the progression of amyloidosis and improvement of renal function can be achieved.

A case of familial Mediterranean fever with cutaneous vasculitis and immune complex nephritis: light, electron, and immunofluorescent study of renal biopsy.

Schlesinger M, Kopolovic J, Viskoper RJ, Ron N.

A 29-year-old patient suffering from familial Mediterranean fever developed severe myalgia and hematuria. Skin biopsy showed vasculitis. The kidney biopsy revealed diffuse proliferative and exudative glomerulonephritis. On immunofluorescent examination, IgM deposits accompanied by C3 were found in coarse granular peripheral distribution. Electron microscopy revealed glomerular subepithelial deposits. Familial Mediterranean fever with vasculitis and immune complex nephritis is discussed.

Effect of colchicine on immunoregulatory abnormalities in familial Mediterranean fever.

Schlesinger M, Ilfeld D, Handzel ZT, Altman Y, Kuperman O, Levin S, Bibi C, Netzer L, Trainin N.

The effect of colchicine on immunoregulatory T lymphocytes in children with familial Mediterranean fever (FMF) was studied. Concanavalin A (Con A)-induced suppressor cell function was significantly ( $P$  less than 0.0001) decreased in five untreated FMF patients ( $15 \pm 3\%$ , mean  $\pm$  s.e.) as compared to six age matched paediatric controls ( $46 \pm 3\%$ ) and eight healthy adults ( $49 \pm 4\%$ ). When the five untreated FMF patients' mononuclear cells were pre-incubated in vitro with Con A plus  $10^{-5}$  M colchicine, their suppressor cell function was significantly increased ( $52 \pm 10\%$ ,  $P$  less than 0.01). Similarly, oral colchicine treatment (0.5 mg twice daily) significantly ( $P = 0.02$ ) increased the five FMF patients' Con A-induced suppressor cell function to levels ( $34 \pm 6\%$ ) that were not significantly ( $P$  greater than 0.05) different than the paediatric controls or the healthy adults. The percentage of OKT8+ cells (but not OKT3+ or OKT4+ cells) was significantly ( $P$  less than 0.0001) decreased in 10 untreated FMF patients ( $16.0 \pm 0.9$ ) as compared to 10 paediatric controls ( $27.6 \pm 2$ ) or 10 healthy adults ( $25.7 \pm 0.6$ ). The 10 untreated FMF patients had a significant ( $P$  less than 0.002) increase in the OKT4/OKT8 ratio ( $2.41 \pm 0.13$ ) as compared to 10 FMF patients treated with 0.5 mg twice daily of colchicine ( $1.81 \pm 0.08$ ), 10 pediatric controls ( $1.47 \pm 0.2$ ), or 10 healthy adults ( $1.78 \pm 0.11$ ).

Colchicine appears to have corrected the FMF patients' elevated OKT4/OKT8 ratio by both decreasing the percentage of OKT4+ cells and increasing (but only partially correcting) the percentage of OKT8+ cells. Thus FMF patients have a suppressor cell deficiency in which colchicine treatment corrects their deficiency of Con A-induced suppressor cell function and their elevated OKT4/OKT8 ratio. This raises the possibility that colchicine might be potentially useful as an immunomodulating drug in treating patients with autoimmune or allergic diseases associated with a suppressor cell deficiency.

Cyclic hematopoiesis: disorders of primitive hematopoietic stem cells.

Quesenberry PJ.

Utilizing both in vivo and in vitro techniques, a great deal of information has been obtained on the structure and regulation of the hematopoietic cell lineages. A number of hematopoietic stem cells and regulators have now been well characterized and their possible physiologic relevance at least in part established. More recently, new "alternative" or primitive stem cells have been described which may provide important insights into the nature of hematopoietic regeneration and regulation. These include late CFUs, high proliferative

potential colony-forming cells, colony-forming unit diffusion chamber and both bipotent and blast colonies assayed in in vitro culture systems. Regulators active at these stem cell levels are also under study and in large part appear to be produced by monocytes or lymphocytes. Cyclical hematopoiesis can be viewed as a genetic abnormality at the multipotent stem cell level with defective cell production. At present however, details of the defect await further investigation possibly including an evaluation of the role of primitive stem cells and their regulators.

The immune system in familial Mediterranean fever.

Melamed I, Shemer Y, Zakuth V, Tzehoval E, Pras M, Spirer Z.

Familial Mediterranean fever (FMF) is a genetic disorder with an obscure aetiology. In attempts to investigate a possible immunoregulatory imbalance involved in this disease we tested 24 FMF patients for suppressor T cell activity and for chemotaxis of mononuclear cells. The suppressor T cell activity and chemotaxis were decreased in untreated FMF patients as compared to colchicine treated patients or normal controls. Amyloid FMF patients manifested significantly increased chemotactic activity, while the suppressor T cell activity was normal. This finding may extend our knowledge concerning the immune mechanism involved in FMF.

The effect of long-term colchicine therapy in patients with recurrent polyserositis on the capacity of blood platelets to synthesize thromboxane A<sub>2</sub>.

Levy M, Eldor A, Zylber-Katz E, Eliakim M.

Thromboxane B<sub>2</sub> (TXB<sub>2</sub>) production during platelet activation was measured in 13 patients with recurrent polyserositis on long-term colchicine therapy and 10 healthy controls. Plasma colchicine concentration in patients ranged between 0.8-7.8 ng/ml (2.0-19.5 X 10<sup>-9</sup> M). Thromboxane production induced during aggregation by arachidonic acid or collagen and serum TXB<sub>2</sub> levels (clotted blood, 37 degrees C, 1 h) did not differ among patients and controls. Previous studies reporting platelet function defects including anomalous TXB<sub>2</sub> production, were performed in vitro using colchicine concentrations markedly exceeding the therapeutic range.

[Familial Mediterranean fever with amyloidosis. Recent pathogenetic and therapeutic aspects].

[Article in German]

Löffler HJ, Brass H, Thoenes W, Linke RP.

Familial Mediterranean fever was diagnosed in a 34-year-old Turkish patient with severe nephrotic oedema. Immunohistochemical classification of a biopsy specimen showed amyloidosis of the AA-type. There was a definite increase of serum amyloid-A-protein (SAA). The typical recurrent fever, attacks of abdominal pain with symptoms of subileus and joint swelling could be treated successfully with colchicine, the oedema with diuretics. The progression of renal failure and proteinuria as indicator of the degree of amyloid-induced renal damage remained unaffected by this treatment. With dimethyl-sulfoxide (DMSO) a marked improvement in renal function and a lowering of the SAA level could be achieved. Thus this treatment inhibits the progression of amyloidosis of the AA-type in Mediterranean fever and may be considered for other forms of AA-type amyloidoses. It is possible that the lowering of the SAA-serum concentration and the improvement of renal function is due to an antiphlogistic effect of DMSO, the mechanism of action of which is so far unknown.

Immunohistochemical identification of the AA protein in lattice dystrophy.

Wheeler GE, Eiferman RA.

We examined the amyloid deposits of lattice dystrophy type I for common components of primary and secondary amyloid using the sensitive unlabelled antibody peroxidase-antiperoxidase technique. Tissue sections of formalin-fixed, paraffin-embedded specimens from three patients with lattice dystrophy were reacted with antisera specific for free immunoglobulin light chains, prealbumin, amyloid A (AA) protein, and amyloid P (AP) protein. The lattice amyloid was

positive for the AA protein associated with secondary amyloid. The deposits were also stained with the protein AP antiserum in each case. We were unable to detect the presence of immunoglobulin light chains associated with primary amyloid or prealbumin associated with another hereditary form of amyloid. Sera from two patients with lattice dystrophy were tested for the presence of the serum amyloid A related protein, the apparent precursor of AA amyloid, by immunoelectrophoresis and immunodiffusion. The sera showed no reaction with the AA antiserum with these techniques. Lattice amyloid differed from secondary systemic amyloid in the reaction with potassium permanganate. Congo red staining of lattice deposits was not abolished by treatment with potassium permanganate. Our findings suggest that the amyloid proteins in lattice dystrophy are antigenically similar to those of secondary amyloid and the hereditary form associated with familial Mediterranean fever.

Colchicine use for familial Mediterranean fever. Observations associated with long-term treatment.

Peters RS, Lehman TJ, Schwabe AD.

Of 85 patients with familial Mediterranean fever receiving continuous prophylactic colchicine therapy, 62 (73 percent) have had a significant reduction

in the severity and frequency of their attacks. All 62 have been observed for three years or more, for a total of 4,680 patient-months and a mean duration of 75.5 months. Of the 85 patients, 23 (27 percent) did not complete three years of treatment for a variety of reasons. Diarrhea was the most common side effect, necessitating reduction of colchicine dosage in 12 patients, but discontinuation of treatment in only one. No other significant side effects were observed. Continuous, prophylactic colchicine therapy is effective in preventing the recurrent febrile paroxysms of familial Mediterranean fever and is indicated in those patients who are incapacitated by frequent attacks or who are at risk for amyloidosis developing.

Prolonged dimethylsulphoxide treatment in 13 patients with systemic amyloidosis.

Ravid M, Shapira J, Lang R, Kedar I.

Continuous oral dimethylsulphoxide (DMSO) treatment (7-15 g/day) was given to 3 patients with amyloidosis of familial Mediterranean fever (FMF), 3 patients with idiopathic amyloidosis, and 7 patients with secondary amyloidosis. The nephrotic syndrome and various degrees of renal insufficiency were the major clinical manifestation in all case. Renal function was used as the main parameter for evaluation of therapy. DMSO treatment for 7-16 months produced no effect in the FMF patients and in the patient with idiopathic amyloidosis; they all ran the predictable clinical course of their disease and either died of cardiac failure or have been maintained on chronic haemodialysis. In the 7 patients with secondary amyloidosis an unequivocal improvement of renal function was observed following 3-6 months of DMSO treatment. It was shown by a 30-100% rise of creatinine clearance and a decline in proteinuria. This new equilibrium has been maintained as long as DMSO was administered. No serious side effects of DMSO were encountered. Mild nausea and an unpleasant breath odour were the patients' main concern. We conclude that a therapeutic trial with oral DMSO is warranted in all patients with secondary amyloidosis. This treatment is unpleasant but bears no exceptional risks. It may significantly prolong life, though its effect on amyloid deposits themselves is doubtful.

[Childhood periodic syndromes and their long-term development].

[Article in Italian]

Cavazzuti GB, Ferrari P.

The long term development of periodic syndromes among children is little known. Our research has revealed that about one third of periodic headaches, two thirds of cyclic vomiting and half the cases of recurring abdominal pain disappear either before puberty or during adolescence. Other Authors have shown that this also happens in most cases of early-onset vertigo. The remaining headache cases develop into migraines in adults. When there is persistent cyclic vomiting, the collateral neurologic phenomena (headaches, vertigo, pallor, hypotonia, drowsiness) become more intense. This also happens in some cases of abdominal pain and paroxysmal vertigo which start in late childhood. Other sufferers from acute abdominal pain develop ulcers, gastroduodenitis and colitis as adults. Altogether, some infantile periodic syndromes (in particular the multi-symptomatic ones) have a common outcome, i.e. develop into more or less typical migraine syndromes. In these cases one can presume a common pathogenetic mechanism. In those cases where the outcome is favorable the pathogenesis may be different. These cases may often be spotted in early childhood on account of the monosymptomatic nature of the complaint or the absence of collateral neurologic symptoms as well as of the infrequency of critical episodes.

Microtubules in PMNs from patients with familial Mediterranean fever.

Bar-Eli M, Wilson L, Peters RS, Schwabe AD, Territo MC.

Polymorphonuclear (PMN) cells derived from patients with Familial Mediterranean Fever (FMF) were evaluated in vitro for the function and concentration of their microtubules. Using the time-decay colchicine binding assay to determine the tubulin concentration in PMN cells, no difference was found in PMN cells derived from FMF patients in comparison with those from normal healthy subjects. Colchicine treatment had no effect on the detectable tubulin concentration in the cells. The mobility of fluorescent con A(F-con A)-receptor complexes on PMN membranes was used to test the function of the microtubules. PMNs from untreated FMF patients showed the same pattern of con A cap formation as seen in normal cells. PMNs derived from colchicine treated patients, however, showed 22-32% spontaneous cap formation. These cells also showed 10-30% more capping in comparison with normal or untreated FMF cells, for any given in vitro colchicine concentration, suggesting that at therapeutic doses, the colchicine does accumulate in the PMNs in vivo. We were unable to demonstrate a microtubule defect in the neutrophils from FMF patients in these studies.

Gastrointestinal effects of long-term colchicine therapy in patients with recurrent polyserositis (familial mediterranean fever).

Ehrenfeld M, Levy M, Sharon P, Rachmilewitz D, Eliakim M.

Twelve patients with recurrent polyserositis (RP, familial Mediterranean fever) on colchicine prophylaxis (1.0-2.0 mg daily) for three years or more were

evaluated for the presence of gastrointestinal effects possibly attributable to the drug. Two patients had bulky stools, two others had transient diarrhea, and one had heartburn. Serum vitamin B12, calcium, and carotene levels were normal in all cases, and D-xylose absorption was normal in 11 of the 12. Three patients had mild steatorrhea (7.5, 7.9, and 9.9 g daily). Jejunal biopsies from these and a fourth patient with bulky stools but normal fecal fat excretion showed no abnormal histological changes. However, (Na + K)-ATPase activity was significantly decreased in all four cases. Colchicine had to be discontinued in only one of the 12 cases. It is concluded that mild steatorrhea and enzyme inhibition may occur in patients on long-term colchicine prophylaxis and that careful periodic observations for this and other adverse effects is imperative in such patients.

[Recurrent fever of unknown etiology lasting more than 6 months. Report on 85 patients].

[Article in German]

Winckelmann G, Lütke A, Löhner J.

85 patients having recurrent fever of unclarified aetiology of more than 38.5 degrees C for more than 6 months were examined in a prospective study. Of these, 10 had an inflammation due to pathogens, 12 a malignant disease, 15 a collagenous or inflammatory vascular disease, while 9 had various diseases, 5 a familial Mediterranean fever and 18 a "periodic fever". In 16 patients, in most of whom the course of the disease extended over several years, the cause of the fever could not be clarified. Among the patients with polycyclic fever over many years or decades, alternating with symptom-free intervals, one can differentiate especially the systemic Still's syndrome, which also occurs in adults and which is identical with the so-called subsepsis allergica, the familial Mediterranean fever and the "periodic fever". There are no satisfactory pointers towards the existence of a relapsing fever of its own caused by an increase of unconjugated aetiocholanolone in the plasma ("aetiocholanolone fever").

Genetic and environmental factors in the aetiology of familial paroxysmal polyserositis. An analysis of 150 cases from Lebanon.

Armenian HK.

To assess the hypothesis that factors other than a single gene are involved in the aetiology of familial paroxysmal polyserositis (FPP) clinical and genetic data on 150 patients have been analyzed. The finding of a significantly lower number of observed-affected compared to the expected in the Lenz-Hogben method of analysis is not in favour for an autosomal recessive mode of inheritance. The absence of a significant difference in the proportion of affected offspring in families where one of the parents has the disease, compared to the families where the parents are normal, is further not consistent with an autosomal dominant mode of inheritance. The observation in the present study of the occurrence of the more severe forms of the disease in the familial cases compared to the non-familial, isolated cases, make a polygenic type of inheritance or an autosomal inheritance where the penetrance of the disease is influenced by extraneous factors, more likely models for the aetiology of FPP. The possible role of an atopic model for the aetiology of FPP is discussed.

Diffuse malignant mesothelioma. Prospective evaluation of 69 patients.

Chahinian AP, Pajak TF, Holland JF, Norton L, Ambinder RM, Mandel EM.

From 1974 to 1980, 69 patients with diffuse malignant mesothelioma were prospectively evaluated. The initial site of involvement was the pleura in 57 patients and the peritoneum in 12. Previous asbestos exposure was found in 53 patients (77%), with a shorter period of latency for peritoneal (mean, 28 years) than for pleural mesothelioma (mean, 35 years). Other associated exposure or diseases included talc, mica, familial Mediterranean fever, and diffuse lymphocytic lymphoma (one patient each). Thrombocytosis was common, as were thromboembolic episodes. Survival was significantly better for patients with an epithelial subtype, with pleural versus peritoneal mesothelioma, and for those under 65 years of age. Surgery was never curative, but its extent was correlated with survival and earlier diagnosis. Results of chemotherapy with doxorubicin and 5-azacytidine yielded a somewhat better survival rate than a combined program with doxorubicin and radiotherapy. Survival after chemotherapy was correlated with performance status, response to chemotherapy, and extent of previous surgery.

Pericardial disease in familial Mediterranean fever: an echocardiographic study.

Dabestani A, Noble LM, Child JS, Krivokapich J, Schwabe AD.

We studied 30 randomly selected patients with familial Mediterranean fever (FMF) by M mode echocardiography to determine the frequency of pericardial involvement. There was no evidence of congestive heart failure, uremia, or any other illness known to be associated with pericardial disease in the study population. Eight of the 30 patients (27 percent) had echocardiographic evidence of pericardial disease. Two had pericardial effusions, two had pericardial thickening, and four either or both. Patients with pericardial involvement had a mean duration of FMF of 28.9 +/- 12.2 (SD) years vs 18.5 +/- 10.6 (SD) years for those without pericardial disease (P less than .02). We concluded that pericardial involvement is common in FMF and that its occurrence as detected by echocardiography increases with duration of illness.

Degradation of amyloid by a serum component and inhibition of degradation.

Kedar I, Sohar E, Ravid M.

ADA of human serum was demonstrated and investigated with an agar gel diffusion technique using amyloid-impregnated agar plates. Sera of 20 healthy adults, 40 patients with AA-amyloidosis, and 86 nonamyloidotic patients were tested. The presence of an ADF, showing enzymatic properties and strongly bound to albumin, was demonstrated in normals and amyloidotic and nonamyloidotic patients. ADA in the serum of amyloidotic and cirrhotic patients was markedly decreased due to the presence of an inhibitor of ADF. ADA of amyloidotic sera was restored to normal by EDTA, citric acid, and ascorbic acid. The ADA of 16 FMF patients and four of 34 patients with rheumatoid arthritis without amyloidosis was intermediate between normal and amyloidotic values, indicating the presence of IADF at low concentrations in these patients. These findings suggest that amyloid is a normal protein metabolite, possibly with a high metabolic turnover. Accumulation of amyloid may be caused by decrease of the ADA of the serum by its inhibitor, rather than by accelerated production.

Evidence for circulating fibrin in familial Mediterranean fever.

Mosesson MW, Wautier JL, Amrani DL, Dervichian M, Cattani D.

Cryofibrinogenemia was found in 10 of 24 plasma samples (42%) from subjects with FMF. This precipitate was found during active disease as well as during intervals between crises. We found a higher incidence of cryofibrinogenemia in subjects with mild to moderately severe disease not being treated with colchicine (six of eight) as compared with colchicine-treated subjects who were in partial or complete clinical remission (four of 16;  $p$  less than 0.02). All cryofibrinogen precipitates contained fibrin, as assessed by electrophoretic analyses showing the presence of multimeric crosslinked forms of fibrin(ogen) linked by gamma-dimers. This finding in clinical specimens supports the hypothesis that fibrin is an obligatory component of cryofibrinogen. Fibrin was also found in HPF (two of six specimens) prepared from cryofibrinogen-negative FMF plasmas, thus

showing that soluble forms of fibrin are even more prevalent in this disorder than is indicated by the frequent finding of cryofibrinogenemia.

Unmasking of isolated hypoaldosteronism after renal allotransplantation in familial Mediterranean fever.

Silver J, Rosler A, Friedlander M, Popovtzer MM.

A patient with familial Mediterranean fever and renal amyloidosis was maintained on intermittent hemodialysis for chronic renal failure. After renal allotransplantation, he became weak, lost 12 kg in weight over 7 wk, and developed marked orthostatic hypotension. His symptomatic volume depletion responded dramatically to i.v. 0.9% NaCl. Metabolic balance studies showed that he was in negative Na balance (on a 44 mEq/24 h Na diet, he excreted 71 mEq/24 h in his urine), which was corrected by mineralocorticoid therapy.

Renin-aldosterone studies demonstrated a hyperreninemic hypoaldosteronism with normal glucocorticoid secretion. The patient probably suffered from amyloidosis selectively involving the glomerulosa zone of his adrenal cortices. While on dialysis he was anuric and therefore not volume depleted, but after successful renal allotransplantation the diuresis of the functioning kidney unmasked his mineralocorticoid deficiency which manifested as symptomatic volume depletion.

Demonstration of AA-protein in formalin-fixed, paraffin-embedded tissues.

Shtrasburg S, Pras M, Langevitch P, Gal R.

AA-protein was identified by SDS-acrylamide electrophoresis in amyloid fibrils fixed in formalin after isolation from fresh-frozen tissues obtained from patients with familial Mediterranean fever (FMF) amyloidosis and idiopathic AA-amyloidosis and, following deparaffination, rehydration and homogenization of embedded formalin-fixed tissues of old autopsy cases of the hereditary amyloidosis of FMF and amyloidosis acquired in association with tuberculosis, bronchiectasis, and rheumatoid arthritis. That AA-protein is unaltered by formalin was firmly established by agar gel diffusion using specific rabbit anti-AA serum. By contrast, AL proteins could not be demonstrated either in formalin-fixed amyloid fibrils derived from fresh-frozen tissues of a patient with presumably AL-amyloidosis dominated by cardiomegaly and one with AL-kappa amyloidosis or in blocks of cases of familial neuropathic amyloidosis, multiple myeloma, and idiopathic amyloidosis with cardiopathy. AA-protein is not denatured by formalin and retains its typical electrophoretic, chromatographic, and immunologic characteristics even 30 years after fixation and paraffin-embedding.

Periodic meningitis and familial Mediterranean fever.

Vilaseca J, Tor J, Guardia J, Bacardi R.

A 33-year-old man had had, since he was 20 years old, recurrent attacks of fever, rash, and aseptic lymphocytic meningitis. A nephrotic syndrome developed that was

found, on renal biopsy, to be due to amyloid deposit. After colchicine therapy, no further recurrence of fever and meningitis was observed. These findings suggest that aseptic periodic meningitis (Mollaret's syndrome) should be considered as an unusual manifestation of familial Mediterranean fever.

Familial Hibernian fever.

Williamson LM, Hull D, Mehta R, Reeves WG, Robinson BH, Toghil PJ.

An Irish family with an unusual periodic syndrome is described. Attacks consist of fever with localized myalgia and painful erythema. Other features include abdominal pain and pleurisy, with leucocytosis and a high ESR. The syndrome resembles classical familial Mediterranean fever (FMF) but differs from it in its prompt response to steroids and its autosomal dominant pattern of inheritance. The disease appears to have a benign course and no patient has developed amyloid.

Schönlein-Henoch syndrome in patients with familial Mediterranean fever.

Flatau E, Kohn D, Schiller D, Lurie M, Levy E.

Ten episodes of Schönlein-Henoch purpura (SHP) in 8 patients with familial Mediterranean fever (FMF) were observed. Five episodes developed 3-14 days after penicillin injections, suggesting an etiologic association. FMF and SHP have clear clinical similarities, and if the frequency of association of the 2 diseases is indeed high, perhaps a common etiologic factor should be sought. An immune complex mechanism might be the link between these 2 disease entities.

Correction of a suppressor cell deficiency and amelioration of familial Mediterranean fever by hemodialysis.

Ilfeld D, Weil S, Kuperman O.

We tested the clinical and immunoregulatory effects of peritoneal dialysis and hemodialysis on a patient with familial Mediterranean fever (FMF), amyloidosis, and chronic renal failure. His frequency of FMF attacks during maintenance hemodialysis (no attacks in 21 months) was significantly less than during conservative medical therapy (10 attacks in 14 months,  $P$  less than 0.00002) or during intermittent peritoneal dialysis (3 attacks in 4 months,  $P$  less than 0.004). His mean ( $\pm$ SE) percentage suppressor cell function was significantly ( $P$  less than 0.001) higher during hemodialysis ( $53 \pm 5$ ) than during conservative medical therapy ( $4 \pm 3$ ) or during peritoneal dialysis ( $2 \pm 7$ ) and was similar to the healthy untreated volunteers ( $46 \pm 3$ ). This suggests that his suppressor cell deficiency may be associated with the pathogenesis of his disease. One possible mechanism by which hemodialysis ameliorates FMF may be the correction of

a suppressor cell abnormality.

A neutrophil lysozyme leak in patients with familial Mediterranean fever.

Bar-Eli M, Territo MC, Peters RS, Schwabe AD.

Polymorphonuclear cells derived from the peripheral blood of patients with Familial Mediterranean Fever release more lysozyme in response to high temperature (42 degrees, 46 degrees C) than do control cells. No differences between the FMF and control cells were observed in the release of acid phosphatase, beta-glucuronidase, or lactoferrin. Colchicine treatment had no effect on the measurable release of the enzyme from PMNs derived from FMF patients. The increased release of lysozyme in response to high temperatures appears to be specific to FMF neutrophils, and was not found in PMNs from non-FMF patients with febrile or inflammatory diseases, nor was it seen in monocytes derived from the FMF patients. It is suggested that the increased release of lysozyme from the neutrophils may be of importance in the pathogenesis of FMF.

Familial Mediterranean fever associated with menstruation. Efficacy of intermittent colchicine therapy.

Milano AM.

The majority of patients with familial Mediterranean fever have a random pattern of attacks without a clear prodrome. Continuous prophylaxis with colchicine has been shown to reduce the frequency of attacks. It is generally considered undesirable, however, to expose young patients to the potential adverse effects of continuous colchicine prophylaxis. The alternative of intermittent short courses of colchicine during acute attacks is often ineffective in patients without a clear prodrome. Case reports of patients with a pattern of attacks occurring 12-24 hours after the onset of menstrual bleeding have appeared. Such patients should be ideal candidates for intermittent colchicine therapy. A review of the literature reveals that a consistent pattern of attacks closely following the onset of menstruation is not uncommon. Such a patient is described who has responded completely to short courses of colchicine begun at the first sign of menstrual bleeding.

Correction of a suppressor cell deficiency in familial Mediterranean fever by colchicine.

Ilfeld D, Weil S, Kuperman O.

We have previously reported a suppressor cell deficiency in four patients with familial Mediterranean fever (FMF). Since colchicine prevents FMF attacks, we tested the effect of colchicine (1 mg twice daily) on the suppressor cell

function in three of these FMF patients. Proliferation of phytohaemagglutinin-stimulated responder cells co-cultured with concanavalin A-induced suppressor cells was measured. The three FMF patients' means ( $\pm$  s.e.m.) percentage suppression of normal responder cells was markedly low before treatment ( $6 \pm 2$ ) but significantly ( $P$  less than 0.001) increased during colchicine treatment ( $41 \pm 5$ ) to levels similar to normal volunteers' mean percentage suppression ( $44 \pm 3$ ). Colchicine corrected their suppressor cell deficiency and prevented FMF attacks during the 15 months of treatment. These findings support the hypothesis that there may be an association between these three patients' suppressor cell deficiency and the pathogenesis of their disease. Furthermore, colchicine may be potentially useful in treating patients with other diseases associated with a suppressor cell deficiency.

Internal potassium balance and the control of the plasma potassium concentration.

Sterns RH, Cox M, Feig PU, Singer I.

The plasma potassium concentration is determined both by external potassium balance and by the distribution of potassium between extracellular and intracellular fluid compartments, i.e., "internal potassium balance." Whenever external potassium balance is altered, the resultant change in the plasma potassium concentration is strongly influenced by concomitant alterations in internal potassium balance. Several factors alter internal potassium balance independently of changes in external balance. Acid-base disturbances produce shifts of potassium into or out of cells, but attempts to quantify these effects are not likely to be clinically useful. Hypertonicity produces a shift of potassium out of cells. Several hormones (insulin, aldosterone, catecholamines, glucagon, and growth hormone) may have roles in internal potassium balance. Digitalis and succinylcholine, by producing efflux of potassium from cells, may cause hyperkalemia. Potassium is released from skeletal muscle during exercise, causing an increase in the plasma potassium concentration. The periodic paralyses are associated with well-defined transient alterations in internal potassium

balance.

Amyloidosis in children with familial Mediterranean fever.

Ludomirsky A, Passwell J, Boichis H.

The clinical and laboratory findings of 35 children with familial Mediterranean fever who developed amyloidosis are described. The types, frequency, and severity of attacks of familial Mediterranean fever in these children were no different from patients with this disease without amyloidosis. Although amyloid was widely deposited in all tissues, the major clinical manifestations of the amyloidosis were proteinuria, the nephrotic syndrome, and progressive renal failure. Only 20% of the patients were alive 5 years after the first appearance of proteinuria.

[Fever of unknown origin with a prolonged course (author's transl)].

[Article in Spanish]

Barbado Hernández FJ, Redondo C, Muñoz A, Gil A, Puig JA, Vázquez Rodríguez JJ.

Out of 110 cases of fever of unknown origin (FUO) that met Petersdorf and Beeson's criteria 15 patients were selected because of prolonged FUO with more than six months elapsed between admission and the final diagnosis. In this group of chronic FUO an etiological diagnosis was reached in 11 cases, distributed as follows: four cases with infections (two with toxoplasmosis, one with brucellosis, and another with a brain abscess); one with colon carcinoma; two with collagen-vascular diseases (systemic lupus erythematosus, temporal arteritis); and four with different diseases (two with familial mediterranean fever, one with idiopathic granulomatous disease, and another with factitious fever). In four cases no cause for the FUO could be determined. The procedures used to obtain the diagnosis were non-invasive in five cases (clinical course and serological tests), and invasive in another five (angiography, biopsies, and exploratory laparotomy). In one case the ethology could only be ascertained at autopsy. In the FUO with a prolonged course the peculiar etiological spectrum, the lesser yield of invasive procedures, and a mortality inferior to that of FUO in general all deserve special emphasis.

Hepatitis in exanthematous mediterranean fever.

Guardia J, Vilaseca J, Moragas A, Martinez-Vazquez JM, Bombi JA, Calders J, Bacardi R.

In 38 patients suffering from rickettsiosis caused by *Rickettsia conorii* (Mediterranean Exanthematous Fever), hepatic involvement was studied via laboratory tests and in 26 cases by means of liver biopsy. SGOT, SGPT and alkaline phosphatase were found to be elevated in more than half of the patients (SGOT 74.4 +/- 93 U.K., SGPT 82.2 +/- 93 U.K., a.p. 58 +/- 21 mU/ml). In 14 patients, liver biopsy showed the existence of inclusion corpules in Kupffer's

cells. Electron microscopic study demonstrated the existence of phagosomes inside the epithelioid cells, which, however, were difficult to categorize. The frequent existence of granulomatous hepatitis in this rickettsiosis was confirmed, while the presence of the infecting agent in the liver could not be established.

Suppressor cell function in a family with familial Mediterranean fever.

Ilfeld DN, Weil S, Kuperman O.

Defective suppressor cell function has been demonstrated in several diseases but has not been tested in familial Mediterranean fever (FMF). We tested the ability of concanavalin A-activated suppressor cells from one family with FMF to inhibit the proliferation of phytohaemagglutinin-stimulated responder cells from normal volunteers. Four FMF patients tested between acute attacks had a mean ( $\pm$  s.e.) per cent suppression ( $5 \pm 2$ ) which was significantly ( $P$  less than 0.0005) less than an FMF patient tested during a spontaneous remission ( $47 \pm 3$ ), 10 healthy family members ( $41 \pm 6$ ) and eight normal volunteers ( $45 \pm 4$ ). Since FMF is inherited as an autosomal recessive disorder, deficient suppressor cell function is expressed in homozygotes between acute attacks, but not in a homozygote in spontaneous remission, homozygotes who are phenotypically normal, nor heterozygotes. This suggests that the suppressor cell abnormality in this family is probably related to the pathogenesis of FMF rather than representing a genetic

marker of FMF or non-specific depression by disease activity.

[Periodic arthralgia: teratogenicity of colchicine and its influence on pregnancy and sterility (author's transl)].

[Article in French]

Ghozlan R, Pras M, Bettoun A.

Pregnancy appears to exert a beneficial effect on periodic arthralgia, the frequency of episodes being reduced by a half. Sterility, probably of anavulatory rather than mechanical origin, occurs in one third of cases. Its frequency could be diminished by colchicine, which by its anti-inflammatory action can prevent the development of mechanical sequelae. Though colchicine appears to lack teratogenetic activity, it should be discontinued three months before pregnancy.

[Familial Mediterranean fever and fatty liver. effect of a long time colchicine treatment on triglyceride storage (author's transl)].

[Article in French]

Moretti G, Le Bras M, Longy M, Veyret V, Bioulac P.

A 35-year-old man, sephardic jew, complains for the last eleven years of typical and frequent attacks of FMF. His liver is hypertrophic. Needle-biopsy reveals an extensive macrovacuolar triglyceride storage (60 per cent) and an active vascular congestion with erythrodiapedesis in the mild and centrolobular zone, without any necrosis, cellular infiltration nor fibrosis. Electron microscopy shows lipofuscin deposits and mild lesions of mitochondrias, endoplasmic reticulum. Blood triglycerides and apo B are rather low. After six weeks of colchicine treatment, needle biopsy shows no more active congestion nor erythrodiapedesis. Triglyceride storage lowers to 40 per cent. After seven months of colchicine treatment, triglyceride storage falls down to 12 per cent. FMF may be considered as a cause of fatty liver when there is not any cause else and only after deep decrease or disparition of triglyceride deposit by a long time colchicine treatment.

[Subacute and chronic joint involvement occurring during the course of familial Mediterranean fever (author's transl)].

[Article in French]

Brodsky A, Vinceneux P, Kahn MF, Bourgeois P, Gintzburger S, Kaplan G.

Subacute and chronic joint involvement occur in less than 5 p. cent of patients with familial mediterranean fever, whereas acute joint lesions are observed in approximately 3 out of 4 cases. The various aspects of these atypical forms are discussed in relation to 10 such cases. In most of these patients the lesions were merely due to the prolongation of the acute process, presenting as a subacute mono-arthritis lasting for several months before regression. X Rays show only regional demineralisation, sometimes predominating in the subchondral zone. Symptoms totally regress without sequelae. A time destructive arthropathy may however develop, especially in the hip. The presentation associates limitation of joint motion with, on X Rays, joint space narrowing and osteophytes. In 2 of our cases and one case reported in the literature, there was a progressive development of a chronic caxopathy without any previous acute involvement of this joint. At last, in some cases, familial mediterranean fever may be associated

with a known arthritidis, usually ankylosing spondylitis.

[Familial Mediterranean fever, complement, cryofibrinogen, colchicine (author's transl)].

[Article in French]

Wautier JL, Mosesson M, Dervichian M, Cattani D.

The components C1, C4, C2, C3 of the complement system were measured in a group of 24 patients with Familial mediterranean fever (F.M.F.). The presence of cryofibrinogen and its analysis was performed in the same patient. C4, C2, C3, were increased in the F.M.F. group. Cryofibrinogenemia was found in 42 p. 100 of the patients. The cryofibrinogen was composed of fibrin, fibrinogen and plasma fibronectin. The cryofibrinogen was less frequent in the group of patients treated by colchicine (p less than 0.02).

[Kidney allograft in familial Mediterranean fever a case report and review of the literature (author's transl)].

[Article in French]

Giraud P, Adoue D, Durand D, Delsol G, That HT, Suc JM.

Chronic renal insufficiency in an Algerian patient with familial mediterranean fever and amyloidosis was treated by kidney transplantation. Diagnosis of the affection was confirmed by the onset of typical acute episodes during haemodialysis, and a bone marrow biopsy established the presence of amyloidosis. The transplant was unsuccessful at an early stage with infective complications. The incidence of similar complications and deaths (11 cases) was particularly high in the 23 previously reported patients in whom transplants had been performed, and no definite relationship was able to be established between the course of the disease and treatment by haemodialysis or transplantation. The functional prognosis of the transplant was apparently not adversely affected by the recurrence of amyloidosis in 3 cases.

[Familial paroxysmal polyserositis: modern therapeutic possibilities (author's transl)].

[Article in French]

Mignon F, Méry JP, Cuvelier R, Delons S, Meyrier A, Rottembourg J.

Prognosis of familial paroxysmal polyserositis is primarily related to the presence of renal insufficiency due to the amyloidosis. Current treatment of terminal renal failure--haemodialysis and renal transplantation--has increased survival in these patients, but prognosis remains relatively poor because of the

extrarenal, mainly cardiac deposits which have had time to develop. Preventive treatment is therefore all that can be hoped for, and initial results of the use of colchicine in this amyloid affection, by Israelian authors, appear encouraging.

[Colchicine treatment of renal amylosis in familial paroxysmal polyserositis (author's transl)].

[Article in French]

Lagrue G, Koeger AC, Benaym JC, Sobel A.

Mortality in familial paroxysmal polyserositis results mainly from renal amylosis, the outcome, until recently, being always fatal. Continuous colchicine administration prevents acute relapses, but certain recent observations have demonstrated that this treatment may be able to prevent the onset of amyloid disease. It could even provoke its regression, at least if administration is during the early stages before the development of renal insufficiency. The mechanism of this preventive action against amyloid disease occurrence is discussed as a function of current knowledge of amyloidogenesis.

[Familial Mediterranean fever in childhood (author's transl)].

[Article in French]

Harpey JP.

Most cases of familial mediterranean fever (periodic disease) begin in childhood. However reports of this disorder in the pediatric literature are rare. This diagnosis is too often missed in pediatric practice. His symptomatology is the same as in adulthood with some particularities. Familial history is often the corner-stone of the diagnosis. Assessment of C'4 fraction of complement seems of good help for the diagnosis. The frequent occurrence of premonitory symptoms heralding the attacks allows us in many cases to start an intermittent colchicine therapy. Long term colchicine therapy should be used very cautiously in children and should be restricted to those children whose activities are disrupted by crisis occurring without alarm or to cases associated with amyloidosis.

[The complement system in familial Mediterranean fever: studies in 41 families (author's transl)].

[Article in French]

Ollier-Hartmann MP, Godeau P, Gouet E, Hartmann L.

A total increase of blood complement components, particularly C4, is found in subjects with familial Mediterranean fever both before and after colchicine therapy. This effect differs from the serum haptoglobin and orosomucoïd

concentration decreases detected after identical therapy, conferring diagnostic value to this inflammatory syndrome. This could be of both hepatic and extrahepatic origin. For the latter, it is possible that up take of circulating monocytes, macrophage precursors, by the connective tissue of the serum sub-mesothelial layer is responsible for the lesion.

Renal uptake of <sup>67</sup>Ga-citrate in renal amyloidosis due to familiar Mediterranean fever.

Banzo-Marraco J, Nerin-Mora E, Abos-Olivares MD, Nerin de la Puerta I, Iribar-Ibabe MC, Prats-Rivera E, Banzo-Marraco JI, Teijeiro-Vidal J.

Renal uptake of <sup>67</sup>Ga-citrate is described in a patient with biopsy-proven amyloidosis of the kidneys, due to Familial Mediterranean Fever. After administration 150 MBq (4 mCi) <sup>67</sup>Ga-citrate, scans were done at 48, 72, and 120 h. Intense uptake was noted in both kidneys. A renal biopsy done 5 days after the <sup>67</sup>Ga-citrate scan revealed a pattern typical of amyloidosis. Gallium scanning can be useful in patients with fever of unknown origin. Renal amyloidosis can be considered when renal uptake of <sup>67</sup>Ga-citrate associated with nephrotic syndrome is observed.

[Cutaneous manifestations of mediterranean periodic disease. Concerning an observation. Review of the literature (author's transl)].

[Article in French]

Devaux J, Belaube P, Garcin G, Gamby T, Privat Y.

Méditerranean Periodic Disease is frequently encountered in non-aschenazic Jews and in Armenians. Aside from the classic triad of pseudo-palustral febrile crises, paroxysms of abdominal and articular pain, and a biological syndrome of inflammation; cutaneous manifestations were noted in 25 to 35% of the cases according to various authors. The most commonly encountered lesions consisted of erysipiel-like plaques and subcutaneous nodules. We observed the case of a 47 years old Armenian male, afflicted with Mediterranean Periodic Disease for 30 years in which the dermatologic symptoms are quite classic aside from a vitiligo having progressively appeared since 15 years. Possibly a coincidental association, but to the best of our knowledge, which has not as yet been reported.

Circulating immune complexes in recurrent polyserositis. (Familial mediterranean fever, periodic disease).

Levy M, Ehrenfeld M, Levo Y, Fischel R, Zlotnick A, Eliakim M.

Increased levels of circulating immune complexes (CIC) were demonstrated by the Clq binding assay in 22 (27%) out of 81 patients with recurrent polyserositis. The prevalence of increased CIC was significantly higher in Jewish patients of North African origin (42%) than in subjects of other ethnic groups (6%). North African patients also manifested an increased familial incidence, earlier onset of symptoms and a higher frequency of arthritis. There was no correlation between increased CIC levels and disease activity. These findings suggest that the immune response of North African patients differs from that of subjects of other ethnic groups and that this difference is possibly genetically determined.

Colchicine kinetics in patients with familial Mediterranean fever.

Halkin H, Dany S, Greenwald M, Shnaps Y, Tirosh M.

Serum colchicine levels were determined by radioimmunoassay after a 1-mg bolus injected intravenously in 4 patients with familial Mediterranean fever and in 6 normal subjects. Mean elimination half-life ( $t_{1/2}$ ) ( $\pm$  SEM) was  $157 \pm 20$  min in the patients and  $65 \pm 15$  min in the normal subjects ( $p$  less than 0.005). Total clearance was  $239 \pm 50$  ml/min in the patients and  $601 \pm 155$  ml/min in the normal subjects ( $p$  less than 0.05). Volume of distribution ( $V_d$ ) was  $76 \pm 16$  and  $49 \pm 91$  and did not differ significantly. In 8 patients receiving colchicine prophylactically with good clinical response, serum colchicine ranged from 0.3 to 2.4 ng/ml after daily doses of 1 mg orally. In 2 responding patients 2-mg doses orally induced levels from 4 to 10 ng/ml, and in one (a nonresponder) a 3-mg dose induced levels of 7.5 to 13 ng/ml. Of 3 patients receiving 2 mg daily with unsatisfactory clinical responses, serum levels were not detectable in one and in the low range of 1.5 to 5.4 ng/ml in the others. It is suggested that lack of response to colchicine orally in some nonresponders could result from inadequate absorption or altered disposition of colchicine.

Absence of interferon activity during acute attacks of familial Mediterranean fever.

Aderka D, Pras M, Bino T, Rosenberg H, Weinberger A, Pinkhas J.

The pharmacokinetics of interferon, the symptoms caused by its administration, the decreased prevalence of viral diseases in FMF patients and the fact that colchicine, the drug of choice in the prevention of FMF attacks is an interferon antagonist, raised the question whether interferon may have a role in the pathogenesis of FMF attacks. An interferon activity was not detected in sera obtained at the height of FMF attacks in 8 patients, six of them under colchicine treatment. It is possible that the interferon activity has to be searched at the very beginning of FMF attacks, since at their height it already disappeared from the serum, while the symptoms of the attack are further mediated by other interferon-induced lymphokines.

[Amyloidosis. II. Current pathogenetic and clinico-nosographic aspects].

[Article in Italian]

Lovisetto P, Frascisco M, Gilardi E, Marchi L, Mairano D.

Amyloidosis is due to the overproduction of a precursor protein and its conversion into products capable of polymerisation into fibrils. The primary form, or that associated with multiple myeloma or Waldenström's macroglobulinaemia, marked by the presence of protein AL, includes the overproduction of Ig light chains followed by conversion on the part of lysosome enzymes. The forms can thus be classified as immunoproliferative diseases (plasma-cell dyscrasias). Secondary amyloidosis is primarily associated with

neoplasia or chronic inflammation. Its biochemical label is the AA protein. Initially, there is overproduction of protein SAA, while the formation of AA-amyloid fibrils may theoretically be attributed to a variety of factors: changes in the amount of circulating SAA, the presence of amyloidogenic SAA, variations in the activity of SAA catabolic systems, insufficient removal of accumulated fibrils. The way in which the immunocompetent system intervenes is a controversial subject. Lesser forms of amyloidosis are known in which there are local deposits of amyloid: AL-amyloidosis, amyloidomas. In some forms, the features of systemic accumulation are maintained, but only one organ is primarily involved. They are rarely of clinical significance (e.g. senile amyloidosis). Current biochemical techniques enable a clinical and nosographic distinction to be drawn between an Ig (AL)-amyloidosis and non-Ig (AA, AL and AS) forms.

AA protein in a case of "primary" or "idiopathic" amyloidosis.

Pras M, Zaretzky J, Frangione B, Franklin EC.

Amyloidosis constitutes a group of diseases in which extracellular fibrils with a characteristic appearance are deposited in a variety of tissues. Several different proteins have been identified as the major subunits of the fibrils. In the primary and myeloma-associated type, the amyloid fibrils consist of immunoglobulin light chain fragments, whereas in the secondary type and the amyloid associated with familial Mediterranean fever the major component is the AA protein. In this report a 21 year old man of Yemenite extraction with no underlying disease and no family history of amyloidosis was found to have amyloid deposits composed of AA protein. Although clinically this might be classified as primary amyloidosis, the absence of light chain fragments makes that diagnosis unlikely. Therefore, it is suggested that whenever possible the clinical classification be supplemented by a description of the biochemical nature of the fibrils.

Familial Mediterranean fever: report of a large family, review of the literature, and discussion of the frequency of amyloidosis.

Meyerhoff J.

Familial Mediterranean Fever is a rare disease which usually begins in childhood and occurs primarily among persons of Mediterranean ancestry. It is characterized by short, self-limited, febrile episodes that may occur alone or with inflammation of serosal surfaces. Some individuals may exhibit an erysipilas-like erythema, almost always on the lower extremities. These attacks are associated with considerable morbidity and may lead to unnecessary surgery, but this disease does not appear to be associated with an increased mortality, except in those individuals who develop amyloid nephropathy. For those patients death usually occurs below the age of 40 years although longer survival has been reported. This complication occurs frequently in Turks and Sephardic Jews, but only rarely in individuals of other ethnic origins. A rare patient may develop destructive changes in a joint that has been subjected to a protracted attack. Recent data indicate that either daily or intermittent colchicine will effectively reduce the severity and frequency of attacks; in some individuals these regimens have induced a complete remission. Preliminary data suggest that colchicine may also reduce the degree of nephropathy associated with amyloidosis. Diagnosis of this disease depends, in the absence of any objective markers, on the recognition of the symptoms in a susceptible individual. Despite the name of the disease, it may occur without a family history and in non-Mediterranean individuals. Most of the attacks, however, are associated with a rise in temperature although the fever spike may be more transient than the associated symptoms. Any individual with suggestive symptoms who is significantly disabled by the attacks should have a therapeutic trial of colchicine.

Dialysis requirements in Israel.

Eliahou HE, Iaina A.

Chronic dialysis is available in Israel to almost all patients who require it. During the last four years the mean number of new patients/million population per year was 44.5 (range, 39.5 to 48.6), excluding patients with systemic diseases such as diabetes mellitus and lupus erythematosus. This number is close to that

estimated in a previous study--53/million per year for the years 1965-66--and the discrepancy is probably methodological in nature. The stage of equilibrium for Israel, when the net gain in patients per year approaches zero, as forecast by the European Dialysis and Transplant Association, will be reached in 1983 with 261 dialysis patients/million population. At present, the number is about 171. Inadequately treated hypertension was found to considerably affect long-term survival.

Amyloid goitre in familial Mediterranean fever.

Danovitch GM, Le Roith D, Sikuler SE, Straus R.

Three patients known to suffer from familial Mediterranean fever (FMF), systemic amyloidosis and chronic renal failure developed large amyloid goitres. Amyloid goitre is an extremely rare complication of systemic amyloidosis not previously described in FMF. The clinical and pathological features of these three cases were similar to those previously described in amyloid goitre. In two of the patients abnormalities in thyroid function were consistent with those documented in chronic renal failure. There was evidence of hypothyroidism in a third patient. There was no evidence of amyloid induced dysfunction of other endocrine organs.

The potassium permanganate method. A reliable method for differentiating amyloid AA from other forms of amyloid in routine laboratory practice.

van Rijswijk MH, van Heusden CW.

Alterations in affinity of amyloid for Congo red after incubation of tissue sections with potassium permanganate, as described by Wright et al, were studied. The affinity of amyloid for Congo red after incubation with potassium permanganate did not change in patients with myeloma-associated amyloidosis, familial amyloidotic polyneuropathy, medullary carcinoma of the thyroid,

pancreatic island amyloid, and cerebral amyloidosis. Affinity for Congo red was lost after incubation with potassium permanganate in tissue sections from patients with secondary amyloidosis and amyloidosis complicating familial Mediterranean fever (consisting of amyloid AA). Patients with primary amyloidosis could be divided into two groups, one with potassium-permanganate--sensitive and one with potassium-permanganate--resistant amyloid deposits. These two groups correlated with the clinical classification in typical organ distribution (presenting with nephropathy) and atypical organ distribution (presenting with cardiomyopathy, nephropathy, and glossopathy) and the expected presence of amyloid AA or amyloid AL. Potassium permanganate sensitivity seems to be restricted to amyloid AA. The potassium permanganate method can be important in dividing the major forms of generalized amyloidosis in AA amyloid and non-AA amyloid. This can be used for differentiating early stages of the disease and cases otherwise difficult to classify. It is important to define patient groups properly, especially in evaluating the effect of therapeutic measures. (Am J Pathol 97:43--58, 1979).

Renal transplantation in the amyloidosis of familial Mediterranean fever.  
Experience in ten cases.

Jacob ET, Bar-Nathan N, Shapira Z, Gafni J.

Ten patients with familial Mediterranean fever (FMF) and histologically confirmed amyloidosis received cadaver kidney transplants for treatment of terminal renal disease. Colchicine, 1 mg daily, was included in the routine postoperative regimen from 1974 for amyloidotic patients. Graft and patient survival were compared with ten nonamyloidotic recipients of renal grafts matched for age, sex, type of allograft, and HLA compatibility. In the FMF group, five of ten grafts have survived from 20 to 64 months; in the control group, six of ten. While only recipients with functioning grafts survived in the FMF group, patient survival in the control group is eight of ten after one year. In all five FMF survivors, graft function is satisfactory, proteinuria is absent, and blood creatinine

levels are normal. Amyloid involvement of an allograft was documented 16 months after transplantation in the only patient whose maintenance colchicine dosage had been reduced to 0.5 mg daily.

Amyloidosis and periodic peritonitis (familial mediterranean Fever).

Bakir F(1), Murtadha M, Issa N.

Author information:

(1)Department of Medicine, College of Medicine, University of Baghdad and Medical City, Baghdad, Iraq.

Some reports indicate that amyloidosis is a rare occurrence in persons with periodic peritonitis (familial Mediterranean fever), while others seem to show it occurs relatively frequently. Two cases were seen among 80 patients in Iraq. Twenty-one consecutive rectal biopsies were negative for amyloidosis. The variation in reported incidence is partly real and partly apparent. Amyloidosis occurs frequently in certain ethnic groups, and it is possible that there are two traits, one for periodic peritonitis and the other for amyloidosis.

The seronegative spondyloarthropathies of childhood.

Schaller JG.

Most chronic arthritis in childhood is seronegative. Within "JRA" several distinct subgroups exist: one of these (pauciarticular disease type II) affects predominantly boys more than 8 years of age. It is clearly associated with sacroiliitis, HLA-B27, family history of spondyloarthropathy, and subsequent ankylosing spondylitis in an as yet underfined percentage of patients. This type of disease is probably classified appropriately with the spondyloarthropathies, although patients often may fulfill diagnostic criteria for "JRA" in the first years of their disease, and accounts for about 15% of "JRA." The other JRA subgroups do not appear to have features of seronegative spondyloarthropathy. Reiter's syndrome and psoriatic arthritis exist in children, but appear to be rare. The arthritis of inflammatory bowel disease in childhood resembles that in adulthood. The recognition of spondyloarthropathy in children, particularly the sizable group of patients with "JRA" pauciarticular disease type II, is of practical importance to permit proper therapy, follow-up and prevention of deformity.

Periodic peritonitis. Present management and future prospects.

Bakir F.

Thirty-three patients with periodic peritonitis were treated with colchicine for 863 patient-months of observation (average, 27 months). There is a personal optimum dose, and the daily requirement varies at 1 or 1.5 mg. All patients responded to treatment. Episodes were precipitated in all patients who stopped their medications. No side effects were noticed. Four normal full-term infants were born to patients taking colchicine during the study.

Multiple sclerosis: the rational basis for treatment with colchicine and evening primrose oil.

Horrobin DF.

Multiple sclerosis (MS) is a disease with no known treatment. In view of this and of its distressing nature patients are attracted by any new concepts. As a reaction to this neurologists are sometimes excessively sceptical and fail to consider new approaches seriously. Recent attempts have been made to treat multiple sclerosis with polyunsaturated fatty acids and with colchicine. This approach is not arbitrary and is firmly grounded in fundamental basic scientific concepts. In patients with multiple sclerosis there is evidence of both an abnormality in essential fatty acid metabolism and an abnormality in lymphocyte function. It is now apparent that the fatty acid abnormality may cause the lymphocyte abnormality and that both may be improved by dietary manipulation. There is also evidence that the demyelination may be associated with recurrent inflammatory episodes and with entry of calcium into the cytoplasm. In vitro colchicine has been shown to have actions compatible with regulation of cytoplasmic calcium and in two diseases characterised by intermittent inflammatory episodes (Behçets syndrome and familial Mediterranean fever) it has been found to prevent or to reduce the severity of such episodes. Preliminary results suggest that combined therapy with evening primrose oil and colchicine may be of considerable value.

Arthritis of the temporomandibular joints.

Marbach JJ.

The most common disease of the temporomandibular joint (TMJ) is osteoarthritis. Rheumatoid arthritis and psoriatic arthritis may also involve this joint. Other diseases that may occasionally affect the TMJ include familial Mediterranean fever, systemic lupus erythematosus, gout, Sjögren's syndrome and infectious

arthritis. Many cases of TMJ syndrome are labeled as idiopathic facial pain syndrome, a category that probably represents a number of different entities. The role of dental malocclusion has been greatly overemphasized in the past.

Temporomandibular joint synovitis with effusion in familial Mediterranean fever.

Cooksey DE, Girard K.

A unique case of TMJ synovitis with effusion associated with FMF is described. This effusion was treated by aspiration, once the diagnosis was established. It is believed that aspiration is the most effective way of avoiding aseptic necrosis and should be carried out as soon as the diagnosis is established. The posterior portion of the compartment is easier to find with the aspirating needle. The use of a corticosteroid in conjunction with aspiration is of questionable benefit in FMF but may play a more important part in effusion from other causes.

[Neurologic manifestations of periodic disease].

[Article in Russian]

Fedorova ML.

Results of comprehensive neurological examinations of 4 patients suffering from periodic disease have shown that the latter may be not only a disease entity, but also a syndrome characterizing some organic affections of the brain. The abdominal and other crises of the periodic disease included cerebrovascular disturbances which manifested hemipareses, syncopes, and migraine-like cephalgia. EEG and REG examinations have revealed dysfunction of the mesodiencephalic structures which, probably, underlies the pathogenesis of the periodic disease. The knowledge of the formerly almost unexplored neurological manifestations of the periodic disease will contribute to improvement of the therapy of this rare ailment.

Phagocyte functions in familial Mediterranean fever.

Bar-Eli M, Levy M, Ehrenfeld M, Eliakim M, Gallily R.

Monocytes derived from peripheral blood of patients with familial Mediterranean fever (F.M.F.) demonstrated lower phagocytic capacity for *Shigella flexneri* and depressed bactericidal activity against *S. albus* when compared to monocytes from healthy individuals. Treatment of patients with colchicine did not alter these functions. On the other hand, chemokinesis of PMN of F.M.F. patients was enhanced especially during attacks. Colchicine treatment decreased significantly the PMN chemotactic migration.

Long-term colchicine therapy of familial Mediterranean fever.

Lehman TJ, Peters RS, Hanson V, Schwabe A.

Familial Mediterranean fever is a disorder characterized by recurrent fever and polyserositis. Continuous prophylactic colchicine therapy has been effective in suppressing attacks in affected adults. From 30 children with FMF, 14 were selected for colchicine therapy. Eight children continued prophylactic colchicine therapy for 29 months (mean) and experienced a marked decrease in the frequency of attacks. Six other children did not comply with the treatment regimen. Although no deleterious side effects were noted, the safety of long-term colchicine administration in childhood is unknown.

[Article in Italian]

Savi M, Asinari G, Gaudio V, Neri TM.

Immunological disturbances in FMF have not been previously reported. In present case, positivity for RA and Waaler-Rose test as well as increase of plasma IgG and IgM immunoglobulins during an episode of acute peritonitis is described. These findings, in association with very high levels of urinary FDP, suggest an autoimmune pathogenesis of the disease.

Unusual immunologic findings in familial Mediterranean fever.

Savi M, Asinari G, Gaudiano V, Olivetti G, Neri TM.

Familial Mediterranean fever (FMF) is an inherited disease of unknown etiology. We report a case in which, during an acute febrile attack, rheumatoid factor and immunoglobulin levels rose, and the levels of complement components fell. The level of urinary fibrinogen degradation products also increased, and all results of tests returned to normal at the end of the acute attack. This suggests that an immunologic phenomenon may play a substantial role in the etiology of FMF.

HLA-B27-negative sacroiliitis: a manifestation of familial Mediterranean fever in childhood.

Lehman TJ, Hanson V, Kornreich H, Peters RS, Schwabe AD.

Familial Mediterranean fever is a polysystemic disease seen most frequently in persons of Mediterranean ancestry. Arthritis is one of the common manifestations. Both symptomatic and asymptomatic sacroiliitis have been reported in adults. We report on two children with familial Mediterranean fever with radiographic abnormalities similar to those described in adults. Although sacroiliitis is strongly correlated with the presence of HLA-B27 in most arthropathies, these children were HLA-B27-negative. The diagnosis of familial Mediterranean fever was delayed in both patients because the association of sacroiliitis with familial Mediterranean fever in childhood was not recognized.

[HL-A and periodic disease].

[Article in French]

Chaquat Y, Tormen JP, Hors J, Dausset J.

In the department of Professor Dausset 41 cases of periodic disease referred by 7 clinics in Paris were examined. Two studies were carried out. A series of 31 not related patients was tested with 30 locus A and B antigen and the frequencies observed were compared with the frequencies in a French and Yemenite Jew population. No statistically valid increase of an HLA gene indicative of a relationship between periodic disease and HLA was found. In 5 cases of amyloidosis HLA A 28 was present and it is possible that this gene is related to the amyloid complication. A family study on 12 families, 7 of which included at least 2 affected children, confirmed the recessive hereditary character of the disease, but not in relation to the HLA system. A parallel clinical study was made, which corroborated the previous studies as regards the frequency of clinical signs. The therapeutic study proved the value of long-term colchicine treatment with or without antihistaminics. The frequency of pain and abdominal crises was reduced, but there was little effect on the articular manifestations.

An investigation of the complement system in patients with periodic disease (results from 29 cases).

Hartmann L, Lego-Crescioni A, Brecy H, Ollier MP, Herreman G, Mouthon JM, Godeau P.

The complement system was investigated in 29 patients suffering from authentic periodic disease. A statistically significant increase in C4, also in total complement and C3 could be demonstrated. It is possible that the increase in C4 was due to the macrophages which are always present in the infiltrates of periodic disease. This biological observation is of clear practical importance for the diagnosis of the condition both before and after colchicine therapy.

Prolonged colchicine treatment in four patients with amyloidosis.

Ravid M, Robson M, Kedar I.

The natural clinical course of four patients with systemic amyloidosis was favourably altered by continuous colchicine therapy. One patient had primary amyloidosis, and the other three suffered from amyloidosis of familial Mediterranean fever. All had a nephrotic syndrome, and one showed features of intestinal malabsorption. The institution of colchicine therapy was followed by a gradual remission of the nephrotic syndrome, a rise of serum albumin to normal values, a slight improvement of renal function, and regression of the intestinal malabsorption. This pattern has remained steady during an observation period of 30 months.

Renal amyloidosis: immunofluorescence and electron microscopy studies.

Müftüoğlu AU, Erben T, Harman M, Karayel T, Gürsoy E, Tahsinoğlu M.

Renal biopsy specimens of 15 patients with renal amyloidosis were studied by immunofluorescence microscopy. The amyloidosis was associated with chronic pulmonary disease in five, rheumatoid arthritis in one, chronic lymphocytic leukemia in one, and familial Mediterranean fever in five patients. In three patients no associated condition could be determined although the pattern of organ involvement resembled that of secondary amyloidosis. IgG and complement (C3) were demonstrated in the glomerular capillary walls and in the mesangium in all patients. The pattern of the deposits was neither granular nor linear. Ig and C3 appeared as large confluent masses or broad ribbon-like segments. In the six patients studied by electron microscopy the fibrillary formation of amyloid was seen in the mesangium and the glomerular capillary walls corresponding to the Ig deposits. No immunofluorescence or ultrastructural differences were observed among the patients with secondary, inherited and leukemia-associated amyloidosis included in this study.

5729. Am J Med Sci. 1977 Nov-Dec;274(3):265-70.

Monocyte function in familial Mediterranean fever.

Bar-Eli M, Gallily R, Levy M, Eliakim M.

Monocytes derived from the peripheral blood of patients with familial Mediterranean fever (FMF) demonstrated a consistently lower phagocytic capacity (38-44%) for 125I-labelled *Shigella flexneri* when compared to monocytes from healthy subjects. Phagocytosis of both viable and killed *Staphylococcus albus* was similar in patients and controls. However, FMF monocytes had a two- to eight-fold depressed bactericidal capacity against *S. albus* in comparison to normal monocytes. Acid phosphatase and beta-glucuronidase monocyte activities were similar in patients and controls. It is suggested that the defects in monocyte function may be of importance in the pathogenesis of FMF. Colchicine had no effect on any of the indices studied.

[HLA markers and periodic disease [familial Mediterranean fever (F.M.F.)]  
(author's transl)].

[Article in French]

Chaouat Y, Tormen JP, Godeau P, Camus JP, Kahn MF, Ryckewaert A, Laula JE, Menkes CJ, Schmid M, Hors J.

Thirty-one unrelated patients, 15-52 years old, were typed by microlymphocytotoxicity for 27 alleles of the HLA system. In addition, 12 families including 1 or more patient were also analysed. This criteria for diagnosis were those of Sohar et al. (Am. Intern. Med., 1967, 43, 227-253). All patients were of Israelite-Sephardin origin except two (Armenian and French); they were from North-Africa (Tunisia, Morocco and Algeria) and Israël. The results were compared to the antigen frequencies of 3 reference normal populations. The frequencies of the studied alleles do not differ from those of controls, except for HL-A28 and B14 slightly increased when compared to the normal frequencies. The study of 7 families with at least two sibs suffering from FMF shows a random distribution of the genotypes : 2 HLA identical, 6 different and 10 haploidentical diseased sibs. This distribution differs significantly ( $p$  less than 0.01) from that expected in the case of a recessive inheritance. These data do not support the hypothesis of a linkage between genes controlling FMF and HLA genes.

A cytogenic evaluation of long-term colchicine therapy in the treatment of Familial Mediterranean fever (FMF).

Cohen MM, Levy M, Eliakim M.

Thirty-eight patients suffering from Familial Mediterranean Fever (FMF) and undergoing colchicine therapy for periods varying from one week to three years were examined cytogenetically. Preparations were derived from short-term lymphocyte cultures; mitotic rate, percent tetraploidy, and chromosome breakage rates were determined. Twenty-one patients were examined prior to treatment, 22 during treatment and 5 both before and during treatment. No statistically significant differences were observed in the parameters studied between ten controls and the patient groups. An in vitro experiment indicated a direct correlation between increased colchicine concentration and mitotic rate. However, tetraploidy or chromosome damage showed no such association with colchicine concentration. Among the patient group, pregnancy occurred in four patients while under treatment; three pregnancies resulted in the birth of normal children while the fourth has not yet been completed. In one pregnancy, cultured fetal amniotic fluid cells demonstrated no effect of colchicine on the cytogenetic parameters investigated. These results indicate no untoward effects on long-term colchicine treatment in FMF with respect to fertility, teratogenicity and chromosomal damage.

The relationship of a serum protein, C1t, to a common nonfibrillar constituent of amyloid (P component) as revealed by immunohistochemical studies.

Katz A, Weicker-Thorne J, Painter RH.

C1t, a serum protein isolated by affinity chromatography on Sepharose bears a remarkable ultrastructural and physicochemical resemblance to P component, a common constituent of amyloid. This study provides further evidence for their similarity by the demonstration of immunologic identity and by the presence of C1t in amyloid deposits of various types using immunoperoxidase and immunofluorescent techniques. In addition, subcomponents of C1, as well as C3, C4, C5, and properdin, were demonstrated to a limited extent. The possible role of C1t/P component in amyloidogenesis is discussed in the light of recent

advances in our knowledge of the nature of amyloid substance.

Colchicine suppression of corneal healing after strabismus surgery.

Biedner BZ, Rothkoff L, Friedman L, Geltman C.

Two patients who had previously undergone uneventful operations for strabismus showed healing of corneal dellen and erosion after withdrawal of colchicine therapy. It is suggested that the exhibition of colchicine therapy for familial Mediterranean fever in these two cases was responsible for initial persistence of these two postoperative complications.

Familial Mediterranean fever. Recent advances in pathogenesis and management.

[No authors listed]

The success of colchicine therapy in the management of familial Mediterranean fever has provided new direction to investigations into the pathogenesis of this disease. Examination of HLA antigen frequencies in 53 patients with familial Mediterranean fever and appropriate controls, as well as various immunologic studies have yielded no significant differences. However, B lymphocyte typing and assays for immune complexes, lymphokines and prostaglandins may be of potential interest. Preliminary studies indicate that leukocytes of patients with familial Mediterranean fever release increased amounts of lysozyme ( $P < 0.01$ ), when subjected to high temperatures, and of both lysozyme and myeloperoxidase at low osmotic concentrations. The known and potential effects of colchicine on leukocyte and cellular metabolism, and the current status of colchicine prophylaxis are reviewed. In patients receiving an optimum colchicine dose of 1.5 to 1.8 mg per day, side effects have been minimal and the frequency of attacks has been decreased significantly.

Amyloid deposition in a renal transplant in familial Mediterranean fever.

Benson MD, Skinner M, Cohen AS.

A patient with familial Mediterranean fever and amyloidosis who received a cadaver renal transplant 6 1/2 years ago was studied to determine the relation of the serum precursor of secondary amyloid (SAA) to the clinical course and to the deposition of amyloid in the transplant. Amyloid fibrils extracted from the patient's kidneys contained protein AA as a major constituent, which identified the amyloid as secondary. Protein AA antiserum was used in an indirect immunofluorescent technique to stain amyloid deposits in sections of the original kidney. A renal biopsy at 2 years showed no amyloid, but a renal biopsy at 4 years showed amyloid. Serum levels of SAA from 3 years before transplant to 6 years after transplant were elevated throughout most of the course.

[Amyloidosis].

[Article in German]

Franklin EC.

Recent studies have clearly indicated that amyloid is a generic term which includes a number of different substances, all of which have a beta-pleated sheet structure and a characteristic fibrillar appearance in the electron microscope. The most common types are made of immunoglobulin light chain (AL) fragments in the primary and myeloma-associated type, and of the AA protein in the secondary

and some familial forms. It seems probable that other localized types are composed of prohormones or other tissue proteins. In systemic amyloidosis, the fibrils seem to be derived from a soluble circulating precursor; immunoglobulin light chains give rise to AL, and the SAA protein, which behaves as an acute phase reactant yields AA, presumably by proteolysis. It is not known whether the disease is due to overproduction or a defect in degradation. Though effective therapeutic agents are still lacking, colchicine has proved useful in preventing or ameliorating the amyloid in Familial Mediterranean Fever and in several experimental forms of the disease. It deserves careful study as a possible therapeutic agent on other types of amyloidosis.

Protracted arthritis in familial Mediterranean fever.

Sneh E, Pras M, Michaeli D, Shanin N, Gafni J.

A review of the files of familial Mediterranean fever (FMF) confirmed the rarity of patients suffering protracted arthritic attacks and the propensity of the joints, in general, to recover. While 70% of those afflicted suffered bouts of synovitis, only 57 patients (5% of the FMF-population) experienced protracted attacks involving a total of 84 joints, 36 of them knees and 25 hips. Functional and, usually, anatomical integrity was regained in all but 27 joints. Of the 27

joints producing residual incapacity, 21 were hips. Seven hips showed roentgenologically typical aseptic necrosis of the femoral head and 14 only sclerosis and narrowing of the joint space. Eight hips eventually required total prosthetic replacement. We suggest that the poor prognosis of the hip, in contrast to other joints affected by protracted FMF-arthritis, is related not directly to the metabolic aberration underlying the disease but to attenuation of the arterial blood supply of the femoral head by synovial exudation. Early aspiration of exudate could alter the prognosis by preventing the complication of aseptic necrosis.

Immunochemical studies on the nature of the serum component (SAA) related to secondary amyloidosis.

Ignaczak TF, Sipe JD, Linke FP, Glenner GG.

The relative occurrence of the amyloid-related serum protein SAA in various disease states and in healthy subjects has been compared by both solid phase radioimmunoassay ((RIA) and immunodiffusion techniques which employ antibodies to purified amyloid fibril protein AA of homogeneous size and charge. SAA levels were elevated above normal in certain categories of neoplastic, inflammatory, and infectious diseases as well as in secondary amyloidosis. The lowest median value, 8 ng./ml., was observed for approximately 150 normal sera, with no age-related increase in subjects ranging in age from 16 to 70 years. The results are consistent with several recent observations that SAA is normal acute phase reactant, and hence the RIA for SAA has no prognostic or diagnostic significance for secondary amyloidosis. The sensitivity of RIA for the detection of SAA is lower than would be expected when AA cross-reactivity values for sera are correlated with their reaction with anti-AA antibodies in immunodiffusion. This observation, along with others reported elsewhere suggests that those determinants which cross-react with anti-AA antibodies are relatively hidden in native SAA. Myeloma sera were less reactive than other groups of pathologic sera in immunodiffusion, although they were similar to other patients' sera when analyzed by RIA. Antibodies to highly purified AA were also used to investigate

the structure of SAA by a double-antibody immunoprecipitation method. Precipitated SAA was partially dissociated during sodium dodecyl sulfate-urea-polyacrylamide gel electrophoresis to a 12,500 molecular weight moiety designated, SAAL. Multiple radiolabeled species of molecular weight intermediate to SAA and SAAL were also detected and appeared to represent incompletely dissociated SAA. The results suggest the SAA is an aggregate of several SAAL chains.

Renal vein thrombosis as the major cause of renal failure in familial Mediterranean fever.

Reuben A, Hirsch M, Berlyne GM.

Eighteen out of 57 patients (31.6 per cent) suffering from Familial Mediterranean Fever (FMF) were found to have the nephrotic syndrome, histologically proven amyloidosis and progressive renal failure. In 14 cases renal function deteriorated rapidly after the first appearance of significant proteinuria, and 12 cases (66.7 per cent) required regular haemodialysis. Seven of these patients, seen in the early stages of renal impairment, were subsequently diagnosed clinically as probably having developed renal vein thrombosis. There was radiological proof of intrarenal or major renal vein occlusion in five which in one patient progressed to inferior vena cava obstruction. Treatment with heparin, plasminogen activators and fibrinolytic agents was disappointing although renal function has stabilized in one patient on long term oral anticoagulant

therapy. It is suggested that renal vein thrombosis is common in FMF with renal amyloidosis and usually causes rapid deterioration of function and irreversible renal failure requiring dialysis. Renal phlebography may delineate clot in the main renal veins or indicate areas of reduced blood flow due to thromboses in intrarenal venules. Treatment is only partially satisfactory but there is some evidence to suggest that renal phlebography should be undertaken promptly when renal function begins to fall followed by anticoagulant therapy to prevent further thromboembolic complications.

Efficacy of intermittent colchicine therapy in familial Mediterranean fever.

Wright DG, Wolff SM, Fauci AS, Alling DW.

Nine patients with familial Mediterranean fever (FMF) were admitted to a controlled, double-blind trial to determine if there are patients with this disease who are able to abort their acute episodes of pain and fever with short courses of colchicine taken at the onset of attacks. Five patients completed their treatment assignments, and colchicine was significantly effective in aborting the attacks of three but was ineffective in two. The remaining four patients could not be assessed because of insufficient numbers of courses. During the 10 months of the trial, 28 courses of colchicine and 31 of placebo were taken during the early stages of FMF attacks. Twenty-one (75%) colchicine courses were followed by attacks considered to have been aborted, compared to only three (10%) placebo courses. This trial shows that patients can recognize the prodrome of their FMF attacks and that some patients can consistently abort their attacks with short courses of colchicine taken at the very onset of symptoms.

Constrictive pericarditis in familial Mediterranean fever.

Zemer D, Cabili S, Revach M, Shahin N.

Fibrosing peritonitis and constrictive pericarditis occurred in an 18-year-old patient who manifested the classic features of familial Mediterranean fever (FMF). Pericardial calcification had been present in chest X-rays taken when the patient was five years old. Intermittent intestinal obstruction and congestive heart failure were relieved by appropriate surgical intervention, but attacks of FMF subsided only after colchicine therapy. This is the first instance of nonuremic pericarditis in our experience with over 1,000 FMF patients. Critical analysis of the reported cases in which pericarditis was attributed to FMF strengthens our belief that the occurrence of pericarditis in a patient with FMF probably represents a fortuitous intercurrent disease.

Probability of survival in hypertensive and nonhypertensive patients on maintenance hemodialysis.

Eliahou HE, Iaina A, Reisin E, Shapira J.

The actuarial survival rate for 58 unselected patients who entered a program of maintenance hemodialysis and transplantation was found to be 43.0 +/- 8.3 (SE)% for the six-year period of observation. The survival rate was considerably lower in hypertensive patients as well as in patients with familial Mediterranean fever with amyloidosis, all of whom were nonhypertensive. When the patients with familial Mediterranean fever were excluded from the non-hypertensive group, the expected survival rate of this group became greater than that of the hypertensive group, the difference being about 25% in five years and about 50% in six years. This difference in the survival rate approaches that between normotensive subjects and untreated severely hypertensive patients in the general population. It is concluded that hypertension is a serious limiting factor in the survival of patients on chronic hemodialysis, and that the difference in survival between the hypertensive and the non-hypertensive patients is attributable to hypertension.

[Gastrointestinal amyloidosis].

[Article in French]

Lévy A, Lender M.

A series of 29 cases of amyloidosis of the alimentary tract is reported. Five cases (17%) were primary amyloidosis; 14 cases (48%) were amyloidosis secondary to other diseases (such as chronic inflammatory and neoplastic diseases); 10 cases (35%) were amyloidosis of the heredo-familial type connected with Familial Mediterranean Fever. In 23 patients (79%) the diagnosis was established by biopsies, and in 6 more cases on autopsy. Gastrointestinal involvement was found in all age groups. Gastro-enterologic complications observed in the present series include: diarrhea, malabsorption, ileus and gastrointestinal bleeding. In addition other conditions such as jaundice (3 cases), esophagitis and acute hemorrhagic pancreatitis were observed. In 22 patients proteinuria was observed

and in 13 patients the nephrotic syndrome. Among 17 patients, in 11 the clinical picture before death was that of terminal renal failure. The survival after diagnosis among 14 patients reached 4 years in 9 cases, and 19 years in one case. The diagnostic value of the rectal biopsy is emphasized.

Effect of prophylactic colchicine therapy on leukocyte function in patients with familial Mediterranean fever.

Dinareello CA, Chusid MJ, Fauci AS, Gallin JJ, Dale DC, Wolff SM.

Patients with familial Mediterranean fever (FMF) who were part of a double-blind trial of daily colchicine as prophylaxis for their disease had leukocyte functions studied while receiving colchicine or placebo. Leukocytes taken from these patients while on prophylactic doses of colchicine produced normal quantities of leukocytic pyrogen, ingested bacteria normally, and migrated

normally in chemotactic chambers. In addition these patients had normal numbers of circulating T and B lymphocytes as well as normal blastogenic responses of their peripheral lymphocytes to mitogenic stimuli. The patients on colchicine, however, had significantly fewer neutrophils and monocytes accumulating at skin-window sites 24 hours after the initial abrasion. Because the early phase of the skin-window response was normal in these patients, the decreased late response may be related to a failure to amplify the initial inflammatory reaction. The reduced capacity to generate a normal inflammatory response may account for the failure of these patients to develop full attacks while taking colchicine.

[Periodic disease (familial paroxysmal polyseritis). 52 cases].

[Article in French]

Bitar E, Naffah J, Nasr W, Khoury K.

On the basis of well defined diagnostic criteria, the authors conclude that periodic disease affects males in particular. It commences before the age of 20 years in 80 percent of cases. In particular it occurs in Armenian and Shiite communities. Its evolution is normally benign ; amyloidosis is found in only 8 percent of cases. Joint manifestations are found in 48 percent of cases and may take on different aspects and occur in several different sites : myalgia or arthralgia, monoarthritis, oligoarthritis, polyarthritis, neck or sacroiliac pain. The authors have not noted prolonged peripheral joint episodes. No cases of amyloidosis were diagnosed before the appearance of the clinical signs of the disease. An autosomal, dominant heredity with incomplete penetration seems to be the most likely hypothesis.

5769. Arch Intern Med. 1976 Apr;136(4):449-51.

Dialysis in renal failure caused by amyloidosis of familial Mediterranean fever.  
A report of ten cases.

Ari JB, Zlotnik M, Oren A, Berlyne GM.

Ten unselected patients with renal failure caused by amyloidosis associated with FMF were treated by regular hemodialysis therapy from 1969 to 1974. They were compared to age-matched control patients treated by hemodialysis in the same unit during the same period, who were suffering from renal failure caused by other disease. Mortality in FMF and control patients was 30% with no significant difference in mean survival, shunt life, serum albumin or hemoglobin levels between the two groups. There was no significant difference in blood pressure measured predialysis or postdialysis in patients with FMF or in controls. The synthetic ACTH stimulation test showed adequate or elevated adrenocortical function. It is concluded that life can be prolonged up to 3 1/2 years by hemodialysis in renal failure caused by amyloidosis complicating FMF, and that renal failure caused by FMF is not a contraindication to regular hemodialysis therapy.

In two Turkish female patients, aged 14 and 29 years, with familial mediterranean fever amyloidosis of the perireticular type was found. The disease was characterized by feverish bouts, abdominal colics, and joint involvements. The younger patient had the diagnosis confirmed at an early stage by renal biopsy, and under heparin and azathioprine the clinical signs, especially the nephrotic syndrome, regressed over a period of seven months. The second patient died of treatment-resistant shock in acute renal failure, due to rapidly progressing renal amyloidosis.

Genetic factors in amyloidosis.

Thomas PK.

In the absence of biochemical distinctions, the nosography of the inherited amyloidoses must at present depend largely upon clinical subdivisions. In the broad classification adopted here, the disorders have for convenience been grouped according to the anatomical system that is predominantly affected. It is evident that the amyloid syndromes display considerable heterogeneity. However, they overlap. Thus in the Iowa type classified with the hereditary amyloid neuropathies (van Allen et al, 1969; Gimeno et al, 1974), renal involvement was

frequent and was the usual cause of death. In the English (Zalin et al, 1974) and Scandinavian (Andersson, 1970) families with neuropathy as the predominant feature, cardiac involvement was a common finding. In certain of the conditions discussed, such as medullary carcinoma of the thyroid and Down's syndrome, amyloid deposition is merely an incidental aspect of the disorder. In those conditions in which generalized or localized amyloid deposition occupies a more central position in the clinical syndrome, an autosomal dominant inheritance has been established or suggested in the majority. An autosomal recessive inheritance has so far only been recognized in familial Mediterranean fever. In the family with hereditary amyloid heart diseases reported by Fredricksen et al (1962), the disorder was confined to a single sibship, raising the possibility of recessive inheritance. This could also be true in sporadic examples of primary amyloidosis. The dominantly inherited amyloidoses comprise a number of geographically widely scattered families with clinical pictures that do not show consistent differences between some families. The families that do not show consistent differences are not necessarily harbouring mutations at the same locus, or the same mutation at any particular locus. However, many of these dominantly inherited clinical syndromes are sufficiently different from each other and the clinical manifestations of each sufficiently consistent to indicate that separate main genes are likely to be involved...

Rhythms and periodicity in health and disease.

Reimann HA.

Biorhythms longer than the circadian that influence reactions of people and characterizes some diseases have not received much medical attention. The lay press describes cycles of 23, 28 and 33 days said to regulate moods, intellectual ability and efficiency, respectively. Whether or not three overlapping cycles actually regulate three different vague reactions may be questioned. Of interest, however, are rhythms of similar tempo which control mensis, cyclic changes in male hormones and a number of periodic diseases. Although reports of more than 2500 cases of periodic diseases have been published, physicians generally are skeptical on the subject. Incorrect diagnosis leads to unnecessary testing, surgical exploration and medication.

Synovitis of familial mediterranean fever. A histologic and ultrastructural study.

Stein H, Yarom R, Makin M.

The microscopic and ultrastructural features seen in the synovium of twelve patients affected by the protracted arthritis variety of FMF is described. It would appear that the small vessels of the synovial membrane are the principle target organ in this articular pathology. Intra articular injections of colloidal radioactive gold, or hydrocortisone, do not alter the histologic and ultrastructural appearance of the affected synovia. Neither do these findings change in the regenerated synovia, growing after a surgical synovectomy. The implications of these findings are discussed.

Amyloidosis of the kidneys. Review of patients and literature.

Lender M, Rosenblueth M.

The clinical findings in 49 patients (27 males) who had histologically confirmed amyloidosis of the kidney, are reviewed. In 28 patients, the diagnosis was arrived at by percutaneous renal biopsy, and in 21 patients it was made at autopsy. The youngest patient was diagnosed at the age of 16 years. In 11 patients (22,5%) no associated disease was found, in a further 11 patients the amyloidosis was of the type connected with familial Mediterranean fever, and in 27 patients (55%) the amyloidosis was of the secondary type. Forty-six patients (94%) presented with proteinuria at some stage of their disease. Twenty-one patients developed the nephrotic syndrome. Thirty-two patients died, and in 18 instances uraemia was the cause of death. In 18 patients there was evidence of renal pathology other than amyloidosis, and in some patients this may have contributed to the impairment of renal function and the appearance of proteinuria.

[Gentic study of paroxystic familial polyseritis. 72 cases].

[Article in French]

Naffah J, Bitar E, Nasr W, Khoury K.

Study of the mode of hereditary transmission of familial paroxystic polyseritis in Lebanon led us to conclude that the disease was transmitted in a dominant fashion. In almost one third of our families, dominant transmission was certain or probable. In the other families, dominant heredity was not excluded if the

hypothesis, supported by many facts, of incomplete penetrance is accepted. The possibility that certain forms of the disease are dominant and others recessive cannot be rejected, but in the absence of biological proof of this genetic heterogeneity it cannot be confirmed. The majority of the patients, as is usual in the disease, were male. The highest risk groups in the Lebanese population are Armenians and Shiite Moslems

Antibodies to Epstein-Barr virus in patients with cryptococcosis.

Levine PH, Diamond RD, Reisher JL.

Antibody levels to the Epstein-Barr virus, the etiological agent for heterophile-positive infectious mononucleosis, have been demonstrated in high titer in a number of lymphomas as well as infectious mononucleosis. Recent reports have suggested that the elevated antibody levels to Epstein-Barr virus may be the nonspecific result of disordered cell-mediated immunity. This study of patients with cryptococcosis was therefore undertaken to examine another disorder of known etiology associated with a defect in cell-mediated immunity. In this study we found that antibody levels in cryptococcosis patients, including a group specifically demonstrated to be anergic to a series of skin test antigens, were no different than those in matched normal controls. At the present time, therefore, it is unlikely that elevated antibody levels can be explained solely on the basis of depressed cellular immunity.

Articular damage in familial Mediterranean fever. Report of four cases.

Herness D, Makin M.

Four cases of familial Mediterranean fever have been reported in which the disease produced organic damage to a joint. The diagnosis was confirmed by clinical and family history and a typical course which included attacks of recurrent joint synovitis. The laboratory findings, while typical, were not specific. The main involvement was in the lower limbs. The findings at operation were of a non-specific synovitis with destruction of cartilage. It is emphasized that in the majority of cases of familial Mediterranean fever the joint involvement is transient and only uncommonly does damage to the joint become permanent. The fact that organic joint damage occurs is not widely recognized, which is the reason for our report of these four cases.

Radiographic changes in the sacroiliac joints in familial Mediterranean fever.

Brodey PA, Wolff SM.

In a series of 43 patients with familial Mediterranean fever, six were found to have radiographic changes in the sacroiliac joints consisting of loss of normal cortical definition, sclerosis on both sides of the joint with or without erosions, and fusion. These changes were noted despite the absence of clinically symptomatic joint disease. The explanation for these findings is unknown.

Colchicine for periodic peritonitis.

Reimann HA.

After 25 years of unsuccessful therapeutic trials, colchicine suppressed episodes of periodic peritonitis (recurrent polyserositis, familial Mediterranean fever) in most reported cases after 1972 and in 12 of 14 patients in this study. Dosage of 0.65 mg daily was continuous, but intermittent therapy timed in accordance with predicted episodes is under trial. Suppression of episodes by the drug serves as the only diagnostic test available.

Familial paroxysmal polyserositis (familial Mediterranean fever); incidence of amyloidosis and mode of inheritance.

Khachadurian AK, Armenian HK.

Findings in 120 cases of familial paroxysmal polyserositis from Lebanon are reported. There was a predominance of male and Armenian patients. Symptoms started before age 20 in 82%. Amyloidosis was diagnosed in 9 patients only. Rectal biopsy in 21 consecutive cases with long-standing illness was negative for amyloid. Amyloidosis without polyserositis was not encountered. Proportion of affected sibs (130) was lower than expected (160) for an autosomal recessive gene. Poor penetrance, especially in females could account for this discrepancy.

Immunologic studies of the major nonimmunoglobulin protein of amyloid. I.  
Identification and partial characterization of a related serum component.

Levin M, Pras M, Franklin EC.

Antisera have been prepared against the major nonimmunoglobulin component of secondary and familial Mediterranean fever (FMF) associated amyloid which has been called A component or acid soluble fraction (ASF). The antisera were shown to be monospecific for ASF by precipitation of (125)I-labeled antigen and gave a reaction of identity with four different ASF preparations. The antisera were able to detect a circulating component in human serum that migrated in the alpha1-globulin region. This circulating component gave a line of identity with degraded ASF by double immunodiffusion. 57 normal sera and 89 sera from patients with diseases known to be frequently associated with amyloidosis were tested by immunodiffusion for the circulating ASF component. 7% of normal sera and 50-80% of the pathologic sera had elevated amounts of this component. Absorption studies showed that all normal sera probably have small amounts of this component while cord sera do not have detectable amounts. This component was partially purified and was shown to be slightly larger than albumin. The relation of the circulating component to the acid soluble fraction of amyloid is discussed.

The amino acid sequence of a major nonimmunoglobulin component of some amyloid fibrils.

Levin M, Franklin EC, Frangione B, Pras M.

The complete amino acid sequence of a protein, acid soluble fraction, (ASF) which constitutes up to 50% of amyloid fibrils from a patient with familial Mediterranean fever has been obtained. Partial amino acid sequences of three other proteins from patients with secondary amyloidosis were identical in the regions studied except for an alanine-valine interchange in one. The ASF contains no cysteine, does not resemble any known immunoglobulin, and has not been detected as yet in myeloma-associated amyloid.

Recurrent fever of unknown etiology: failure to demonstrate association between fever and plasma unconjugated etiocholanolone.

George JM, Wolff SM, Diller E, Bartter FC.

A sensitive method for determination of plasma unconjugated etiocholanolone by double-isotope-derivative dilution has been described. The mean values for normal subjects was  $0.038 \pm 0.003$  (SEM)  $\mu\text{g}/100 \text{ ml}$ . 40 patients, 20 with familial Mediterranean fever and 20 with other diseases characterized by recurrent fever were studied. The over-all mean concentration of plasma unconjugated etiocholanolone for the patients (febrile or afebrile) was  $0.101 \pm 0.012 \mu\text{g}/100 \text{ ml}$ , significantly above that of normals. Mean plasma values for the patients while they were febrile did not differ from the mean values when they were afebrile. It is suggested that the concentration of plasma unconjugated etiocholanolone is not related to fever in these patients.

Longitudinal study of periodic catatonia. Long-term clinical and biochemical study of a woman with periodic catatonia.

Cookson BA(1), Quarrington B, Huszka L.

Author information:

(1)Research Unit, Ontario Hospital Toronto and Department of Psychiatry, University of Toronto, Ontario, Canada.

A woman with periodic catatonia had a 600-day metabolic study. The results were analyzed by harmonic analysis. Her periodic stupors showed a regular 36-day rhythm apparently related to a 24-day menstrual cycle; but the rhythm persisted when menstrual function was blocked by continuous Enovid (norethynodrel + mestranol) administration. During the menstrual block, weight, sodium balance, magnesium and 17-ketosteroid (17-KS) excretion gave indications of 12- and 36-day fluctuations. Further studies on steroid excretion indicated that similar fluctuations in 17-KS output occurred when the patient was menstruating normally. The peaks of the 12-day cycle coincided with menses and the mid-menstrual phase; while the peak of the 36-day cycle coincided with the onset of stupor. 17-hydroxycorticosteroid (17-OHCS) excretion had a 36-day cycle which lagged 4 days behind the 36-day 17-KS cycle. There were no indications of a 12-day 17-OHCS cycle. In the discussion it is suggested that the 17-KS fluctuations may partly reflect gonadotrophin activity rather than being exclusively due to ACTH. It is noted that Enovid may block only LH activity not total gonadotrophins. It is speculated that there may be a relationship between gonadotrophin activity and the psychic disturbance.

THE EXTRACTION OF PLASMA 3-HYDROXY-17-OXO STEROID SULPHATES AND THE MEASUREMENT OF THE CONSTITUENT DEHYDROEPIANDROSTERONE SULPHATE AND ANDROSTERONE SULPHATE.

MCKENNA J, RIPPON AE.

1. A simple method for the extraction of 17-oxo steroid sulphates of plasma is described; glucosiduronates and orthophosphates are extracted, but to a smaller extent. 2. Four methods of analyses of the extracts are given and are relatively simple. Three of these are specific for steroid sulphates and two measure the sulphate conjugates directly. 3. Values for dehydroepiandrosterone sulphate and androsterone sulphate concentrations of normal and pathological plasmas are given.
